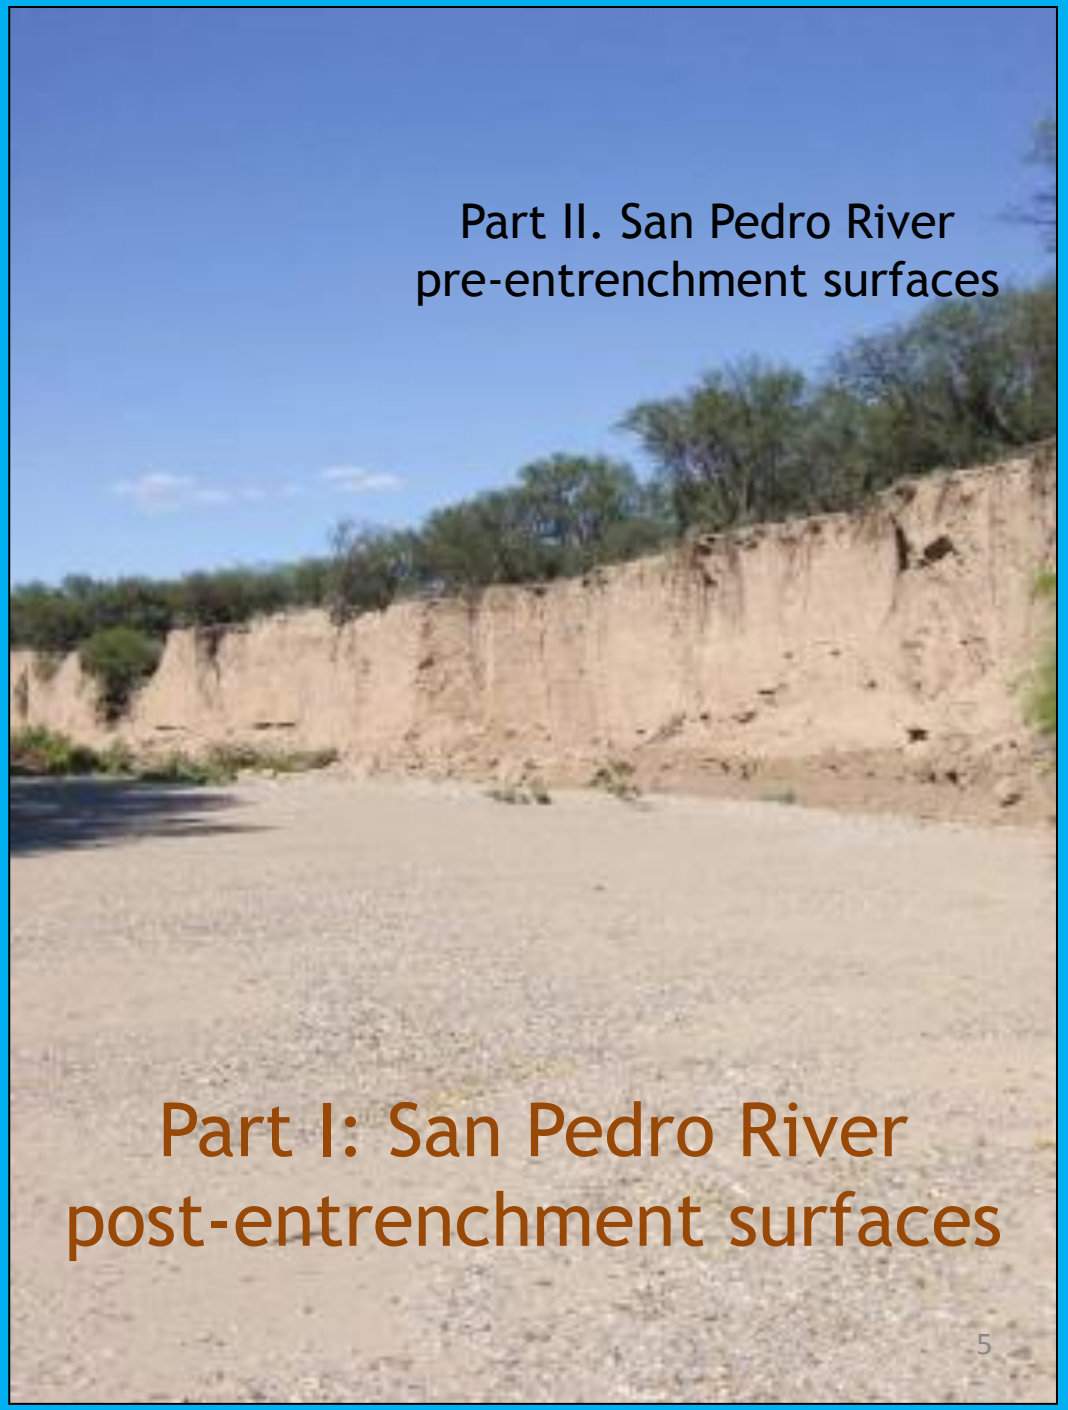
Fire

Drought

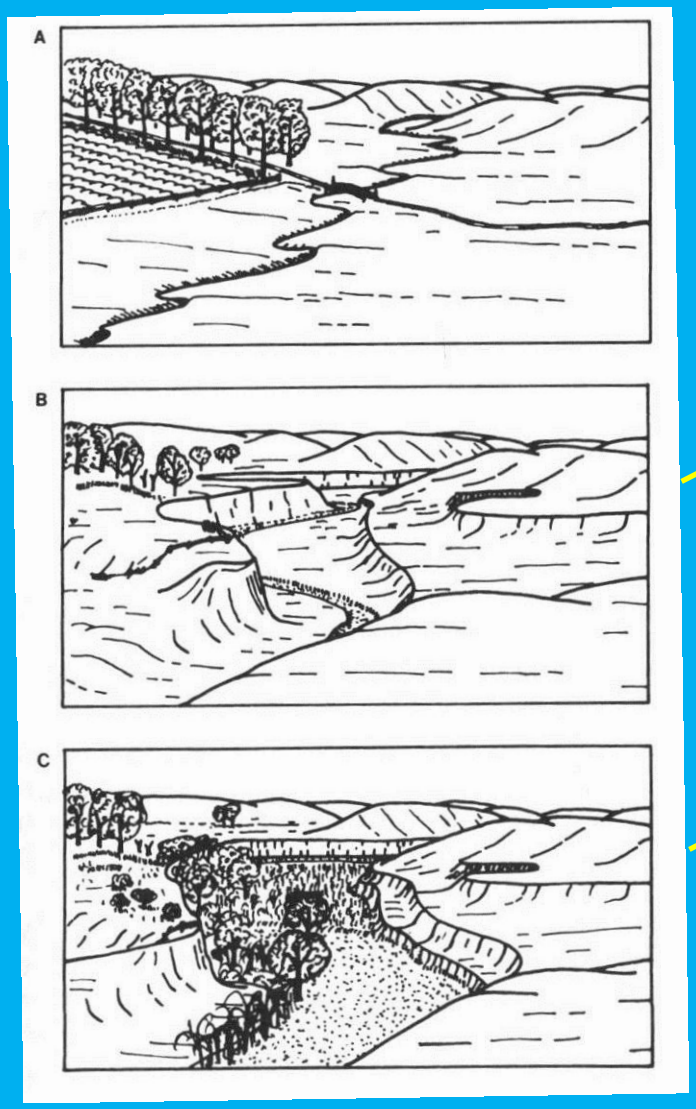
Beaver

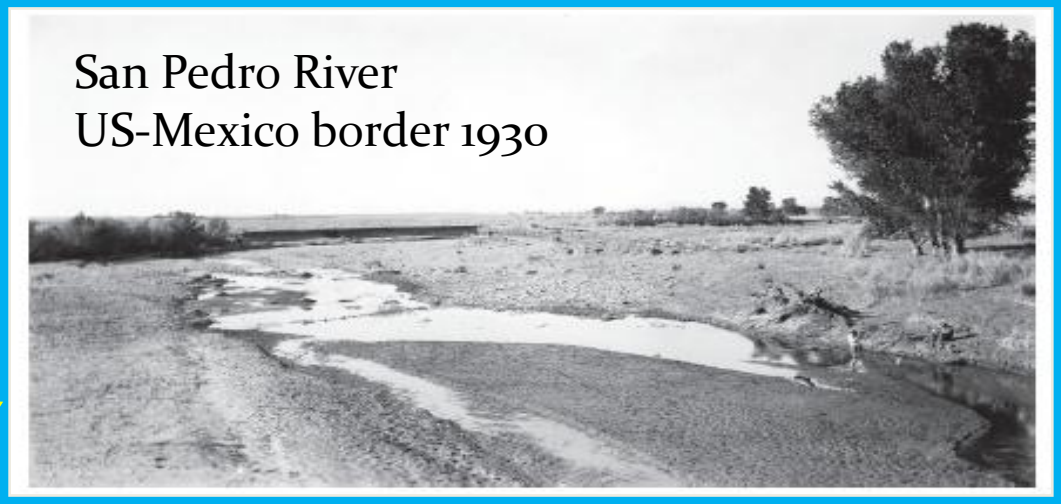
River entrenchment

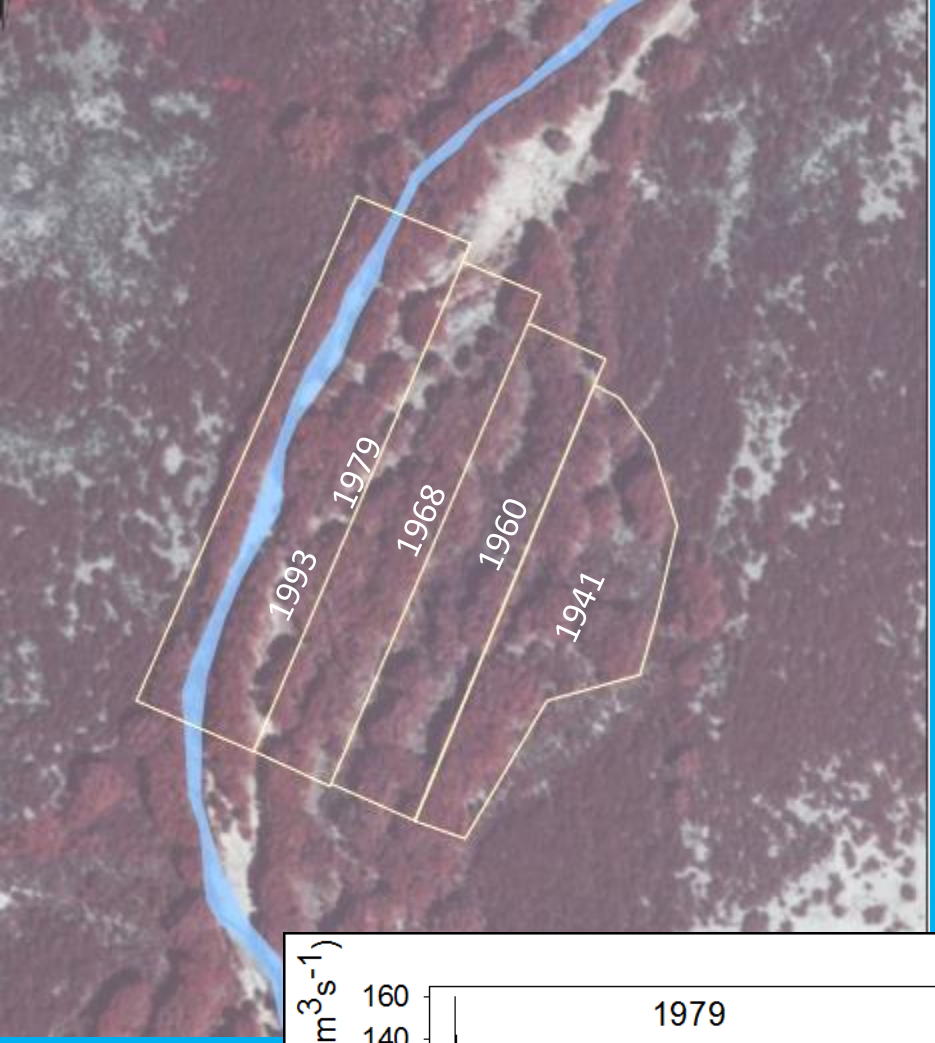
"It was probably during the 1896 flood that a channel almost 244 m wide and 6 m deep developed…" (Hereford and Betancourt 2009).

