Kirol et al. 2012	WY	8m of nest	Nesting	Nest selection was negatively related to the presence of cheatgrass when compared to available habitat. "Cheatgrass occurred at 6% of the nest locations and 19% of the corresponding random locations."
Lockyer et al. 2015	NV/CA	0.01ha of nest	Nesting	Average cover of cheatgrass at nests and random sites was 7.1% (SE=1.0) and 13.3% (SE=1.2), respectively. Sites with >7.1% cheatgrass cover had lower nest success. Cheatgrass was the single greatest micro-habitat feature distinguishing nests from random sites.
Schreiber et al. 2015	WY	20m of brood	Brood-rearing	Cheatgrass cover was lower at early brood-rearing sites (0.55% +/-0.38%) than at random points (0.71% +/-0.30%) but similar. Cheatgrass cover was lower at late brood-rearing sites (1.44% +/-0.65%) than at random points (2.13% +/-0.72%) but similar.
Stonehouse et al. 2015	WA		Nesting	Mean cover of invasive annual grasses at nest sites was 13% (SE=1); random sites were not assessed.
Wik et al. 2002	ID	20m of nest	Nesting	All nests had an average of 3% cover. Successful nests had lower average cheatgrass cover (1% in 20m transect) than unsuccessful nest (4% in 20m transect).
		20 m of brood	Brood-rearing	All broods had average of 5% cheatgrass. Unsuccessful broods has lower cheatgrass (2% in 20m) at use-sites than successful broods (6% in 20m).
Wing et al. 2014	UT	15m of nest	Nesting	All nest, brood, and non-brooding use sites had cheatgrass which was similar in cover to random sites. Cheatgrass cover means: Nest mean = 17.6% (0.8), Brood mean = 15.6% (0.8), non-brood females and males = 14.3% (0.7), random sites mean = 15.9% (0.8).

RECOMMENDATIONS

Based on the findings of the research summarized above (**Table 1**), invasive annual grass cover should be assessed as a habitat indicator for nesting/early brood-rearing, late brood-rearing, and wintering habitat during a HAF site-scale assessment using the following benchmarks, adjusted as warranted by best available science. Note that these benchmarks were based more heavily on research that examined nest and brood *success* relative to invasive annual grass cover (more so than research that examined *use versus availability* of habitat) because sage-grouse have been shown to exhibit maladaptive site selection (Coates et al. 2017, Brussee et al. 2022, Cutting et al. 2019). Invasive annual grasses are not assessed at the site-scale for leks because the AIM strategy does not include leks in its sampling strategy; however, invasive annual grasses are assessed for lekking habitat at the HAF *fine-scale*. There was not sufficient research to suggest different benchmarks for winter habitat due to a lack of research on winter habitat as compared to nesting and brood-rearing. If future research indicates otherwise, benchmarks may be adjusted accordingly.

Table 2. Recommended habitat suitability benchmarks for assessing invasive annual grass at the HAF site-scale.

Habitat Indicator	Metric	Benchmarks		
		Suitable	Marginal	Unsuitable
Invasive Annual Grass	% cover	<2%	2 – 5%	>5%

Attachment 8-2. Justification for Conifer as a Habitat Suitability Indicator at the Sage-grouse Habitat Assessment Framework (HAF) Site-Scale

Written by: Megan McLachlan, Wildlife Biologist, Bureau of Land Management (BLM) National Operations Center (NOC)

Reviewed by: Anthony Titolo (BLM-NOC), Paul Makela (BLM-ID), Kaitlin Lubetkin (BLM-NOC), Sam Litschert (BLM-NOC), Leah Waldner and Chris Domschke (BLM-CO), David Wood (BLM-MT/DK), Glenn Frederick and Matthew Shirley (BLM-OR/WA), and Matt Holloran (BLM-WY)

Finalized on: October 12, 2023

BACKGROUND

Recent research has shown that conifer expansion into native sagebrush communities can reduce habitat suitability for sage-grouse (Nisbet et al 1983, Doherty et al. 2010, Fedy et al. 2014, Doherty et al. 2016, Westover et al. 2016, Baxter et al. 2017, Picardi et al. 2020, Saher et al. 2021, Brussee et al. 2022, Roth et al. 2022). The Bureau of Land Management (BLM) uses the Sage-grouse Habitat Assessment Framework (HAF; Stiver et al. 2015) to assess sage-grouse habitat suitability at multiple spatial scales (mid-, fine- and site-scale) by examining scale-specific indicators that represent both habitat requirements (i.e., food, water, cover, security) and threats to habitat (i.e., anthropogenic disturbances, predation risk). However, conifer cover is not included as an indicator of habitat suitability at any scale of the HAF (Stiver et al. 2015). This omission has been recognized by BLM personnel as a shortcoming of the HAF that should be remedied, as supported by scientific literature.

The purpose of this document is to:

- Provide scientifically based rationale for including conifer as an additional habitat indicator in HAF site-scale habitat assessments (Stiver et al. 2015, revised), and
- Recommend scale-specific thresholds for conifer for HAF site-scale assessments based on scientific literature relevant to that scale.

RATIONALE

Studies that examine site-scale sage-grouse habitat (also referred to as microhabitat) often do not report or analyze conifer as a habitat characteristic, likely because it is not a habitat requirement of sage-grouse but rather a deterrent, especially at such a small scale (e.g., within 10m of a nest site). In a review of over 40 peer-reviewed microhabitat studies on sage-grouse, no study reported conifer cover as a standard microhabitat characteristic for sage-grouse (such as sagebrush cover, grass height, forb cover) nor did they test for a relationship between conifer and sage-grouse. A few studies, such as Duvuvuei 2013 and Wing 2014, reported frequency of nests located under conifer in Utah (see **Table 1**). Wing 2014 reported that nesting under juniper was rare and that only one of those nests was successful. Duvuvuei 2013 showed that nests were commonly placed under junipers, especially by translocated females, but suggested that use of juniper for nesting was due to maladaptation caused by a lack of sagebrush cover and extensive juniper expansion into the study area.

Most studies that examine the potential impacts of conifer on sage-grouse and their habitat are conducted at landscape scales, typically estimating conifer cover near sage-grouse locations (e.g., within 1,000m of a nest site) using remotely sensed landcover data. These studies have established that conifer cover, even in low amounts (e.g., <2 % cover), can negatively impact sage-grouse across all seasons (lekking, nesting, brood-rearing and wintering) causing avoidance and/or reduced vital rates (Nisbet et al 1983, Doherty et al. 2010, Fedy et al. 2014, Doherty et al. 2016, Westover et al. 2016, Baxter et al. 2017, Picardi et al. 2020, Saher et al. 2021, Brussee et al. 2022, Roth et al. 2022). However, these findings are mostly applicable to HAF mid- and/or fine-scale assessments which are also landscape level.

Given the established negative impacts of conifer cover on sage-grouse at landscape scales and the lack of conifer being reported in microhabitat studies (i.e., suggesting avoidance of conifer at site-scales), it is recommended that conifer be included as a habitat suitability indicator for sage-grouse habitat assessments conducted at the HAF site-scale, as described in the Recommendations section below.

Table 1. The table below lists and describes key aspects and findings from research that has examined the relationship of conifer to greater sage-grouse habitat selection and/or survival at the site-scale (i.e., microhabitat). Note that no studies specifically examined the potential impacts of invasive annual grasses on Gunnison sage-grouse.

Name	Tree Type	State	Season	Applicable Findings
Wing 2014	Juniper	UT	Nesting	GRSG females rarely selected juniper as a nesting shrub (n=4) and only one nest was successful.
Duvuvuei 2013	Juniper	UT	Nesting	Translocated GRSG females (24%) nested under juniper but was accredited to lack of sagebrush cover and extensive conifer expansion in study area.

RECOMMENDATIONS

Based on the rationale above, conifer should be assessed as a habitat indicator during HAF site-scale assessments for nesting, brood-rearing, and wintering habitat. Conifer is not being added as an additional indicator in lek assessments because existing lek indicators already incorporate conifer and other trees. The metric used to assess conifer suitability is the count of conifer and, if available, the height of those conifer relative to surrounding sagebrush (or native shrubs, if used as a surrogate), using the benchmarks shown below (adjusted as warranted by best available science). Percent conifer is not recommended as the primary metric for conifer suitability because there is insufficient science to support a benchmark at the site-scale; however, percent conifer cover may still be used as ancillary information, as interpreted by local experts, to support assessment of conifer as a habitat suitability indicator.

Table 2. Recommended habitat suitability benchmarks for assessing conifer at the HAF site-scale.

Habitat Indicator	Metric	Benchmarks		
		Suitable	**Marginal**	**Unsuitable**
Conifer	Count	• 0 trees (absence of conifer)	If height is unknown: • 1 tree If height is known: • 1 tree that is taller than local average sagebrush height, and/or • <=3 trees that are not taller than local average sagebrush height	If height is unknown: • >1 tree If height is known: • >1 tree that is taller than local average sagebrush height, and/or • >3 trees that are not taller than local average sagebrush height

Table 3-10. Solar PEIS - Reasonably Foreseeable Development Scenarios

State	Estimated BLM-Administered Acres Developed by 2045 under RFDs	Estimated Non-BLM-Administered Acres Developed by 2045 under RFDs
Arizona	198,210	66,070
California*	109,972	413,706
Colorado	45,207	15,069
Idaho	89,574	29,858
Montana	5,387	1,796
Nevada	48,119	16,040
New Mexico	11,123	3,708
Oregon	51,387	17,129
Utah	39,793	13,264
Washington	71,781	23,927
Wyoming	27,255	9,085
TOTAL	**697,809**	**326,865**

Source: BLM 2024

* To account for exclusion of the Desert Renewable Energy Conservation Plan (DRECP) area in California, the proportion of BLM-administered lands outside of the DRECP area (28%) was applied to the estimated RFDs development acres. It is estimated that 282,787 acres of BLM-administered land within the DRECP planning area would be developed by 2045 under the RFDs.

Table 3-11. Locatable Mineral Types in the Planning Area*

States	Precious and Base Metals	Industrial Minerals
Colorado	Gold, Molybdenum, and Uranium	Gypsum
Idaho	Gold, Silver, Copper, Lead, Iron, Molybdenum, Beryllium, Uranium, and Vanadium	Limestone, Bentonite, High-alumina clay, and Gypsum
Nevada	Gold, Silver, Copper, Lithium, Galena, Iron, Zinc, Cobalt, Vanadium, Tungsten, Antimony, and Molybdenum	Gypsum, Limestone, Diatomite, Bentonite, Silica Sand, Magnesium, and Barite
Montana	Gold, Silver, Mercury	Bentonite, Diamonds
Oregon	Gold, Silver, Lead-silver-zinc, Copper, Uranium, Iron, Arsenic	Borax, Dimension stone, Mercury, Limestone, Diatomaceous earth, Zeolites, Kaolinite, Perlite, Gemstones, and Bentonite
Utah	Gold, Silver, Copper, Lead, Iron, Molybdenum, Beryllium, Uranium, and Vanadium	Limestone, Bentonite, High-Alumina Clay, and Gypsum
Wyoming	Uranium, Gold, Titanium, Lithium, Rare earths	Limestone, Marble, Bentonite, Jade

Source: EPA 2023c

[1] Area sources are stationary sources that are too small or too numerous to be treated as individual point sources. Source categories include agricultural and prescribed burning, outdoor grilling and residential wood combustion, trains and commercial marine vessels, and other sources not covered by the point source category.

[2] Oil and Gas includes oil and exploration and production.

[3] Mobile sources include off-road equipment and vehicles (e.g., construction, agriculture, industrial, lawn and garden, commercial, logging, recreational vehicles, some recreational marine vehicles, and underground mining equipment) that do not operate on roads; on-road highway vehicles; and fugitive dust from paved and unpaved roads.

[4] Point sources include individual facilities such as large energy and industrial sites (e.g., petroleum refineries, electric generating utilities, and manufacturing facilities), smaller point sources included voluntarily by state, local, and Tribal agencies (e.g., crematoria, dry cleaners, and gas stations), airport operation and aircraft landing and take-off emissions, and locomotive missions within railyards.

[5] Natural (nonanthropogenic) emissions from forests, vegetation, and soils

Table 3-18. Climate Trends and Projections for Planning Area States

State	Climate Trends
California	The average annual temperatures in California have increased by nearly 3°F since the beginning of the 20th century. Multiple record warm years have been recorded in the last decade, and the most recent 10-year period (2011-2020) was the warmest on record. Since 1995, California has experienced a below normal number of cold nights and its highest number of very warm nights over the historical record (NOAA 2022). The record warmth, in combination with multiple years of below average precipitation, including the driest year, led to the most severe drought of the past 1,200 years (Griffin and Anchukaitis 2014). Precipitation and snowpack vary greatly from year to year. Statewide April 1 snowpack has averaged about 10% lower during the first two decades of the 21st century as compared with the last two decades of the 20th century, with 2015 likely featuring the lowest snowpack in the Sierra Nevada in the last 500 years (Belmecheri et al. 2015).
Colorado	The rugged topography of western Colorado causes large variations in climate within short distances, and few climatic generalizations apply to the whole area. Temperatures in Colorado have risen about 2.5°F since the beginning of the 20th century and have remained above the long-term average since 1998. Six of the eight warmest years on record have occurred since 2012, and warming has been seen in all four seasons. Long-term average annual precipitation has been variable. Unlike many areas of the United States, Colorado has not seen an increase in the frequency of heavy precipitation events (NOAA 2022).
Idaho	Idaho experiences dramatic seasonal temperature differences due to its northerly latitude and interior location, with cold winters and warm summers. Temperatures have risen almost 2°F since the beginning of the 20th century. For the 126-year record, there has been significant variation in precipitation across the state, but no overall trend. However, since 2000, the number of 1-inch extreme precipitation events has been increasing and has been above average for the last 16 years. Snowfall is highly variable from year to year and has generally decreased since the middle of the 20th century. Extreme weather and weather-related events in Idaho include severe winter storms, wildfires, floods, droughts, and heat and cold waves (NOAA 2022).

State	Climate Trends
Montana	Due to its diverse geography and extensive altitudinal range, Montana experiences significant climatic variations. Since the turn of the century, temperatures in Montana have increased by almost 2.5°F. Warming has occurred in most parts of the state and during all seasons. Montana's topographic variety generates significant regional variances in precipitation; however, there is no clear long-term trend in precipitation. Frequent thunderstorms during the summer months can produce hail, lightning, and strong winds. Precipitation events in the spring can cause severe flooding (NOAA 2022). Rising temperatures and recent droughts have killed many trees by drying out soils, increasing the risk of forest fires, or enabling outbreaks of forest insects (BLM 2020).
Nevada	Nevada is mostly a dry state with a wide range of elevations and a very variable climate. Since the beginning of the 20th century, temperatures in Nevada have increased by about 2.4°F. The total annual precipitation has been around or below the average since 2000, but there has been no overall trend over the 126-year period of record. Throughout the state, there are different seasonal patterns of precipitation, but in most places, the winter is when it rains the most. Drought poses a serious climatic threat to Nevada. Since 2004, the state has experienced multiple severe wildfire and flooding events (NOAA 2022).
North and South Dakota	The Dakotas have significant temperature extremes as a result of their location in the middle of the North American continent, distant from the oceans' climate-moderating influence. Temperatures in North Dakota have risen more than 2.6°F since the beginning of the 20th century, while temperatures in South Dakota have risen almost 2°F. Most precipitation falls between late spring and early summer, when the number of thunderstorms is at its peak. The strongest thunderstorms have the potential to create hail, tornadoes, or destructive straight-line winds that reach 75 mph. Compared to other northern states, North Dakota receives less annual snowfall. Conversely, South Dakota is particularly vulnerable to heavy snowfall, strong winds, and low wind chill temperatures, although, snowfall totals are highly variable from year to year. Both North and South Dakota are highly prone to the hazards of flooding and drought (NOAA 2022).
Oregon	Oregon's climate varies widely from the eastern to western regions of the state. Since the beginning of the 20th century, temperatures in Oregon have increased by around 2.5°F, with the highest temperatures recorded in the last 30 years. The amount of precipitation differs considerably from year to year and across the state, with areas west of the Cascades also experiencing significant seasonal variations in rainfall. Compared to many other parts of the country, Oregon has not seen an increase in the frequency of extreme precipitation events (NOAA 2022; Fleishman 2023).
Utah	With forested, alpine, and desert areas, Utah has a diverse geographic landscape contributing to its variable climate. Utah has had a temperature increase of over 2.5°F since the turn of the century, and the early 21st century has been the warmest period on record. The past three decades have seen a decrease in the frequency of very cold nights and an increase in very warm nights (NOAA 2022). There has been no statistically significant trend in precipitation. As the state has warmed, the percentage of precipitation falling as snow during the winter has decreased, as has snow depth and snow cover (BLM 2020).
Wyoming	Wyoming's interior, mid-latitude location and exposure to sporadic storm systems results in a primarily semiarid climate. Temperatures have increased by around 2.5°F since the beginning of the 20th century. Warming is most noticeable during winter, as seen by a generally below-average number of extremely cold days since 2000 (NOAA 2022). There is no long-term trend in annual mean precipitation. Summer thunderstorms are common, which can bring about hail, lightning, and powerful winds, and the state is prone to the effects of winter storm systems, such as significant snowfall, strong winds, and low wind chill temperatures (BLM 2020; NOAA 2022).

Chapter 4 Methodology, Assumptions, Indicators, and Environmental Consequences for Alternatives 1-6

This page intentionally left blank.

Appendix 10. Chapter 4 Methodology, Assumptions, Indicators, and Environmental Consequences for Alternatives 1-6

10.1 Introduction

This section provides an overview of the general methodology used to analyze impacts, discusses incomplete or unavailable information, outlines the analytical assumptions applied, and provides the environmental consequences for Alternatives 1-6 for each resource analyzed in this EIS.

10.1.1 General Methodology for Analyzing Impacts

The discussion of impacts is based on best available data. Knowledge of the planning area and decision area and professional judgment, based on observation and analysis of conditions and responses in similar areas, are used for environmental impacts where data are limited. Acreage figures and other numbers used in the analyses are approximate projections for comparison and analytic purposes only. Readers should not infer that they reflect exact measurements or precise calculations. Potential impacts are described in terms of type, context, duration, and intensity, which are generally defined below.

Type of impact—The analysis discloses impacts, both beneficial and adverse. Because types of impacts can be interpreted differently by different people, this chapter seeks to avoid differentiation between beneficial and adverse impacts. Notable exceptions are cases where such characterization is required by law, regulation, or policy. The presentation of impacts for key planning issues is intended to provide the BLM decision maker and reader with an understanding of the multiple use trade-offs associated with each alternative.

Context—This describes the area or location (site-specific, local, planning area-wide, or regional) in which the impact would occur. Site-specific impacts would occur at the location of the action, local impacts would occur within the general vicinity of the action area, planning area-wide impacts would affect a greater portion of decision area lands, and regional impacts would extend beyond the planning area boundaries. Refer to **Chapter 1** for a description of the planning area and decision area.

Duration—This describes the continuance of an effect, which can be classified as short term or long term. Short-term is defined as anticipated to begin and end within the first 5 years after the action is implemented; long term is defined as lasting beyond 5 years to the end of or beyond the life of this RMPA.

Intensity—Rather than categorize impacts by subjective intensity rankings (e.g., major, moderate, or minor), this analysis discusses the intensity of impacts using quantitative data wherever possible.

Direct, indirect, and cumulative impacts—Direct impacts are caused by an action or implementation of an alternative and occur at the same time and place; indirect impacts result from implementing an action or alternative but usually occur later in time or are removed in distance and are reasonably certain to occur. Cumulative impacts are effects on the environment that result from the impact of implementing any one of the alternatives in combination with other actions, either within the planning area or adjacent to it, regardless of who is taking or has taken that other action. Cumulative effects analysis is provided in **Section 4.21**, Cumulative Impacts.

10.1.2 Incomplete or Unavailable Information

The CEQ established implementing regulations for NEPA that require federal agencies to identify relevant information that may be incomplete or unavailable for evaluating reasonably foreseeable significant adverse impacts in an EIS (40 CFR Section 1502.21). If the information is essential to a reasoned choice among alternatives, it must be included or addressed in an EIS. Knowledge and information is, and will always be, incomplete, particularly with infinitely complex ecosystems considered at various scales.

The BLM used the best available information pertinent to the decisions to be made in developing the RMPA. The BLM made a considerable effort to acquire and convert resource data into digital format for use in the RMPA, both from the BLM and from outside sources.

Under the FLPMA, the inventory of public land resources is ongoing and continuously updated. However, a comprehensive inventory of wildlife and special status species habitat and condition has not been completed across the planning area, and as such, discussions of impacts on potential habitat are included.

For resources where there is incomplete or unavailable information, estimates were made concerning the number, type, and significance of these resources based on previous surveys and existing knowledge. In addition, some impacts cannot be quantified, given the proposed management actions. Where this gap occurs, impacts are projected in qualitative terms or, in some instances, are described as unknown. Subsequent project-level analysis would provide the opportunity to collect and examine site-specific inventory data to determine appropriate application of RMP-level guidance. In addition, the BLM and other agencies continue to update and refine information used to implement this RMPA.

GIS data was used to perform acreage calculations, and to generate the maps in **Appendix 1**. Calculations are dependent upon the quality and availability of data. Given the scale of the analysis, the compatibility constraints between datasets, and lack of data for some resources, all calculations are approximate and serve for comparison and analytic purposes only. Likewise, the maps in **Appendix 1** are provided for illustrative purposes and subject to the limitations discussed above. No warranty is made by the BLM as to the accuracy, reliability, or completeness of these data for individual use or aggregate use with other data.

10.1.3 Analytical Assumptions

Several overarching assumptions were made to facilitate the analysis of the project impacts. These assumptions set guidelines and provide reasonably foreseeable projected levels of development that would occur in the planning area during the planning period. These assumptions should not be interpreted as constraining or redefining the management objectives and actions proposed for each alternative, as described in **Chapter 2**.

The following general assumptions apply to all resource categories. Any specific resource assumptions are provided in the methods and assumptions section for that resource.

- Sufficient funding and personnel would be available for implementing the decision.
- Implementing actions from any of the RMPA alternatives would comply with all federal regulations, BLM policies, and other requirements.
- Implementation-level actions necessary to execute the decisions in this RMPA would be subject to further environmental review, including that under the NEPA, as appropriate.
- Most direct and indirect impacts of implementing the RMPA would primarily occur on BLM-administered lands in the planning area. However, indirect impacts are also likely, such as limiting

development on BLM-administered land that may redirect development to other adjacent and nearby non-BLM-administered land.

- Local climate patterns of historic record and related conditions for plant growth may change. Changes to the timing, type, and amount of precipitation will likely occur over the life of this plan.
- In the future, as tools for predicting climate changes in a management area improve and changes in climate affect resources, the BLM would be able to better incorporate climate change into the implementation of projects.
- Restrictions (such as siting, design, and mitigation measures) would apply, where appropriate, to surface-disturbing activities associated with land use authorizations and permits issued on BLM-administered lands.
- When used in the EIS, the terms "mineral development" or "mineral resource development" refer broadly to development of a range of minerals, including fluid minerals, nonenergy leasable minerals, saleable minerals, and locatable minerals. Elsewhere, the analysis specifies a given type of mineral as applicable.
- Removal of livestock grazing on BLM-administered lands may require fences to separate BLM-administered lands from adjacent lands under different surface land ownership to prevent trespass.

10.2 GREATER SAGE-GROUSE

10.2.1 Methods and Assumptions

Methodology

Impacts on GRSG would primarily result from management actions described in **Chapter 2** that result in habitat removal, fragmentation, or other alteration, and actions that result in injury or mortality, displacement, or other disturbance. The types of actions that can result in these impacts are discussed in more detail in **Section 4.2.1**, Nature and Type of Effects. For management actions not specifically described below, the effects would remain as described in the 2015 and/or 2019 plans.

Indicators

Indicators of impacts on GRSG are as follows:

- Acres of habitat management area within the planning area.
- Habitat loss/degradation – Likelihood for habitat impacts caused by the loss of habitat function or value, including connectivity, and the extent to which it may influence lek and population persistence/ viability.
- Behavioral disturbance to individuals – Likelihood of impacts on survival or reproduction due to direct or indirect effects, including habitat avoidance, and the extent to which it may influence lek and population persistence/viability.

Assumptions

In addition to the assumptions in **Section 4.1.1**, Analytical Assumptions, this analysis includes the following assumptions:

- GRSG habitat management area designations are assumed to represent habitat adequate to maintain GRSG populations in the planning area.
- Seasonal ranges of migratory and nonmigratory GRSG are largely encompassed within GRSG habitat management area designations.

- GRSG habitat management area designations encompass adequate habitat for providing connectivity within populations and subpopulations. Connectivity is considered by incorporating population area information in the design and implementing restoration projects.
- If adverse impacts are identified, mitigation measures could be implemented to reduce the impacts. If analysis indicates remaining residual impacts, compensatory mitigation may be required. If monitoring reveals that mitigation is unsuccessful in reducing or eliminating impacts, measures to prevent further impacts would be implemented as appropriate to the species affected.
- Short-term effects would occur over a timeframe of 5 years or less, and long-term effects would occur over longer than 5 years.
- BMPs, COAs, and SOPs are used for analysis and would be implemented to reduce impacts on GRSG. These are subject to modification based on subsequent guidance and new science.
- Ground-disturbing activities could modify habitat and cause loss or gain of individuals, depending on the size of the area disturbed, the nature of the disturbance (e.g., development vs. habitat restoration), and the location of the disturbance. For example, habitat restoration treatments in sagebrush steppe disturb the ground but are assumed to positively modify habitat quality and quantity in the long term. Roads, transmission lines, pipelines, and other infrastructure generally cause fragmentation of habitat that can impact lek persistence, lek attendance, winter habitat use, recruitment, chick survival, yearling annual survival rate, and female nest site choice (Holloran 2005; Aldridge and Boyce 2007, Walker et al. 2007a; Doherty et al. 2008; Holloran et al. 2010; Hagen et al. 2007; Johnson et al. 2011; Taylor et al. 2012).
- Because GRSG are highly sensitive to habitat fragmentation, development, and changes in habitat conditions and require large, intact habitat patches, alternatives proposing to protect the most GRSG habitat from disturbance are considered of greatest beneficial impact to the species. These impacts can be described both qualitatively and quantitatively.

10.2.2 Alternative 1

Habitat Designation and Management

Rangewide Environmental Consequences

Under Alternative 1, GRSG habitat is separated into SFAs, PHMA, GHMA, and other HMAs for certain states (see **Table 2-3**). Restrictions to land use and surface-disturbing activities would occur within each HMA and SFA, depending on the classification (see **Chapter 3**). Corresponding management actions, including lek buffers, required design features, fluid mineral leasing prioritization, and habitat objectives, would provide a hierarchy of potential conditions to minimize effects in HMAs. Withdrawal from location and entry under the US mining laws, subject to valid existing rights, would be recommended for lands within SFAs to promote protection of GRSG and its habitat. If the Secretary approves the proposed withdrawal, management for SFAs would provide the highest level of protection to GRSG. The lack of WEMs in SFAs, even for actions that would benefit GRSG, could limit habitat improvements. In general, restrictions to land use and surface-disturbing activities in HMAs and SFAs reduce the likelihood for habitat loss, fragmentation, and direct disturbance to GRSG. Effects from specific restrictions associated with each resource use are described in the sections below. However, restrictions to development on BLM lands might push development onto private land, which could result in indirect impacts as described under *Nature and Types of Effects*. In most cases management actions for state-specific HMA (IHMA, OHMA, etc.) would be consistent with those for PHMA; where differences occur, they are analyzed under *State-Specific Environmental Consequences*. Alternative 1 includes lek buffers for all HMAs. These buffers are consistent with the lek buffer distances identified in the USGS Report, *Conservation Buffer Distance Estimates for Greater Sage-Grouse - A Review* (a 1-mile buffer would be used as the minimum threshold in Colorado). Modifications to

the buffer distances are allowed if they meet the criteria outlined in the report. Lek buffers would reduce disruption to GRSG, minimize habitat loss, and reduce habitat degradation, and should contribute to maintaining nesting habitat effectiveness and brood survival.

Alternative 1 incorporates an adaptive management strategy composed of soft and hard triggers based on population and habitat changes. BLM would rely on data from several sources to track and identify population changes to assess the population trigger in the adaptive management approach. Triggers would be determined by population area, making the strategy more locally responsive than if triggers were determined on a sub-regional or statewide basis. Responses to soft triggers may require adjustment of future project level/plan implementation activities, as consistent with the individual site-specific NEPA analyses. Soft trigger responses can come in the form of terms, conditions, RDFs, or site-specific mitigation measures. Hard triggers mean that immediate action is necessary to stop a severe deviation from conservation objectives set forth in the Proposed RMP Amendment. If new scientific information becomes available demonstrating that the hard-wired response would be insufficient to stop a severe deviation from sage-grouse conservation objectives set forth in the ARMPA, BLM will implement interim management direction to ensure conservation options are not foreclosed. BLM will also undertake plan amendments or revisions if necessary. The use of adaptive management would benefit GRSG by allowing flexible resource management decision making that can be adjusted in the face of uncertainties as outcomes from management actions and other events become better understood. If management changes are successful, they would reduce impacts to GRSG by limiting disturbances and improving habitat conditions. BLM would require and ensure mitigation that achieves a net conservation gain in all HMA types and in all states (except WY GHMA). Mitigation should offset any loss of GRSG habitat resulting from land use activities.

Under Alternative 1, all states would include language to maintain and enhance sagebrush habitats with the intent of conserving GRSG populations. Habitat objectives would be considered when authorizing activities in GRSG habitat. The exact language varies by state, but in general, inclusion of specific habitat objectives could result in increased certainty and greater levels of consistency when considering implementation-level actions. Following these objectives could prevent activities such as improper grazing practices and result in increased habitat quality. Improved habitat conditions would increase nest success, chick survival, and GRSG persistence over the long term.

State-Specific Environmental Consequences

There could be impacts to GRSG in WY GHMA associated with land use activities as described under *Nature and Types of Effects*. No mitigation would be required in WY GHMA.

In CO, ID, NV/CA, OR, and UT, a 3% disturbance cap would apply to land use activities (except wildfire and agriculture) at both biologically significant unit (BSU)-scale and at proposed project analysis area within PHMA. In ID, the same cap would apply but it could be exceeded in utility corridors if it benefits GRSG. Calculating disturbance at the project-level may prevent some development that could occur if disturbance is only calculated at a coarser scale. Disturbance would also be calculated for each BSU. The definition of a BSU would vary by state, but in general, a BSU is defined as a spatial area that contains relevant and important GSRG habitats and is used for comparative calculations to support evaluation of changes to habitat. Including caps at both project and BSU scales would reduce disturbance on both the local and landscape scales, therefore, provide protection for both the larger population and individual leks and their surrounding habitat.

Excluding wildfire and agriculture from the disturbance calculation for those states listed above may result in a higher level of disturbance overall. Since wildfire was the primary source of habitat loss in previous years (Herren et al. 2021), this may contribute to continued declining habitat trends. Wildfire and agriculture are

factored into the soft and hard habitat triggers and included as part of the HAF boundary and 70% sagebrush cover habitat objective; if these disturbances lead to the trip of a trigger, adaptive management would be applied to reverse the trends. In PHMA and IHMA, the Anthropogenic Disturbance Screening Criteria would apply stringent criteria to any proposed projects. No disturbance cap would apply in GHMA or GRSG brood-rearing habitat and migration corridors.

Managing RHMA in MT would add protections to GRSG in those areas. Management actions in RHMA would emphasize restoration for the purpose of restoring habitat to provide the ability for establishing or enhancing GRSG populations to sustainable, dense levels. Management in RHMA that leads to restrictions to land use and surface-disturbing activities would reduce the likelihood for habitat loss, fragmentation, and direct disturbance to GRSG. The restoration focus in RHMA would further improve GRSG habitat. The higher disturbance cap in MT, WY, and the Dakotas could lead to greater levels of anthropogenic disturbance within a project area, and therefore greater potential for habitat loss and alterations as well as direct disturbance to GRSG, depending on the degree to which wildfire and agriculture contribute to disturbance in a given area. Disturbance will only be calculated at the project level, so cumulative disturbance over a larger area could potentially occur at levels that influence GRSG populations within a BSU. In areas with reduced habitat due to wildfire and/or agriculture, additional anthropogenic development would be limited, reducing the combination of threats and habitat degradation.

Although all states would include an adaptive management strategy, the metrics, thresholds, timeframes, and spatial scales for evaluating and responding to triggers would vary state by state. As a result, there would be no consistency in how triggers are calculated across the range and responses may not be implemented across an area that encompasses an entire population group and/or seasonal habitats needed throughout the year. If management changes do not apply to all populations and habitats being affected, some individuals and/or habitat areas may improve while others remain impacted.

In UT, the GHMA identified in Alternative 1 generally comprises poor-quality habitat on the periphery of larger PHMA. The extent to which some of these GHMA areas may provide connectivity, be used as corridors, or provide certain seasonal habitat during portions of a bird's life cycle is largely unknown due to limited telemetry. Most of these GHMA areas are predominantly private, Tribal, and TLA lands, and because of the limited regulatory discretion (other than split estate where BLM administers the mineral estate) that the BLM has on resources in these areas impacts on GRSG from development are likely to continue at current rates. Only 6 of the 13 leks in GHMA are in areas affected by BLM management, with the other 7 in areas predominantly managed by USFS, tribal, or private entities. Development could still occur in UT GHMA potentially resulting in alteration, direct loss, and fragmentation of seasonal GRSG habitats. Fragmentation could further limit the amount of usable habitat available for the small and declining population of GRSG that occupy GHMA.

Minerals Management

Rangewide Environmental Consequences

Leasing of fluid minerals would be allowed in PHMA and ID IHMAs, subject to NSO stipulations and/or seasonal restrictions. This would increase HMA acres subject to effects from fluid mineral development compared to alternatives in which PHMA would be closed to leasing. In SFAs, there would be no exceptions, waivers, or modifications allowed. In PHMA outside of SFAs, no waivers or modifications would be allowed but exceptions could be considered on a very limited basis, and only in circumstances where granting an exception would have either have no impacts or would reduce impacts on GRSG.

NSO stipulations on new leases would protect PHMA from surface-disturbing activities on BLM lands. In large contiguous areas primarily managed by the BLM, GRSG exposure to disruption would be limited to the human activity that accompanies construction, development, or production activities. Access to fluid mineral deposits would require horizontal drilling from outside the boundaries of the NSO area. In areas of mixed ownership, impacts could still occur due to directional/horizontal drilling NSO on BLM lands may encourage co-location of leases, which could help prevent fragmentation and preserve connectivity between leks by concentrating effects outside of PHMA.

PHMA in all states would be closed to saleable mineral development (except where authorized in MT and open subject to restrictions in WY), but open for new free use permits (except ID). PHMA in all states and ID IHMAs would be closed to nonenergy mineral development, but they could consider expansion of existing leases. Most states would include minimization measures for saleable mineral and nonenergy mineral development in GHMA, but they were not recommended for withdrawal. These are described in the 2015 EISs for CA, CO, ID, MT/DK, NV, OR, UT, and WY (BLM 2015a-2015h). SFAs in all states were recommended for withdrawal from location and entry under the United States mining laws, subject to valid existing rights. Following publication of the RODs, the BLM applied for a withdrawal of the SFAs, pursuant to section 204 of FLPMA. The Secretary accepted the BLM's application and the BLM initiated the withdrawal process for those lands; the EIS for the withdrawal is underway. These restrictions would reduce the HMA acres affected and potential impacts to GRSG and habitat within PHMA and GHMA, such as disturbance and habitat alterations. Indirect effects on wildlife include noise, dust, and light impacts resulting from locatable mineral development and associated transportation.

State-Specific Environmental Consequences

In WY, applying an NSO within 0.6 miles of occupied GRSG leks in PHMA would protect fewer areas than in other states. Buffer distances from 0.5 to two miles from oil and gas infrastructure have been shown to be inadequate to prevent declines of birds from leks (Walker et al. 2007a). Studies have shown that greater distances, anywhere from two to four miles, are required for viable GRSG populations to persist (Walker et al. 2007a).

In WY and MT PHMA, fluid mineral development in areas that are already leased (and thus are exempt from NSO stipulations) would also be subject to density and disturbance limits, which would limit the extent of development and associated impacts. GHMA would be subject to NSO stipulations for fluid mineral development within 2 (CO), 1 (OR) or 0.25 (WY) miles of leks. GHMA in UT would also be subject to NSO stipulations but the distance varies by BLM office. PHMA and GHMA in CO and GHMA in OR would be closed to fluid mineral development within 1 mile of leks; this would provide increased protections to GRSG and contribute to lek persistence because no development (surface or subsurface) could occur. Fluid mineral development would be subject to Controlled Surface Use (seasonal restrictions and/or buffers) stipulations in ID, NV/CA OR, and WY GHMA. MT-DK would include a 0.6-mi NSO in GHMA and seasonal limitations (breeding, nesting, early brood-rearing & winter habitat) and CSU (density and disturbance) for the rest of the GHMA. Applying these restrictions to fluid mineral development would reduce potential impacts to GRSG associated with fluid mineral development.

Development of fluid mineral resources in GHMA would still result in the localized direct loss and fragmentation of seasonal habitats and displacement of GRSG from current use areas outside of the applicable lek buffers. The general effects of fragmentation, habitat loss, and displacement are discussed in *Nature and Types of Effects*. Application of lek buffers as required conservation measures or COAs would protect lekking, most nesting, and some brooding habitat; however, nesting and brooding habitat located

outside of the buffer would be afforded no specific protections other than the restrictions associated with management of PHMA and GHMA. Impacts of development outside buffer areas could be offset by mitigation because operators would be required to mitigate impacts until there is a net conservation gain. Mitigation may be conducted off-site if it would provide greater benefit to GRSG as a whole in the planning area, thus potentially resulting in unmitigated impacts on local populations in GHMA.

In CO, ID, ND, NV/CA, OR, UT, WY, and parts of MT/DK (Billings, HiLine, Miles City, ND, SD), priority would be given to leasing and development of fluid mineral resources, including geothermal, outside of PHMA and GHMA, or within the least impactful areas within PHMA and GHMA if avoidance is not possible. Leasing outside of HMAs would reduce potential for impacts associated with horizontal drilling (in PHMA which would be NSO) and with fluid mineral leasing, exploration, and development in GHMA. The prioritization objective could potentially result in temporarily deferring a parcel in PHMA from leasing to a later sale. There would be no similar objective in the Lewistown or Butte Field Offices, and therefore, potential for impacts would be greater.

For both saleable mineral and nonenergy mineral development, WY PHMA would be subject to seasonal restrictions, while WY and MT PHMA would be subject to density and disturbance limits. These additional restrictions would reduce potential impacts to GRSG associated with saleable mineral development, but to a lesser extent than if they were completely closed to development. In Idaho, IHMA would be open to nonenergy mineral development in Known Phosphate Lease Areas, and similar impacts (e.g., displacement and habitat impacts from loss, disturbance, and erosion could occur from open pit mining) could occur in areas open to development.

PHMA in CO, MT/DK, UT, and WY would be considered "essential habitat" for coal unsuitability evaluation. This would likely lead to PHMA in these states being considered unsuitable for coal development and would limit the potential for impacts associated with coal development. ID, NV/CA, and OR would not address coal development due to absence of the mineral.

The oil and gas lease stipulations summarized in **Appendix 2** would be applied in MT/DK; these stipulations would reduce the potential for impacts associated with fluid mineral leasing.

In CO PHMA and within 4 miles of an active lek, siting criteria would be applied to guide development of the lease or unit that would result in the fewest impacts possible to GRSG. Criteria include consideration of location of proposed lease activities in relation to critical GRSG habitat areas, and evaluation of the potential threats from proposed lease activities, and an evaluation of the proposed lease activities, including design features, in relation to the site-specific terrain and habitat features. To authorize an activity based on these criteria, the environmental record of review must show no significant direct disturbance, displacement, or mortality of GRSG.

Lands and Realty Management

Rangewide Environmental Consequences

Under Alternative 1, PHMA in all states, ID IHMAs, and some MT RHMAs would be identified as ROW avoidance areas to allow for management flexibility (except for minor ROWs in WY, as described under state analysis). PHMA would be exclusion areas for wind and solar (utility scale solar only in ID, NV/CA and OR) development (with exceptions in WY, OR, and ID IHMA, see state-specific analysis). Classifying PHMA as exclusion or avoidance areas would decrease the potential for impacts associated with ROW development, such as disturbance and increased potential for predation GHMA in all states would be open to minor ROWs with mitigation measures (WY does not require mitigation, see state-specific analysis).

Impacts associated with ROW development, such as disturbance and increased potential for predation, could occur in these areas if developed, but mitigation measures would help to offset the impacts.

New ROWs in PHMA would not be allowed except in accordance with the Anthropogenic Disturbance Screening Criteria outlined in Alternative 1. The BLM would collocate new ROWs with existing infrastructure when possible. Alternative 1 would apply at implementation a protective buffer from disturbance around leks in PHMA, IHMA and GHMA, depending on the type of disturbance and based on the latest science. BLM would retain management flexibility to route ROWs to minimize overall impacts on GRSG habitat. Existing ROW corridors are preferred for collocation of new ROWs but could not be widened more than 50% greater than the original footprint. These measures would protect GRSG and their habitats from fragmentation, disturbance and predation, and other impacts.

State-Specific Environmental Consequences

In IHMA new ROWs could be considered if in accordance with the IHMA Anthropogenic Disturbance Development Criteria. PHMA in WY would be open to minor ROWs with buffers and mitigation. Effects from ROWs could occur; buffers and mitigation would help offset the impacts, but to a lesser extent than ROW exclusion/avoidance. GHMA in WY would be open to minor ROWs and no mitigation measures would be required. There would be a greater potential for impacts associated with ROWs in these areas.

CO, NV/CA, and OR GHMA would be identified as avoidance areas for major ROWs, which would reduce impacts. ID and UT GHMA would be open to major ROWs with minimization measures, while WY GHMA would be open to major ROWs. In ID and UT, minimization measures would help reduce the impacts, but to a lesser extent than ROW exclusion/avoidance.

Classifying GHMA in CO, NV/CA, and OR as avoidance areas for major ROWs would decrease the potential for impacts associated with ROW development. Opening UT and ID GHMA to major ROWs with minimization measures, would increase the potential for impacts, such as disturbance and increased potential for predation, but mitigation measures would help to offset the impacts. Opening GHMA in WY to major ROWs would also increase the potential for impacts, and there would be no mitigation measures to offset the impacts.

Renewable Energy Management

Rangewide Environmental Consequences

Under Alternative 1, PHMA in all states would be exclusion areas for wind and solar (utility scale solar only in ID, NV/CA and OR) development (with exceptions in WY, OR, and ID IHMAs; see state-specific analysis). Within the exclusion areas, this would eliminate direct impacts from potential renewable energy development on GRSG in PHMA. As a result, GRSG would experience reduced potential for disturbance, habitat alterations, and habitat fragmentation.

State-Specific Environmental Consequences

In WY, PHMA would be avoidance areas for wind development or open if it can be sufficiently demonstrated that development would not result in population declines. ID IHMAs would be avoidance areas for utility-scale solar and wind development. PHMA in OR would be avoidance areas for wind and solar development in Lake, Harney, and Malheur Counties. Classifying PHMA as avoidance areas would decrease the potential for impacts, but to a lesser extent than exclusion areas.

Classifying GHMA in CO, MT/DK, NV/CA, and OR as avoidance areas for wind development, GHMA in CO, MT/DK and OR as avoidance areas for solar development, and GHMA in NV/CA and UT as exclusion

areas for solar development, would decrease the potential for impacts associated with wind and/or solar development. GHMA in ID, UT and WY would be open to wind development and GHMA in ID and WY are open to solar development, so there would be a greater potential for impacts *s*.

Depending upon the potential for renewable energy development and the size and location of permitted development in GRSG habitat, there could be impacts ranging from discountable in less important habitats to decreasing the population growth rate if placed in important habitats. COAs could be applied to reduce impacts on GRSG, but they would not be consistently applied across the decision area. Renewable energy development in GRSG habitat would be expected to result in habitat loss, degradation, fragmentation, and direct disturbance to the birds. Based on previous research (e.g., LeBeau 2012), nests and broods near wind facilities would have a lower rate of success and such declines in these vital rates, especially impacts on nest success, would decrease the population growth rate in these populations and may lead to loss of the population over time (Taylor et al. 2012).

Livestock Grazing Management

Rangewide Environmental Consequences

Under Alternative 1, PHMA and GHMA in all states, and ID IHMA, and would be available for domestic livestock grazing. Impacts to GRSG and habitat from grazing, such as habitat alterations, could occur in PHMA, GHMA, and ID IHMAs.

Priority for review and processing of grazing permits/leases would be in SFAs, followed by PHMA outside of SFAs. Precedence would be given to existing permits/leases in these areas not meeting land health standards, with focus on those containing riparian areas, including wet meadows. Prioritization would help LM identify issues that may be associated with improper grazing and implement corrective actions in the areas that have the greatest habitat value. Management changes, if required, would be tailored to meet land health standards and GRSG habitat objectives. BLM would also require thresholds and responses to address and respond to future conditions in new fully processed permits. The review process described above would reduce impacts to GRSG from grazing if review leads to adjustments to existing permits/leases that improve land health standards.

State-Specific Environmental Consequences

In MT/DK, BLM would use applicable RDFs to mitigate potential impacts from West Nile virus when developing or modifying water developments. This would reduce potential for impacts to GRSG from disease spread associated with livestock subsidies.

Under Alternative 1 all or portions of 13 key RNAs in Oregon would be unavailable for livestock grazing (see **Appendix 17** for further analysis). In key RNAs, 21,959 acres would be unavailable to livestock grazing (**Table 3-25**, Oregon Key RNA Acreages). Two key RNAs (Foster Flat and Guano Creek-Sink Lakes) would remain unavailable to livestock grazing. **Tables 4-2** and **4-3** provide corrections and updates to the vegetation communities with the various key RNAs and are based on new, site-specific information gathered or generated by the Lakeview, Vale, and Burns districts in Oregon. Under Alternative 1, fencing would be present in and adjacent to key RNAs in Oregon. The ability to distribute livestock would generally be maintained, and impacts would be limited from these actions (BLM 2015a, p. 4-203). Making portions of RNAs that contain plant communities important to GRSG unavailable to grazing could provide the BLM with areas for baseline vegetation monitoring without the influence of BLM-permitted activities. Whether removal of grazing would reduce the risk of invasive plant spread into the key RNAs is uncertain.

Wild Horse and Burro Management

Rangewide Environmental Consequences

Under Alternative 1, wild horse and burro populations would continue to be managed for AMLs and in balance with other resource uses. Wild horse and burro gathers would be prioritized based on escalating or potential emergencies, public safety, nuisance animals, court orders, population growth suppression, and resource impacts associated with monitoring data, which is generally based on wild horse and burro population inventories, wild horse and burro condition, availability of sufficient water and forage resources, rangeland health, use levels of upland habitats, and riparian resource conditions. Evaluation of land health assessments in wild horse and burro HMAs could identify vegetation conditions that could prompt gathers, reducing wild horse numbers and the associated impacts on GRSG habitats.

Predation Management

Rangewide Environmental Consequences

Under Alternative 1, following more specific vegetation objectives and reducing opportunities for predators may, in some cases, improve the quality of habitat and decrease opportunities for predation. Improved habitat conditions and decreases in predation would increase nest success, chick survival, and GRSG persistence over the long term.

State-Specific Environmental Consequences

In NV/CA, UT, and WY, habitat objectives to minimize human resource subsidies, and coordinate with other partners on predator management would likely reduce exposure of predatory birds to GRSG nests and chicks, thereby ensuring GRSG persistence until habitat conditions improve (O'Neil et al 2018). Similarly, habitat management in CO, NV/CA, and UT to provide GRSG concealment from predators may help reduce predation and increase GRSG persistence.

ACEC Designation

Alternative 1 would not result in any impacts from ACEC designation since it does not include designation or management for ACECs.

10.2.3 Alternative 2

Habitat Designation and Management

Rangewide Environmental Consequences

Impacts from designating GRSG habitat as SFAs, PHMA, IHMAs, and GHMA and associated management would be similar to those described for Alternative 1 (**Table 2-3**). The overall acreage would be slightly less with less than 1% fewer acres of PHMA and approximately 1.5% fewer acres of GHMA. Some SFAs would be removed in states as described under state impacts. Impacts from language to maintain and enhance sagebrush habitats would be the same as described for Alternative 1. Additionally, habitat objectives would be the same as described for Alternative 1.

State-Specific Environmental Consequences

Removing SFAs in CA, ID, NV, UT, and WY would reduce protections to GRSG and habitat. However, previous management area classifications (e.g., PHMA, GHMA) would remain, but protections may be lower under some of those other classifications. Reducing restrictions to land use and surface-disturbing activities could increase the likelihood for habitat loss, fragmentation, and direct disturbance to GRSG. Habitats in these areas would likely be reduced in quality due to impacts associated with mineral development. If protections are lacking from adjacent lands and the lands are developed, this could lead to habitat fragmentation due to large, contiguous areas of habitat losing habitat suitability. Protections to GRSG and

habitat from restrictions to land use and surface-disturbing activities would continue in SFAs in MT and OR, and impacts would be as described under Alternative 1. Management of RHMA would be the same as described for Alternative 1.

Under Alternative 2, the GHMA designation in UT would be removed with all its corresponding management actions from the 2015 plan amendments. Removal of GHMA and their associated management actions would likely incentivize development in areas formally identified as GHMA and could therefore lead to GRSG habitat loss and alterations.

Requirements for mitigation that achieves a net conservation gain in all HMA types would apply in MT/DK, NV/CA, and OR, and impacts would be the same as described for Alternative 1. CO and ID would enforce mitigation resulting in no net loss in HMAs. This would help offset impacts associated with land use activities, but to a lesser extent than Alternative 1, in which a net conservation gain would be required. In UT and WY, the net conservation gain requirement would be removed. Although the BLM would not require compensatory mitigation in HMAs, it would enforce state mitigation policies and programs. In CO, ID, NV/CA, OR, UT, and WY HMAs, compensatory mitigation would be voluntary unless required by laws or by the State. As a result, the potential for impacts from land use activities would be greater relative to Alternative 1.

Impacts from applying a 3% (CO, ID, NV/CA, OR, UT, and the Dakotas) or 5% (MT, WY, and the Dakotas) disturbance cap in PHMA would be similar to those described for Alternative 1. In UT and ID the cap could be exceeded if it would benefit GRSG. The cap would be applied at the BSU and project scale, except in ID which would only apply it at the BSU scale. Consequently, some additional development could occur in ID, which may increase potential for habitat loss and alterations, particularly for individual leks and their surrounding habitat.

The ability to exceed the disturbance and density caps could result in loss and degradation of GRSG habitat and impacts on local GRSG populations. Exceedances to the caps would only be allowed if site-level analysis indicates that the project, in combination with all voluntary and required design features, will improve the condition of GRSG habitat. The risk in allowing this exceedance is the possible loss of a specific type of habitat that mitigation may not address because it does not require compensation for the exact same habitat value. Consequently, it is possible that while the required habitat improvement will occur, it may not address the loss of a specific habitat type. This may result in a long-term impact on GRSG in the project area.

Impacts from including an adaptive management strategy would be similar to those described for Alternative 1. Some states would include the addition of "un-triggers", meaning that the management change implemented to reverse a trigger could be revoked and the original management would be reimplemented once the issue is resolved. Reverting back to the original management that resulted in the trigger being tripped could lead to additional population declines and/or habitat degradation that could cause the trigger to be tripped again.

In Idaho, BLM would apply the lek buffer distances for certain land uses from the 2019 Idaho GRSG ARMPA, or Alternative 2, and as described in **Appendix 19**. In general, the buffer distances would vary by HMA type, with buffer distances in PHMA being the largest followed by IHMA, then GHMA. Buffer exception criteria would be included for IHMA/GHMA as described in the appendix. Under Alternative 2, buffer distances in PHMA and IHMA are based upon the 'lower end of the interpreted range' and mostly the 'literature minimum', respectively, as summarized in the USGS Report, *Conservation Buffer Distance Estimates for Greater Sage-Grouse – A Review* (Manier et al. 2014). Buffers would reduce disruption to GRSG, minimize

habitat loss, and reduce habitat degradation, which should result in maintaining nesting habitat effectiveness and brood survival. Protections would be greatest in PHMA, followed by IHMA, then GHMA. This approach would encourage development outside of the best habitat and into lesser quality or non-habitat.

In UT, the GHMA designations would be removed with all its corresponding management actions from the 2015 plan amendments. Alternative 2 prioritizes the importance of management prescriptions on PHMA to protect the seasonal habitats that support over 95% of GRSG populations in Utah. Impacts would likely accelerate the effect on resources in the former GHMA since those acres will be removed from management consideration. GRSG management would revert to the management in place prior to the 2015 ARMPA; therefore, some protections such as lek buffers, seasonal restrictions may still be applied depending on the GRSG resource present.

Minerals Management

Rangewide Environmental Consequences

Impacts from fluid mineral management in PHMA and GHMA would be the same as described for Alternative 1, except in CO PHMA and CO GHMA.

Impacts from saleable mineral management in PHMA and GHMA would be the same as described for Alternative 1, except in ID IHMAs and NV/CA PHMA.

Impacts from nonenergy mineral management in PHMA and GHMA would be the same as described for Alternative 1, except in NV/CA PHMA.

Impacts from coal management in PHMA and GHMA would be the same as described for Alternative 1, except in UT PHMA.

Removing the recommendation for locatable mineral withdrawal in SFAs in all states (except in MT/DK, which did not have a 2019 amendment) has no impact. The Secretary proposes and makes withdrawals through a separate process pursuant to section 204 of FLPMA not through BLM land use planning.

State-Specific Environmental Consequences

Removing the closure of CO PHMA to fluid mineral development would increase potential for disturbance and habitat alterations/degradation since mineral development activities could occur in previously closed areas and potentially result in impacts described under *Nature and Types of Effects*. Changing GHMA from closed to fluid mineral development to NSO would likely have minimal impacts since the stipulation would avoid potential for disturbance and habitat alterations/degradation from surface-disturbing activities.

Impacts from prioritizing fluid mineral leasing outside of HMAs in CO, ID, OR, and MT/DK offices would result in the same impacts in these states as described under Alternative 1. Removing the objective in UT and NV/CA would increase the potential for impacts because land in PHMA and GHMA could be leased. Removal of the fluid mineral leasing prioritization objective would not increase threats, since the NSO stipulation would still be in effect. In WY, fluid mineral leasing would be allowed in PHMA, which would increase the potential for impacts. If BLM has a backlog of Expressions of Interest for leasing, the BLM would prioritize work first in non-habitat followed by lower habitat management areas (e.g., GHMA). For fluid mineral development on existing leases that could adversely affect GRSG populations or habitat, the BLM would work with the lessees, operators, or other project proponents to avoid, reduce, and mitigate adverse impacts consistent with lessees' rights.

Adding exception criteria to saleable and nonenergy mineral closures for NV/CA PHMA and allowing consideration of new free use permits for saleable minerals in ID IHMA and NV/CA PHMA would increase the potential for associated impacts.

Identifying essential habitat in UT PHMA as part of future coal unsuitability criteria would likely lead to these areas being considered unsuitable for coal development and would limit the potential for associated impacts.

In CO PHMA and within 4 miles of an active lek, impacts from applying siting criteria for fluid mineral development would be the same as those described for Alternative 1.

Lands and Realty Management

Rangewide Environmental Consequences

Impacts from ROW management would be the same as described for Alternative 1 (with additional exception criteria in NV/CA, see state-specific analysis).

State-Specific Environmental Consequences

There would be additional exception criteria for ROW development in NV PHMA and for wind development in NV/CA GHMA. This could increase the potential for impacts associated with ROW and renewable energy development.

Renewable Energy Management

Rangewide Environmental Consequences

Impacts from renewable energy management would be the same as described for Alternative 1 (with additional exception criteria in NV/CA).

State-Specific Environmental Consequences

There would be additional exception criteria for ROW and wind/solar development in NV/CA PHMA and for wind development in NV/CA GHMA. This could increase the potential for impacts associated with ROW and renewable energy development.

Livestock Grazing Management

State-Specific Environmental Consequences

Impacts from domestic livestock grazing management would be the same as described for Alternative 1, with the following exceptions. The removal of review prioritization and processing of grazing permits in UT, WY, and NV/CA, may have minimal impacts as BLM still has the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value.

In Oregon, all or portions of 13 key RNAs would be available to livestock grazing, consistent with all applicable regulations and policies. The 13 key RNAs available for livestock grazing would be Black Canyon, Dry Creek Bench, East Fork Trout Creek, Fish Creek Rim, Foley Lake, Lake Ridge, Mahogany Ridge, North Ridge Bully Creek, Rahilly-Gravelly, South Bull Canyon, South Ridge Bully Creek, Spring Mountain, and Toppin Creek Butte (BLM 2019a, p. 1-6). The key RNAs would be required to meet land health standards and other applicable BLM regulations and policies and would remain subject to management, including regulation of grazing, to maintain and promote the characteristics of the RNAs (BLM 2018, p. 4-6). Grazing impacts would vary within and among the key 13 RNAs, depending on site productivity, timing of grazing, stocking intensity, and duration of grazing (Oregon Greater Sage-Grouse Proposed RMPA/Final EIS 2018, p. 4-6). Alternative 2 would result in 21,959 fewer undisturbed acres within Oregon available for additional

research in plant communities important to GRSG (Oregon Greater Sage-Grouse Proposed RMPA/Final EIS 2018, p. 4-7). The small size of the RNAs likely limit any impacts of livestock grazing on larger GRSG populations. Two key RNAs (Foster Flat and Guano Creek-Sink Lakes) would remain unavailable to livestock grazing.

In MT/DK, impacts from using applicable RDFs to mitigate potential impacts from West Nile virus when developing or modifying water developments would be the same as described for Alternative 1.

Wild Horse and Burro Management

Rangewide Environmental Consequences

Impacts from wild horse and burro management would be the same as described for Alternative 1.

Predation Management

Rangewide Environmental Consequences

Impacts from objectives to reduce opportunities for predators would be the same as described for Alternative 1.

State-Specific Environmental Consequences

Impacts from state-specific predation management objectives in CO, NV/CA, and WY would be the same as described for Alternative 1. Adding specific language to address corvid nests in UT may reduce human subsidies that attract corvids, which would reduce predation levels (Coates et al. 2015; O'Neil et al 2018).

ACEC Designation

Alternative 2 would not result in any impacts from ACEC designation since it does not include designation or management for ACECs.

10.2.4 Alternative 3

Habitat Designation and Management

Rangewide Environmental Consequences

Under Alternative 3, all HMAs would be managed as PHMA, over double the acreage of PHMA compared with Alternatives 1 and 2 (**Table 2-3**). Management actions for PHMA, such as lek buffers, required design features, fluid mineral leasing prioritization, and habitat objectives, would be more restrictive. Managing previously designated GHMA as PHMA would minimize potential impacts to GRSG. Expanding PHMA in some states to include areas of adjacent non-habitat, unoccupied historic habitat, or areas with potential to become habitat as PHMA would decrease potential for disturbance to birds and habitat alterations because management restrictions associated with PHMA would occur over a larger area.

There are no SFAs under this alternative, but their absence would likely not reduce protections to GRSG habitat rangewide. Although management actions for PHMA would be less restrictive than those for SFAs, management restrictions in PHMA under this alternative would be more restrictive than Alternatives 1 and 2 and applied to a greater overall area, designed to promote GRSG conservation and reduce potential impacts from land-use activities. Management restrictions would only be applied to development associated with valid existing rights as no new activities would be authorized.

Impacts from mitigation would be similar to Alternative 1 as BLM would require and ensure mitigation that achieves a net conservation gain in all HMA types. Compensatory mitigation would need to fully offset any residual effects on habitat function and value at the scale necessary to meet the RMP GRSG goals and objectives. These requirements reduce the potential for impacts from land use activities such as habitat loss

or alterations. Maintaining habitat function and value would help increase nesting success and brood survival, thereby contributing to the species' persistence.