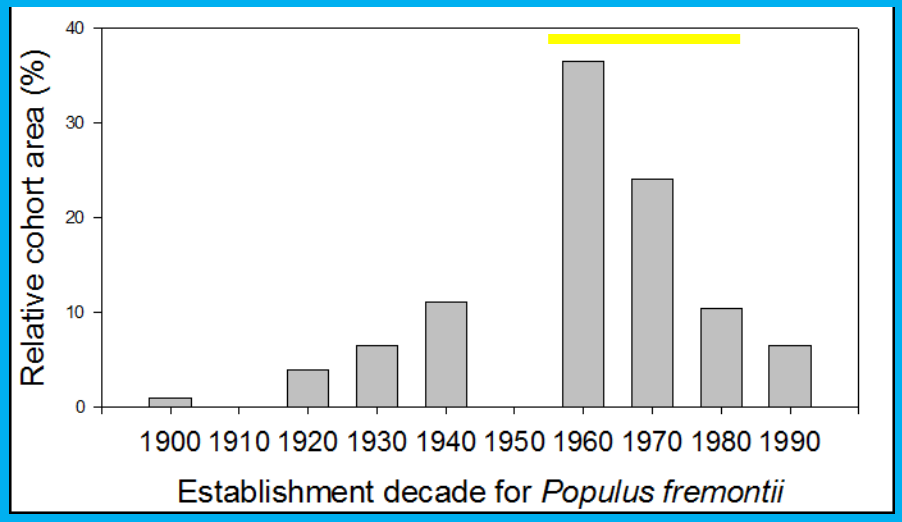


Extreme disturbance reset the San Pedro, triggering a century of forest expansion