BLM would apply a 3% cap for pre-existing authorizations or disturbances (including infrastructure, wildfire, and agriculture) at the project scale and within HAF fine scale habitat selection area (for all states except WY, which does not have fine scale HAFs) while honoring valid existing rights. The disturbance cap would not be applicable to new authorizations since all PHMA would be closed to new infrastructure projects. If disturbance from existing infrastructure developments exceeds 3% of habitat at the project scale or HAF fine scale area, new infrastructure associated with pre-existing authorizations would be deferred. The smaller size of most HAF fine-scale areas compared to BSU-scales might result in the cap being reached more quickly. This may prevent some development and associated impacts to GRSG. Fine scale HAFs represent an individual's home range and are determined in part by the quality and juxtaposition of resources within and between seasonal habitats, so reducing disturbance in these areas may help ensure that habitat function and quality remains to support seasonal movements. There would be no disturbance cap exceptions under this alternative, which may result in a lower level of disturbance overall. Including wildfire and agriculture as part of the overall disturbance cap would also result in a lower level of disturbance, particularly since wildfire was the cause of most of the habitat loss between 2012 and 2018 (Herren et al. 2021).

Currently, the percentage of disturbance in PHMA/IHMA within fine scale HAF boundaries is well below 3% and below 1% in most areas (BLM GIS 2023), yet population and habitat trends are still declining (Herren et al. 2021). Implementing a 3% disturbance may result in a continuation of these trends, but to a lesser extent than if the disturbance cap were higher (or non-existent). Habitat connectivity is important to maintaining gene flow and ensuring genetic diversity and distribution (Row et al. 2018), so limiting fragmentation by adhering to disturbance caps would help maintain population connectivity.

BLM would include an adaptive management strategy for habitat loss due to development under this alternative. Management is already restrictive, so additional management would be limited to proactive measures, which are dependent on budget and staffing.

Effects from habitat management and conservation would be similar to those described for Alternative 1. Alternative 3 would include additional objectives to maintain existing connectivity between GRSG populations. This would contribute to GRSG persistence and viability by continuing to facilitate gene flow and allowing for genetic variation (Row et al. 2018). Genetic variation and connectivity are necessary for GRSG resilience as described under the affected environment.

State-Specific Environmental Consequences

In Wyoming, BLM would apply a 3% cap (including infrastructure, wildfire, and agriculture) at the project scale and within neighborhood cluster boundaries. Clusters are used in place of fine scale HAF boundaries as HAF boundaries have not been delineated for Wyoming. Two of the Wyoming clusters (D-151 and D-147) are currently exceeding the 3% disturbance cap, and therefore, no more development could occur in these areas. Disturbance levels on the remaining 110 clusters are below 2% (BLM GIS 2023).

In Montana and the Dakotas, allowing treatments in PHMA to conserve, enhance or restore GRSG habitat and re-establishment of sagebrush cover and desirable understory plants would improve habitat quality and quantity, which would potentially contribute to GRSG persistence and viability. Lek buffers would apply to all surface disturbing activities associated with pre-existing authorizations and disturbances, and would therefore, reduce GRSG habitat loss and lek disturbance.

In NV/CA, lek-buffer protections included in 2015 and 2019 ARMPAs applies to all active or pending active leks regardless of HMA designation (see **Appendix 4** for lek definitions). This change is consistent with FLPMA (43 United States Code (USC) 1701 Sec. 201) and BLM Manual 6840 in that it provides protections for special status species. Impacts to discretionary surface-disturbing activities include an increase in area where GRSG surveys are conducted beyond PHMA and adoption of no surface disturbance buffers within potential project areas. This would benefit GRSG by applying protective buffers to leks which otherwise might not be applied until an updated HMA model is available.

In Idaho, lek buffers would be applied to active and pending active leks according to Idaho's lek definitions (see **Appendix 4** for lek status definitions by state) with distances the same as those described under Alternative 1 (see **Appendix 19**). Lek buffers would apply to all surface disturbing activities. Since all HMA would be treated as PHMA, and PHMA would be closed to new infrastructure projects, buffers may provide limited additional protection for GRSG since PHMA allocations are more restrictive and are larger than areas protected by buffers.

In UT, all habitat would be PHMA, including GHMA from Alternative 1. PHMA would include some areas of unoccupied habitat, historic habitat where birds have not been observed in 20 years or more or may have never occurred (e.g., habitat west of Sanpete Valley), areas of non-habitat (e.g., phase 3 pinyon-juniper, rock outcrops), and areas which are currently not habitat but could become habitat through significant restoration. Including these areas under the more restrictive management of Alternative 3 raises the concern that BLM would not use the least restrictive constraint to meet the resource protection objective in leasing restrictions for existing development rights. Under Alternative 3 in UT, all occupied leks are encompassed by PHMA.

Minerals Management

Closing PHMA to fluid mineral leasing, saleable minerals, and nonenergy minerals would reduce potential impacts to GRSG and habitat, such as disturbance and habitat alterations. Valid existing leases may be developed under this alternative. Impacts would be reduced to a greater extent than Alternatives 1 and 2 since areas closed to leasing could not be developed. Closing PHMA to mineral leasing and development would protect GRSG habitat from surface-disturbing activities and associated habitat fragmentation and maintain connectivity between leks. GRSG would not be exposed to disturbance associated with noise and human activity that accompanies construction, development, or production activities. Restrictions to development on BLM lands might push development onto private land, which could result in indirect impacts.

State-Specific Environmental Consequences

Impacts from managing coal in CO, MT/DK, UT and WY would be same as described for UT in Alternative 2. In UMRBNM in Montana, BLM land will not be disposed of other than by exchange, and only when necessary to further the protective purposes of the Monument. Protecting this area would also reduce impacts to GRSG and habitat by reducing surface disturbances associated with mineral resource management. In CO PHMA and within 4 miles of an active lek, impacts from applying siting criteria for fluid mineral development would be the same as those described for Alternative 1.

Lands and Realty Management

All PHMA would be excluded from new ROW authorizations. New linear ROWs would be allowed only in designated ROW corridors. This would decrease the potential for impacts associated with ROW development. The inability to site ROWs in PHMA could lead to longer ROW routes in order to bypass closed areas. Longer routes would increase surface disturbance and other impacts of ROW siting on GRSG

habitats outside of PHMA and may result in increased impacts on GRSG populations using habitat on adjacent state, tribal, or private lands.

Renewable Energy Management

PHMA in all states would be ROW exclusion areas for wind and solar energy development. Prohibiting wind energy development would eliminate the likelihood for habitat loss, degradation, fragmentation, and direct disturbance to birds in these areas. Alternative 3 would offer more protection from renewable energy development than under Alternatives 1 and 2 because more areas would be excluded from renewable energy development with no exceptions.

Livestock Grazing Management

Rangewide Environmental Consequences

All PHMA would be unavailable for domestic livestock grazing. Livestock would be removed from PHMA and impacts to GRSG and habitat associated with grazing, such as habitat alterations would be reduced. Removing livestock could lead to increases in herbaceous understories, which would increase forage availability and nesting habitat suitability for GRSG. Changes would depend on factors such as current conditions, climate, other land uses, etc. Removing livestock could also result in changes to the vegetation community composition, which could alter GRSG habitat suitability depending on the change.

Removing livestock from PHMA would reduce the potential for disease transmission assuming removal of man-made water sources to support livestock, such as water troughs, which may house vectors for diseases, such as West Nile virus (Naugle et al. 2004). Avian predators may be reduced if range improvements, including artificial water sources and fences, are also removed (Stevens et al. 2012; Manier et al. 2013, Coates et al. 2016). If livestock are removed on BLM, fences may be erected to fence out BLM lands from adjacent private grazing lands. If fencing increases in areas of mixed ownership, there would be increased potential for impacts such as injury or mortality from fence strikes and predation. removing livestock from BLM lands may also concentrate grazing on private lands, potentially leading to overgrazing and decreased GRSG habitat suitability where concentrated grazing occurs. There would be the possibility of increased wildfires without livestock to reduce fine fuels on a large portion of the landscape (see **Section 4.4**). If the potential for a large-scale wildfire were to increase, this could put large areas of GRSG habitat at risk of damage or loss.

State-Specific Environmental Consequences

In MT/DK, CHMA would be available for grazing. Impacts would occur in CHMA BLM would assess and modify as needed water features to reduce the risk of potential impacts from West Nile Virus or other disease outbreaks.

Impacts in key RNAs in Oregon would be the same as described for Alternative 1.

Wild Horse and Burro Management

Removing wild horses and burros in PHMA would increase total vegetation, grass abundance and cover, sagebrush canopy cover, species richness, and dominance of palatable forbs (Chambers et al. 2017). This would increase habitat quality for wildlife, including GRSG. Where range improvements, such as fences and water troughs are removed, it would decrease potential perch sites for avian predators and potential drowning hazards and/or potential for disease transmission. Gathers needed to remove wild horses and burros from herd management areas could disturb GRSG in the short term through human presence and noise. Additional fencing may be needed to keep wild horses off BLM-administered PHMA.

Predation Management

Under Alternative 3, the risk of predation may be reduced by reducing habitat disturbance, anthropogenic subsidies, and stopping or slowing the incursion of novel predators. Reduced predator numbers would help reduce predation levels and may increase GRSG persistence to a greater extent than Alternatives 1 and 2.

ACEC Designation

Under Alternative 3, all ACECs would be managed as PHMA. The management in ACECs under this alternative would be similar to management in PHMA, with the exception of ROW management and locatable minerals requirements. Managing ACECs as exclusion to ROWs both within and outside of designated corridors would expand protections to GRSG from ROW development compared to PHMA. Plans of operations for locatable mineral disturbances would reduce effects if measures were included to reduce disturbance to GRSG and habitat alterations.

10.2.5 Alternative 4

Habitat Designation and Management

Rangewide Environmental Consequences

Impacts from designating GRSG habitat as HMAs would be similar to those described for Alternative 1, although PHMA would increase by approximately 10% and GHMA would decrease by 1-2% (**Table 2-3**). Impacts from applying a 3% disturbance cap at the project scale and within HAF fine scale habitat selection area would be similar as to those described for Alternative 3, however, the cap would apply to both existing and proposed infrastructure authorizations (subject to valid existing rights). Wildfire and agriculture would not be included in the disturbance calculation, possibly resulting in more room for new authorizations and infrastructure projects. Since wildfire was the cause of the majority of habitat loss between 2012 and 2018 (Herren et al. 2021), the 3% cap would limit additional disturbance above habitat loss from wildfire.

Exceptions to the disturbance cap could allow for habitat fragmentation and an increased GRSG behavioral responses to the additional development. Habitat avoidance, changes in habitat use, and increased mortality risk from increased predators associated with developed areas, may have compounding adverse effects on GRSG populations. The exception would only be approved if site-specific NEPA analysis indicates that doing so will improve the condition of GRSG habitat in comparison to siting a project outside the designated corridor, so these effects are not anticipated. There would be no exceptions to the 3% PHMA (and IHMA) disturbance cap at the HAF fine scale habitat selection area, which would limit the overall level of disturbance at this scale.

BLM would include population-level adaptive management informed by the results of state wildlife management agency analysis and TAWS, a framework developed to inform anomalies in population trends (Coates et al. 2021). If one of these thresholds is tripped, it would allow management changes in response to population declines. Adaptive management could help slow or reverse negative trends that may reduce GRSG population persistence and viability. If more than 3% of GRSG habitat within a HAF fine scale habitat area is lost from non-anthropogenic (non-development) disturbances, a soft threshold would be met and future new infrastructure projects or permits would be deferred within these areas until habitat services (as indicated by sagebrush recovery) are restored. Inclusion of these non-anthropogenic losses will lessen future habitat declines from anthropogenic disturbances.

State-Specific Environmental Consequences

In Colorado, BLM would clarify the activity period for the leks being included in management allocations and decisions, increasing the amount of BLM-administered lands within buffer distances, and therefore, lands that

would be subject to more intensive management decisions for lek and habitat protection. Alternative 4 would also increase the acreage of GHMA in Colorado where NSO stipulations would be applied compared to Alternatives 1 and 2. The same acreage under major stipulation (NSO) in Alternative 4 would be under moderate stipulation (CSU). This would increase the area of GRSG habitat protected from surface disturbance.

CHMA in Montana and the Dakotas (**Table 2-31**) are areas of connectivity important to facilitate the movement of GRSG and maintain ecological processes, including between priority populations, adjacent states, and across international borders. Management in CHMA that leads to restrictions to land use and surface-disturbing activities would reduce the likelihood for habitat loss, fragmentation, and direct disturbance to GRSG. The restoration focus in RHMA would further improve GRSG habitat. Including more protective management in GHMA (such as ROW avoidance and utility scale solar and wind exclusion or avoidance in some areas) would make management more consistent with the state plan and reduce potential for GRSG impacts such as habitat alterations and disturbance.

In Idaho, lek buffer distances would be the same as under Alternative 1, but buffers would apply to 'active' and 'pending active' leks using the Idaho lek definitions (Cook et al. 2022; see **Appendix 4** for lek status definitions). Lek buffers would apply to a total of 1,254 leks (1,093 active; 161 pending active), where 76% of these leks are in PHMA, 19% of leks in IHMA and 4% of leks in GHMA. This change from Alternative 1 could increase the amount of BLM lands where lek buffers may apply but would depend on HMA type and buffer distance. For the largest buffer distance (3.1 miles), this could result in an increase of 14% of HMA with more restricted BLM management. Effects of this increase in acres of BLM lands where lek buffers may apply would be realized where allocations for resources are open or avoided in HMA, but not for those resources with closed or exclusion allocations in PHMA, such as wind or solar energy development, or nonenergy leasables or saleable minerals (**Table 2-4**).

In NV/CA, impacts from clarifying use of lek-buffer protections included in 2015 and 2019 ARMPAs applies to all active or pending active leks (see **Appendix 4**) regardless of HMA designation would be the same as described for Alternative 3. Of the 380 known occupied leks in Utah, 366 (96.3%) are in PHMA under Alternative 4. As a result, there would be no substantial effect of impacts on small populations in former GHMA.

Minerals Management

Rangewide Environmental Consequences

Leasing would be permitted in HMAs, which would increase the HMA acres affected and potential for impacts in most states. However, BLM would include management actions to minimize potential for conflict and associated impacts from subsequent development. BLM would also prioritize projects that avoid, minimize, reduce, rectify, and/or adequately mitigate direct and indirect impacts to PHMA/IHMAs, and include applicable and technical COAs. The 3% disturbance cap would apply at the fine scale HAF habitat selection area within PHMA/IHMA, which would help reduce overall disturbance and habitat impacts, including fragmentation. Applying an NSO stipulation within PHMA (except WY, see below), IHMA, and some RHMA would also decrease the potential for disturbance and habitat loss, alterations, and fragmentation. Reduced habitat fragmentation would help maintain habitat connectivity and population persistence and viability.

State-Specific Environmental Consequences

Expansion of the NSO stipulation to all PHMA in WY in an area that is already developed will only achieve the protections for new activities. Leks in PHMA would still be impacted by ongoing existing disturbances due to human presence. Greater protections would result where the NSO applies to leks not experiencing as much existing disturbance.

The oil and gas lease stipulations summarized in **Appendix 2** would be applied in MT/DK, limiting the potential for impacts associated with fluid mineral leasing. In all MT/DK HMAs management to refine, streamline, and make stipulations consistent would be applied. A CSU stipulation would be applied to all GHMA rather than just to a lek buffer. This would improve consistency among BLM offices and partner natural resource entities and provide clear and consistent direction to applicants and partners for cross-office boundary projects. Applying stipulations would reduce impacts to GRSG and habitat from fluid mineral resource management. Impacts from closing UMRBNM to mineral leasing and development would be the same as those described for Alternative 3.

In CO PHMA and GHMA, siting criteria would be applied to guide development of the lease or unit that would result in the fewest impacts to GRSG. The following criteria would apply: location of the proposed authorization was determined to be nonhabitat; topography/areas of non-habitat create an effective barrier to impacts; co-locating the proposed authorization with existing disturbance; and/or the proposed location would be an alternative to a similar action occurring on a nearby parcel. Applying these criteria would reduce the potential for impacts to GRSG. If the criteria do not apply but it can be demonstrated that the direct and indirect impacts of the proposed activity would be offset through compensatory mitigation, the authorized officer may consider permitting the action. Construction, drilling, and completion in CO PHMA or GHMA within 4 miles of an occupied lek during lekking, nesting, and early brood-rearing (March 1 to July 15) would be prohibited, but the TL may be adjusted based on application of the criteria described above.

In NV/CA PHMA, GHMA, and OHMA, management direction identifies six criteria used to grant exceptions to the allocation decisions (**Table 2-3**). The criteria narrow the use of mitigation to gain an exception to the allocation decisions. The changes are a benefit to GRSG by reducing consideration of surface disturbing projects that could remove GRSG habitat and/or disturb individuals, and a cost to proponent driven projects in that there would be fewer opportunities to gain exceptions.

All ID PHMA will be closed to new mineral materials development but continued use of existing pits would be allowed. New free use permits and expansion of existing pits may be allowed in certain circumstances and an exception would be possible for new free use permits in areas with existing anthropogenic disturbance. Impacts to GRSG would continue since the disturbance is already existing.

Lands and Realty Management

Rangewide Environmental Consequences

Impacts from managing PHMA in all states, ID IHMA, MT CHMA, and some MT RHMA as ROW avoidance areas would be similar to those described for Alternative 1. Where development cannot be avoided, breeding and nesting habitats, or in limiting/high value seasonal habitats would be avoided unless certain criteria are met. This would reduce the potential for impacts by precluding alteration to high value and seasonal habitats and disturbance to GRSG during important life history stages. Where major ROWs cannot be avoided, applying minimization measures (disturbance cap, seasonal constraints, tall structure limitations, RDFs, nest and perch deterrents, etc.) would also minimize potential for impacts. Residual direct and indirect

impacts would be offset through compensatory mitigation. The magnitude of impacts would not be expected to be of a level that would impact GRSG population and lek persistence or viability.

Managing GHMA as ROW avoidance areas within breeding, nesting habitats and other limited seasonal habitats would reduce the potential for impacts particularly by avoiding alteration to high value and seasonal habitats and disturbance to GRSG during important life history stages (breeding, migration). The potential for GRSG to be affected may vary in GHMA depending on the location and ability to relocate the ROW. Some areas, such as plains and prairies, may be more suitable for ROW development, whereas in may be less likely for ROWs to be sited in areas with mountainous or rugged topography.

Avoiding placement of ROWs within one-half mile of PHMA or IHMA would protect those areas from indirect impacts. Because all other areas would be managed as ROW open, impacts, such as habitat alteration and disturbance, could occur, however, compensation would be required.

State-Specific Environmental Consequences

Effects from applying an NSO stipulation within 0.6 miles of leks in PHMA in WY would have effects as described for Alternative 1.

In Colorado, a timing limitation would be expanded to include GHMA and added to leased areas as conditions of approval of the ROW; this would reduce impacts to GRSG and habitat.

In Idaho, lek buffers would be the same as under Alternative (**Appendix 19**). Lek buffers would protect leks from new disturbance and together with other restrictions in HMA, such as RDFs, Mitigation, Disturbance Cap, would serve to ensure responsible development.

Renewable Energy Management

Rangewide Environmental Consequences

Impacts from managing PHMA in all states and some MT RHMA as ROW exclusion areas for wind and solar energy development would be similar to those described for Alternative 3 (excludes IHMAs). Since PHMA would apply to a smaller area under this alternative, the extent of protection from disturbance associated with from renewable energy development would be less.

Managing GHMA as avoidance areas for wind and solar energy development in all states would decrease the potential for impacts associated with wind and/or solar development. Where avoidance is not possible, impacts to GRSG habitat would be minimized through measures such as avoiding surface use, occupancy, or placement of utility scale wind and solar facilities within one-half mile of PHMA, within one mile of active leks, and outside limited/high value seasonal habitats and movement corridors. Such measures would protect PHMA from indirect impacts; reduce potential for habitat alterations in breeding areas, migration corridors, and high value habitat; and minimize disturbance to breeding and migrating birds. Managing GHMA and MT CHMA as avoidance areas for wind and solar energy development would limit opportunities for development but reduce potential for GRSG disturbance and habitat alterations and fragmentation, in GHMA that are adjacent to PHMA.

State-Specific Environmental Consequences

Managing ID IHMAs as exclusion areas for wind and solar energy development within 3.1 miles from active leks and avoidance in the remainder of the IHMA would decrease the potential for impacts but to a lesser extent than if the entire IHMA were managed as an exclusion areas as there would be greater potential for development to occur outside of 3.1 miles from leks. Development outside of this buffer would likely not

disturb leks or alter lekking or nesting habitat. Infrastructure would be considered only if it would not impair habitat use by GRSG and will meet RMP GRSG goals and habitat objectives, so any alternations or disturbance would not impact lek or population persistence/ viability.

Surface use, occupancy, or placement of utility scale wind and solar facilities would be prohibited within one-half mile of PHMA, so adjacent PHMA would be protected from indirect impacts from development in IHMAs. This would limit opportunities for development but reduce potential for disturbance and habitat alterations adjacent to PHMA.

Livestock Grazing Management

Rangewide Environmental Consequences

The presence of GRSG HMAs would not affect whether an area is available for livestock grazing or change existing status of lands available or unavailable for livestock grazing, so impacts from domestic livestock grazing management would be similar to those described for Alternative 1. BLM would alter management objectives and actions to minimize, reduce, or correct for any impacts to GRSG and habitat, managing livestock grazing to meet or make progress toward meeting the GRSG habitat objectives. Adjustments to existing AUMs would be made based on site-specific conditions providing flexibility to adjust permits conditions to avoid or reduce impacts to GRSG or habitat. If land health assessment conditions are not met as indicated by an assessment specific to site capability, adjustments to grazing practices would be made to provide for suitable GRSG habitat at the HAF site scale. Range management improvements and existing infrastructure would be evaluated with respect to their effect on GRSG and GRSG habitat. This could help prevent impacts associated with grazing infrastructure such as increased predation and disease transmission (Coates et al. 2016). These management actions and objectives would help to minimize, reduce, or correct for GRSG disturbances and habitat alternations that could otherwise lead to impacts on population persistence and viability.

State-Specific Environmental Consequences

Impacts from permitting grazing in CHMA and from reducing the risk of potential impacts from West Nile Virus would be the same as described for Alternative 3. Impacts in key RNAs in Oregon would be the same as described for Alternative 1.

Wild Horse and Burro Management

Impacts from wild horse and burro management under Alternative 4 would be the same as described for Alternative 1.

Predation Management

Impacts from reducing opportunities for predators would be similar to those described for Alternative 1 with the exception that precluding new anthropogenic infrastructure new anthropogenic infrastructure would be avoided where possible. There would be a slightly greater potential for new infrastructure to occur, which could attract predators and increase predation on GRSG. Other measures to maintain predation at natural levels would be applied, so this is not expected to increase predation to a level that would influence lek or population persistence and viability.

ACEC Designation

Alternative 4 would not result in any impacts from ACEC designation since it does not include management for ACECs.

10.2.6 Alternatives 5 and 6

Habitat Designation and Management

Rangewide Environmental Consequences

Impacts from designating GRSG habitat as HMAs would be similar to those described for Alternative 1, though the BLM would manage approximately 7% more PHMA than Alternatives 1 and 2 and 10% fewer acres of GHMA (**Table 2-3**). Impacts from applying a 3% cap would be the same as described for Alternative 4, except in WY and MT (see State-Specific Environmental Consequences). Impacts from exceeding the 3% disturbance cap would be similar to those described for Alternative 4, but more exceptions would be allowed, which may result in increased development and disturbance to GRSG and habitat. Allowing a project to proceed before compensatory mitigation is in place would result in a time lag, during which GRSG habitat would be fragmented and reduced in carrying capacity by project impacts, so habitat and population trends may continue to decline to a greater extent compared to Alternative 4. Impacts from population and habitat adaptive management would be the same as described for Alternative 4.

State-Specific Environmental Consequences

Impacts from applying a 5% disturbance cap at the project scale in WY and MT would be similar to those described for Alternative 1. The 3% disturbance cap would still apply at the HAF fine scale habitat selection area, which may limit additional development reducing fragmentation of GRSG seasonal habitats and ensuring habitat function and quality remain to support seasonal movements. WY and MT would include wildfire and agriculture in the disturbance calculation, so the level of disturbance from other sources (energy development, roads, RPWs, etc.) would be relatively lower.

In Colorado, impacts from applying a 1-mile lek buffer as the minimum threshold would be the same as described for Alternative 1. These alternatives would allow for more flexibility in development while maintaining the BLM's ability to apply site-specific criteria for GRSG habitat protection. Alternative 6 also includes potential CSU stipulations to be applied in GHMA within 1 mile of PHMA. This would allow for increased flexibility while considering indirect effects that development in GHMA may have on PHMA.

Management in Wyoming SHMA would be consistent with GHMA restrictions, which would increase protections to GRSG and habitat.

Impacts from designating RHMA and CHMA in Montana and the Dakotas would be the same as described for Alternative 4. Including more protective management in GHMA (ROW avoidance within 1.2 miles of active leks and crucial winter range, and utility scale solar and wind exclusion or avoidance in some areas) would make management more consistent with the state plan and decrease potential for impacts such as habitat alterations and disturbance.

In Idaho, lek buffers would be similar as those under Alternative 2 and consistent with the 2021 Idaho Sage-grouse Plan (State of Idaho 2021). Buffers would apply to active and pending active leks (Cook et al. 2022; **Appendix 4**) resulting in a potential increase in the amount of BLM lands where lek buffers, similar to Alternative 4. Lek buffers would remain the same in PHMA, except for minor linear features where less PHMA would be protected (**Appendix 19**).

Compared to Alternative 2, buffer distances would increase in IHMA for major linear features and transmission line towers, resulting in more IHMA potentially protected from these disturbances (**Appendix 19**). Buffer distances would be decreased in IHMA for communication and meteorological towers in IHMA, and in GHMA for surface disturbances due to continuing human activities that alter or remove the natural

vegetation. These decreases in buffer distances would result in less IHMA and GHMA protected from these types of disturbances.

Compared to Alternatives 1, 3, and 4, Alternatives 5 and 6 would have reduced buffers in IHMA and GHMA (**Appendix 19**). Alternatives 5 and 6 would have buffer exception criteria, where BLM may approve actions within IHMA and GHMA if it is impracticable to locate the project outside of the buffer and impacts are avoided through project siting and design, to the extent reasonable. The reduced buffer distances in IHMA and GHMA would reduce restrictions while maintaining buffers for PHMA, and are in line with Idaho's three-tiered habitat approach. Since development and anthropogenic disturbance could occur closer to leks in IHMA and GHMA, some leks would be at higher risk of effects from development, such as avoidance behavior, reduced productivity, or decline in lek abundance. A more detailed analysis would occur during project-specific NEPA analysis.

In NV/CA, impacts from clarifying use of lek-buffer protections included in 2015 and 2019 ARMPAs applies to all active or pending active leks (see **Appendix 4** for lek definitions) regardless of HMA designation would be the same as described for Alternative 3.

In UT, Alternatives 5 and 6 would prioritize habitat management areas (PHMA and GHMA) that encompass 95.6% of the male GRSG counted on leks during 2023 surveys. This includes 2,740 (93.8%) males counted within PHMA, 54 (1.8%) counted in GHMA and 127 (4.3%) counted outside of any HMA. GHMA designations in Morgan-Summit, South Slope Uintah/Blue Bench, and Uintah Population Area (Deadman's Bench, East Bench, and Book Cliffs) would be removed, including any corresponding management actions. 90% of Utah's GRSG are supported by habitat in PHMA under these alternatives so there would be no substantial effect of accelerating impacts on the small populations in former GHMA.

Minerals Management

Rangewide Environmental Consequences

Impacts from mineral resource management would be similar as described for Alternative 4 with state-specific differences described below.

State-Specific Environmental Consequences

The oil and gas lease stipulations summarized in **Appendix 2** would be applied in MT/DK, limiting the potential for impacts associated with fluid mineral leasing. Applying a 5% disturbance cap at the project scale in MT and WY, and 3% disturbance cap at the HAF fine scale area could allow for more potential mineral development, which could increase disturbance and habitat alterations, including fragmentation (see **Table 2-3**). Allocations in PHMA in WY differ between Alternative 4 and Alternative 5.

Impacts from consistency in stipulations in MT/DK HMAs and from closing UMRBNM to mineral leasing and development would be similar to those described for Alternative 3.

Impacts from applying siting criteria for development in CO PHMA and GHMA would be similar to those described under Alternative 4. To grant an activity based on compensatory mitigation, the compensation project must be planned, funded, and approved in coordination with the State of Colorado.

In NV/CA, impacts from identifying criteria for granting exceptions to allocation decisions would be the same as described for Alternative 4.

Impacts from closing ID PHMA to new mineral materials development but allowing continued use of existing pits would be the same as described for Alternative 4. Impacts from reduced lek buffers in IHMA and GHMA

would provide for additional opportunities for mineral resource management, specifically saleable minerals and nonenergy leasables.

Lands and Realty Management

Rangewide Environmental Consequences

Impacts from managing PHMA in all states, ID IHMA, MT CHMA and some MT RHMA as ROW avoidance areas and applying minimization measures where major ROWs cannot be avoided would be similar to those described for Alternative 4. Micro-siting to avoid placement near leks or in connectivity corridors to avoid dividing breeding habitat from adjacent nesting or other seasonal habitats would reduce potential for alteration to high value and seasonal habitats and disturbance to GRSG during important life history stages (e.g., breeding, migration). Major ROWs that are located inside RMP designated ROW corridors would not need to comply with disturbance cap or compensatory mitigation requirements, so habitat alteration and disturbance could occur where these corridors overlap PHMA.

Managing GHMA in all states and WY SHMA as ROW open with minimization measures and compensation, to maintain habitat supporting GRSG populations consistent with state agency habitat designations and to preclude negative impacts to any adjacent PHMA habitats would reduce the potential for impacts. Reduction of impacts would be to a lesser extent than if managed as avoidance areas.

State-Specific Environmental Consequences

In Colorado, impacts from expanding a timing limitation to include GHMA for conditions of approval of the ROW would be the same as described for Alternative 4.

In Idaho, lek buffers would be similar as those under Alternative 2 and consistent with the 2021 Idaho Sage-grouse Plan (State of Idaho 2021). Lek buffers would be reduced in IHMA and further reduced in GHMA. Effects would be similar to those described under Minerals Resource Management under Alternatives 5 and 6. These effects would be analyzed in detail during the project-level NEPA analysis.

Renewable Energy Management

Rangewide Environmental Consequences

Classifying PHMA and IHMA as avoidance areas for wind and solar energy development but exclusion in breeding/nesting habitat and limited seasonal habitat would decrease the potential for impacts but to a lesser extent than if all HMA were exclusion areas. Solar and wind development would be considered on a case-by-case basis in avoidance areas. Development would not be allowed in breeding and nesting habitats, or in limited/high value seasonal habitats unless certain criteria are met (refer to **Table 2-10**), so the magnitude of impacts, such as disturbance and habitat alterations, would not be expected to be of a level that would influence lek or population persistence/ viability.