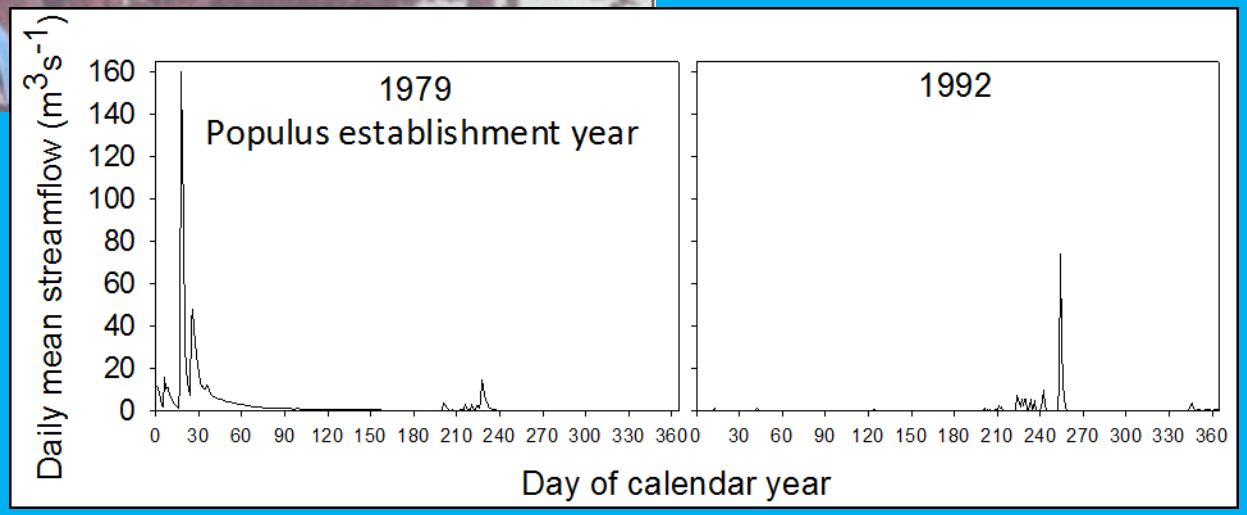


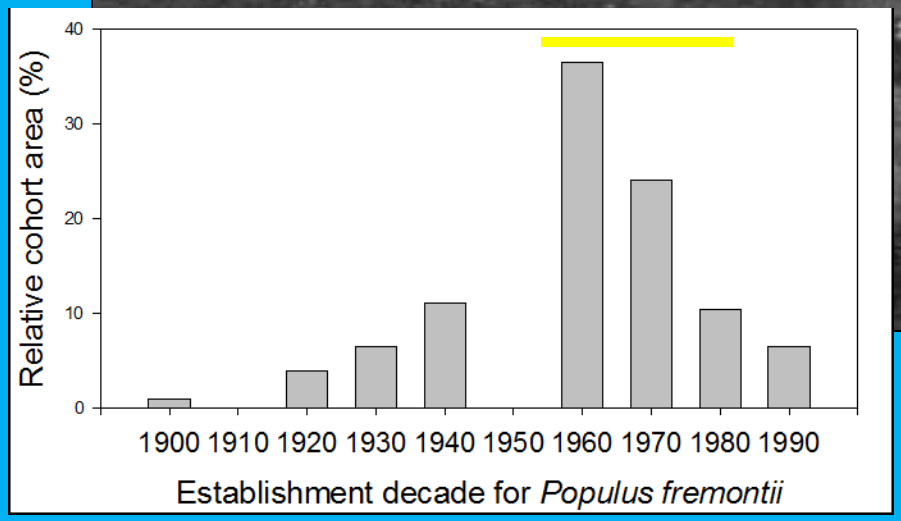






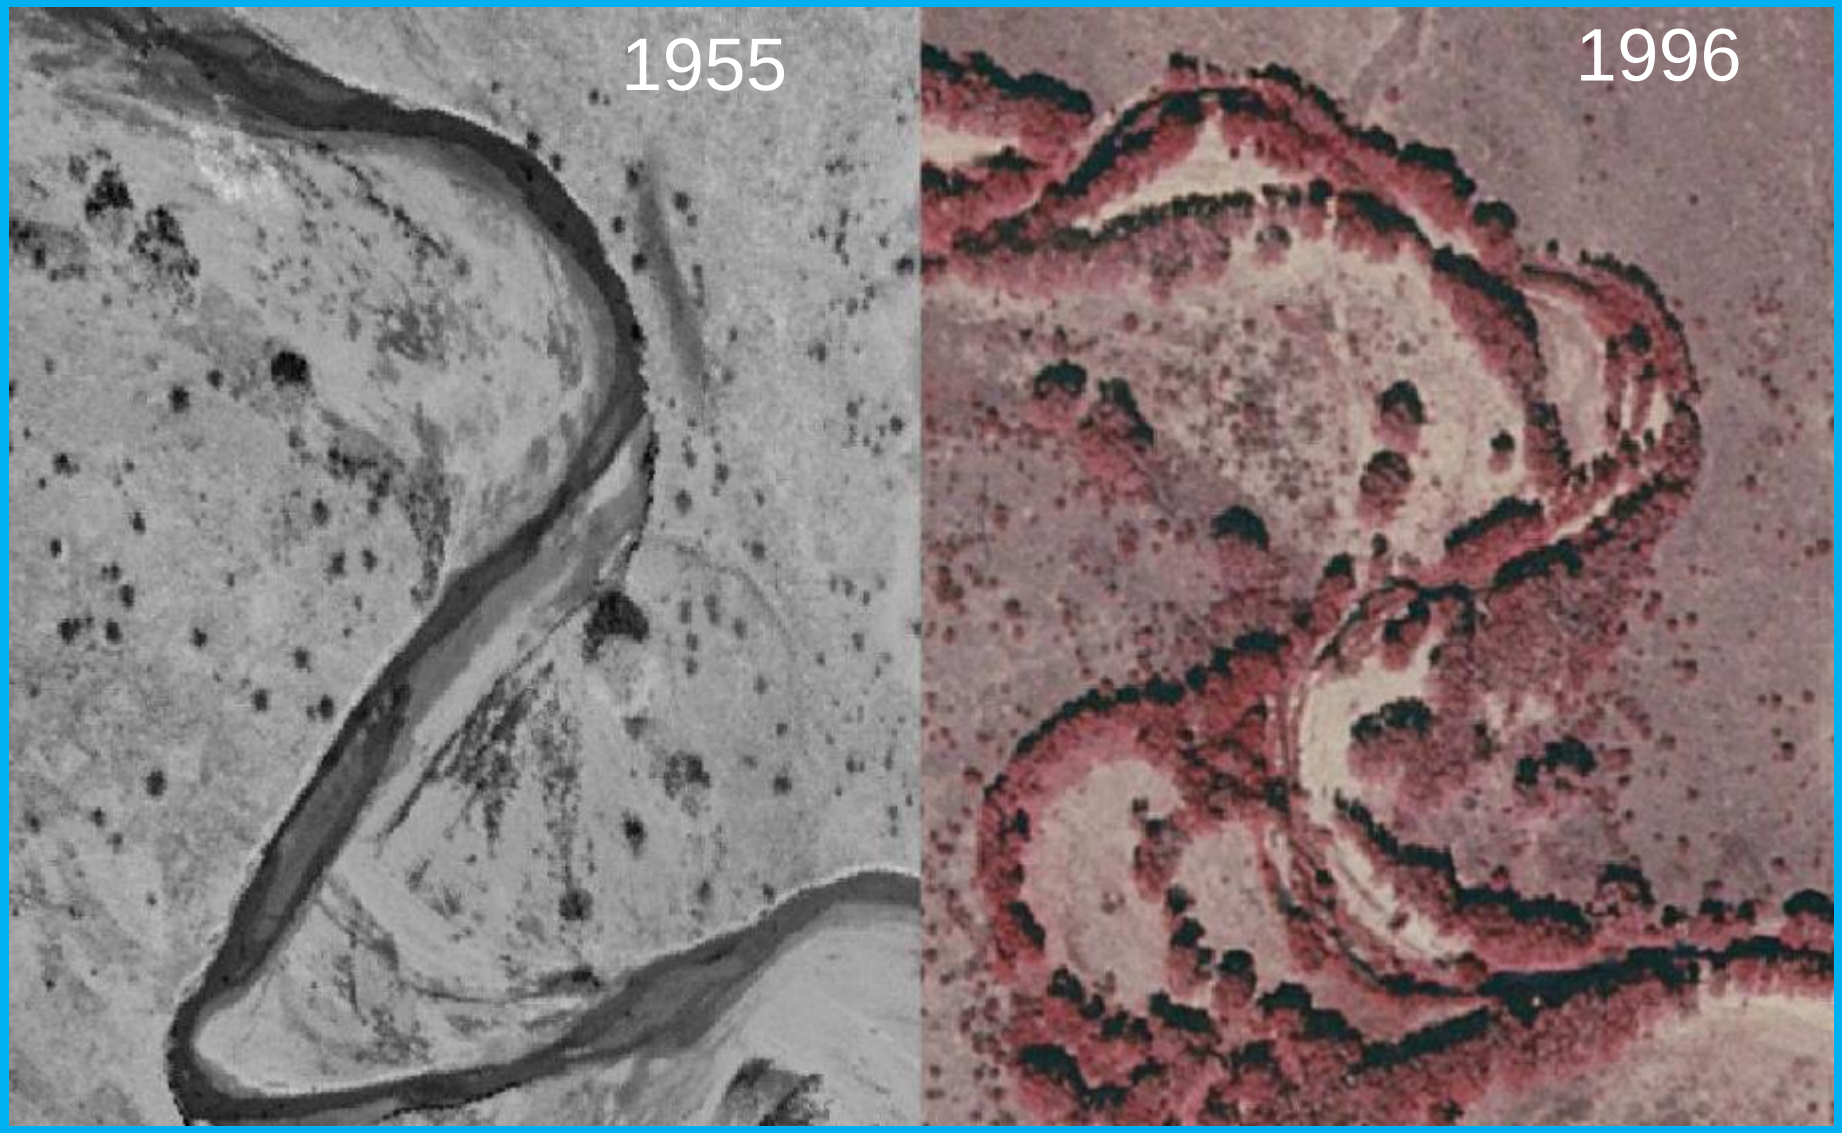
Episodic forest infill during years with winter floods





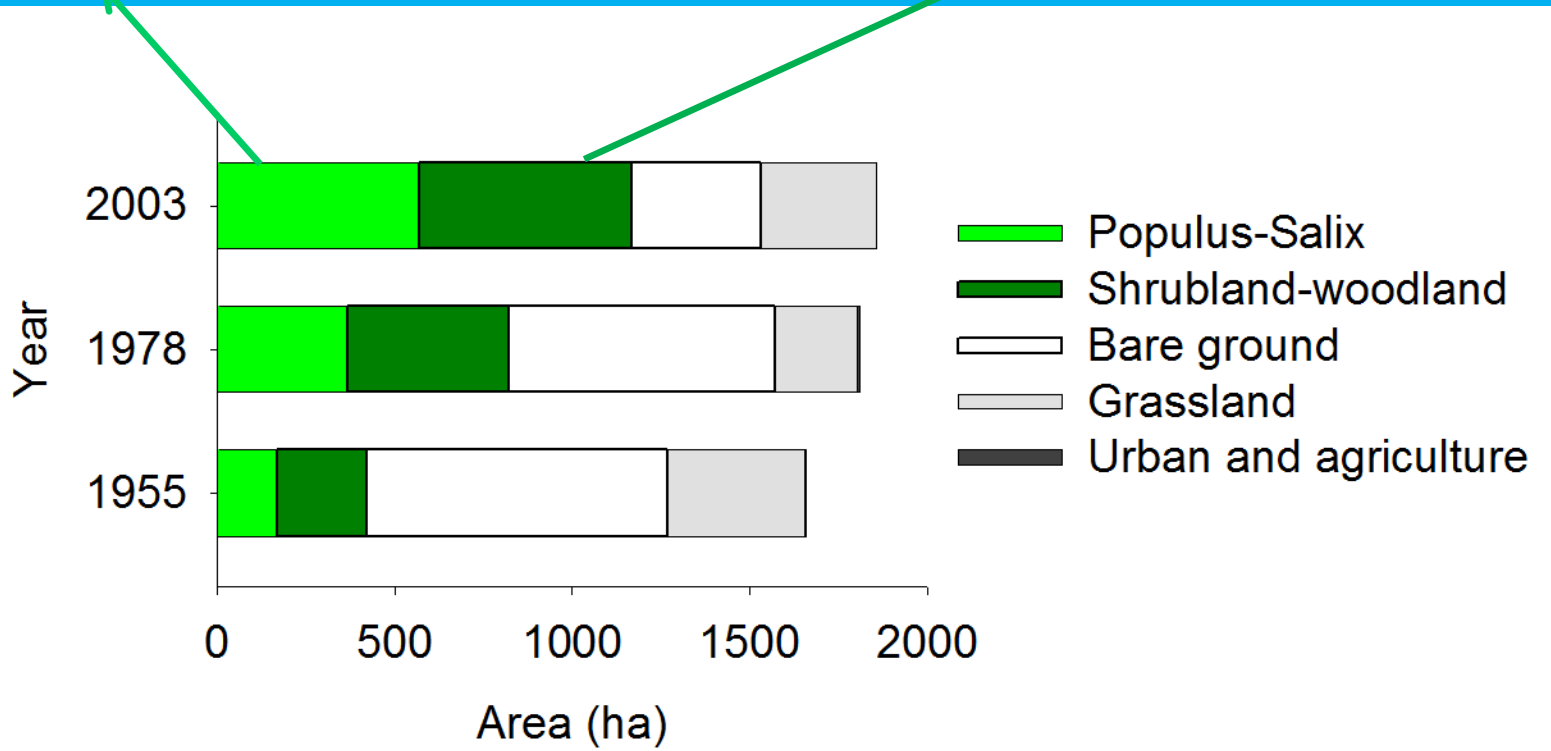
The San Pedro River near Charleston, April 1950.