Managing GHMA and WY SHMA as open to wind and solar energy development would result in potential impacts. The inclusion of minimization measures and compensation to maintain habitat supporting GRSG populations consistent with state agency habitat designations (e.g., restoration, connectivity, seasonal, or other), and to preclude negative impacts to any adjacent PHMA habitats would reduce the potential for those impacts in high value and seasonal habitats.

State-Specific Environmental Consequences

In Idaho, PHMA and IHMA would be avoidance areas for utility scale wind and solar energy development (including met towers). Development would not be allowed in breeding and nesting habitats, or in limited/high value seasonal habitats unless one of the criteria below is met. Development would not be

allowed within breeding and nesting habitat inside lek buffers (**Appendix 3**), but breeding and nesting habitat outside of lek buffers would be avoidance areas.

Differences in effects between Alternatives 4, 5, and 6 are described under Greater Sage-grouse, Habitat Designation and Management and Minerals Resource Management, State-specific Circumstances, Alternatives 5 and 6 above. With the increased interest in renewable energy development including utility scale wind and solar energy development in Idaho, there may be increased impacts to GRSG leks in PHMA, IHMA and GHMA under Alternatives 5 and 6. Reduced lek buffers in IHMA and GHMA and a possible buffer exception could result in possible lek abandonment, avoidance behavior, or reduced productivity due to increased anthropogenic disturbance around a lek. The extent of impacts would depend on a variety of factors, including habitat type and condition, proximity to other leks, unique seasonal habitats, or connectivity, etc. Energy development would likely be limited by proximity to transmission line corridors and substations and would not extend to all PHMA, IHMA or GHMA. Leks in IHMA and GHMA would be at higher risk from effects from energy development due to the reduced buffers and buffer exception under Alternatives 5 and 6 than under Alternative 4.

Livestock Grazing Management

Rangewide Environmental Consequences

Impacts from livestock grazing management under Alternatives 5 and 6 would be the same as described for Alternative 4.

State-Specific Environmental Consequences

In Montana and Dakotas impacts from permitting grazing in CHMA and from reducing the risk of potential impacts from West Nile Virus would be the same as described for Alternative 3.

In Oregon, the 15 key RNAs in Oregon would be retained under Alternatives 5 and 6. Their associated areas allocated as unavailable to grazing are proposed to be retained, modified, or re-allocated to grazing based on district-generated, site-specific updated information since the 2015 ARMPA. The key RNAs would be required to meet land health standards and other applicable BLM regulations and policies and would remain subject to management, including regulation of grazing and invasive plant removal. The amount of land within key RNAs that would be made available to grazing is small relative to the size of the species' range and any impacts of livestock grazing on GRSG populations using these areas would likely be minimal and undetectable.

Although key RNA boundaries are not being modified (with the exception of data updates and clarifications), district site visits and analysis since the 2015 ARMPA have found vegetative communities that would not be consistent with why key RNA designations for sage-grouse habitats were made. They include mountain mahogany vegetation communities (Dry Creek Bench, Mahogany Ridge, Fish Creek Rim, and Spring Mountain Key RNAs) and the old-growth juniper (Black Canyon Key RNA) vegetation community.

Wild Horse and Burro Management

Impacts from wild horse and burro management under Alternatives 5 and 6 would be similar to those described for Alternative 1. Management within established AML could reduce impacts from wild horses and burros on GRSG in some areas.

Predation Management

Impacts from objectives to reduce opportunities for predators under Alternatives 5 and 6 would be the same as described for Alternative 4. That is, impacts from reducing opportunities for predators would be

similar to those described for Alternative 1 with the exception that precluding new anthropogenic infrastructure would be avoided where possible. There would be a slightly greater potential for new infrastructure to occur, which could attract predators and increase predation on GRSG. Other measures to maintain predation at natural levels would be applied, so this is not expected to increase predation to a level that would influence lek or population persistence and viability.

ACEC Designation

Alternative 5 would not result in any impacts from ACEC designation since it does not include management for ACECs.

Under Alternative 6, impacts would be as described for Alternative 5 except within ACECs as described below.

Impacts from mineral development could occur. Plans of operations for locatable mineral disturbances would reduce effects if measures were included to reduce disturbance to GRSG and habitat alterations.

Managing ACECs as open to fluid mineral leasing subject to NSO stipulations would decrease the HMA acres subject to effects from fluid mineral development. The NSO stipulation could protect these acres from surface-disturbing activities. Limiting surface disturbance would ensure that connectivity between leks would be preserved and not contribute to fragmentation. Including an exception/modification to allow occupancy if there are drainage concerns from adjacent development and if no direct or indirect impacts can be demonstrated is not expected to result in additional impacts.

Managing ACECs as closed to new or expansion of nonenergy minerals associated with existing operations (fringe leases) would reduce potential impacts to GRSG and habitat, such as disturbance and habitat alterations. Managing ACECs as closed to new saleable mineral/mineral material operations for all sale types except for free-use pits would reduce potential impacts to GRSG and habitat but to a lesser extent than if free use pits were also prohibited.

Managing ACECs as exclusion areas for major ROWs and avoidance areas for minor ROWs would reduce potential impacts to GRSG and habitat, such as disturbance, habitat alterations, and increased potential for predation. Managing ACECs as ROW exclusion areas for wind and solar energy development would eliminate the likelihood for GRSG impacts including habitat loss, degradation, fragmentation, and direct disturbance to birds in these areas.

10.3 VEGETATION

10.3.1 Methods and Assumptions

Methodology

Impacts on vegetation would primarily result from management actions described in **Chapter 2** that result in vegetation removal, fragmentation, or other alteration. The types of actions that can result in these impacts are discussed in more detail in **Section 4.3.1**, Nature and Type of Effects. For management actions not specifically described below, the effects would remain as described in the 2015 and/or 2019 plans.

Indicators

Indicators of impacts on vegetation are as follows:

Upland and Riparian Vegetation

- Acres and condition of vegetation communities
- Extent of sagebrush or riparian vegetation fragmentation

Noxious Weeds and Invasive Species

- Likelihood for noxious weed or invasive species introduction or spread
- Likelihood for conifer encroachment

Assumptions

This analysis includes the following assumptions:

- All plant communities would be managed toward achieving a diverse native species composition, cover, and age classes across the landscape.
- The degree of impact attributed to any one disturbance or series of disturbances would be influenced by several factors, including location in the watershed; the type, time, and degree of disturbance; existing vegetation; precipitation; and mitigating actions applied to the disturbance.
- Noxious and invasive weeds would continue to be introduced and spread because of ongoing vehicle traffic in and out of the planning area, recreational activities, wildland fire, wildlife and livestock grazing and movements, and surface-disturbing activities.
- Activities that would disturb soils could cause erosion, loss of topsoil, and soil compaction, which could affect the ability of vegetation to regenerate. Further, surface-disturbing activities could increase dust, which could cover existing vegetation and impair plant photosynthesis and respiration. Resulting impacts could include lowered plant vigor and growth rate, altered or disrupted pollination, and increased susceptibility to disease. These impacts may be reversed by wind or precipitation, which can remove dust from vegetation.
- Ecological health and ecosystem functioning depend on a number of factors, including to but not limited to vegetative cover, species diversity, nutrient cycling and availability, water infiltration and availability, and percent cover of weeds.
- Climatic fluctuation would continue to influence the health and productivity of plant communities on an annual basis.

10.3.2 Alternative 1

Greater Sage-Grouse Management

Rangewide Environmental Consequences

Under Alternative 1 restrictions on land use and surface-disturbing activities would occur within each HMA and SFA (**Table 2-3**) and would limit impacts to vegetation as described under *Nature and Type of Effects*. More restrictive management within SFAs emphasizes protection of GRSG in these areas and would provide the highest level of protection to vegetation. In general, restrictions on land use and surface-disturbing activities in HMA and SFAs would reduce the likelihood of vegetation loss, sagebrush or riparian vegetation fragmentation, and introduction and spread of invasive weeds.

Structural changes to sagebrush shrublands have caused an increase in encroachment of pinyon pine, juniper, and noxious weeds that are replacing native plant communities. Fire suppression, a major contributor to this expansion, has allowed these tree species to encroach more extensively into sagebrush habitats. Treatments designed to prevent encroachment of trees and nonnative species vary across the range and would alter the condition of native vegetation communities by changing the density, composition, and frequency of species within plant communities. Fuels treatments, where allowed, would result in either more open-forested conditions, which would improve the habitat for species selecting these habitats, or decreased encroachment of juniper and pinyon species, which would improve habitats for GRSG and other sagebrush-dependent

species. Habitat connectivity for GRSG could be increased over the planning time frame through vegetation manipulation designed to restore vegetation, particularly sagebrush overstory cover.

Alternative 1 would also incorporate an adaptive management strategy composed of soft and hard thresholds based on population and habitat changes. See **Section 4.2.2** for a detailed description of thresholds. In general, an adaptive management strategy would help to ensure that actions are taken to limit impacts to vegetation in an appropriate time frame to offset impacts.

Under Alternative 1, all states would include language to maintain and enhance sagebrush habitats with the intent of conserving GRSG populations. Habitat objectives would be considered when authorizing activities in GRSG habitat. The exact language varies by state, but in general, inclusion of specific habitat objectives would result in improved vegetation conditions. Following these objectives could prevent rangeland not meeting range health standards that degrade vegetation communities, reduce conifer encroachment, and reduce the introduction and spread of invasive weeds.

State-Specific Environmental Consequences

In MT and WY, a 5% disturbance cap would apply to land use activities, including wildfire and agriculture, at the project area scale in PHMA. States with higher disturbance caps could see greater levels of disturbance within a project area, and therefore greater potential for impacts to vegetation as described *under Nature and Types of Effects*. WY has no required mitigation in GHMA potentially increasing impacts to vegetation.

In CO, ID, NV/CA, OR, UT, and the Dakotas, a 3% disturbance cap would apply to land use activities (except wildfire and agriculture) at both BSU-scale and at proposed project analysis area within PHMA. In ID, the same cap would apply but it could be exceeded in utility corridors if it benefits GRSG. Calculating disturbance at the project-level means that the amount of disturbance allowed could not exceed 3% of the site-specific project area; this may prevent some development that could occur if disturbance is only calculated at a coarser scale. In addition to calculating disturbance at the project-level, disturbance would also be calculated for each BSU. Including caps at both project and BSU scales would reduce the likelihood for sagebrush or riparian vegetation removal, degradation, or fragmentation, and improve the acreage and condition of sagebrush vegetation on both the local and landscape scales.

Although all states would include an adaptive management strategy, the metrics, thresholds, timeframes, and spatial scales for evaluating and responding to thresholds would vary state by state. As a result, there would be no consistency in how thresholds are calculated across the range and responses may not be implemented across an area that encompasses an entire population group and/or seasonal habitats needed throughout the year. If management changes do not apply to all populations and habitats being affected, some vegetation communities may improve while others remain impacted.

Minerals Management

Rangewide Environmental Consequences

Leasing of fluid minerals would be allowed in PHMA and IHMA subject to NSO stipulations and/or seasonal restrictions. In general, NSO stipulations on new leases would protect vegetation in PHMA from surface-disturbing activities and would not contribute to fragmentation. Restrictions on mineral development within PHMA and GHMA as described in the 2015 EISs for CA, CO, ID, MO/DK, NV/CA, OR, UT, and WY (BLM 2015a-2015h) would reduce potential impacts to vegetation such as vegetation removal and increased weed spread as described under *Nature and Types of Effects*.

State-Specific Environmental Consequences

In WY, management of PHMA as NSO within 0.6 miles of leks would protect vegetation in these areas, though to a lesser extent than elsewhere rangewide where all PHMA would be NSO. In WY and MT PHMA fluid mineral development in areas that are already leased (and thus are exempt from NSO stipulations) would also be subject to density and disturbance limits. In CO, OR, WY, and UT NSO stipulations within lek buffers (buffer distance varies by state) in GHMA would provide increased protection to vegetation in these areas. PHMA and GHMA in CO and GHMA in OR would be closed to fluid mineral development within 1 mile of leks which would also provide increased protections to vegetation and limit impacts from surface disturbance in these areas. However, development of fluid mineral resources in GHMA would still result in the localized direct loss and fragmentation of vegetation from current use areas outside of the applicable lek buffers. The general effects of mineral development on vegetation are discussed in *Nature and Types of Effects*.

Impacts of development outside buffer areas could be offset by mitigation because operators would be required to mitigate impacts until there is a net conservation gain. However, mitigation may be conducted off-site if it would provide greater benefit to GRSG, potentially resulting in unmitigated impacts on vegetation in GHMA.

Prioritizing leasing outside of PHMA and GHMA within CO, ID, ND, NV/CA, OR, UT, WY, and parts of MT/DK (Billings, HiLine, Miles City, ND, SD) would reduce the potential for impacts to vegetation associated with fluid mineral development as described under *Nature and Type of Effects* in these areas. There would be no similar objective in the Lewistown or Butte Field Offices, and therefore, potential for impacts would be greater. In WY and MT, saleable mineral and nonenergy mineral development in PHMA would also be subject to density and disturbance limits which would also reduce potential impacts to vegetation, but to a lesser extent than if they were completely closed to development. In Idaho, IHMA would be open to nonenergy mineral development in Known Phosphate Lease Areas; therefore, similar impacts (e.g., direct vegetation loss, surface disturbance, and erosion) could occur in areas open to development.

Lands and Realty Management

Rangewide Environmental Consequences

Under Alternative 1, PHMA in all states and ID IHMA would be identified as ROW avoidance areas to allow for management flexibility (except for minor ROWs in WY, as described under state analysis). PHMA would be exclusion areas for wind and solar development (with some differences between states, see state-specific analysis). Classifying PHMA as exclusion or avoidance areas would decrease the potential for impacts associated with ROW development, such as disturbance and increased potential for weed spread, as described *in Nature and Types of Effects*. GHMA in all states would be open to minor ROWs with mitigation measures (except for in WY where mitigation is not required). Impacts associated with ROW development, such as surface disturbance and increased potential for weed spread, could occur in these areas if developed, but mitigation measures would help to offset the impacts.

New ROWs in PHMA would not be allowed except in accordance with the Anthropogenic Disturbance Screening Criteria outlined in the Proposed RMP Amendment. In IHMA new ROWs could be considered if in accordance with the IHMA Anthropogenic Disturbance Development Criteria. The BLM would collocate new ROWs with existing infrastructure when possible. Alternative 1 would apply a buffer from disturbance around leks in PHMA, IHMA and GHMA, depending on the type of disturbance and based on the latest science (Manier et al. 2014) which would protect vegetation in the buffer. Existing ROW corridors are preferred for collocation of new ROWs but could not be widened more than 50% greater than the original

footprint. These measures would protect vegetation from fragmentation and other impacts as described in *Nature and Types of Effects*.

State-Specific Environmental Consequences

PHMA in WY would be open to minor ROWs with buffers and mitigation. Buffers and mitigation would help offset the impacts, but to a lesser extent than ROW exclusion/avoidance. GHMA in WY would be open to minor ROWs and no mitigation measures would be required which would increase the potential for impacts associated in these areas.

Classifying GHMA in CO, NV/CA, and OR as avoidance areas for major ROWs would continue to reduce the potential for impacts associated with ROW development as described *in Nature and Types of Effects*. Opening UT and ID GHMA to major ROWs with minimization measures would increase the potential for impacts, but mitigation measures would help to offset the impacts. Opening GHMA in WY to major ROWs would also increase the potential for impacts, and there would be no mitigation measures to offset the impacts.

Livestock Grazing Management

Under Alternative 1, PHMA and GHMA in all states and ID IHMA would be available for domestic livestock grazing. Therefore, impacts to vegetation from grazing such as increased weed spread as described under *Nature and Types of Effects*, could occur in these areas. The BLM would prioritize SFAs and PHMA outside of SFAs for additional livestock grazing management. This would include the option to adjust permit terms and conditions as needed to meet land health standards and GRSG habitat objectives.

Wild Horse and Burro Management

The BLM within all states where wild horses and burros overlap with GRSG habitat would need to manage populations within established AML, incorporating GRSG habitat objectives into wild horse and burros management. Monitoring wild horses and burros would gather prioritization information for GRSG habitat activities within SFAs, PHMA, IHMA (ID) and GHMA. Under Alternative 1, evaluation of land health assessments in wild horse HMA could identify vegetation conditions that would determine prioritization of areas to reduce wild horse numbers and the associated impacts on vegetation. Disturbances that are found in *Nature and Types of Effects* would have similar grazing impacts and may increase noxious weeds and invasive species presence, while also promoting conifer encroachment. Removing wild horses and burros in those PHMA with existing herd management areas in all states would increase total vegetation, grass abundance and cover, and sagebrush canopy cover, species richness, and dominance of palatable forbs (Manier et al. 2013; Chambers et al. 2017).

Hard thresholds (see **Appendix 2**) represent a trigger indicating that immediate action is necessary to stop a severe deviation from GRSG conservation objectives set forth in the BLM plans. Adaptive management strategies and the potential for changes in management would be consistent between all states and would benefit GRSG habitat, especially in wild horse and burro areas. However, there is no consistency in the specific thresholds between states or the strategies associated with responding to those thresholds. The metrics, thresholds, and timeframes and spatial scales vary state by state, as does the level of detail that explains each of these. Similarly, the responses associated with adaptive management thresholds vary by state, with some prescribing specific actions and others identifying teams to develop a response.

10.3.3 Alternative 2

Greater Sage-Grouse Management

Rangewide Environmental Consequences

Areas managed as HMAs would vary slightly from Alternative 1 (**Table 2-3**). Rangewide effects to vegetation from GRSG habitat management and conifer encroachment treatment under Alternative 2, would be the same as those described for Alternative 1.

State-Specific Environmental Consequences

Removing SFAs in UT, WY, NV, and ID would reduce protections to vegetation by removing restrictions on land use and surface-disturbing activities in those areas. However, previous management area classifications (e.g., PHMA) would remain, but protections may be lower than what is required in SFAs. Protections afforded to vegetation from restrictions to land use and surface-disturbing activities would continue in SFAs in MT and OR, where the habitat classification would be retained; impacts would be as described under Alternative 1.

Under Alternative 2, the GHMA designation in UT would be removed with all its corresponding management actions. This would likely incentivize development in areas formally identified as GHMA, and could lead to vegetation loss, sagebrush or riparian vegetation fragmentation, and increased weed spread.

Requirements for mitigation that achieves a net conservation gain in all HMA types would apply in MT/DK, NV/CA, and OR, and impacts would be the same as described for Alternative 1. CO and ID would enforce mitigation resulting in no net loss in HMA. This would help offset impacts associated with land use activities, as described under *Nature and Types of Effects*, but to a lesser extent than Alternative 1, in which a net conservation gain would be required. In UT and WY, the net conservation gain requirement would be removed, which would increase potential for impacts.

Although the BLM would not require compensatory mitigation in HMA, it would enforce state mitigation policies and programs. In CO, ID, NV/CA, OR, UT, and WY HMA, compensatory mitigation would be voluntary unless required by laws other than FLPMA or by the State. As a result, the potential for impacts from land use activities, as described under *Nature and Types of Effects*, would increase relative to Alternative 1, in which a net conservation gain would be required.

Impacts from applying a 3% (CO, ID, NV/CA, OR, UT, and Dakotas) or 5% (MT and WY) disturbance cap in PHMA would be similar to those described for Alternative 1. However, in UT and ID the cap could be exceeded if it would benefit GRSG. The cap would be applied at the BSU and project scale, except in ID which would only apply it at the BSU scale. Consequently, some additional development could occur in ID, which may increase potential for impacts to vegetation compared to Alternative 1.

Impacts of including an adaptive management strategy would be similar to those described for Alternative 1. However, some states would include the addition of "un-triggers", meaning that the management change implemented to reverse a threshold could be revoked and the original management would be reimplemented once the issue is resolved. Reverting to the original management that resulted in the threshold being met would likely lead to impacts to vegetation that could cause the threshold to be met again.

Minerals Management

Rangewide Environmental Consequences

Impacts from mineral development would generally be the same as described for Alternative 1 except for slight differences among the states (see state-specific analyses). Removing the recommendation for locatable

mineral withdrawal in SFAs in all states (except in MT/DK, which did not have a 2019 amendment) would have no on the ground impact. The Secretary proposes and makes withdrawals according to a separate process pursuant to section 204 of FLPMA not through the BLM land use planning.

State-Specific Environmental Consequences

Removing the CO PHMA closure to fluid mineral development would increase potential for disturbance and vegetation loss or degradation. This is because mineral development activities could occur in previously closed areas and cause impacts as described under *Nature and Types of Effects*. Changing GHMA from closed to fluid mineral development to NSO would likely not change impacts to vegetation because the NSO stipulation would avoid potential for disturbance and associated impacts due to surface-disturbing activities.

Impacts from prioritizing fluid mineral leasing outside of HMA in CO, ID, OR, and MT/DK offices would result in the same impacts as described under Alternative 1. Removing the objective in UT, NV/CA would increase the potential for impacts because land in PHMA and GHMA could be leased. In WY, fluid mineral leasing would be allowed in PHMA, which would increase the potential for impacts. However, if the BLM has a backlog of Expressions of Interest for leasing, the BLM would prioritize work first in non-habitat followed by lower habitat management areas (e.g., GHMA). For fluid mineral development on existing leases that could adversely affect GRSG populations or habitat, the BLM would work with the lessees, operators, or other project proponents to avoid, reduce, and mitigate adverse impacts consistent with lessees' rights.

Adding an exception criterion to saleable and nonenergy mineral closures for NV/CA PHMA with free use permits and allowing consideration of new free use permits for saleable minerals in ID IHMA would increase the chance for activities to occur in these areas and thus the potential for associated impacts as described in *Nature and Types of Effects* would be greater.

Lands and Realty Management

Rangewide Environmental Consequences

Impacts from ROW management would be the same as described for Alternative 1 (with additional exception criteria in NV/CA, see state-specific analysis).

State-Specific Environmental Consequences

There would be additional exception criteria for ROW development in NV/CA PHMA and for wind development in NV/CA GHMA. This could increase the potential for impacts associated with ROW and renewable energy development because there would be a higher chance of development.

Livestock Grazing Management

Impacts from domestic livestock grazing management would generally be the same as described for Alternative 1, with differences across states as described below.

State-Specific Environmental Consequences

Removing SFAs in UT, WY, NV, and ID would remove the prioritization for review and processing of grazing permits in these areas. However, the BLM would still have the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value.

Adding clarification of habitat objectives to land health standards in WY, ID, and NV and clarifications on grazing in riparian areas and management of range improvements in WY may, in some cases, help move vegetation toward desired conditions.

In OR, livestock grazing in the 13 key RNAs would be returned to language that pre-dated the 2015 amendments. Because this language would not specifically address habitat objectives for GRSG, these habitat objectives may not be met, and potential for impacts to vegetation and overall vegetation degradation would increase relative to Alternative 1.

Wild Horse and Burro Management

Impacts from wild horse and burro management in Alternative 2 would be the same as Alternative 1, except for the removal of references to SFAs for the states that removed them, and removal of the reference to GHMA in UT, which removed that HMA type under this alternative. This would potentially lead to disturbances in extensive portions of the PHMA, IHMA, and GHMA that aren't required to protect SFAs. Disturbances to these areas, see *Nature and Types of Effects*, would increase the likelihood of native vegetation degradation and fragmentation for GRSG habitat with an increase in bare ground soils that would potentially increase noxious weeds and invasive species establishment and conifer encroachment.

10.3.4 Alternative 3

Greater Sage-Grouse Management

Under Alternative 3, the BLM would manage the largest acreage of HMAs, all as PHMA (**Table 2-3**). In addition, the BLM would manage ACECs for GRSG. Conifer encroachment impacts and treatments for Alternative 3 would be the same as those described for Alternative 1. Management actions for PHMA would be more restrictive and designed to promote GRSG conservation to a greater extent in areas previously designated as GHMA. Therefore, managing previously designated GHMA as PHMA would minimize potential impacts to vegetation to a greater extent than if they remained managed as GHMA. Expanding PHMA in some states to include areas of adjacent non-habitat, unoccupied historic habitat, or areas with potential to become habitat as PHMA would also increase protections for and minimize impacts to vegetation.

Classifying previously designated SFAs as PHMA would likely not reduce protections to vegetation rangewide. This is because although management actions for PHMA would be less restrictive than those for SFAs under other alternatives, the management restrictions in PHMA under this alternative would be more restrictive than Alternatives 1 and 2 (e.g., PHMA would be closed to fluid, saleable, and nonenergy minerals) and applied to a greater overall area.

Impacts from mitigation would be similar to those described for Alternative 1, as the BLM would require and ensure mitigation that achieves a net conservation gain in all HMA types. An emphasis would be placed on avoiding impacts, which would reduce potential for effects. Additionally, compensatory mitigation would need to fully offset any residual effects on habitat function and value and at the scale necessary to meet the RMP GRSG goals and objectives. These requirements would reduce the potential for impacts from land use activities, such as direct vegetation loss and sagebrush or riparian vegetation fragmentation.

The BLM would apply a 3% cap for new and pre-existing authorizations for infrastructure, wildfire, and agriculture (subject to valid existing rights) at the project scale and within HAF fine scale habitat selection area while honoring valid existing rights. Calculating disturbance at the project scale and HAF fine scale habitat selection area may prevent some development, and therefore reduce impacts to vegetation. Because fine scale HAFs typically represent a local population's home range and are determined in part by the quality and juxtaposition of resources within and between seasonal habitats, reducing disturbance in these areas may help to reduce sagebrush or riparian vegetation fragmentation and impacts to vegetation from surface disturbance.

Effects to vegetation from habitat management and conservation would be similar to those described for Alternative 1, however, Alternative 3 would include additional objectives to maintain existing connectivity between GRSG populations. Maintaining connectivity would reduce the potential for increased sagebrush or riparian vegetation fragmentation. Adaptive management would more accurately reflect GRSG habitat conditions and strive to better manage vegetation to support GRSG.

Minerals Management

Closing PHMA in all states to fluid mineral leasing, saleable minerals, and nonenergy minerals would reduce the potential for impacts to vegetation, such as direct vegetation loss, increased fragmentation, and increased weed spread as described under the *Nature and Types of Effects*. Impacts would be reduced to a greater extent than Alternatives 1 and 2 because areas closed to leasing could not be developed at any point.

Recommending PHMA for withdrawal from location and entry under the United States mining laws would have no impact. However, if the BLM were to apply for a withdrawal pursuant to section 204 of FLPMA and the Secretary were to accept the application, the BLM could initiate the process to withdraw PHMA. A withdrawal would reduce potential impacts to vegetation associated with locatable mineral development as described under *Nature and Types of Effects* since surface disturbance associated with location and entry would be less likely to occur in withdrawn areas.

Lands and Realty Management

Under Alternative 3, all PHMA would be excluded from new ROW authorizations. New linear ROWs would be allowed only in designated ROW corridors. These restrictions would decrease the potential for impacts to vegetation in PHMA to a greater extent than under Alternatives 1 and 2. However, the inability to site ROWs in PHMA could lead to longer ROW routes in order to bypass closed areas which would in turn increase surface disturbance overall and other impacts of ROW siting on vegetation outside of PHMA.

Livestock Grazing Management

Under Alternative 3, all PHMA would be unavailable for domestic livestock grazing. As a result, livestock would be removed from PHMA and impacts to vegetation associated with livestock grazing, as described under *Nature and Types of Effects* would not occur. Alternative 3 would reduce the likelihood for spread of weeds, would allow for native understory perennial plant recovery, and would increase herbaceous vegetation cover (Strand and Launchbaugh 2014). Not utilizing livestock as a tool available for implementing fuels management treatments or invasive species control in sagebrush habitat areas could make PHMA more susceptible to a large-scale wildfire that would decrease native vegetation and increase the potential for noxious weed and invasive species growth in sagebrush vegetation communities within PHMA. Increased risk of wildfire would decrease protection of sagebrush habitats and may require repeated post-fire rehabilitation treatments to recover habitat function and continuity.

Wild Horse and Burro Management

Under Alternative 3, no wild horse and burro herd management areas would be designated in PHMA and wild horses and burros would be removed in areas where there are currently herd management areas. This could potentially increase protections for native plant communities within PHMA and decrease the potential for introduction and spread of noxious weeds and invasive species. Reducing ground disturbances to the herd management areas in PHMA would improve GRSG habitat and would assist in reducing the potential for conifer encroachment opportunities from compacted and bare soils.

10.3.5 Alternative 4

Greater Sage-Grouse Management

Under Alternative 4, more PHMA and less GHMA would be managed than Alternatives 1 and 2 (**Table 2-3**). Restrictions within HMAs would improve GRSG habitat by increasing acres and conditions of vegetation communities, connect sagebrush or riparian vegetation fragmented areas, mitigate noxious weed or invasive species introduction and spread, and decrease conifer encroachment. HMA protections would be expanded to new areas based on updated science.

The disturbance cap would be applicable to new authorizations under Alternative 4. Disturbance cap calculations would also be specific to activities that would remove vegetation and increase the potential for noxious weeds due to an increase in bare-ground areas. This would require more mitigation that could assist in preserving native vegetation populations or reducing invasive plants and noxious weeds for GRSG management. However, areas of GRSG non-habitat within the HMA boundaries would either be removed from the HMA or would be recategorized with decreased protections. Removing areas from HMA classification would have noticeable impacts to native vegetation in those areas and increase the potential for noxious and invasive species as well as soil degradation from surface disturbing activities. The 3% disturbance cap would include all acres of habitat classified as PHMA (and IHMA in Idaho). Areas outside those designations could experience disturbance and be converted to an earlier seral stage that would change vegetation community succession and reduce the extent of native plant communities.

As under Alternative 1, the BLM would continue to include language to maintain and enhance sagebrush habitats with the intent of conserving GRSG populations under Alternative 4. However, habitat objectives tables would be updated based on best available science which would reinforce current or provide new thresholds. The updated language would allow for flexible management that could identify problems sooner and assist in reducing potential vegetation disturbances and invasive plants and noxious weeds spread. Impacts from adaptive management would be as described for Alternative 3.