3x Increase in Riparian Forest since 1950s

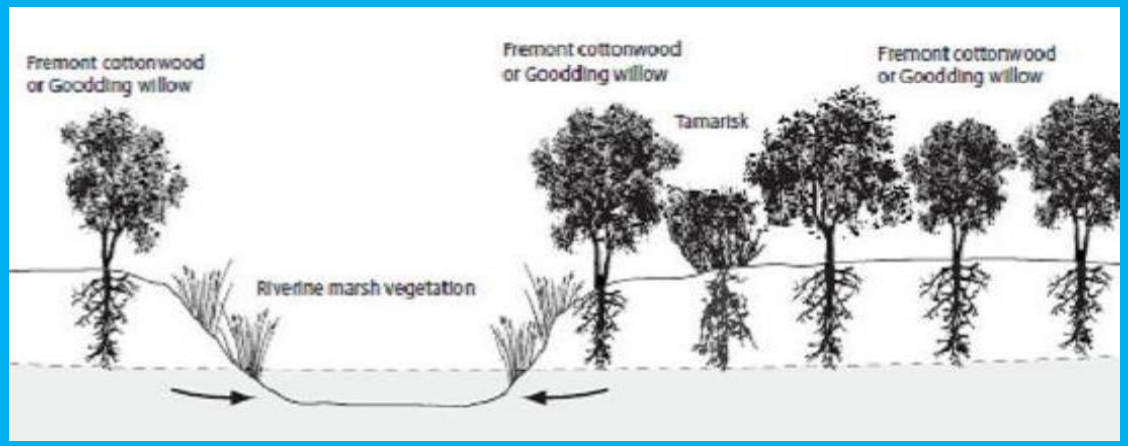


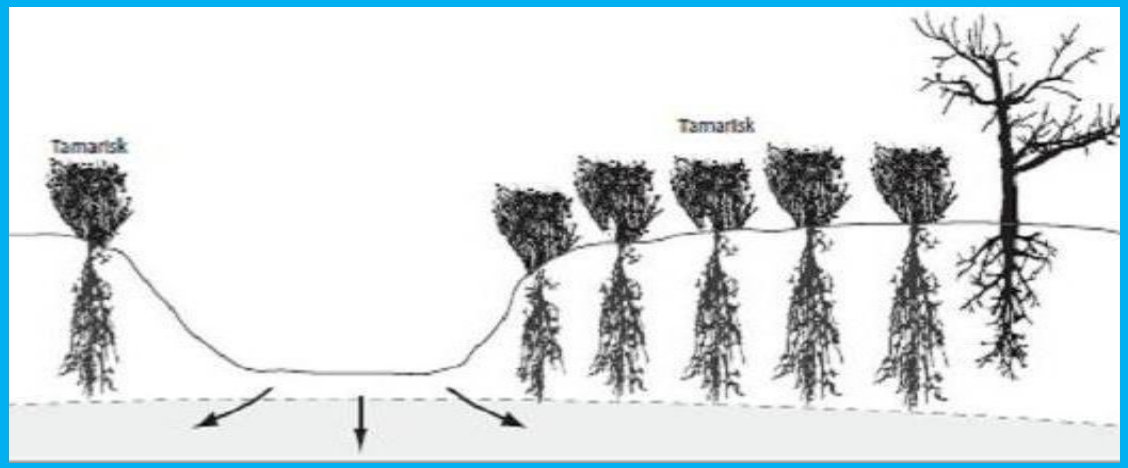
Cottonwood-willow

Tamarix

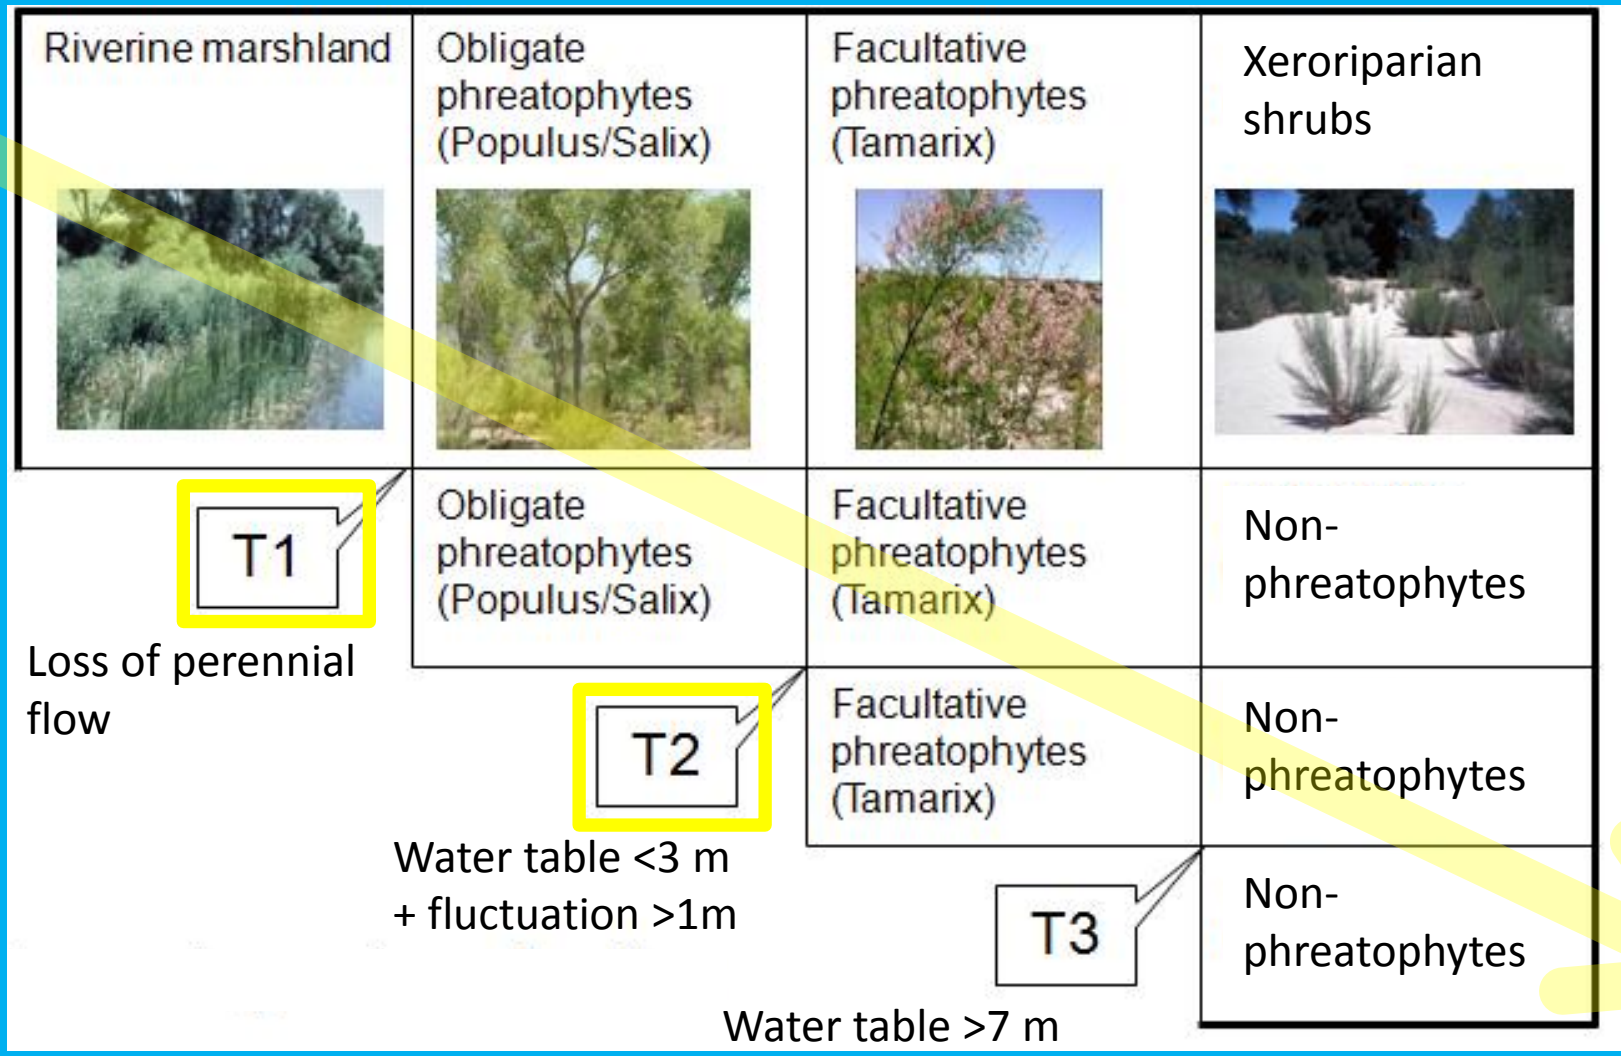


Threshold: Cottonwood-willow forests decline where water tables are >10 feet





Thresholds of change simplification of community structure as stream water is depleted



Threshold #1: Wetland herbaceous perennials decline sharply as stream flow becomes non-perennial

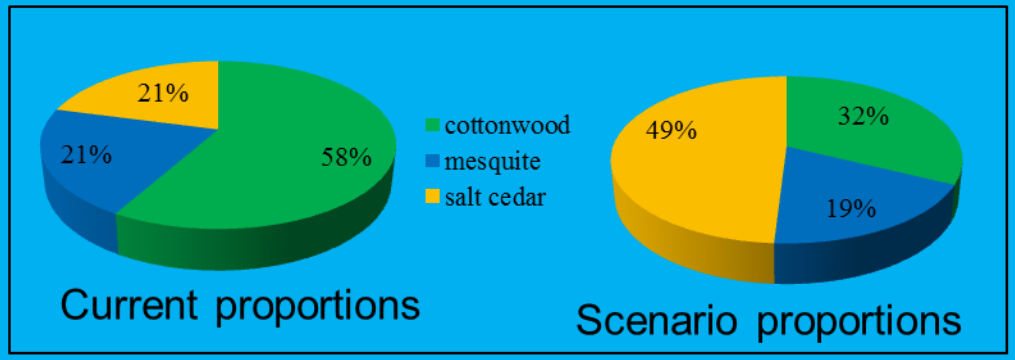
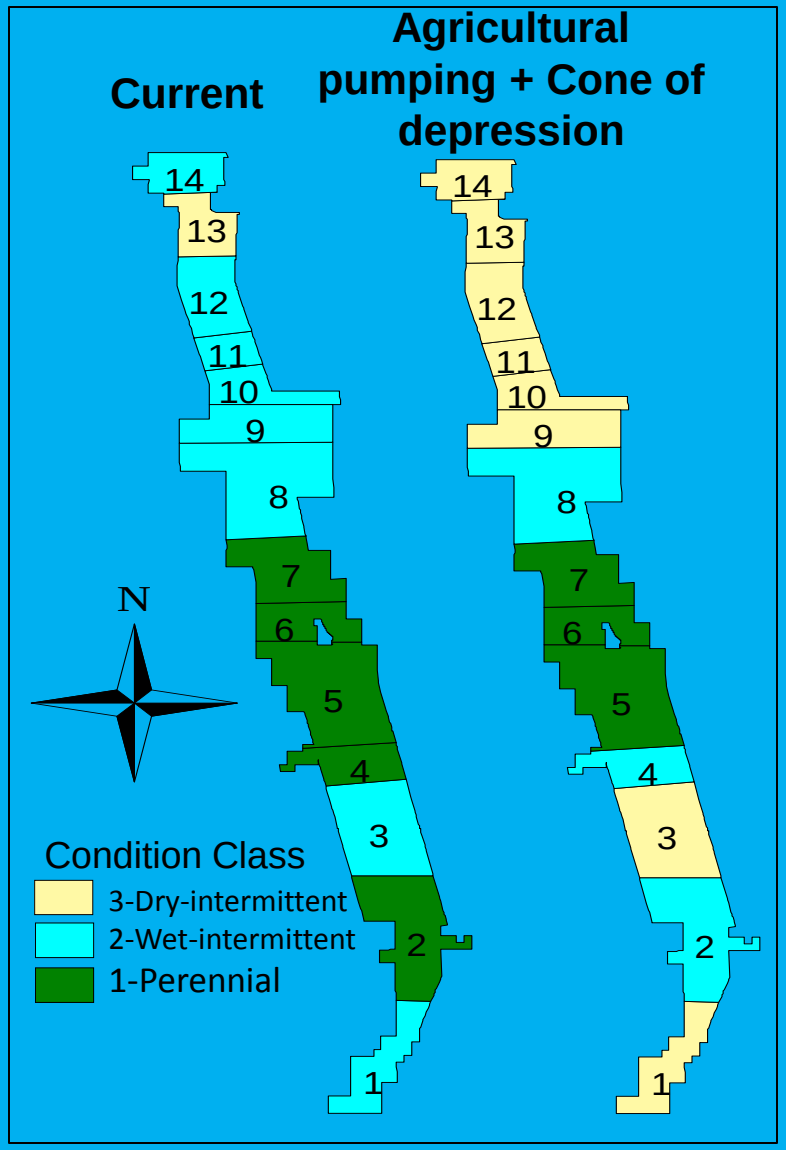
Scenario modeling: Groundwater decline