Minerals Management

Alternative 4 and NSO stipulations would be similar to Alternative 1, including in WY where the NSO stipulations would be expanded to include all of PHMA. Leasing would be focused to areas that have the least potential for conflicts. The BLM would evaluate parcels identified in Expressions of Interest (EOIs) associated with GRSG HMA and determine which to potentially analyze for potential inclusion in a lease sale. This would be applied to a larger area compared with Alternative 1 due to the increase in acres that would be managed as PHMA. As a result, Alternative 4 could reduce fragmentation of vegetation communities and could maintain the extent and condition of native populations where development doesn't occur.

The BLM would work with project proponents to promote measurable GRSG conservation objectives such as, but not limited to, consolidation of project related infrastructure to reduce habitat fragmentation and loss and to promote effective conservation and connectivity of seasonal habitats and PHMA (and IHMA). Vegetation communities in HMA that are considered to have least potential for conflicts with GRSG management and therefore more likely to be considered for development would see a potential increase in impacts to vegetation communities and in invasive plants and noxious weeds.

Lands and Realty Management

Alternative 4 would be similar to Alternative 1 with varying PHMA and IHMA exclusions for utility scaled ROWs. State-specific differences for facilities and activities would be guided by the strategy to avoid,

minimize, or mitigate impacts on GRSG habitat. Wind and solar energy development would be excluded in PHMA and within specified areas of IHMA. Vegetation and soils disturbance from energy development would be eliminated in GRSG habitat containing sagebrush/perennial grass vegetation communities. By exclusion of development, the vegetation and soil conditions would neither be adversely nor beneficially impacted, but rather maintain current conditions and trends. Alternative 4 would exclude wind and solar energy testing and generation facilities in PHMA and in IHMA exclusions would apply within 3.1 miles from active leks that would reduce impacts compared to Alternative 1. Maintaining current conditions in PHMA and IHMA would provide consistent habitat for GRSG, reduce noxious weed and invasive species introduction, and decrease sagebrush or riparian vegetation fragmentation.

Livestock Grazing Management

Impacts to GRSG habitat from Alternative 4 would be the same as Alternative 1, although no SFAs would be managed under Alternative 4. As a result, these areas would not receive additional priority for grazing management. However, the BLM would still have the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value.

Wild Horse and Burro Management

Alternative 4 is similar to Alternative 1 with the exception of references to SFAs, for all states, would be removed from the management plan. Removal of SFAs would have similar impacts to vegetation communities as states that have removed them under Alternative 2.

10.3.6 Alternative 5

Greater Sage-Grouse Management

Under Alternative 5, more PHMA and less GHMA would be managed than Alternatives 1 and 2 (**Table 2-3**). Lands would be managed for avoiding and minimizing direct and indirect disturbances on sagebrush vegetation and sagebrush communities that would require compensatory mitigation to achieve no net habitat loss. Alternative 5 habitat objectives would be similar to Alternative 4. Impacts from adaptive management would be as described for Alternative 3.

Minerals Management

Under Alternatives 5, fluid mineral development could be more flexible compared with Alternative 1 due to WEMs, though adherence to the WEM criteria would ensure no impacts to GRSG within 0.6 miles of leks or provide for off-setting effects through compensatory mitigation in PHMA beyond 0.6 miles (except in WY, where the NSO only applies within 0.6 miles). In addition, compensatory mitigation could be used more frequently under Alternative 5 to offset both direct and indirect adverse impacts on riparian and sagebrush habitats in PHMA and GHMA. Protective effects of PHMA would increase under Alternative 5 compared to Alternative 1, as PHMA would be expanded (**Table 2-3**). Approved fluid mineral developments would cause surface disturbances that would lead to vegetation community degradation, sagebrush or riparian vegetation fragmentation, and increases in noxious weeds and invasive species presence.

Lands and Realty Management

Avoidance for utility scale wind and solar in Alternative 5 would be similar to management under Alternative 1 but would keep GHMA open for utility scale projects with minimization measurements. This would result in more impacts on native vegetation and GRSG habitats from renewable energy development, in comparison to Alternative 1 where GHMA are only open in ID and WY for solar and wind. Under Alternatives 5, GRSG habitat would be fragmented from new ROWs in GHMA resulting in an increase in

the potential for invasive species and noxious weeds throughout the open ROW areas from impacts as described under *Nature and Types of Effects*.

Livestock Grazing Management

Impacts from livestock grazing management under Alternative 5 would be the same as those described for Alternative 4.

Wild Horse and Burro Management

Impacts from wild horse and burro management under Alternative 5 would be the same as described for Alternative 4. Under Alternative 5, the BLM would manage WHB populations within their established AML levels and would reduce the potential for impacts from wild horses and burros on vegetation such as those described under Nature and Type of Effects, compared with Alternatives 1, 2, and 4.

10.3.7 Alternative 6

All impacts would be the same as described for Alternative 5 except for those from ACECs. ACECs under Alternative 6 would cover the same areas as Alternative 3 and would provide further protection to vegetation communities from surface disturbing activities as described under *Nature and Types of Effects*.

10.4 WILDLAND FIRE ECOLOGY AND MANAGEMENT

10.4.1 Methods and Assumptions

Methodology

Impacts on wildland fire ecology and management would primarily result from management actions described in **Chapter 2** that would change the BLM's ability to control the amount or location of fuels. The types of actions that can result in these impacts are discussed in more detail in **Section 4.4.1**, Nature and Type of Effects. For management actions not specifically described below, the effects would remain as described in the 2015 and/or 2019 plans.

Indicators

The indicator of impacts on wildland fire management is a substantial change in the likelihood or severity of wildfire.

Assumptions

This analysis includes the following assumptions:

- The spread of invasive annuals (e.g., cheatgrass) has lengthened the fire season in many parts of the planning area. These species often cure sooner than native perennial species and are more prone to ignition. Therefore, actions that reduce the spread or footprint of invasive annuals or restore perennial vegetation communities would reduce the frequency and intensity of wildfires, while reducing wildfire management costs.
- Fire is an important functional natural disturbance in many of the ecological systems found in the planning area.
- In many cases, a direct relationship exists between fuel loading and potential fire intensity and severity.

10.4.2 Alternative 1

A comprehensive strategy for wildland fire management would be implemented under Alternative 1, including the FIAT. The FIAT would identify PHMA areas and management strategies to reduce the threats to GRSG from invasive annual grasses, wildfires, and conifer expansion. It would incorporate recent scientific

research on resistance and resilience of Great Basin ecosystems as well as interdisciplinary team knowledge. Potential management strategies include proactive measures, such as fuels management and habitat restoration and recovery, and reactive measures, such as fire operations and post-fire rehabilitation. Together, these actions would improve wildland fire management, given the limited resources available, and would target those areas that need most protection. The likelihood for wildfire would be reduced and subsequent impacts on vegetation, particularly vegetation that meets GRSG habitat requirements, described under **Section 3.2**. would also be reduced. Providing adequate rest from livestock grazing would improve the likelihood that ESR seedings would stabilize the site, compete effectively against invasive annuals, and successfully establish native vegetation over the long term.

10.4.3 Alternative 2

Impacts on wildland fire management under Alternative 2 would be the same as described for Alternative 1.

10.4.4 Alternative 3

Under Alternative 3, all PHMA and proposed ACECs would be unavailable for livestock grazing. This could limit the BLM's ability to achieve resource objectives as described under the *Nature and Type of Effects* and could alter the risk of large-scale wildfires.

10.4.5 Alternative 4

Impacts on wildland fire management under Alternative 4 would be the same as described for Alternative 1.

10.4.6 Alternatives 5 and 6

Impacts on wildland fire management under Alternatives 5 and 6 would be the same as described for Alternative 1.

10.5 FISH AND WILDLIFE

10.5.1 Methods and Assumptions

Methodology

Impacts on fish and wildlife species would primarily result from management actions described in **Chapter 2** that result in habitat removal, fragmentation, or other alteration, and actions that result in injury or mortality, displacement, or other disturbance to species. The types of actions that can result in these impacts are discussed in more detail in **Section 4.4.3**, Nature and Type of Effects. For management actions not specifically described below, the effects would remain as described in the 2015 and/or 2019 plans (Colorado 2015 Section 4.3; Oregon 2015 Section 4.5, 2019 Section 4.7; South Dakota 2015 pages 686-725; Utah 2015 Section 4.5, 2019 Section 4.6.6; Wyoming 2015 Section 4.21).

Indicators

Indicators of impacts on fish and wildlife species are as follows:

- Amount and condition of available habitat
- Likelihood of mortality, injury, or direct disturbance
- Likelihood of habitat disturbance

Assumptions

This analysis includes the following assumptions:

- Implementing the management actions for GRSG would have mostly negligible or beneficial impacts on fish and wildlife species. Impacts on fish and wildlife species from resource use actions can have detrimental effects on fish and wildlife, though not all resource uses will have such effects.
- Impacts on big game populations would result from disturbance and/or loss of seasonally important habitat (for example, overwintering, breeding, or migration corridors) to a point that would cause the species' population to decline. Impacts that reduce the population of any herd unit that currently exceeds population objective levels would not be considered significant, so long as impacts would not reduce the population below defined objective levels.
- If adverse impacts are identified, the full suite of mitigation measures could be implemented to minimize, eliminate, or offset the impacts. If monitoring reveals that mitigation is unsuccessful in reducing or eliminating impacts, measures to prevent further impacts would be implemented as appropriate to the species affected.
- Short-term effects would occur over a timeframe of 5 years or less, and long-term effects would occur over longer than 5 years.

10.5.2 Alternative 1

Under Alternative 1, lands would be managed to conserve, enhance, and restore sagebrush ecosystems. By separating GRSG habitat into SFAs, PHMAs, IHMAs, and GHMAs, management actions would then be applied within identified designations, as well as in certain areas outside of PHMA, IHMA, and GHMA, including vegetation objectives to achieve improvements in GRSG habitat. SFA designations would have the most restrictions, and therefore the most protection for wildlife species that occupy these habitat types. However, restrictions to development on BLM lands might push development onto private land, which could result in indirect impacts as described under *Nature and Types of Effects*.

In most of the planning area, priority will continue to be given to leasing and development of fluid mineral resources, including geothermal, outside of PHMAs and GHMAs, or within the least impactful areas within PHMA, IHMA, and GHMA if avoidance is not possible. Applying a disturbance cap can help reduce effects to wildlife within the areas, as well as applying seasonal restriction when wildlife species are more vulnerable to disturbance. Impacts on wildlife species from mineral development would be as described under *Nature and Types of Effects*. Allowing exceptions to lease stipulations, COAs, and terms and conditions to be considered on a case-by-case basis during restricted time periods could lead to additional surface disturbing activities and functional habitat loss. It is unknown, however, what type or degree of exceptions would occur, because the outcome is dependent on each lease and the habitat where the lease is being developed.

Fluid Minerals Management

Under Alternative 1, restrictions on fluid mineral leasing, application of the disturbance cap, and use of conservation measures would reduce the extent of direct habitat loss for terrestrial wildlife species whose ranges overlap PHMA. However, scale of disturbance (both direct and indirect) would depend on lease size and configuration. In instances where several small leases occur entirely within PHMA or the 4-mile lek perimeter, pad and road development may have substantial impacts on wildlife species. Excluding or reducing surface-disturbing activities in PHMA would shift development into other areas and may influence those species that use non-sagebrush communities for nesting, cover, and forage.

Under this alternative, NSO and CSU stipulations would be applied to protect GRSG, which would further reduce wildlife habitat loss and degradation caused by fluid mineral development. While GHMA would be available for fluid minerals leasing and other types of minerals and energy development, such activities would be subject to conservation measures (i.e., net conservation gain, lek buffers, and RDFs). This would generally have a local protective impact on some wildlife in those areas.

The primary impacts on wildlife species (especially big game) from minerals development within the planning area would be the reduction in usable wildlife habitat and disruption of migration corridors that link crucial habitats (winter range) and parturition areas. Reductions would be particularly severe in areas with continuous surface disturbance. As discussed by (Bartmann et al. 1992), crowding of animals may have a density-dependent impact of reducing animal survival and damaging resources. Human disturbance of big game results in increased energy costs (Bromley 1985) and disturbed big game animals incur a physiological cost, either through excitement (preparation for exertion) or locomotion. A fleeing or displaced animal incurs additional costs through loss of food intake and potential displacement to poorer (lower) quality habitat. If the disturbance becomes chronic or continuous, these costs can result in reduced animal fitness and reproductive potential (Geist 1978). Additionally, a fleeing or displaced animal is also more visible to predators and at a higher risk for predation. Displacement of fluid mineral development outside of suitable GRSG habitats could negatively affect raptors and migratory birds that commonly nest in pinyon-juniper and other treed areas. Direct removal or modification that compromises nest stand character would reduce the habitat quality or carrying capacity for local raptor and migratory bird populations.

Saleable Mineral Management

All saleable mineral pits located in PHMA that are no longer in use would be restored to meet GRSG habitat conservation objectives. As such, this alternative would benefit those wildlife species whose ranges and habitats are coincident with PHMA. Surface-disturbing activities from saleable minerals development would be relocated outside of PHMA. This would result in habitat loss or modification of other vegetation types (mountain shrub and pinyon-juniper), with negative impacts on those wildlife species associated with non-sagebrush communities.

Nonenergy Leasable Minerals

Under Alternative 1, no new nonenergy mineral leasing would be allowed in PHMA and existing mines would not be permitted to expand. RDFs would be applied for solution mining wells in PHMA. By reducing the amount of direct habitat loss, this alternative would retain habitat for terrestrial wildlife species whose ranges or habitats are coincident with PHMA.

Locatable Minerals Management

SFAs were recommended for withdrawal from the Mining Law of 1872, as amended. Such a withdrawal, if it occurs, would close the SFA to location and entry under the Mining Law of 1872, subject to valid existing rights. The BLM would request that operators include appropriate mitigation and applicable seasonal restrictions in plans of operation which would reduce impacts on fish and wildlife.

Lands and Realty Management

Under Alternative 1, PHMA in CO, NV/CA, ID, and OR would be managed as an avoidance area. ROW projects would be allowed in PHMA if the project would not adversely affect GRSG populations. GHMA would also be managed as avoidance for ROWs. Additionally, no aboveground structures would be authorized within 1 mile of active leks in occupied habitat. As a result, protections would be greater under

this alternative for those species that overlap all GRSG habitat. Both PHMA and GHMA would be managed as avoidance for large transmission lines, except for several ongoing projects.

Alternative 1 in UT would provide management flexibility in developing infrastructure, focusing on GRSG habitat. PHMA would be ROW avoidance for new linear and site type ROWs, permits, and leases; high voltage transmission lines ROWs (100 kV or greater); major pipelines; and communication sites. Additional protection would be provided by managing PHMA and GHMA as ROW exclusions areas for solar energy development and PHMA as ROW exclusion areas for wind energy development. RDFs would be applied to further reduce impacts. Ensuring a net conservation gain to GRSG under the regional mitigation strategy may require projects to avoid, minimize, or mitigate for their potential impacts on GRSG, which could reduce the loss or disturbance of habitat from specific projects. Offsite mitigation may not always benefit species impacted at the disturbed site. Therefore, there could be a local impact on certain species.

In WY there would be an increase in ROW avoidance areas that could reduce ROW construction activities and related impacts to wildlife habitat. Existing ROWs would be used whenever possible for placement of new linear facilities, which would minimize overall habitat loss and fragmentation. Exceptions could occur, and in those cases, disturbance is to be limited and mitigated. New projects would have seasonal stipulations that would help prevent disturbance to wildlife species during those timeframes. Management for construction would consider impacts to GRSG populations and be designed to minimize impacts through project design and mitigation. The considerations could reduce the impacts from disturbance and habitat loss for other wildlife species. Requiring raptor perching deterrents could reduce the effects to prey species from hunting by predatory bird species; however, predatory birds would not benefit from hunting perches.

Under Alternative 1, a 3% disturbance cap (5% on lands in WY and MT which would include fire, agriculture, and urban development [MT only]) on discrete anthropogenic disturbances would be applied in PHMA and IHMA in ID, at both the BSU and project levels. Additionally, a limit would be placed on the density of energy and mineral development facilities, which would reduce impacts on wildlife habitat caused by such disturbances. Including transmission lines outside of transmission corridors in the 5% disturbance calculation could reduce wildlife habitat loss and reduce disruptions in habitat connectivity. Disturbance and development can create travel or migration barriers which can alter distribution patterns, increasing stress and energy loss and fitness in wildlife species.

Renewable Energy Management

Under Alternative 1, renewable energy development would be permitted in some states. As a result, sagebrush associated wildlife species would experience reduced potential for disturbance, habitat alterations, and habitat fragmentation as described *in Nature and Types of Effects*. Within exclusion areas, direct impacts would be eliminated on wildlife species, but development in avoidance areas would have more effects on wildlife as some development would occur on a case-by-case basis. Impacts include altered habitat, habitat fragmentation, and noise associated with development. Additionally, the potential exists for both solar and wind facilities to cause direct mortality of some wildlife, particularly birds and bats (Frick et al. 2015; DOE 2021).

Mitigation and Adaptive Management

Under Alternative 1, anthropogenic disturbances in PHMA, IHMA, and GHMA would be mitigated to ensure a net conservation gain to GRSG, which would also maintain habitat for other wildlife species that use GRSG habitat. Conservation measures would be imposed to complement mitigation and further reduce anthropogenic disturbance in PHMA and GHMA, including RDFs and lek buffers.

Application of Habitat Objectives

The habitat objectives would identify the desired outcome for habitat on BLM-administered lands in all GRSG HMAs. Some wildlife species that co-exist in sagebrush communities with GRSG and which have similar habitat requirements would benefit most from the desired habitat conditions. These include management of activities to support suitable GRSG habitat at multiple scales, supporting connected mosaics of sagebrush to provide seasonal habitats and dispersal. The specific tables identifying indicators and benchmarks supported by various scientific publications throughout the range would be retained in the monitoring appendix as a tool through which suitability is informed.

Livestock Grazing Management

Under this alternative, site-specific reviews during grazing permit renewals could allow for adjustments to the number of AUMs on federal lands. Within SFAs, the prioritization of grazing permit/lease reviews not meeting Land Health Standards for special status species, especially in areas containing riparian and wet meadow vegetation, would improve these habitats. Riparian and wet meadow areas are critical for fish and wildlife, serving as essential habitat for breeding, feeding, and shelter.

Adjustments in grazing use or management of BLM-administered lands to meet Standards for Rangeland Health could minimize the impacts of grazing on fish and wildlife by improving habitat conditions. These actions could help sustain wildlife populations, particularly species dependent on sensitive habitats, such as riparian zones. Reducing the intensity of grazing in these areas could decrease soil compaction, enhance water quality, and restore vegetation structure, which is important for species and habitats.

Improved grazing management could also result in overall landscape health improvements, reducing the spread of invasive, nonnative plant species that threaten native wildlife habitats. These actions would provide greater forage and cover for wildlife, particularly in riparian areas, and contribute to maintaining biodiversity by balancing the needs of livestock with habitat conservation for fish and wildlife species.

Wild Horse and Burro Management

Alternative 1 would place some restrictions on the management of wild horses and burros, however the BLM would consider all resource values in conjunction with GRSG when managing wild horses. These management strategies would benefit wildlife species whose ranges overlap herd management areas within PHMA or GHMA. Management within the established levels of AMLs could reduce impacts from wild horses and burros on fish and wildlife in some areas.

ACEC Designation

Alternative 1 does not include management for ACECs.

10.5.3 Alternative 2

Habitat Management Area Designation

Impacts from designating GRSG habitat as SFAs, PHMA, IHMAs, and GHMA (**Table 2-3**) would be similar to those described for Alternative 1. However, some SFAs would be removed in states as described under state impacts. Impacts from language to maintain and enhance sagebrush habitats would be the same as described for Alternative 1.

Removal of GHMA in UT and associated management may reduce some indirect protection for all wildlife species, including crucial habitat for big game species that rely on the area for wintering and fawning/calving within mapped GHMA. Impacts on big game are considered negligible because big game uses a variety of habitat types beyond sagebrush. Additionally, GHMA is not the only management for these areas but is

merely complimentary to management of habitat under applicable RMPs and according to the BLM Land Health Standards. Removing GHMA minimization measures that, as noted above would not preclude development, would not likely result in additional impacts that are not already addressed by management of crucial habitats in existing land use plans.

The offsite mitigation in PHMA to replace impacted habitat in occupied GRSG habitat outside of PHMA may not always benefit the same other wildlife species that were impacted at the disturbed site. While it could lead to a local improvement for species in treated areas, especially those that rely on sagebrush habitats, it could also result in an unmitigated loss in the quantity and quality of habitat at the location of the impact. As the amount of development increases in the GRSG habitat outside PHMA, the impact from disturbances mitigated in PHMA would mount and could affect the use patterns of wildlife in those areas.

Fluid Minerals Management

Impacts on fish and wildlife species from the leasing objective would be similar to Alternative 1, except it would not be relevant in UT or NV/CA. In WY, leasing would be allowed in PHMA, which would increase the potential for impacts on wildlife species that occupy PHMA and surrounding habitat. Impacts from fluid mineral development is discussed under *Nature and Types of Effects*.

Impacts on fish and wildlife species from WEMs would be similar to Alternative 1, except that they would no longer be applied in NV/CA and UT. Allowing placement of developments in non-habitat portions of PHMA may increase impacts on certain wildlife and migratory birds whose habitat requirements do not overlap sagebrush areas. Adjacent non-sagebrush habitats could see an increase in development and disturbance when trying to avoid and minimize disturbance to sagebrush communities.

Saleable Mineral Management, Nonenergy Leasable Minerals, and Locatable Minerals

Impacts on wildlife species would be the same as Alternative 1, except PHMA in ID allows consideration of new free use permits and NV/CA added exception criteria to the closure. Increased potential for related impacts as outlined in *Nature and Types of Effects* would result from providing consideration of new free use permits for saleable minerals in ID IHMA and adding an exemption criterion to saleable and nonenergy mineral closures for NV/CA PHMA. This is because there would be a higher likelihood of saleable and/or nonenergy mineral activities taking place in these areas. Removing the recommendation for locatable mineral withdrawal in SFAs in all states (except in MT/DK, which did not have a 2019 amendment) has no impact. This is because a recommendation to withdraw lands under the Mining Law of 1872 has no impact. The Secretary proposes and makes withdrawals not through the BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Lands and Realty

Under Alternative 2, impacts from ROWs on wildlife species would be the same as Alternative 1, with additional exception criteria added in Nevada. Alternative 2 proposes to remove the requirement to consider burying transmission lines (except when not technically feasible) and allow increased flexibility to consider site-specific impacts and minimization options. This action could impact wildlife such migratory birds, small mammals, and reptiles by increasing predator perches from unburied lines that may lead to increased take of migratory birds and their nests by raptors and corvids; however, impacts of predator perches could be minimized on a site-scale by use of perch deterrents on poles. Additionally, Alternative 2 would result in more aboveground power lines that increases the risk of birds and bat collisions (Frick et al. 2017). There could be beneficial impacts on big game and migratory bird habitat by not burying transmission lines because it offers more protection for sensitive habitat areas. Removal of sagebrush and associated

vegetation can be avoided with placement of surface lines, which minimizes habitat disturbance and potential for weeds.

In addition, there would be a 3% disturbance cap, not including wildfire or agriculture for CO, ID, NV/CA, OR, UT, and the Dakotas. In UT the cap may be exceeded if it will benefit GRSG. The 3% cap may be exceeded at either scale if a technical team determines that site specific GRSG habitat and population information, combined with project design elements indicates the project will improve the condition of GRSG habitat within the proposed project analysis area or within the PHMA in the population area where the project is located. Factors considered by the team will include GRSG abundance and trends, movement patterns, habitat amount and quality, extent and alignment of project disturbance, location and density of existing disturbance, project design options and other biological factors. Such exceptions to the 3% disturbance cap may only be approved by the BLM Authorized Officer with the concurrence of the State Director. The finding and recommendation shall be made by the technical team, which should consist of, at least, a BLM field biologist, other local GRSG experts, and biologists and other representatives from the appropriate State of Utah agency.

Allowing exceedances to the disturbance and density caps in PHMA could affect wildlife by a reduced level of protection for habitat from disturbance. These disturbance impacts may increase by allowing exceptions to the disturbance cap, especially within areas of non-sagebrush, therefore impacting wildlife species that use these other habitat types (e.g., pinyon-juniper woodlands and pinyon jays); however, exceptions to the disturbance and density cap may also benefit some wildlife species with habitats that overlap with GRSG. This would come about by improving habitat conditions through the increased potential for voluntary vegetation treatments.

Renewable Energy Management

Impacts from renewable energy would be similar under Alternative 1. However, in Nevada, PHMA would have additional exception criteria added. This could increase the potential for impacts associated with ROW and renewable energy development because there would be a higher chance of development. These impacts are described under *Nature and Types of Effects*.

Mitigation and Adaptive Management

Maintaining a mitigation strategy in PHMA that leads to a planning area-wide improvement of GRSG habitat would include management for vegetation communities. Generally, these areas include habitats that are dominated by grasses and shrubs rather than by trees. However, the removal of trees such as pinyon and juniper are included in some habitat management strategies. While each individual project proponent would no longer be required to increase habitat to obtain an authorization for use of public lands, the effects of habitat improvements that were described in the 2015 Final EIS would continue to be achieved: namely, increasing the quantity and quality of sage-steppe vegetation communities in early- to mid-seral condition. Additionally, the effects of habitat improvements would still occur where voluntary mitigation occurs. This would increase habitats for wildlife species with habitats that overlap that of GRSG; however, it would also generally decrease habitat availability for wildlife species or seasonal habitats of species that are not sage dependent.

Application of Habitat Objectives

Impacts from habitat objectives would be the same as for Alternative 1.

Livestock Grazing Management

Impacts from domestic livestock grazing management would be the same as described for Alternative 1, except for in the states described below. In UT, WY, and NV/CA, the prioritization for review and processing of grazing permits was removed; however, the BLM would still have the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value.

Wild Horse and Burro Management

Impacts on fish and wildlife species would be the same as described under Alternative 1.

ACEC Designation

Impacts on fish and wildlife species would be the same as described under Alternative 1.

10.5.4 Alternative 3

Habitat Management Area Designation

Managing the largest area as PHMA would minimize potential impacts on wildlife species that occupy previously designated GHMA as there would be more restrictions in the areas. Expanding PHMA in some states to include areas of adjacent non-habitat, unoccupied historic habitat, or areas with potential to become habitat as PHMA would also decrease potential for disturbance to sagebrush associated wildlife species and habitat alterations because management restrictions associated with PHMA would occur over a larger area.

Minerals Management

Closing PHMA in all states to fluid mineral leasing, saleable minerals, and nonenergy minerals would reduce potential impacts to wildlife that occupy GRSG range, such as disturbance and habitat alterations. The type of impacts associated with mineral development are described in detail under *Nature and Types of Effects*. Compared to the other Alternatives 1 and 2, the impacts would be lessened. This is because areas closed to leasing would not be developed and there would be a decrease of HMA acres that would be subjected to effects from mineral development. Closing PHMA to mineral leasing and development would protect habitat for wildlife in these areas from surface-disturbing activities as well as subsurface activities (e.g., directional drilling), maintain connectivity between leks and big game habitat, and not contribute to fragmentation. Sagebrush associated wildlife would not be exposed to disruption that is often associated with the noise and human activity that accompanies construction, development, or production activities in PHMA. However, restrictions to development on BLM lands might push development onto state, tribal, or private land, which could result in indirect as described under *Nature and Types of Effects*.

Recommending PHMA for withdrawal from location and entry under the United States mining laws would have no impact. However, if the BLM were to apply for a withdrawal pursuant to section 204 of FLPMA and the Secretary were to accept the application, the BLM could initiate the process to consider withdrawing PHMA from location and entry under the Mining Law of 1872. Such a withdrawal would reduce potential impacts to wildlife associated with GRSG range and habitat associated with locatable minerals as described under *Nature and Types of Effects*. This is because surface disturbance associated with location and entry would be less likely to occur in withdrawn areas because only claimants who demonstrate a valid existing right would be able to proceed.

Excluding or reducing surface-disturbing activities in PHMA could shift development into habitats outside of PHMA. This may influence those species that use non-sagebrush communities for nesting, cover, and forage. Of note would be woodland raptors and migratory birds that commonly nest in pinyon-juniper. Direct removal or modification that compromises nest stand character would reduce the habitat quality or carrying

capacity for local raptor and migratory bird. Additional development in habitats outside of PHMA would affect small mammals and big game populations and connectivity between habitats could be reduced by habitat loss and degradation. This would depend largely on the amount and distribution of development.

Lands and Realty

Compared to Alternatives 1 and 2, new infrastructure development would be far more restricted. All PHMA would be excluded from new ROW authorizations. Only new linear ROW would be allowed in designated ROW corridors. The potential impacts on wildlife that occupy PHMA would be decreased because of the exclusion of ROWs. In PHMA, there would be a decreased probability of habitat degradation and fragmentation. However, because ROWs cannot be placed in the PHMA, more lengthy ROW routes may be necessary to go around closed areas. Longer routes could have more negative effects on wildlife species using habitat outside of PHMA because the ROW would be located in PHMA adjacent habitats, non-federal lands, or private lands.

Renewable Energy Management

Under Alternative 3, PHMA in all states would be ROW exclusion areas for wind and solar energy development. Prohibiting wind energy development would eliminate the likelihood for habitat loss, degradation, fragmentation, direct mortality to birds and bats and direct disturbance to wildlife in PHMA. Alternative 3 would offer more protection from renewable energy development compared to Alternatives 1 and 2 because more areas would be excluded from renewable energy development with no exceptions. Impacts from wind and solar projects are described under *Nature and Types of Effects*.

Mitigation and Adaptive Management

Impacts on wildlife species from mitigation would be similar as described for Alternative 1, because the BLM would require and ensure mitigation that achieves a net conservation gain in all HMA types. These requirements would reduce the potential for impacts from land use activities, such as habitat loss or alterations. Maintaining habitat function and value would benefit wildlife species associated with sagebrush habitats.

Application of Habitat Objectives

Impacts from habitat objectives would be similar to those described for Alternative 1. Since the habitat objectives would be modified under this alternative, the species affected may vary slightly.

Livestock Grazing Management

Alternative 3 would make all PHMA unavailable for livestock grazing and therefore would have the fewest direct impacts on terrestrial wildlife. The reduction in herbivory from livestock grazing under this alternative would allow for herbaceous forage and cover for wildlife to increase and would prevent impacts as described under *Nature and Type of Effects*. There would also be less trampling or compacting of vegetation and/or soils, and less competition for forage, water, space, and habitat alteration.

In contrast, livestock grazing may reduce invasive species and noxious weeds or enhance forage and brood-rearing conditions for some wildlife species, so the removal of livestock grazing may increase the risk of invasion of noxious or invasive weeds. Relatedly, without a reduction in fine fuels, there may be an increased risk of large-scale wildfire that would remove wildlife habitat. Additionally, more fencing may be needed to separate PHMA from adjacent non-federal grazed lands, which could increase collision risk, change or prevent movements by some wildlife species, and increase predator perching opportunities for some species.

Wild Horse and Burro Management

Under Alternative 3, wild horses and burros would be removed from herd management areas within PHMA. This would increase habitat quality for wildlife because there would be a reduction in grazing competition, which could result in improvements to vegetation cover, forb abundance, forage for native wildlife, and spring habitat. Where range improvements, such as water troughs are removed, there would be a reduction in potential drowning hazards and/or potential for disease transmission. Additional fencing may also be needed to keep wild horses off BLM-administered HMAs which could increase collision risk, change or prevent movements by some wildlife species, and increase predator perching opportunities for some species.

ACEC Designation

Under Alternative 3, all ACECs would be managed as PHMA. The management in ACECs under this alternative would be similar to management in PHMA, with the exception of ROW management and locatable minerals requirements. Managing ACECs as exclusion to ROWs both within and outside of designated corridors would expand protections to fish and wildlife from ROW development compared to PHMA. Plans of operations for locatable mineral disturbances would reduce effects if measures were included to reduce disturbance, which would incidentally benefit fish and wildlife in these areas.

10.5.5 Alternative 4

Habitat Management Area Designation

Under Alternative 4, PHMA boundaries would be expanded compared with Alternatives 1 and 2 and acres managed as GHMA would decrease (**Table 2-3**). By managing these areas, wildlife species whose range overlaps with GRSG would benefit from management actions to protect GRSG to a greater extent where PHMA and other HMA designations have expanded. Under this alternative, impacts on wildlife would be similar under to those described under alternatives 1 and 2 with a focus on improving GRSG habitat by increasing acres and conditions of vegetation communities, habitat connectivity, mitigation of noxious weeds and/or invasive species, and decrease conifer encroachment.

Minerals Management

Range wide, leasing would be permitted in HMAs, which would increase potential impacts to wildlife in these areas as described in the *Nature and Types of Effects*. The BLM would, however, implement management strategies that would reduce the possibility of conflict and associated consequences from potential development in GRSG habitats or linking regions as described in **Section 4.2.3**. Giving preference to lands that would not obstruct the suitability and proper operation of GRSG habitat, considering their proximity to already-existing development, potential for development, and the presence of significant GRSG habitats or connectivity areas, would minimize potential impacts to wildlife species that overlap GRSG habitat. In contrast, this may shift operations to nonfederal lands and impact other wildlife species whose range does not overlap GRSG.

The fluid mineral development and leasing objective would consider leasing in areas where there is the least potential for conflicts with GRSG and its habitat. The avoidance strategy will ensure minimal disturbance on wildlife species that overlap GRSG range. However, impacts may be shifted to non-federal lands which may pose greater impacts for wildlife species that do not overlap with GRSG habitat. Those impacts are discussed under *Nature and Types of Effects*.

Other impacts from minerals management would be similar to those described for Alternative 1.

Lands and Realty

Under Alternative 4, in all states managing PHMA (IHMA in ID) as ROW avoidance areas would be similar to Alternative 1. In areas where development cannot be avoided, there would be additional protection by avoiding important GRSG habitat such as leks and nesting/early brood-rearing habitat. This would reduce impacts on wildlife species who also utilize high value GRSG habitat, however, this may shift impacts to other potentially important wildlife habitat that doesn't overlap with GRSG. Impacts on wildlife species are described in *Nature and Types of Effects*.

GHMA would also be managed as ROW avoidance areas within breeding and nesting habitats, along with other limited seasonal use habitats. Avoiding placement of ROWs within one-half mile of PHMA or IHMA would help protect or buffer those areas from indirect impacts. Because all other areas would be managed as ROW open, impacts, such as habitat alteration and disturbance, could occur, however, compensation would be required (see Alternatives). Similar to impacts from PHMA management described above, potential for impacts on wildlife whose range overlaps with GRSG habitats would be reduced, while other wildlife species whose range is outside of GRSG habitat may have increased potential for impacts. Those impacts are described in *Nature and Types of Effects*.

Since HMAs would be extended to additional regions based on best available science, restrictions inside HMAs would lessen impacts on wildlife species whose range overlaps with GRSG, as discussed under *Nature and Types of Effects*. Alternative 4 would have restrictions on disturbance caps between states that would decrease surface disturbances impacting wildlife habitat and improve protection for GRSG habitat within new HMA boundaries.

Renewable Energy Management

Under Alternative 4, wind and solar development would be managed by HMA, and proximity to lek locations, similar to Alternative 3. Management stipulations for PHMA would be exclusion for utility scale wind and solar development. For IHMA exclusion would be within 3.1 miles of active lek locations and avoidance strategies for the remainder. All GHMA would be managed as avoidance. Within the exclusion areas impacts on wildlife that overlap GRSG habitat would be reduced as development would not be permitted. As a result, development would likely shift to areas outside of GRSG habitat, causing direct impacts on wildlife species whose range does not overlap with GRSG. Those impacts are described under *Nature and Types of Effects*.

Mitigation and Adaptive Management

Impacts under this alternative would likely be higher than Alternative 3 because more projects would take place if PHMA, IHMA, and GHMA were not closed to new projects. There would also be the addition of required compensatory mitigation that would meet the requirements set by the state wildlife agency or appropriate authority (See alternatives). Depending on GRSG population triggers there may be additional mitigation in some areas, and the BLM would coordinate with state wildlife management agencies to consider project activities, direct and indirect impacts, and restoration success rate. Impacts on wildlife would potentially be minimized depending on GRSG population triggers in the area and the overlap of wildlife habitat with GRSG habitat. On the contrary, management actions may be shifted to non-federal lands or other wildlife habitat where development and disturbance may occur. These impacts are discussed under *Nature and Types of Effects*.

Application of Habitat Objectives

Impacts on wildlife from application of habitat objectives under this alternative would be the same as Alternative 3.

Livestock Grazing Management

Impacts on wildlife would be similar to those described under Alternative 1. However, because SFAs would not be managed, Alternative 4 does not include a programmatic prioritization strategy. However, the BLM would still have the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value. In addition, the BLM would include additional management objectives and actions that give GRSG and GRSG habitat further protection from livestock grazing impacts. Some of these management objectives and actions include site-specific adjustments to AUMs, flexibility to adjust permits, and meeting land health conditions. These added management objectives and actions would potentially reduce impacts to other wildlife species that overlap GRSG range. The impacts are further discussed under *Nature and Types of Effects*.

Wild Horse and Burro Management

Impacts on wildlife from wild horse and burro management would be the same as described for Alternative 1.

ACEC Designation

Alternative 4 does not include management for ACECs and thus there would be no effects on fish and wildlife from ACEC management under this alternative.

10.5.6 Alternative 5

Impacts on fish and wildlife from fluid, saleable, nonenergy leasable, and locatable minerals management would be the same as described for Alternative 2. Impacts from application of habitat objectives and minimizing threats from predation would be the same as described for Alternative 3. Impacts from the fluid mineral development and leasing objectives, mitigation, adaptive management, and grazing would be the same as described for Alternative 4.

Habitat Management Area Designation

Under Alternative 5, the BLM would manage protections in more PHMA and less GHMA compared with Alternatives 1 and 2. This would lead to increased protection for other wildlife whose ranges overlap with PHMA but less protection for those whose ranges overlap with GHMA.

Lands and Realty

Impacts under this alternative would be similar to those described under Alternative 4 in comparison to the management of PHMA and IHMA in ID as ROW avoidance areas with the application of minimization measures in areas where major ROWs cannot be avoided.

Renewable Energy Management

Under this alternative, PHMA and IHMA would be classified as avoidance areas. This would minimize the potential impacts from wind and solar development, but to a lesser degree than exclusion areas because development would be considered on a case-by-case basis, whereas development would be prohibited in exclusion areas. Impacts from wind and solar development are described under *Nature and Types of Effects.*

In high value GRSG habitat such as leks and nesting/early brood-rearing habitat, development would not be permitted, therefore impacts to other wildlife species in these areas would be negligible unless certain criteria are met (nonhabitat/unsuitable habitat or the project prevents indirect impacts).

Managing GHMAs as open to wind and solar energy development range wide would result in potential for impacts on wildlife species as described in *Nature and Types of Effects*. However, the inclusion of minimization measures and compensation to maintain GRSG habitats consistent with state agency habitat designations (e.g., restoration, connectivity, seasonal, or other), and to preclude negative impacts to any adjacent PHMA habitats would reduce the potential for those impacts on wildlife in high value and seasonal GRSG habitats.

Under this alternative, a 3% disturbance cap would be applied range wide at the fine scale, similar to Alternative 4, however, there would be a 5% disturbance cap for the project scale in MT and WY (which would include fire, agriculture, and urban development (MT only)). Impacts on wildlife species under this alternative would be similar as described under Alternative 4 but with more exceptions which would potentially result in more development and disturbance in GRSG habitat.

Livestock Grazing Management

Impacts from livestock grazing management under Alternative 5 would be the same as those described for Alternative 4.

Wild Horse and Burro Management

Impacts from wild horse and burro management under Alternative 5 would be the same as those described for Alternative 1.

10.5.7 Alternative 6

Impacts would be the same as described for Alternative 5 but with the additional designation of ACECs. Under this alternative, ACECs would be open to fluid mineral leasing with NSO stipulations. These stipulations would minimize impacts on wildlife in these areas, however, this would increase the HMA acres that are potentially at risk to effects from mineral development that are discussed in *Nature and Types of Effects*. While limiting surface disturbance would ensure habitat connectivity between lek locations, this would benefit other wildlife that utilize sagebrush habitat in these areas. On the contrary, this may push surface disturbance into other important wildlife habitats that do not overlap with GRSG habitat.

Managing ACECs and saleable mineral/mineral material operations as closed to new or expansion of nonenergy minerals associated with existing operations (e.g., fringe leases) would reduce potential impacts on wildlife species and habitat. Management of these resources would reduce potential impacts on wildlife and habitat such as disturbance and habitat degradation or alteration which is discussed in *Nature and Types of Effects*. However, saleable mineral/mineral material operations would not close all free-use pits and would have more impacts than if not permitted.

Management of ACECs as exclusion areas for major ROWs and wind and solar development and avoidance areas for minor ROWs would reduce potential impacts on wildlife and associated sagebrush habitat, such as disturbance, habitat alterations, and increased potential for predation, as described under *Nature and Types of Effects.* While ROWs would not be permitted in exclusion areas, they would be evaluated on a case-by-case basis in avoidance areas, therefore impacts would be reduced to a greater extent in exclusion areas compared to avoidance areas.

10.6 SPECIAL STATUS SPECIES

10.6.1 Methods and Assumptions

Methodology

Although data on many known locations and habitats within the planning area are available, the data are not complete or comprehensive concerning all special status species known or suspected to occur, or potential

habitat that might exist. Known and potential special status species and habitats for key special status species that use sagebrush ecosystems in the planning area were considered in the analysis.

As described for Fish and Wildlife in **Section 4.4.2**, impacts on special status species would primarily result from management actions described in **Chapter 2** that result in habitat removal, fragmentation, or other alteration, and actions that result in injury or mortality, displacement, decreased water quality, or other disturbance to species. The types of actions that can result in these impacts would be the same as those described for fish and wildlife species, in **Section 4.4.3** and vegetation, in **Section 4.3.3**. For management actions not specifically described below, the effects would remain as described in the 2015 and/or 2019 plans.

This analysis focuses on a number of key special status species that would have the greatest potential to be affected by the GRSG management decisions outlined in **Chapter 2**. These are typically species that have overlapping ranges with GRSG, and that are closely associated with sagebrush and pinyon-juniper habitats.

Indicators

Indicators of effects on special status species would be the same as those described for fish and wildlife in **Section 4.4.1**.

Assumptions

This analysis includes the following assumptions:

- The analysis presented is largely qualitative due to the lack of data or uncertainty in existing data on certain special status species' occurrences. Further, because many special status species may potentially use habitats that are currently unoccupied and populations fluctuate, any quantitative analysis of occupied habitat would change over time as knowledge of species locations increases.
- Impacts on special status species (for example, habitat degradation or direct disturbance) would be more intense than similar impacts on common species. This is because population viability may be already uncertain for special status species, and certain species, such as special status plants, tend to be poor competitors, and habitat may be more limited or fragmented.
- All federal actions would comply with ESA consultation requirements and BLM policy for threatened, endangered, and sensitive species, and all implementation actions would be subject to further special status species review before site-specific projects are authorized or implemented. The USFWS would be consulted on any action that could potentially affect any listed plant or wildlife species or their habitat, including critical habitat.
- The potential for changes to the distribution and extent of special status plant populations and seedbanks.
- Implementing the management actions for GRSG would have mostly negligible or beneficial impacts on other special status species and, therefore, impacts from each alternative are not discussed separately in detail. The key impacts from resource uses, as well as management actions for GRSG, on other special status species are described below.
- If adverse impacts are identified, compensatory mitigation measures could be implemented to minimize or eliminate the impacts. If monitoring reveals that mitigation is unsuccessful in reducing or eliminating impacts, measures to prevent further impacts would be implemented as appropriate to the species affected.
- Short-term effects are defined as those that would occur over a timeframe of 5 years or less, and long-term effects would occur over longer than 5 years.

All new and renewed leases and permits would be subject to terms and conditions determined by the BLM Authorized Officer to manage and achieve resource condition objectives and land health standards for BLM-administered lands.

In general, impacts on special status fish and wildlife species would be similar to those discussed under **Section 10.5**, Fish and Wildlife, and **Section 10.2**, Greater Sage-Grouse, while impacts on special status plant species would be similar to those discussed under **Section 10.3**, Vegetation. However, impacts on special status species may be greater than impacts on common species because population viability is already uncertain for special status species. A detailed analysis of impacts on federally listed and proposed species and designated and proposed critical habitat will be prepared in the biological assessment for this RMPA/EIS. The biological assessment is under development and will be included with the Final RMPA/EIS.

Those species more closely associated with sagebrush communities or whose ranges are largely coincident with PHMA and GHMA (e.g., Brewer's sparrow and to a lesser extent white-tailed prairie dog, black-footed ferret, pygmy rabbit, western burrowing owl, ferruginous hawk, Holmgren lupine, Beatley's buckwheat, and squalid milkvetch) would benefit from conservation measures designed to protect GRSG and sagebrush habitat.

Conversely, excluding or avoiding development in GRSG habitats most likely outside of PHMA and IHMA, in GHMA inclusions, may lead to increased activity in other vegetation types (e.g., pinyon-juniper, mountain shrub, and aspen/spruce/fir). Special status species associated with these habitat types, such as pinyon jay, northern goshawk, BLM-sensitive bat species, Canada lynx, Columbian sharp-tailed grouse, sand cholla, Reese River phacelia, and Eastwood milkweed, may be adversely influenced to varying degrees, depending on alternative and development scenarios.

10.7 WILD HORSES AND BURROS

10.7.1 Methods and Assumptions

Methodology

The following section analyzes impacts on wild horses and burros, including herd management areas and associated AMLs from the potential planning decisions in this document. Under Alternatives 1 through 5, the BLM has proposed various management actions in relation to GRSG habitat objectives, and their analyses are outlined below.

Indicators

Indicators of impacts on wild horses and burros are as follows:

- Changes to population size or AML in mapped GRSG Habitat, changes to forage availability, changes to water resource availability, and climate change
- Ability to perform management activities within herd management areas including gathers and contraceptive activities.

Assumptions

In addition to the assumptions in **Section 4.1.1**, Analytical Assumptions, this analysis includes the following assumptions:

- While wild horses and burros may be found on lands outside herd management areas, these areas have no forage allocated to wild horses and burros. The BLM has no authority to manage wild horses and burros outside of herd management areas, except to remove them.

- Wild horses compete with other wildlife species, including GRSG, for various habitat components. When populations exceed AML or when habitat resources become limited (e.g., reduced water flows, low forage production, or dry conditions), they expand beyond the boundaries of the herd management area.
- Factors contributing to failure to meet Land Health Standards within herd management areas commonly include western juniper encroachment, invasive annual grass and other noxious weed infestations, wildfire, and impacts of livestock and wildlife grazing.
- Population growth suppression (fertility control agents, sterilization, and sex ratio adjustments) can aid in population control, but periodic gathers are still necessary to remove excess wild horses and burros.

10.7.2 Alternative 1

Alternative 1 would require a 3% disturbance cap on human surface-disturbing activities in PHMA. It would incorporate RDFs consistent with applicable law in PHMA, GHMA, and IHMA and would also require all human disturbances to result in a net conservation gain for GRSG and their habitat. Lek buffers would also be required.

Collectively, these GRSG conservation management actions would increase mitigation requirements for land use authorizations. This would result in more complex project designs, could exclude infrastructure placement in the most cost-effective locations, and would result in overall greater development costs. A corresponding effect could be a reduction in the number of authorization applications received for activities in PHMA and longer, more complicated review periods for those that are proposed in PHMA.

Protections afforded to GRSG and their PHMA or GHMA habitats would benefit wild horses and burros where herd management areas overlap these areas. This is because habitat conditions and forage would be improved, there would be less impact from human disturbances, and wildfire would be strategically managed in habitats. Temporary or long-term management changes to wild horses and burros may be necessary to achieve and maintain the desired habitat condition. Examples are reducing AMLs, designations, removals, movement patterns, and forage access. Alternative 1 would require more intensive management, particularly in the boundaries of SFAs.

10.7.3 Alternative 2

Alternative 2 would remove references to management within SFAs in some states and remove reference to GHMA in Utah. Management is more restrictive on lands within SFAs to emphasize protection of GRSG, management for SFAs provides the highest level of protection to forage. Without these protections, there could be additional surface disturbance, and thus removal of forage Removal of SFAs would increase impacts on wild horses and burros when compared with Alternative 1. Impacts on wild horses and burros, herd management areas, and AML under Alternative 2 within PHMAs would be the same as those described under Alternative 1.

10.7.4 Alternative 3

Under Alternative 3, no new designation of herd management areas would occur in any herd areas that overlap with PHMA unless the area outside of the PHMA boundary could still support a herd management area. All wild horses and burros would be removed from existing PHMA and proposed ACECs, which would result in short-term disturbance of herds by human presence and round up activities. Round ups would occur based on congressional budget appropriations for these actions, therefore the exact timeline is unknown. In the long-term, all wild horses and burros would be removed from PHMA and moved to holding

facilities per wild horse and burro herd-removal guidelines under Public Law 92-195 as amended and 43 CFR Part 4700. Herd management areas in PHMA under Alternative 3 are shown in **Figure 2.80**.

Wild horses and burros outside of herd management areas in PHMA but in adjacent lands could be impacted by changes in management within the herd management area. Because herd management areas would no longer be managed for AML under this alternative, there is potential for removal of resources, primarily water developments. Under Alternative 3, livestock grazing would become unavailable within PHMA, and thus range and water improvements may be removed or reclaimed, which would decrease the availability of developed water sources.

10.7.5 Alternative 4

Impacts on wild horses and burros under Alternative 4 would be similar to those under Alternative 1, with additional management direction to remove reference to SFAs. Removal of SFAs could increase impacts to wild horses and burros as forage will not be protected from surface disturbing activities. Management to the low end of the AMLs could reduce wild horse and burro populations in some areas.

10.7.6 Alternative 5

Impacts from wild horse and burro management under Alternative 5 would be similar to those described for Alternative 1.

10.7.7 Alternative 6

Under Alternative 6, the BLM would additionally manage ACECs. These ACEC would cover the same areas as under Alternative 3, however management would include restrictions on fluid minerals, nonenergy minerals, major ROWs, wind, and solar projects. ACEC management would provide further protection to forage for wild horses and burros from surface disturbing activities outside of the HMA.

10.8 LIVESTOCK GRAZING

10.8.1 Methods and Assumptions

Methodology

The following section analyzes impacts on livestock grazing, including range facilities, and rangeland improvements from the planning decisions in this document. Under Alternatives 1 through 6, the BLM has proposed various livestock grazing management actions in relation to GRSG management objectives, and their analyses are outlined below.

Indicators

Indicators of impacts on livestock grazing are as follows:

- Changes in permitted AUMs in areas available for livestock grazing.
- Prohibitions or limitations of the construction or maintenance of structural and nonstructural range improvements
- Modifications to or removal of structural range improvements
- Changes to the intensity, timing, duration, or frequency of permitted use, including temporary closures.
- Making areas unavailable for livestock grazing

Assumptions

In addition to the assumptions in **Section 4.1.1**, Analytical Assumptions, this analysis includes the following assumptions:

- All new and renewed leases and permits would be subject to terms and conditions determined by the BLM Authorized Officer to manage and achieve resource condition objectives and land health standards for BLM-administered lands.

10.8.2 Alternative 1

Greater Sage-Grouse Management

Alternative 1 could directly impact livestock grazing through its requirement through the BLM's management to meet GRSG-specific habitat objectives in PHMA, GHMA, and other HMAs, as well as other actions to achieve desired GRSG habitat conditions. In addition to restricting management in GRSG habitat management areas and including livestock grazing-specific actions in GRSG habitat (prioritizing reviews), the BLM would manage SFAs, which provide additional restrictions on development and disturbance.

These management actions, designed to enhance GRSG habitat on BLM-administered lands, could affect livestock grazing by the following:

Modifying grazing strategies or rotation schedules
Changing duration and the season of use
Changing the kind or class of livestock
Reducing livestock numbers
Reducing AUMs

Management to achieve these desired conditions would also impact permittees by increasing the amount of time permittees spend to manage livestock on BLM-administered lands and the total costs to a livestock operation. Restricting development in SFA would reduce disturbance on livestock and their forage.

Implementing management direction to achieve desired conditions in GRSG seasonal habitat could impact livestock grazing in the long term. It would do this by implementing management that improves rangeland conditions. Improved rangeland condition could also contribute to increased forage production.

Minerals Management

During the planning initiative that culminated in the 2015 RMP decisions, carried forward here as Alternative 1, SFAs were recommended for withdrawal from location and entry under the Mining Law of 1872, subject to valid existing rights. The BLM applied for a withdrawal of the recommended area and the Secretary accepted the application. The Secretary initiated a separate withdrawal process in 2015 pursuant to Section 204 of FLPMA. That process is currently underway. If the Secretary were to withdraw the lands identified in the proposed withdrawal, any resulting reduction in locatable mineral development would reduce impacts on livestock grazing through protection of forage from surface disturbance and a reduction in harassment of livestock from disturbance; the greatest reduction would be in allotments in SFA.

Under Alternative 1, PHMA would be closed to new mineral materials sales, but GHMA would be open. While these restrictions would limit livestock and forage disturbance, they could push development to allotments outside of PHMA. PHMA would be managed as closed to new nonenergy leasable mineral leasing, and impacts would be similar to those described above.

Alternative 1 would prioritize development of fluid minerals outside PHMA, GHMA, and IHMA. This approach would reduce disturbance to livestock and would maintain forage condition in allotments that fall in GRSG occupied habitat. Implementing the GRSG disturbance cap, mitigation strategy, monitoring framework, and hard trigger adaptive management responses under Alternative 1 would ensure that this reduction in disturbance of livestock, while forage condition would be maintained.

SFA would be managed as NSO without waivers, exceptions, or modifications. Unleased fluid mineral actions would be subject to objectives and screening criteria in GRSG habitat. This approach would not increase disturbance to livestock and forage in allotments that fall in GRSG-occupied habitat, but it would result in the fewest reductions in permitted use and the fewest restrictions on range improvement construction. This approach would also result in fewer reductions in permitted livestock use.

Renewable Energy Management

Increased restrictions on renewable energy development under Alternative 1 would reduce impacts on forage and harassment of livestock. Alternative 1 would designate PHMA and SFA as ROW exclusion for utility-scale commercial wind and solar energy facilities. There would be fewer potential reductions in permitted livestock use due to forage destruction and quality reduction. Fewer acres would be subject to restrictions on range improvement construction.

Management direction prohibiting solar and wind development in PHMA and restricting development in GHMA and IHMA would limit any impacts of ground disturbances from developing these resources. This management direction would limit the direct impacts of development and surface disturbances on rangelands, which would be beneficial to livestock grazing. This may shift impacts in areas outside of priority and general GRSG habitats.

Lands and Realty Management

Under Alternative 1, ROW development would be limited in avoidance and exclusion areas within PHMA. This would maintain forage sustainability and would not increase disturbance to livestock. Most of GHMA would remain open to ROW development. ROW development and associated disturbance to livestock and their forage are likely to be concentrated in designated corridors and GHMA. Implementing the GRSG mitigation strategy, monitoring framework, and hard trigger adaptive management responses under Alternative 1 would maintain livestock forage.

Alternative 1 would retain all public lands in public ownership; therefore, there would be no effect on current grazing operations. Limits on human disturbance, mitigation strategy, lek buffers, and other conservation measures would further limit disturbance. This would result in reduced indirect impacts on livestock and their forage in PHMA.

As described above, Alternative 1 would include a cap on human disturbance; the 3% disturbance cap (5% in MT and WY) on discrete human disturbances would be applied in PHMA. Human disturbances in PHMA, GHMA, and IHMA would be mitigated to ensure a net conservation gain to GRSG. Conservation measures would be implemented, such as adaptive management and defined monitoring protocols (**Appendix 2**).

Livestock Grazing Management

Under Alternative 1, the effect of livestock grazing management could increase the management actions necessary to maintain GRSG objectives in PHMA, GHMA, and IHMA.

Impacts could include modifying grazing strategies or rotation schedules, changing the season of use, changing the kind and class of livestock, deferring grazing use until a set objective is met, or reducing livestock numbers. Implementing this management direction could reduce AUMs on some allotments and present challenges to livestock operation viability.

Impacts from modification of grazing strategies could result in a decline in permitted grazing, anticipated over time as permits are modified to meet objectives. Under the Alternative 1, priority for land health assessment and permit renewal on BLM-administered lands would be tiered to include SFA first, followed by PHMA outside the SFA. Existing permits and leases in these areas not meeting Land Health Standards would be given priority, with a specific focus on those containing riparian areas, including wet meadows. The timeline for changes in management would generally follow this priority. In the long term, this prioritization could improve rangeland conditions for livestock and wildlife by focusing management on PHMA that are in most need of improvement.

In GHMA and PHMA, the potential risk to GRSG and its habitats from existing structural range improvements will be evaluated, and modifications of those structural range improvements identified as posing a risk will be addressed. Supplements and supplemental feeding will continue to be authorized where appropriate. New range improvement projects would be designed to monitor, adjust, and limit impacts from new and existing water and structural range improvements, as well as fences. Existing range improvements would be evaluated to make sure they conserve, enhance, or restore GRSG habitat. Consideration of GRSG habitat needs would likely limit the number and types of constructed range improvements. In some instances, improvements may be removed to help attain GRSG habitat objectives.

Under Alternative 1, all or portions of 15 key RNAs would be unavailable to grazing. In those areas, permittees and lessees would need to locate alternative forage or reduce AUMs, with the potential for economic impacts.

Modifications to grazing systems could be required to meet seasonal habitat objectives, increasing costs to lessees and permittees. Acres within nesting habitat may be more likely to require changes to grazing management, due to the desired conditions for this habitat type. Impacts would occur on an allotment scale as permit renewal and related management changes were implemented. The level and intensity of impacts would vary on a site-specific basis.

Under Alternative 1, the BLM may determine if voluntarily relinquished grazing permits and leases and associated allotments should remain available for livestock grazing or be used for other resource management objectives, in accordance with WO IM 2013-184. This may result in some reduction of overall available AUMs, but relinquishment is likely to remain uncommon.

Wild Horse and Burro Management

Management to adjust or reduce AMLs would enhance vegetation productivity and sustainable forage, particularly where rangeland conditions could be improved. Tiered prioritization of gathers in HMAs in SFA, followed by PHMA, GHMA, and IHMA to meet established AMLs would reduce any current levels of forage competition between wild horses and burros and livestock on allotments in PHMA.

10.8.3 Alternative 2

Greater Sage-Grouse Management

Rangewide Environmental Consequences

Impacts from designating GRSG habitat as SFAs, PHMA, IHMAs, and GHMA (**Table 2-3**) would be similar to those described for Alternative 1.

State-Specific Environmental Consequences

SFAs would be removed in UT, WY, NV/CA, and ID, thereby reducing restrictions due to GRSG habitat protection on livestock grazing operations in those areas. Removing SFAs would also prevent restrictions on land use and surface disturbing activities, and the impacts on livestock grazing from those surface disturbing activities would be as described under *Nature and Type of Impacts*. Removing restrictions on SFAs would likely result in fewer impacts on livestock grazing operations when compared with Alternative 1. Protections afforded to forage from restrictions to land use and surface-disturbing activities would continue in SFAs in MT and OR, where the habitat classification would be retained; impacts would be as described under Alternative 1.

Under Alternative 2, the GHMA designation in UT would be removed with all corresponding management actions from the 2015 plan amendments. Removal of GHMA and their associated management actions would likely lead to development in areas formally identified as GHMA and could therefore lead to removal of forage and increased human-livestock conflicts, which would increase impacts on livestock grazing operations when compared with Alternative 1.

Requirements for mitigation that achieves a net conservation gain in all HMA types would apply in MT/ND, NV/CA, and OR, and impacts would be the same as described for Alternative 1. CO and ID would enforce mitigation resulting in no net loss in HMAs. In UT, there would be a requirement to minimize or eliminate threats affecting the status of GRSG or to improve the condition of GRSG habitat. These requirements would help reduce impacts on livestock grazing associated with land use and surface disturbing activities but to a lesser extent than Alternative 1, in which a net conservation gain would be required. In WY, the net conservation gain requirement would be removed, which would increase potential for impacts.

The BLM would not require compensatory mitigation in HMAs, but it would enforce state mitigation policies and programs in CA, CO, ID, OR, UT, and WY. Compensatory mitigation would be voluntary unless required by laws other than FLPMA or by the state. As a result, the potential for impacts from land use activities would increase relative to Alternative 1, in which a net conservation gain would be required.