In cottonwood/willow forest, fire caused

- canopy decline
- increased grass cover
- shift towards older cottonwoods
- shift towards younger willows

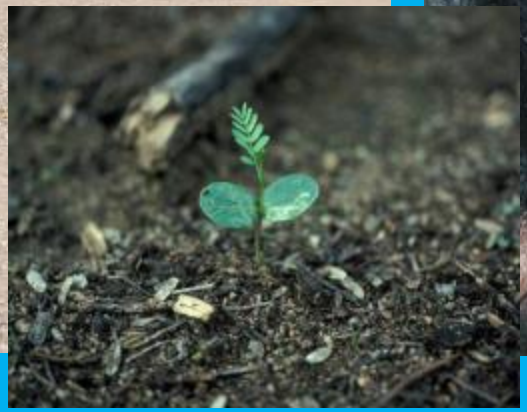
Questions?

Part II. San Pedro River
pre-entrenchment surface
Part I: San Pedro River
post-entrenchment surface

Velvet mesquite woodlands

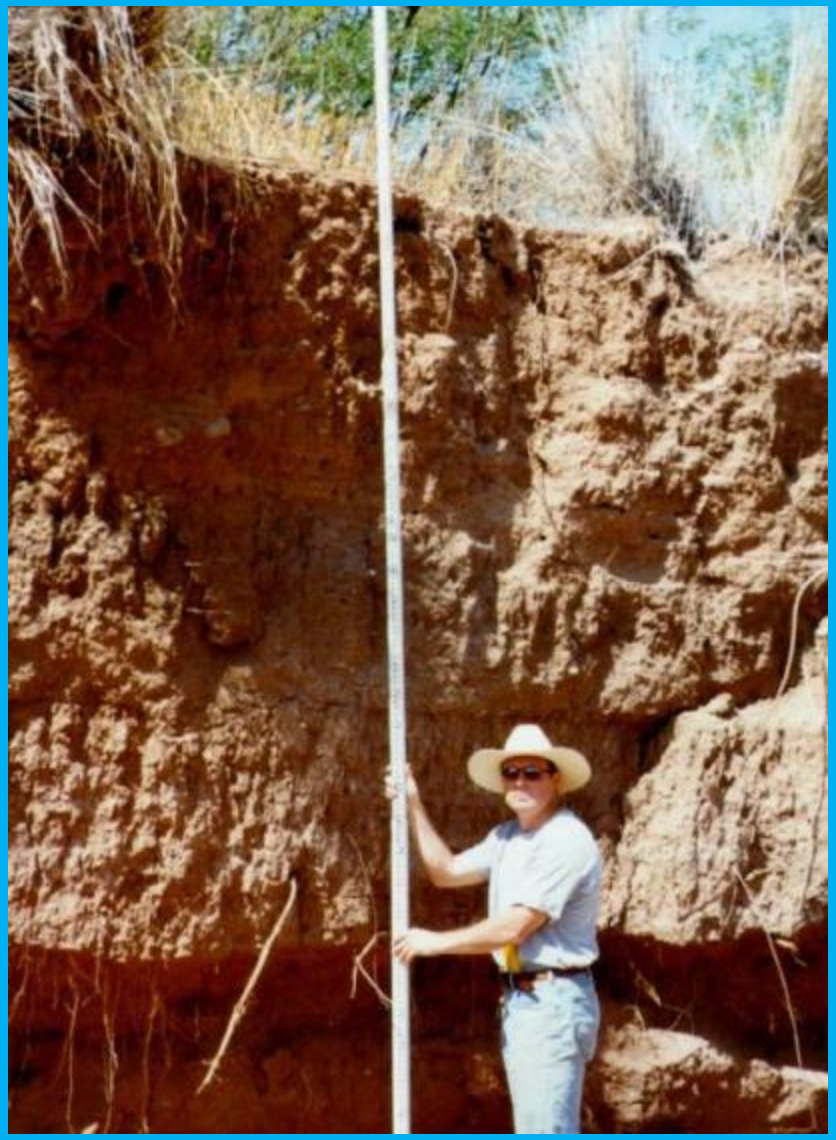
(*Prosopis velutina*)

Roots to 15 m or more



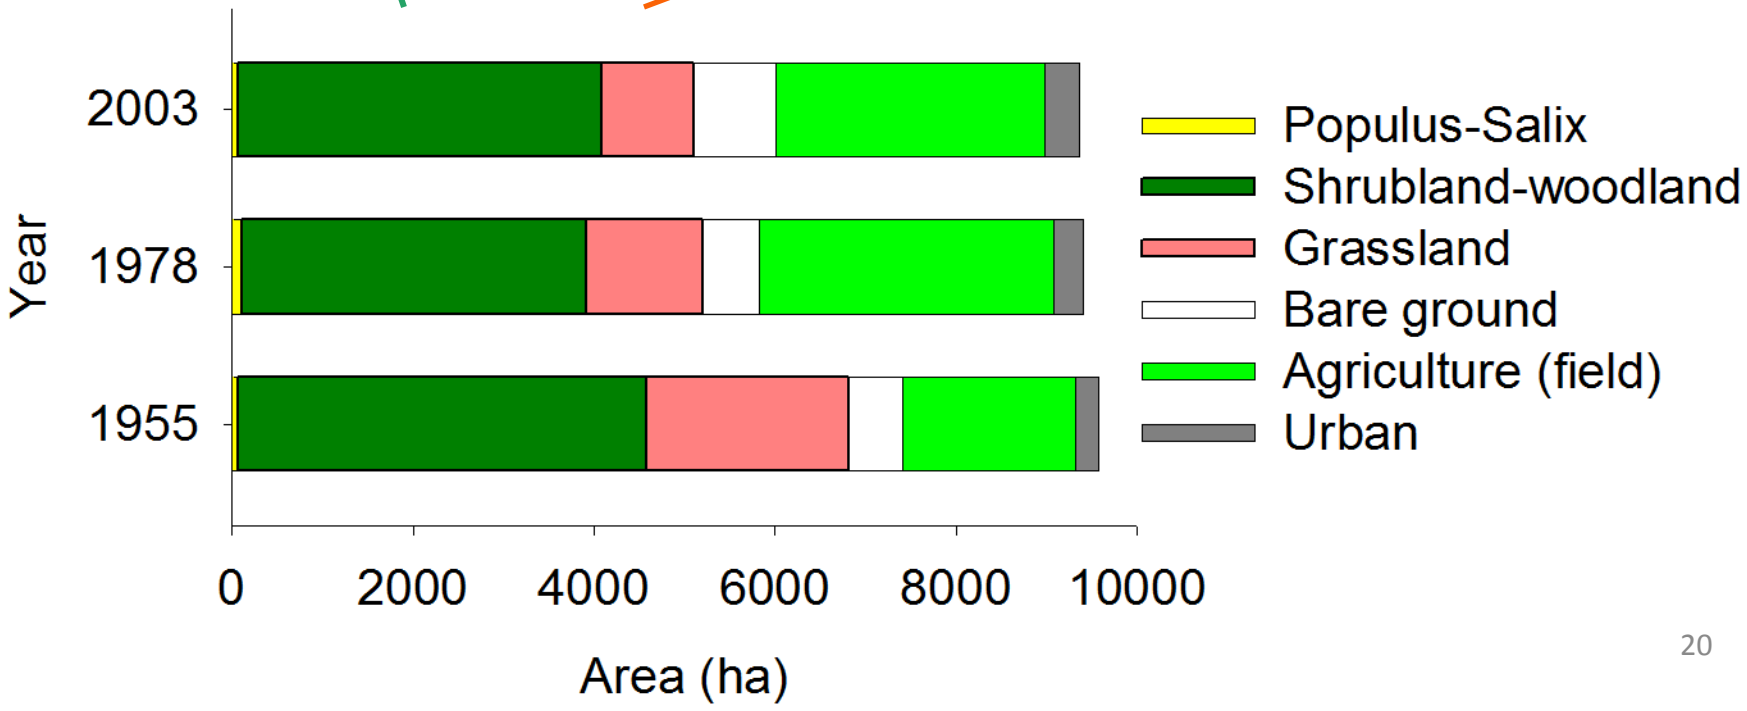
Sacaton grasslands

(Sporobolus wrightii)



Roots to about 4 meters

Vegetation change on terraces



Some grasslands converted to mesquite woodlands after river entrenchment

During the early and mid-1900s, many grasslands and forests were converted to agricultural fields.

Palominas, May 2003 fire

Palominas, September 2003

After fire:

- Sacaton resprouts (unless plants are too dry)
- Mesquite resprouts, becomes “shrubbier”

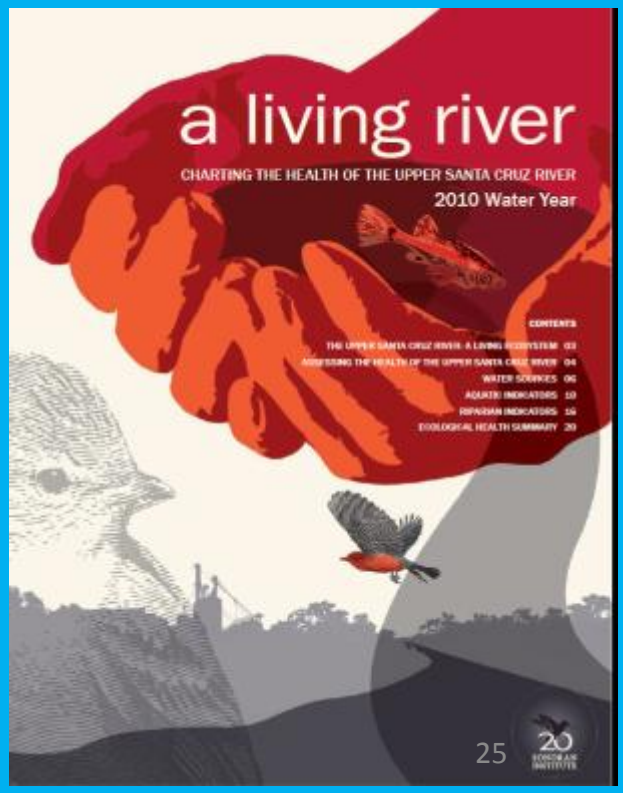
Monitoring indicators: Santa Cruz River, Pima Co.

Draft, Reviving River Technical Committee

Riparian vegetation indicators

1. Wetland indicator score (ranges from 1=obligate wetland to 5=obligate upland), based on sampling of plant cover at fixed stations along the low-flow channel during June

2. Canopy cover of hydroriparian trees (cottonwood, willow)



Contact: Claire Zugmeyer, Sonoran Institute
http://www.sonoraninstitute.org/where-we-work/southwest/santa-cruz-river.html

Vegetation Monitoring in SPRNCA

Multiple riparian transects: Suggested path forward

1. Channel-side abundance of herbaceous wetland plants. Annually, measure of cover of wetland herbaceous plants along low-flow channel during June, and calculate wetland indicator score.

2. Riparian forest cover. Bi-annually, measure total canopy cover on floodplain and terrace. Determine the percentage that is tall, hydroriparian trees (cottonwood, willow). The ratio of cottonwood/willow to saltcedar is a strong indicator. Field sampling or remote sensing (e.g., LiDAR).