Impacts from applying a 3% disturbance cap in CO, ID, NV/CA, OR, UT, and the Dakotas or a 5% disturbance cap in MT and WY in PHMA would be like those described for Alternative 1. In UT and ID, the 3% disturbance cap could be exceeded if it would benefit GRSG. The cap would be applied at the BSU and project scale, except in ID which would only apply it at the BSU scale. Some additional development could occur in ID, which may increase potential for forage loss. The ability to exceed the disturbance and density caps could result in loss and degradation of livestock forage and increased human-livestock conflicts. Surface disturbing projects that would be precluded under if no exceedances were allowed could proceed under Alternative 2; however, exceedances to the caps would only be allowed if site-level analysis indicates the project, in combination with all voluntary and required design features, will improve the condition of GRSG habitat, thus likely improving forage conditions.

Minerals Management

Rangewide Environmental Consequences

Impacts on livestock grazing operations from fluid mineral management in PHMA and GHMA would be the same as described for Alternative 1, except in CO PHMA and CO GHMA (see *State-Specific Environmental Consequences*, below).

Impacts from saleable mineral management in PHMA and GHMA would be the same as described for Alternative 1, except in ID IHMAs and NV/CA PHMA (see *State-Specific Environmental Consequences*, below).

Impacts from nonenergy mineral management in PHMA and GHMA would be the same as described for Alternative 1, except in NV/CA PHMA (see *State-Specific Environmental Consequences*, below).

Removing the recommendation for withdrawal of the SFAs in all states (except in MT and Dakotas, which did not have a 2019 amendment) from location and entry under the Mining Law of 1872 would have no impact. This is because recommendations for withdrawal do not restrict any activities; therefore, such recommendations have no impact. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

State-Specific Environmental Consequences

Removing the closure of CO PHMA to fluid mineral development would increase potential for surface disturbance, forage loss, and human-livestock conflicts. This is because mineral development activities could occur in previously closed areas. Changing GHMA from closed to fluid mineral development to NSO would likely not change impacts to livestock grazing operations because the NSO stipulation would avoid potential for surface disturbance and forage loss or degradation.

Impacts from prioritizing fluid mineral leasing outside of HMAs in CO, ID, OR, and MT/Dakotas would result in the same impacts in these states as described under Alternative 1. Removing the objective in UT, NV/CA would increase the potential for impacts because land in PHMA and GHMA could be leased. In WY, fluid mineral leasing would be allowed in PHMA, which would increase the potential for impacts. If the BLM has a backlog of interest for leasing, the BLM would prioritize work first in non-habitat followed by lower-tier habitat management areas (e.g., GHMA).

Adding an exception criterion to saleable and nonenergy mineral closures for NV/CA PHMA and allowing consideration of new free use permits for saleable minerals in ID IHMA would increase the potential for associated impacts on livestock grazing operations. This is because there would be a greater chance for saleable and/or nonenergy mineral activities to occur in these areas.

Lands and Realty Management

Rangewide Environmental Consequences

Impacts from ROW management would be the same as described for Alternative 1, with additional exception criteria in NV/CA.

State-Specific Environmental Consequences

There would be additional exception criteria for ROW development in NV/CA PHMA and for wind development in NV/CA GHMA. This could increase the potential for impacts associated with ROW and renewable energy development because there would be a higher chance of development.

Renewable Energy Management

Rangewide Environmental Consequences

Impacts from renewable energy management would be the same as described for Alternative 1 (with additional exception criteria in NV/CA).

State-Specific Environmental Consequences

There would be additional exception criteria for ROW and wind/solar development in NV/CA PHMA and for wind development in NV/CA GHMA. This could increase the potential for impacts associated with ROW and renewable energy development because there would be a higher chance of development and surface disturbance.

Livestock Grazing Management

Rangewide Environmental Consequences

Impacts from domestic livestock grazing management would be the same as described for Alternative 1, except for in the states described below.

State-Specific Environmental Consequences

In UT, WY, and NV, the prioritization for review and processing of grazing permits was removed. The BLM would still have the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value.

The additional clarification of habitat objectives to land health standards in WY, ID, and NV/CA and clarifications on grazing in riparian areas and management of range improvements in WY may lead to a loss of AUMs in some cases, prohibitions or limitations on range improvements and water developments. Over the long-term movement towards desired conditions under land health standards could improve overall forage conditions.

Wild Horses and Burro Management

Impacts from wild horse and burro management would be the same as described for Alternative 1.

10.8.4 Alternative 3

Livestock Grazing Management

Under Alternative 3, all PHMA and proposed ACECs (see **Table 2-3**) would be made unavailable to livestock grazing. To make grazing unavailable, the BLM may have to construct and maintain a large amount of fencing, particularly in areas with mixed surface ownership, to effectively make grazing unavailable. Removing the ability to graze livestock would directly impact permittees/operators through a reduction in income provided by grazing livestock on BLM lands across the rangewide planning area (see **Section 4.12**).

The requirement to remove livestock grazing in PHMA would result in direct and indirect economic impacts on individuals, companies, and the local community. Most ranches are dependent seasonally on forage on public lands, and some are dependent year-round. Eliminating AUMs on public lands would affect the entire ranching operation by reducing the total amount of available forage Without the opportunity to graze public lands, ranchers would be incentivized to sell their private lands leading to an increased potential for urbanization in some areas, leading to a loss of forage for both livestock and native grazers, and would remove the opportunity to graze livestock in the future, should management decisions change in subsequent resource management and land use plans.

Removal of grazing also means less landscape-scale removal of fine fuels. Eliminating livestock grazing may increase the potential for large and severe wildfires as fuel loads increased in the absence of managed grazing. There would be potential for the BLM to conduct targeted grazing as a means to reduce fine fuels but would not be near the scale that currently exists.

Where areas are made unavailable for grazing due to a permit or lease is being relinquished, the agency may have to compensate the permittee or lessee for the range improvement projects constructed under a range improvement permit or cooperative agreement, in accordance with 43 CFR Part 4120.3-6(c).

Wild Horses and Burro Management

Impacts from wild horse and burro management would be the same as described for Alternative 1.

10.8.5 Alternative 4

Greater Sage-Grouse Management

Impacts on livestock grazing operations from designating GRSG habitat as HMAs (**Table 2-3**) would be similar to those described for Alternative 1. Impacts from applying a 3% disturbance cap at the project scale would be similar as to those described for Alternative 2, however, the disturbance cap would apply to both existing and proposed infrastructure authorizations, subject to valid existing rights, while wildfire and agriculture would not be included in the disturbance cap calculation. The level of disturbance from other sources such as energy development, roads and ROWs, and other surface disturbing activities would be higher than if wildfire and agriculture were included in the disturbance calculation. The disturbance cap could be exceeded at the project scale under certain conditions, which may lead to more development and increased impacts on livestock grazing operations, forage, and increased human-livestock conflicts. There would be no exceptions to the 3% PHMA (and IHMA) disturbance cap at the HAF fine scale habitat selection area, which would limit removal of forage or disturbance livestock at this scale.

Minerals Management

Increasing the acres subject to NSO Alternative 4 compared with Alternative 1 would reduce the HMA acres affected and potential for impacts. Prioritizing projects that avoid, minimize, reduce, rectify, and/or adequately mitigate for direct and indirect impacts to PHMA/IHMAs and including applicable and technical COAs would also reduce impacts on livestock grazing operations and forage.

Lands and Realty Management

Impacts on livestock grazing from managing PHMA in all states and ID IHMAs as ROW avoidance areas would be like those described for Alternative 1. Where development cannot be avoided, additional protection would arise unless certain criteria are met (see **Chapter 2**). This would reduce the potential for impacts.

Managing GHMA as ROW avoidance areas within limited GRSG habitats to meet the RMP GRSG goals and habitat objective would reduce the potential for impacts on forage. Within ROW avoidance areas in GHMA, the potential for livestock grazing operations and forage to be affected may vary depending on the location. Avoiding placement of ROWs within one-half mile of PHMA or IHMA would protect those areas from impacts. All other areas would be managed as ROW open, so impacts, such as surface disturbance or forage removal could cause a reduction in AUMs, thus reducing the amount of forage available for grazing.

Renewable Energy Management

Rangewide Environmental Consequences

Impacts from managing PHMA in all states as ROW exclusion areas for wind and solar energy development would be similar to those described for Alternative 2. Since PHMA would apply to a smaller area under this alternative, the extent of reduction in impacts on livestock grazing from disturbance associated with from renewable energy development would be less.

Managing GHMA as avoidance areas for wind and solar energy development in all states would decrease the potential for impacts associated with wind and/or solar development but to a lesser extent than exclusion areas. Where avoidance is not possible, impacts to livestock grazing and forage would be minimized through certain measures such as avoiding surface use and occupancy. Such measures would protect PHMA and the forage within from indirect impacts.

State-Specific Environmental Consequences

Managing ID IHMAs as exclusion areas for wind and solar energy development within 3.1 miles from active leks and avoidance in the remainder of the IHMA would decrease the potential for impacts on livestock grazing and forage as described in Nature and Types of Effects, but to a lesser extent than if the entire IHMA were managed as an exclusion area. This is because solar and wind development would be considered on a case-by-case basis in avoidance areas, whereas it would be prohibited in exclusion areas. As such, there would be greater potential for development to occur in avoidance areas.

Livestock Grazing Management

Because the presence of GRSG HMAs would not affect whether an area is available for livestock grazing (except in Oregon key RNAs) and existing areas designated would be maintained as available or unavailable for livestock grazing, impacts from livestock grazing management would be the similar to those described for Alternative 1.

The BLM would include additional livestock grazing management objectives and actions to minimize or reduce impacts to GRSG and habitat. For example, in HMAs, livestock grazing would be managed to toward meeting land health standards the GRSG habitat objectives, avoid direct adverse impacts to key GRSG habitats from range improvements, and employ grazing management strategies that avoid concentrating livestock on key GRSG habitats during key seasons. This could lead to prohibition of range improvement construction as well as adjustments to existing AUMs to meet these management objectives. There would be increased flexibility to adjust the terms and conditions of grazing permits conditions to help avoid or reduce impacts to GRSG or habitat.

Additionally, where the land health standards for GRSG habitat are not met - as indicated by an unsuitable site-scale HAF assessment specific to site capability – and existing livestock grazing is a significant causal factor, adjustments to livestock grazing practices would be made at the authorization, allotment, or activity plan level and in accordance with applicable regulations (43 CFR Part 4180.2(c)(1) or subsequent changes to regulations or policy). Range improvements and other existing infrastructure, such as water developments, would be evaluated with respect to their effect on GRSG and GRSG habitat. These evaluations could lead to limitations on the placement, repair, or construction of range improvements.

Wild Horses and Burro Management

Impacts from wild horse and burro management would be the same as described for Alternative 1. Management of wild horse and burro populations to the low end of the AMLs could reduce forage competition between wild horse and burro populations and livestock in some areas.

10.8.6 Alternatives 5 and 6

Greater Sage-Grouse Management

Rangewide Environmental Consequences

Impacts from applying a 3% disturbance cap would be the same as described for Alternative 4, except in WY and MT (see State-Specific Environmental Consequences). Impacts from exceeding the 3% disturbance cap under certain conditions would be similar to those described for Alternative 4, but more exceptions would be allowed, which may result in increased development, leading to a potential reduction in forage availability.

State-Specific Environmental Consequences

Impacts from applying a 5% disturbance cap at the project scale in WY and MT would be similar to those described for Alternative 1. The 3% disturbance scale would still apply at the HAF fine scale habitat selection area, which may prevent some additional development within those areas, reducing impacts on livestock grazing operations. WY and MT would include wildfire and agriculture in the disturbance calculation, and therefore, the level of disturbance from other human-made surface disturbing activities would be relatively lower than if wildfire and agriculture were not included in the disturbance calculation, similar to Alternative 2.

Minerals Management

Impacts on livestock grazing from mineral resource management would be the same as described for Alternative 4. The exception is in WY and MT, where applying a 5% disturbance cap at the project scale could allow for more potential mineral development, depending on the degree to which wildfire and agriculture contribute to disturbance in a given area, which could increase surface disturbance and forage removal, as well has increased human-livestock conflicts.

Renewable Energy Management

Classifying PHMA and IHMA as avoidance areas for wind and solar energy development would increase the potential for surface disturbing impacts and disturbance to livestock compared with Alternative 1 under which most PHMA would be exclusion areas.

Managing GHMA as open to wind and solar energy development in all states would result in potential for surface disturbing and limitation on livestock grazing availability.

Lands and Realty Management

Impacts from managing PHMA in all states and ID IHMAs as ROW avoidance areas and applying minimization measures where major ROWs cannot be avoided would be similar to those described for Alternative 4.

Compared with Alternative 1, managing GHMA in all states as open to ROW with minimization measures and compensation would increase the potential for ground disturbing impacts and disturbance to livestock. Such management would benefit grazing in the instances where a ROW is needed to access an allotment or where a structural range improvement is desired.

Livestock Grazing Management

Rangewide Environmental Consequences

Impacts from livestock grazing management would be the same as described for Alternative 4.

State-Specific Environmental Consequences

In OR, the 15 key RNAs would be retained; but their associated areas allocated as unavailable to grazing are proposed to be retained, modified, or re-allocated to grazing based on district-generated, site-specific

updated information since the 2015 ARMPA. This would result in an increase in acreage available for grazing in the Black Canyon, Dry Creek Bench, North Ridge Bully Creek, South Ridge Bully Creek, and Spring Mountain Key RNAs (see **Appendix 3**).

Wild Horse and Burro Management

Impacts from wild horse and burro management under Alternative 5 would be similar to those described for Alternative 1.

10.9 LANDS AND REALTY (INCLUDING WIND AND SOLAR)

10.9.1 Methods and Assumptions

Indicators

Indicators of impacts on lands and realty, including renewable energy, are as follows:

- Acres of ROW restrictions (avoidance and exclusion areas) that would limit or preclude new transmission line development to support renewable energy projects

Assumptions

In addition to the assumptions in **Section 4.1**, this analysis includes the following assumptions:

- Existing ROWs, designated utility corridors, and communication sites would be managed to protect valid existing rights.
- On renewal, assignment, or amendment of existing ROWs, permits, and leases, additional stipulations could be included in the land use authorization.
- Major ROWs would be needed to develop and operate renewable energy facilities.
- Maintaining and upgrading utilities, communication sites, and other ROWs is preferred before the construction of new facilities in the decision area, but only if the upgrading can be accommodated within the existing ROW.
- Activities on dispersed private, state, tribal, or non-BLM federal parcels within a decision area would continue to require new or upgraded access, communication, and utility services.
- Federal energy policies including (42 USC Section 13201 et seq. [2005], Executive Order 14008, and the Energy Act of 2020), would continue to support and promote domestic energy production, including renewable energy such as wind and solar.
- The number of ROW applications for new communication and computer technology, such as fiber optic cable, would continue to increase.
- Where demand for new ROWs exists on public lands, restricting ROW development in those areas would likely redirect ROW development to adjacent nonfederal or non-GRSG habitat federal land areas to accommodate the demand where feasible.
- Power lines and other vertical structures in areas naturally devoid of perching opportunities provide a perch for raptors and subsequently increase the potential for GRSG to abandon leks (Johnson and Holloran 2010). Mitigation in the form of burying lines or including non-perching design features on lines could be required to reduce perching opportunities and subsequent impacts on GRSG.
- For all alternatives, a major ROWs is defined as transmission lines over 100kv and distribution pipelines over 24" diameter but may also include smaller electrical transmission and/or distribution lines and pipelines, as well as, other ROW projects that require large distances, density or footprints, with high levels of activity or surface disturbance. In addition, major ROW sites may contain multiple types of above and below ground features leading to a high density of infrastructure, or many tall structures. All others are considered minor ROWs (see Glossary).

- Wind speeds for utility scale wind are often placed in areas with average annual wind speeds of 14.5 miles per hour (mph) or higher. However, newer technologies may make it possible to place turbines in areas with wind speeds of 12–14 mph in some circumstances.
- The types of actions that can result in the impacts described below are discussed in more detail in **Section 4.9.1**, Nature and Type of Effects.

Impacts Common to All Alternatives

All action alternatives for each state would increase the restrictions of ROWs in PHMA by applying exclusion and avoidance areas. This would result in adverse effects to lands and realty and renewable energy since it would decrease the acreage available to new development, which could lead to more complex designs, exclude infrastructure placement in cost effective locations, result in overall greater development cost and increased review periods. Such stipulations could limit future access, delay or increase the cost of energy supplies, or delay or restrict communications service availability. ROW exclusion and avoidance areas decrease the amount of land available for new development and could promote collocation. Collocating of new infrastructure within existing ROWs could reduce land use conflicts, additional land disturbances, and demarcate the preferred locations for utilities, which would simplify the processing on BLM-administered lands.

Avoidance areas require ROW applicants to meet additional project criteria, which could influence project location, delay the availability of energy supply (by delaying or restricting pipelines or transmission lines) or delay or restrict communications service availability. Within exclusion areas, new ROW development would be prohibited, which would prevent the lands and realty program from approving new applications in these areas and shifting them to GHMA and nonhabitat areas where fewer restrictions would apply. These restrictions would prevent the BLM from accommodating future demand for ROW development within the decision area.

10.9.2 Alternative 1

Under alternative 1 the entire plan area with the exception of Wyoming would limit lands used for ROWs in PHMA (or IHMA in Idaho) and GHMA for GRSG. Variations range from blanket restrictions on ROW development in PHMA and GHMA to variable restrictions by industry or project type. Plan details are derived from each state's 2015 ARMPA. **Table 38** in **Appendix 12** provides each state's proposed management of ROWs under Alternative 1 for all ROW types. Wind acres associated with the RFD are in **Appendix 12**, **Table 37** and solar acres associated with the RFD are in **Appendix 9**, **Table 3-10**.

Under Alternative 1, most of the states would manage PHMA and GHMA as ROW avoidance areas. PHMA would be managed as exclusion areas for ROWs including wind and solar major ROWs if the state has sufficient solar potential and differentiates solar ROWs.

Key elements in the planning area include the following:

- All states except North Dakota, South Dakota, and Utah would each have some form of disturbance caps on surface disturbing activities.
- Colorado, Idaho, Southwest Montana, and Utah would have land use authorizations that require avoiding disturbance to any BSU.
- Nevada, Northeastern California, Idaho, Southwest Montana, Utah, and Wyoming would require lek buffers.
- All states except for Colorado and Oregon would have requirements and/or restrictions for power lines.

- In Nevada, Northeastern California, Idaho, Southwest Montana, and Utah ROWs would be allowed if they could be demonstrated to provide a net conservation gain for GRSG habitat. A further description of this is located in **Appendix 2**. Existing GRSG Management.

Additionally, in Oregon, the BLM would manage SFA and PHMA outside of SFA as ROW exclusion areas for wind and solar, with the exception of Lake, Harney, and Malheur Counties. Within the avoidance areas of Lake, Harney, and Malheur Counties, Alternative 1 would establish a hierarchy to development opportunities, beginning with nonhabitat as the first preference, followed by poor quality GRSG habitat before considering high quality GRSG habitat.

Allowing future development in Lake, Harney, and Malheur Counties would accommodate future demand since these areas contain the most developable wind resources in the state. Demand for new transmission lines, access roads, and related ancillary features to serve new wind generation projects in Lake, Harney, and Malheur Counties, GHMA, and in nonhabitat or private lands could result in new ROW applications in PHMA.

In areas where the ROW avoidance and exclusion restrictions listed above would apply the impacts would be as described in the *Nature and Type of Effects*, above. Additionally, restrictions to development on BLM lands might push development onto private land, which could result in indirect impacts as described under *Nature and Types of Effects*.

Collectively, these GRSG conservation management actions would increase mitigation requirements for land use authorizations. This would result in more complex project designs, potentially excluding infrastructure placement in the most cost-effective or environmentally-suitable locations and potentially resulting in overall greater development costs. Another effect could be a reduction in the number of authorization applications for activities and longer, more complicated review periods for those that are proposed in GRSG habitat. A potential limiting factor for ROWs would be the width increase limit placed on existing ROWs. This limit would not accommodate the width of a fallen transmission line tower.

10.9.3 Alternative 2

Alternative 2 is derived from each region's respective 2019 RMPA/EIS, if completed by the state. Three of the states updated their plans with respect to lands and realty management. Colorado, Idaho, Montana, Oregon, North Dakota, and South Dakota did not provide a new or updated management for lands and realty and thus impacts would be as described under Alternative 1 for these states.

State-Specific Environmental Consequences

In Nevada, Alternative 2 would update the HMA boundaries for PHMA, GHMA, and OHMA to reflect the best available science, and outline a process for periodically revising these boundaries in the future as new data becomes available. Updating the HMA boundaries would result in a relatively minor shift in PHMA (-0.5%) and GHMA (+0.5%); these changes would not result in discernible differences from Alternative 1. The decrease in OHMA (-17%) would have negligible impacts on land use and realty, as there are limited allocation decisions tied to OHMA; therefore, the difference between the nature and types of impacts described would be negligible. These impacts are discussed under Alternative 1.

In Utah, Alternative 2 would remove the GHMA designation for GRSG from the 2015 plan. This would decrease impacts on lands and realty projects by allowing site-specific GRSG habitat analysis and population information, as well as proponent-developed project design elements, to be considered on a project-specific basis. If those voluntary measures were to improve GRSG habitat, both the disturbance and density caps

could be exceeded, allowing for more flexibility to allow consideration of infrastructure projects. There would be an option to exceed the cap by proponents developing measures that improve GRSG habitat. This would provide more opportunities for ROW development within PHMA.

The mitigation strategy for Alternative 2 in Utah would no longer require proponents to provide for compensatory mitigation on a project-by-project basis to show a net conservation gain. While the strategy would be similar, it would be achieved by the totality of GRSG management actions applied by the BLM. Not requiring proponents to pay for vegetation and habitat treatments could decrease project costs, providing more opportunities for ROW development in PHMA; however, during project design, the BLM would consider voluntary compensatory mitigation actions as a component of compliance with the State of Utah law, statute, or policy or when offered voluntarily by a project proponent. If such mitigation were volunteered, impacts would be the same as those described under the No-Action Alternative of the 2019 EIS.

Under Alternative 2 in Utah, changes in MA-SSS-3B[1] that allow site-specific GRSG habitat analysis and population information and project design elements to be considered on a project-specific basis, could potentially lessen impacts on renewable energy as it allows for more flexibility to allow infrastructure projects that exceed the disturbance cap if they meet the described criteria. This would likely have little impact on renewable energy development because PHMA would still be closed to commercial wind and solar development unless the project meets the exception criteria identified in MA-SSS-1.

In Wyoming under Alternative 2, impacts on the lands and realty program as a result of changes to habitat management areas would likely be minor over the landscape, with site-specific impacts potentially occurring where new restrictions are applied in areas that previously did not have restrictions (i.e., new PHMA in what was previously GHMA). This would require some projects to have additional restrictions and others to have fewer restrictions (i.e., projects in areas that transitioned from PHMA to GHMA designations). Depending on the change in acreage, impacts on lands and realty would likely be negligible.

Wind development in PHMA in Wyoming would be managed under the 2014 and 2015 decisions. If additional PHMA were identified in areas that were previously GHMA, then it could become more challenging for wind energy development to occur in those newly identified PHMA due to the restrictions on wind energy development in PHMA. If any areas were identified as GHMA (that were previously PHMA), those areas would then be available and open to wind energy development.

There would be no impact on solar energy development in Wyoming, beyond that identified under Alternative 1.

10.9.4 Alternative 3

Under Alternative 3 all HMAs and proposed ACECs would be managed as PHMA, there would not be GHMA classification and GRSG habitats would not be differentiated. This would result in all habitat being considered and managed as PHMA, and result in the most restrictions to lands and realty of all the alternatives.

Limitations on new ROWs and above-ground linear features, such as transmission lines and pipelines could restrict the availability of energy or service availability and reliability for communication systems. ROW exclusion areas could extend the processing time for renewals of existing ROW authorizations and make

[1] MA-SSS-3B – 2015 ARMPA Decision Number

siting of new linear or block ROWs more difficult. For linear ROWs, avoiding GRSG habitat could lead to the abandonment of the project based on increased costs or the inability to locate the project without using public lands. Costs also would be incurred as a result of requirements for mitigation in areas with limits on surface disturbance.

In some areas, there is a high concentration of intermixed landownership, corridors, oil, gas, and geothermal development, and existing authorizations. In these areas, restrictions on the ability to authorize ROWs and land tenure/landownership adjustments would have a greater impact than in areas with lesser degrees of intermixed ownership, ROW corridors, minerals development, and existing authorizations. The existing network of developed ROWs could provide opportunities for the collocation of compatible authorizations, but these may be limited due to size and availability. If the upgrading can be accommodated within the existing ROW and as long as it does not affect the integrity of, or the ability to operate facilities or their ability to operate their facilities (43 CFR Part 2807.14)

Managing habitat as exclusion areas for utility-scale wind and solar energy ROW development would eliminate LM's ability to accommodate new wind or solar energy demand on that portion of GRSG habitat. This would shift the burden to adjacent non-federal lands that do not have the siting requirements or mitigation standards and could increase costs. ROW exclusions would also inhibit development on adjacent private and state land where transmission infrastructure would be needed across BLM-administered lands. Alternative 3 would restrict the possibility for urban expansion and housing affordability, as well as limit necessary infrastructure development, including that required for emergency services.

10.9.5 Alternative 4

Under Alternative 4, areas within 0.5 miles of PHMA/IHMA would be designated as ROW avoidance areas to address the impacts to adjacent PHMA/IHMA. If these areas are mapped, then the remainder of GHMA that lies outside the 0.5-mile buffer, would be managed as open to major ROWs. If these areas are not mapped, the entire GHMA would be managed as ROW avoidance areas and the habitats would be identified during implementation. Designated corridors would be managed as open to ROWs and all habitats would be subject to mitigation, this would result in a less restrictive planning process for projects. GHMA would be managed as ROW avoidance areas within breeding, nesting, and limited-seasonal habitats. The identification of these habitats would be the responsibility of each state's wildlife agency. This would allow for states to have an additional involvement in the planning process.

Utility scale wind and solar projects in PHMA would be managed as ROW exclusion areas. IHMA would be managed as ROW exclusion areas within 3.1 miles of active leks, outside of the 3.1-mile buffer, and IHMA would be managed as ROW avoidance areas. Areas within 0.5 miles would be managed as ROW avoidance areas to address the indirect impacts to the adjacent PHMA and IHMA. GHMA not included in the 0.5-mile buffer would be managed as ROW avoidance areas for utility scale wind and solar projects. The impacts under Alternative 4 would result in standardized management practices across the project area and would remove State-by-State restrictions. This would allow for easier planning for large interstate projects such as transmission lines and simplify management expectations across the planning area. However, similar to Alternative 3, Alternative 4 could restrict the possibility for urban expansion and housing affordability as well.

10.9.6 Alternative 5

Under Alternative 5, lands encompassing major ROWs and utility scale wind and solar in PHMA would be managed as ROW avoidance areas, while in GHMA they would be managed as open to ROWs. GHMA

would be subject to mitigation measures for both major ROWs and utility scale projects. Designated corridors would remain open to ROW development and mitigation would not be required.

Similar to Alternative 4 the impacts would result in standardized management practices across the planning area. The impacts to ROWs would be less than all other alternatives since the BLM would not designate ROW exclusion areas, mitigation would not be required in corridors, and buffers would not be placed in areas surrounding HMAs.

10.9.7 Alternative 6

Impacts would be the same as Alternative 5. Additionally, management of ACECs as ROW exclusion under Alternative 6 could prevent ROWs from being developed, could increase costs, or could increase development pressure on adjacent lands.

10.10 MINERAL RESOURCES

10.10.1 Fluid Minerals (including Geothermal)

Methodology

The analysis of impacts on fluid minerals focuses on impacts of existing and proposed conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on oil and gas development would result from closing an area to fluid mineral leasing, particularly an area that has moderate to high potential for the development of an oil or gas resource. An indirect impact would result from managing an area as a ROW exclusion, which could prohibit construction of necessary off-lease facilities and access, thereby changing the economic feasibility of developing the leased resource. The types of actions that can result in these impacts are discussed in more detail in **Section 4.10.1**, Nature and Type of Effects. Additional actions or conditions that would cause direct or indirect impacts on fluid minerals are described under indicators below.

Indicators

Indicators of impacts on fluid minerals are as follows:

- The amount of land identified as closed to fluid mineral exploration and leasing
- The amount of land open to leasing subject to NSO stipulations
- The amount of land open to leasing subject to CSU stipulations
- The amount of land open to leasing subject to TL stipulations
- Application of COAs on fluid mineral exploration and development activities on existing and future leased lands for the protection of GRSG
- The amount of land managed as ROW avoidance areas
- The amount of land managed as ROW exclusion areas
- The amount of land closed to mineral material disposal

Assumptions

The analysis includes the following assumptions:

- Fluid mineral operations on existing federal leases, regardless of surface ownership, would be subject to COAs by the BLM Authorized Officer and the authorized officer of the surface management agency at the time of APD approval. The BLM and Forest Service can deny surface occupancy on portions of leases with COAs to avoid or minimize resource conflicts if this action does not eliminate reasonable opportunities to develop the lease. Existing leases would be developed consistent with

applicable laws and valid existing rights, using as many of the RDFs and conservation measures as possible while still allowing reasonable opportunities for development. Access to producing leases, including roads and pipelines to those leases, would not be affected by this RMPA.

- Valid existing leases would be managed under the stipulations in effect when the leases were issued; new stipulations proposed under this RMPA would apply only on new leases.
- Under all alternatives, reclamation bonds would be required, pursuant to 43 CFR 3104, in an amount sufficient to ensure full restoration of lands to the condition in which they were found. In addition, APDs, including drilling plans and surface use plans of operations, would be required under all alternatives in accordance with 43 CFR 3162.
- If an area is leased, it could be developed; however, not all leases would be developed within the life of this RMPA.
- As the demand for energy increases, so will the demand for extracting energy resources in areas with potential.
- Technological advancements, such as directional drilling, could lead to changes in levels of fluid mineral development potential throughout the planning area as additional resources become more easily accessible.

Alternative 1

Rangewide Environmental Consequences

All states include language to maintain and enhance sagebrush habitats with the intent of conserving GRSG populations. The exact language varies by state, see the state headings below for more details. This Alternative affirms habitat management area (HMA) boundaries from 2015 amendments (as maintained).

Most states are NSO (in PHMA and IHMA) and/or have seasonal restrictions. Wyoming and Montana are also subject to density and disturbance limits. Colorado closes PHMA within 1 mile of leks to fluid mineral leasing. This Alternative maintains the Sagebrush Focal Areas (SFAs) from the 2015 amendments.

If a state is not specifically mentioned under its own environmental consequences heading, the rangewide consequences would apply.

Colorado Environmental Consequences

Management actions related to lands and realty in conjunction with protection of GRSG and its habitats and use area could adversely impact fluid minerals leasing and development. This potential for impacts includes reduced availability, reduced accessibility, and increased costs.

Reduced availability is the least significant impact from lands and realty actions. This is because the BLM does not require a lands action (Issuance of a ROW grant) for surface occupancy of federal lands to drill into federal minerals. Accessibility to federal minerals with new leases could be significantly reduced or precluded when management of specific areas as ROW exclusion areas would prohibit access roads or pipelines into those areas.

Identification of ROW avoidance areas, while not creating absolute barriers to use of the area for access roads or pipelines, or for locating surface facilities on federal lands for the purpose of accessing private minerals, could make permissible facilities infeasible for technical or economic reasons. Some other potential management actions or BMPs could also affect costs that would make a project infeasible.

Alternative 1 would manage all PHMA and GHMA (**Table 2-3**) as ROW avoidance areas with exceptions for pending large transmission lines. No aboveground structures would be authorized within 1 mile of active

leks. Avoidance areas would require that impacts be avoided. The ROW could be allowed, subject to COAs, all applicable surface use stipulations, and any site-specific stipulations identified through the NEPA process. Potentially large local impacts on access of fluid minerals where the PHMA and GHMA are open for large transmission lines. Areas open to large transmission lines could preclude development of facilities required for access to fluid minerals.

New leasing would be prohibited within 1 mile of all active leks. Potentially large local impacts on access of fluid minerals where the PHMA and GHMA are open for large transmission lines. No modifications or waivers would be permitted, and the BLM Authorized Officer may grant an exception to this NSO stipulation only where the proposed action:

1. Would not have direct, indirect, or cumulative effects on GRSG or its habitat
2. Is proposed to be undertaken as an alternative to a similar action occurring on a nearby parcel, and would provide a clear conservation gain to GRSG

Exceptions based on conservation gain (number 2, above) may only be considered in PHMA of mixed ownership where federal minerals underlie less than 50% of the total surface, or areas of the public lands where the proposed exception is an alternative to an action occurring on a nearby parcel subject to a valid federal fluid mineral lease existing as of the date of this RMP. Exceptions based on conservation gain must also include measures, such as enforceable institutional controls and buffers, sufficient to allow the BLM to conclude that such benefits would endure for the duration of the proposed action's impacts.

Any exceptions to this NSO lease stipulation may be approved by the BLM Authorized Officer only with the concurrence of the State Director. The BLM Authorized Officer may not grant an exception unless the applicable state wildlife agency, the USFWS, and the BLM unanimously find that the proposed action satisfies 1 or 2, above. Such finding would be made initially by a team of one field biologist or other GRSG expert from each respective agency. In the event the initial finding is not unanimous, the finding may be elevated to the appropriate BLM State Director, USFWS State Ecological Services Director, and state wildlife agency head for final resolution. In the event their finding is not unanimous, the exception would not be granted.

Approved exceptions would be made publicly available at least quarterly. Because all of PHMA would be managed as NSO with very rare potential for exceptions, impacts would be increased difficulty of access, increased costs, and decreased efficiency of oil and gas development in PHMA.

The following BMPs have the potential to significantly affect the economic feasibility of individual oil and gas projects. Those with the greatest potential for affecting future developments are the following:

- Place liquid gathering and storage facilities outside PHMA—Potentially cost prohibitive where a well pad would be located several miles from the storage tanks due to the additional piping costs when water or liquid condensates are produced in very small quantities from a natural gas well and more efficiently hauled off-site with trucks. However, because all PHMA would be NSO with limited exceptions under this alternative, very few well pads might be subject to this BMP.
- Place new utility developments in existing utility or road corridors—Potentially cost prohibitive where the road follows a long and topographically complex route, thereby lengthening the utility development and potentially requiring one or more lift stations for liquids.
- Bury electric distribution lines—Potentially cost-prohibitive where a well pad would be located a long distance from the nearest utility tie-in, compared to the cost of constructing an aboveground line fitted with raptor deterrents.

- Limit noise to less than 10 decibels above ambient levels at sunrise at a lek perimeter during the lek season and require noise shields during the lek, brood-rearing, and winter-use seasons—This could increase development costs if it were to require erecting expensive, site-specific, acoustical barriers for wells.
- Locate all new compressors outside PHMA—This could be cost prohibitive or not technically feasible in certain situations, depending on the topography over which gas-gathering pipelines are installed, the pressure of the natural gas at the wellhead, and the location and availability of a permissible compressor in relation to commercial pipelines, access roads, and other utilities.
- Incorporate GRSG habitat requirements in reclamation—This is unlikely to be an issue for well pad reclamation. However, very long road or pipeline corridors could be prohibitively expensive if they require including GRSG components if planting or transplanting sagebrush is required instead of including sagebrush in a seed mix with native perennial bunchgrasses and forbs.

A determination of the extent to which increased costs and decreased efficiency would affect fluid minerals development is a function of project- and site-specific considerations and of market forces at the time. It is possible that some well pads, access roads, pipelines, and other facilities would be affected to the extent that marginal projects are economically nonviable, reducing the number of future oil and gas wells to an extent that may be considered significant at the local, state, or regional levels.

Idaho Environmental Consequences

Impacts from Lands and Realty Management

Under Alternative 1, all PHMA and IHMA would be managed as ROW avoidance areas. All acres in PHMA and IHMA would be either closed to leasing or open subject to NSO stipulations, so no oil and gas activities on future leases within these areas would require new rights-of-way. Therefore, oil and gas activity in PHMA and IHMA would not be impacted by management of ROW avoidance areas under Alternative 1.

All GHMA would be managed as ROW avoidance for high voltage transmission lines and major pipelines but open to other fluid mineral-related ROW location under Alternative 1. Transportation of fluid minerals might be impacted by the major pipeline ROW avoidance but fluid minerals beneath those acres would be unlikely to be significantly impacted by the ROW avoidance area.

Application of RDFs, BMPs, buffers, and seasonal timing restrictions to ROW construction in all GRSG habitat would also limit construction of new ROWs for oil and gas development. If these limitations made it uneconomic to develop a ROW for oil and gas development, development of federal oil and gas resources in the planning area could decrease.

Impacts from Fluid Minerals Management

Under Alternative 1, approximately 257,400 unleased acres with medium development potential (33% of the federal oil and gas estate with medium development potential) would remain closed to oil and gas leasing. Closing unleased lands to leasing, especially those with medium potential, would have the greatest impact on fluid minerals resources in Idaho by prohibiting oil and gas development. Impacts of closing these areas to leasing are the same type as those described under Nature and Type of Effects.

Approximately 348,100 acres, or 44% of unleased federal oil and gas estate with medium development potential (including all areas in PHMA and IHMA not already closed) would be open to oil and gas leasing subject to NSO stipulations. Under this alternative there would be no waivers or modifications to the NSO stipulation, and only one exception would exist. A total of approximately 77% of unleased federal oil and gas

estate with medium oil and gas potential in the decision area would be inaccessible, either due to closure or NSO, under Alternative 1.

Under Alternative 1, approximately 121,900 unleased acres, or 17% of the unleased federal oil and gas estate with medium development potential would be open to oil and gas leasing, subject to lek buffers and TL stipulations. This would include all areas in GHMA not already closed. These stipulations would restrict the timing and location of oil and gas exploration and development activities**.**

Under Alternative 1, it is reasonably foreseeable for planning purposes that 15 new oil and gas exploratory wells would be developed on federal fluid mineral estate in the decision area in the next 20 years.

The BLM could not apply COAs that would eliminate reasonable opportunities to develop an existing lease. Therefore, although restrictions on development would increase where COAs were applied, oil and gas development would still be allowed in these areas.

Geophysical exploration would be allowed on the over 8 million acres of federal mineral estate within PHMA but would be subject to TLs and other restrictions. Geophysical exploration would be allowed only for gathering information about fluid mineral resources outside PHMA. Because of these limitations and the fact that PHMA would be closed to fluid mineral leasing, geophysical exploration in PHMA would decrease under this alternative. Decreases in geophysical exploration in PHMA could impact the fluid minerals program.

Under Alternative 1, RDFs would be applied as COAs to existing leases on PHMA and GHMA overlying federal mineral estate. Only management actions related to master development plans and unitization would apply. Application of the 3% disturbance cap in PHMA and IHMA could impact both new and existing fluid mineral activities by preventing or restricting new surface development. New fluid mineral activities and new surface development on existing leases could be affected or temporarily delayed if the cap were exceeded. Application of lek buffers in GHMA could impact both new and existing fluid mineral activities by preventing or restricting new surface development. Applying lek buffer distances when approving actions could also restrict development of infrastructure related to fluid mineral development.

Under Alternative 1, RDFs would be applied as COAs to existing leases on occupied habitat overlying federal mineral estate. These RDFs would include such requirements as surface disturbance limitations, TLs, noise restrictions, structure height limitations, design requirements, water development standards, remote monitoring requirements, and reclamation standards. The BLM could not apply COAs that would eliminate reasonable opportunities to develop the lease. Restrictions and costs on development would increase where COAs were applied, but oil and gas development would still have reasonable opportunity to occur.

Geothermal

Impacts from Fluid Minerals Management

Under Alternative 1, 11,296,800 acres, or 44% of planning areas, would remain closed to geothermal leasing. This includes 2,832,200 acres with moderate to high geothermal potential (32% of the moderate to high geothermal potential acres in the decision area). An additional 8,464,000 acres (34%) with no or low geothermal potential would remain closed to geothermal leasing. Geothermal resource potential may be outdated or inaccurate in some areas and it is possible that developable resources exist in these areas. New technologies such as Enhanced Geothermal Systems (EGS) could make areas considered low or moderate feasible in the future, therefore it is difficult to predict the impacts of closure of low to moderate geothermal potential areas.

13,834,400 acres would be subject to TL and CSU stipulations (including 1,278,100 acres in moderate to high geothermal potential areas) and 9,630,000 acres would be subject to NSO stipulations, including 2,906,800 acres in moderate to high geothermal potential areas.

Under the Alternative 1, RDFs and BMPs would be applied as COAs when a geothermal drilling permit or other post-lease activity is approved. In addition to affecting new leases, the COAs would be applied to the 25,571 acres of existing leases within GRSG habitat, consistent with existing lease terms and special stipulations. These RDFs and proposed management actions would include such requirements as noise restrictions, structure height limitations, design requirements, water development standards, remote monitoring requirements, and reclamation standards.

The BLM could not apply COAs that would eliminate reasonable opportunities to develop an existing lease. Restrictions on development would increase where COAs were applied, but geothermal development would still be allowed in these areas.

Impacts from Lands and Realty Management

Under Alternative 1, 8,365,000 acres (33%) of BLM-administered surface in the decision area (including all PHMA) would be managed as ROW avoidance areas, where development of new ROWs for geothermal development could not occur unless the Anthropogenic Disturbance Development and Screening Criteria (AD-3 and AD-4) were satisfied. These restrictions would only allow new ROWs to be developed pursuant to a valid existing authorization.

1,013,800 acres (4%) of BLM-administered surface in the decision area (including all IHMA) would be managed as ROW exclusion areas where development of new ROWs for geothermal development could not occur unless the Anthropogenic Disturbance Development Criteria (AD-4) were satisfied (including the requirement that the project would not exceed the 3% disturbance threshold). Lessees would be unable to site off-lease features, such as transmission lines, roads, and pipelines that may be necessary to transport the product to market, on public lands. These actions could result in the stranding of a geothermal lease and its resources, if surrounded by federal lands subject to these constraints.

Application of RDFs, BMPs, buffers, and seasonal timing restrictions to ROW construction in GRSG habitat would also limit the construction of new ROWs for geothermal development to certain times of the year or in certain locations. If these limitations made it uneconomic to develop a ROW for geothermal development, development of federal geothermal resources in the planning area could decrease.

Impacts from Anthropogenic Disturbance Management, Adaptive Management, and Coordination

Under Alternative 1, anthropogenic disturbance, including leasable mineral development, would be limited to 3% of nesting and wintering habitat within PHMA and IHMA within a Conservation Area (BSUs). In BSUs where the 3% cap is already exceeded, new development of federal leasable mineral resources would be prohibited until enough habitat was restored to maintain the area under the threshold. Development of federal leasable mineral resources that would result in exceedance of the 3% cap in a BSU would also be prohibited. Impacts would be greatest where these caps limit development in unleased portions of high geothermal potential because these areas have the highest potential for leasable mineral development. The uncertainty from this limitation could decrease the value of any future lease, disincentivize geothermal energy development in the western United States, and could affect the ultimate scope of rights authorized under any lease offered in the future.

Montana Environmental Consequences

Under Alternative 1, priority will be given to leasing and development of fluid mineral resources, including geothermal, outside of PHMA and GHMA. When analyzing leasing and authorizing development of fluid mineral resources, including geothermal, in PHMA and GHMA, and subject to applicable stipulations for the conservation of GRSG, priority will be given to development in non-habitat areas first and then in the least suitable habitat for GRSG. Where a proposed fluid mineral development project on an existing lease could adversely affect GRSG populations or habitat, the BLM will work with the lessees, operators, or other project proponents to avoid, reduce, and mitigate adverse impacts to the extent compatible with lessees' rights to drill and produce fluid mineral resources.

Alternative 1 would apply an NSO stipulation within all GRSG PHMAs and apply an NSO stipulation within 0.6 miles of GRSG leks in Restoration Areas and GHMAs. Development on existing leases within PHMAs would be subject to density and disturbance limits. CSU stipulations would be applied within RAs in order to maintain GRSG habitat. TL stipulations would be applied from March 1 to June 15 in GRSG nesting habitat within 3 miles of a lek within RAs and GHMAs, and from December 1 to March 1 within designated GRSG winter range within 3 miles of a lek.

In PHMA, this alternative would implement an anthropogenic disturbance cap of 5% at the BSU and project area scale and implement a density cap of an average of 1 energy and mining facility per 640 acres.

Nevada Environmental Consequences

Alternative 1 would require a 3% disturbance cap on human surface-disturbing activities in PHMA and would incorporate RDFs consistent with applicable law in PHMA, GHMA, and OHMA. It requires all human disturbances to result in a net conservation gain for GRSG and their habitat, and lek buffers would be required.

Collectively, these GRSG conservation management actions would increase mitigation requirements for land use authorizations. This would result in more complex project designs, potentially excluding infrastructure placement in the most cost-effective locations, and potentially resulting in overall greater development costs.

A corresponding effect could be a reduction in the number of authorization applications received for activities in PHMA and longer, more complicated review periods for those that are proposed in PHMA. Implementing the GRSG habitat conservation management actions listed above would also place NSO stipulations on fluid mineral development in PHMA, which would further reduce the demand for new ROW development in those areas.

North Dakota Environmental Consequences

Impacts from Lands and Realty

Under Alternative 1, all BLM-administered surface in PHMA (32,900 acres, or approximately 100% of BLM-administered surface in the decision area) would be managed as ROW avoidance areas for oil and gas-related activities. All fluid mineral development in PHMA would be subject to NSO stipulations under Alternative 1, so managing ROW avoidance areas in PHMA would have no impact on fluid minerals.

All GHMA would be open to ROW location for oil and gas-related activities under Alternative 1. Identification of conservation measures to minimize surface disturbance and disrupting activities could increase the expense of developing facilities for oil and gas operations by limiting routing options and requiring the use of more expensive technology.

Impacts from Fluid Minerals (Including Mineral Split Estate)

Application of the density and disturbance caps in PHMA and lek buffers in PHMA and GHMA could impact both new and existing oil and gas activities by preventing or restricting new surface development. New oil and gas activities could be precluded if the cap were exceeded in a BSU or a proposed project analysis area. New surface development on existing leases could be restricted if the cap were exceeded. The BLM would not apply the density and disturbance caps in a manner that would eliminate reasonable opportunities to develop an existing lease. Applying lek buffer distances when approving actions could also restrict development of infrastructure-related fluid mineral development. Under Alternative 1, except that the lack of waivers and modifications, combined with the limited exceptions for NSO stipulations under Alternative 1 Amendment, would further restrict oil and gas activities.

Under Alternative I, federal oil and gas estate in PHMA would be open to fluid mineral leasing subject to NSO stipulations. The unleased federal oil and gas estate in PHMA would be subject to these stipulations. Under this alternative, there would be no waivers and modification, and limited exceptions for NSO stipulations which would further restrict oil and gas activities.

All GHMA would be subject to CSU stipulations. Impacts of these stipulations would be the same type as those described under *Nature and Type of Effects* in **Section 4.2.1** above.

Under Alternative 1, it is projected that 51 new exploratory and development wells would be drilled on federal oil and gas estate in the short term. Of these new wells, 42 are expected to be producing oil and gas wells in the long term**.**

In addition to RDFs and limitations on disturbance, structure height restrictions would apply under Alternative 1. Closing areas within GRSG habitat to fluid mineral leasing would directly impact the fluid minerals program by prohibiting the development of those resources on federal mineral estate. Fluid mineral operations would be limited in their choice of project locations and may be forced to develop in areas that are challenging to access or have less economic resources because more ideal areas could be closed to leasing. No quantitative percentage limit, surface occupancy buffers, or TL would apply to surface disturbance. Surface disturbance would prevent or minimize disturbance to GRSG and their habitat. Unitization would occur on a case-by-case basis.

Geophysical exploration would be allowed, except for in PHMA, where geophysical exploration would be limited to use of existing roads and trails, as well as helicopter-portable methods on the 61,197 acres of federal oil and gas estate but would be subject to TLs and other restrictions, reducing exploration opportunities.

Oregon Environmental Consequences

Impacts from Lands and Realty Management

Under Alternative 1, all BLM-administered surface in PHMA (totaling 4,547,000 acres, or approximately 36% of BLM-administered surface in the decision area) would be managed as ROW avoidance areas for fluid mineral-related activities. All PHMA would be subject to NSO stipulations on fluid mineral leases, so no fluid mineral activities on future leases within these areas would require new ROWs. Managing PHMA as ROW avoidance areas would have minimal impact on fluid minerals development but could impact the location of fluid mineral transportation pipelines if any were proposed.

All BLM-administered surface in GHMA would be managed as ROW avoidance for high voltage transmission lines and major pipelines, but open to other fluid mineral-related ROW location under Alternative 1. Fluid minerals beneath those acres would be impacted by the ROW avoidance area**.**

Impacts from Fluid Leasable Minerals Management

Under Alternative 1, 4,333,700 acres (31% of the federal mineral estate decision area), including all federal mineral estate in PHMA, would be subject to NSO stipulations; 4,319,800 acres subject to NSO stipulations would be unleased, so this management would apply NSO stipulations to 31% of the 14,147,900 unleased acres in the decision area. Application of NSO stipulations to leases on these acres would directly impact the fluid minerals program. The lack of waivers and modifications combined with the limited exceptions for NSO stipulations under Alternative 1 would further restrict oil and gas and geothermal activities. SFA would be subject to NSO stipulations with no waivers, exceptions, or modifications.

Approximately 4,847,400 acres of federal mineral estate would be subject to CSU and TL stipulations. This includes all federal mineral estate in GHMA not subject to other existing stipulations, or 34% of the federal mineral estate decision area; 4,715,500 of these acres are unleased. Application of CSU and TL stipulations to leases on these acres would directly impact the fluid minerals program

Under Alternative 1, the BLM would manage lands to conserve, enhance, and restore GRSG habitat. PHMA and GHMA would be designated, and the BLM would implement numerous conservation measures to reduce impacts from human activities in PHMA, including a maximum 3% disturbance cap to human activities, not including wildfire, in PHMA. Application of the 3% disturbance cap in PHMA and lek buffers in GHMA could impact both new and existing fluid mineral activities by preventing or restricting new surface development. New fluid mineral activities could be precluded if the cap were exceeded in an Oregon priority area of conservation and the proposed project area. New surface development on existing leases could be restricted if the cap were exceeded. The BLM would not apply the disturbance cap in a manner that would eliminate reasonable opportunities to develop an existing lease. Applying lek buffer distances when approving actions could also restrict development of infrastructure related to fluid mineral development.

Geophysical exploration would be allowed on the 11,234,800 acres of federal mineral estate within GRSG habitat but would be subject to seasonal restrictions. Because of these limitations, geophysical exploration in GRSG habitat would decrease under this alternative. Decreases in geophysical exploration in GRSG habitat would impact the fluid minerals program.

Under Alternative 1, conservation measures in addition to RDFs would be applied as COAs to the five federal leases in PHMA. These RDFs and conservation measures would include such requirements as surface disturbance limitations, TLs, noise restrictions, structure height limitations, design requirements, water development standards, remote monitoring requirements, and reclamation standards. The only conservation measures applied would relate to master development plans and unitization.

South Dakota Environmental Consequences

Impacts from Lands and Realty Management

Under Alternative 1, all BLM-administered surface in PHMA, exclusive of GRSG winter range, would be managed as ROW exclusion areas for fluid mineral-related activities. GHMA and GRSG winter range would be ROW avoidance areas. All PHMA would be subject to NSO stipulations on fluid mineral leases, so no fluid mineral activities on future leases within these areas would require new ROWs. Managing PHMA as ROW exclusion areas would have minimal impact on fluid minerals development but could impact the location of fluid mineral transportation pipelines if any were proposed.

Impacts from Fluid Leasable Minerals Management

Under Alternative 1, 152,100 acres (45% of the federal mineral estate decision area), including all federal mineral estate in PHMA and GRSG winter range in GHMA, would be subject to NSO stipulations. Application of NSO stipulations to leases on these acres would directly impact the fluid minerals program**.** The lack of waivers and modifications combined with the limited exceptions for NSO stipulations under Alternative 1 would further restrict oil and gas and geothermal activities.

Approximately 21,175 acres of federal mineral estate would be subject to CSU stipulations and 1,169 acres subject to TL stipulations. This includes all federal mineral estate in GHMA in nesting and brood-rearing habitat near leks. Application of CSU and TL stipulations to leases on these acres would directly impact the fluid minerals program.

Under Alternative 1, the BLM would manage lands to conserve, enhance, and restore GRSG habitat. PHMA and GHMA would be designated, and the BLM would implement numerous conservation measures to reduce impacts from human activities in PHMA, including a maximum 3% disturbance cap to human activities in a BSU and 5% cap including wildfire and agriculture at the project level. Application of the disturbance cap in PHMA and lek buffers in GHMA could impact both new and existing fluid mineral activities by preventing or restricting new surface development. New fluid mineral activities could be precluded if the cap were exceeded in a BSU and the proposed project area. New surface development on existing leases could be restricted if the cap were exceeded. The BLM would not apply the disturbance cap in a manner that would eliminate reasonable opportunities to develop an existing lease. Applying lek buffer distances when approving actions could also restrict development of infrastructure related to fluid mineral development.

Under Alternative 1, conservation measures in addition to RDFs would be applied as COAs to federal leases in PHMA. These RDFs and conservation measures would include such requirements as surface disturbance limitations, TLs, noise restrictions, structure height limitations, design requirements, water development standards, remote monitoring requirements, and reclamation standards.

Utah Environmental Consequences

Application of the 3% disturbance cap in PHMA could impact both new and existing fluid mineral activities by preventing or restricting new surface development. New fluid mineral activities could be precluded if the cap were exceeded in a BSU or a proposed project analysis area. New surface development on existing leases could be restricted if the cap were exceeded. The BLM would not apply the disturbance cap in a manner that would eliminate reasonable opportunities to develop an existing lease. Currently there are no population areas where the level of disturbance exceeds the disturbance cap. Tere are areas within 4 miles of a lek in population areas that are near or exceeding the disturbance cap, including in the Carbon and Uintah Population Areas where there is higher potential for oil and gas.

Application of lek buffers in GHMA could impact new and existing fluid mineral activities by restricting new surface development. Lek buffers in PHMA would not impact fluid mineral development because all PHMA would be subject to NSO stipulations. Any development for which the limited exception to the NSO stipulation were granted would not be within the lek buffer. In GHMA, applying lek buffer distances when approving actions for linear features, infrastructure related to energy development, tall structures (including transmission lines), surface disturbance, and noise could also restrict development of infrastructure related to fluid mineral development, especially in areas of high potential for oil and gas.

In PHMA, the density of energy and mining facilities would be limited to one energy/mining facility per 640 acres. When calculated at the project level, this requirement would push developers to consolidate facilities and, where technically feasible, directionally or horizontally drill from outside of GRSG habitat.

RDFs would be applied in PHMA and GHMA. However, exceptions to the application of RDFs could mitigate impacts on fluid minerals. Exceptions would occur where a design feature was not applicable (e.g., a resource is not present on a given site) or where the design feature would not actually provide additional protection for GRSG or its habitat. Disturbance caps, lek buffers, and density restrictions, additional conservation measures in PHMA would include net conservation gain requirements, restrictions on noise and tall structures, and seasonal restrictions. These combined would restrict oil and gas development. In the Carbon and Uintah Population Areas, where oil and gas potential is relatively high and some areas are at or exceeding the disturbance cap, the cumulative effect of all of the restrictions would likely reduce opportunities for oil and gas development on public lands.

Exploration would be allowed on federal mineral estate within GRSG habitat but would be subject to seasonal restrictions.

Infrastructure Development (including all ROWs and utility corridors)

Management actions for programs related to infrastructure development other than lands and realty would not impact fluid minerals. Only the impacts from lands and realty management actions are discussed in the paragraphs below.

Under Alternative 1, all BLM-administered surface within PHMA not already managed as ROW exclusion would be managed as ROW avoidance for new linear and site-type ROWs, except for within ROW corridors designated for aboveground use. All acres in PHMA would be either closed to leasing or open subject to NSO stipulations, so no oil and gas activities on future leases within these areas would require new ROWs.

Under Alternative 1, 3,219,000 acres (97%) of BLM-administered surface within the decision area in Utah would continue to be open to ROW location. Wherever there is overlap between federal oil and gas leases and the 94,800 acres (3%) of BLM-administered surface in the decision area that would continue to be managed as ROW avoidance or exclusion under this alternative, the fluid minerals program could be indirectly impacted by the resulting limits on the available means for transporting fluid minerals to processing facilities and markets. Impacts would be mitigated where new ROWs could be collocated within existing ROWs. Leases within units would not be impacted as much because infrastructure within these unitized leases is exempt from ROW requirements.

Impacts would be mitigated for existing leases in PHMA because collocation of new ROWs close to existing ROWs and minimal construction of new roads would be allowed. In PHMA, ROW development that was able to occur would be subject to RDFs, lek buffers, the disturbance cap, and limitations for tall structures, and net conservation gain requirements, which could impact fluid minerals development. The expense of these mitigation activities would increase the costs of oil and gas development.

Under Alternative 1, GHMA would be available for the types of ROW location that could impact fluid minerals development, except for 17,600 acres already managed as exclusion. While fluid minerals development would not be directly impacted because of ROW avoidance or exclusion areas, ROW development in GHMA would be subject to RDFs, lek buffers, and net conservation gain requirements,

which could impact fluid minerals development. The expense of these mitigation activities would increase the costs of oil and gas, oil shale, and tar sands development.

Mineral Development

Management actions for mineral programs other than mineral materials and fluid minerals would not impact fluid minerals. Therefore, only the impacts from mineral materials and fluid mineral management actions are discussed in the paragraphs below.

Mineral Materials

Under Alternative 1, PHMA in Utah would be closed to commercial mineral material disposal. PHMA on lands in the Utah portion of the planning area would be closed to commercial mineral material disposal. This includes 1,196,000 acres with mineral material occurrence (92% of federal mineral estate with mineral material occurrence in the decision area). Closing these areas to mineral material disposal could indirectly impact fluid minerals in the areas by reducing the amount of readily available material for road and pipeline construction. This could limit the available means for accessing fluid mineral resources and transporting those resources to processing facilities and markets and could ultimately decrease the amount of development of federal fluid minerals in the planning area.

Free use permits and expansion of existing active pits in PHMA would be subject to the disturbance cap, density of energy/mining facilities restrictions, lek buffers, RDFs, noise restrictions, seasonal restrictions, and net conservation gain requirements. These requirements, particularly on the expansion of existing active pits, would further restrict access to mineral materials and increase costs associated with fluid minerals development.

Fluid Minerals

Outside of the areas closed to new fluid mineral leasing, the remaining PHMA would be open to new oil and gas leasing subject to an NSO stipulation. Of this area, NSO stipulations on approximately 7% of federal mineral estate would not be available with waivers, exceptions, or modifications. These areas are in the Rich and Box Elder Population Areas. The Box Elder Population Area does not have high potential for oil and gas, so impacts would be minimal. The potential in the Rich Population Area is high. Most federal mineral estate in the Rich Population Area is already under lease, and many oil and gas fields have already been depleted. Impacts of the 233,400 acres subject to NSO with no waivers, exceptions, or modifications would be minimal.

In the remainder of PHMA, an exception to the NSO stipulation could be granted if the activity would not have direct, indirect, or cumulative effects on GRSG or its habitat or is proposed as an alternative to a similar action occurring on a nearby parcel and would provide a clear conservation gain to GRSG. Any exception must have to concurrence of the state wildlife agency and the USFWS. As such, exceptions would only be granted on rare occasions. Any development that did occur in PHMA would be subject to the pertinent management for discretionary activities (mitigation measures, disturbance cap, minerals/energy density restrictions, lek buffers, seasonal restrictions, and RDFs). Impacts of which are discussed under Special Status Species – GRSG.

Approximately 30,000 acres in GHMA would also be closed to fluid mineral leasing. GHMA near leks would be managed as NSO, the NSO buffer from the leks would vary by office. In GHMA, development would be subject to the disturbance cap, mitigation, lek buffers, and RDFs.

Wyoming Environmental Consequences

Under Alternative 1, 883,670 acres in Wyoming would be closed to oil and gas leasing. This, in addition to other restrictions, such as NSO on 441,690 acres and CSU on 6,438,480 acres within PHMAs and GHMAs would reduce the number of projected oil, gas, and CBNG wells projected under this alternative. In total, 12,355 oil and gas and 2,462 CBNG wells are projected over the life of the plan under this alternative. Drainage of federal minerals on areas closed to leasing or on leases that are shut in on an annual basis due to timing and distance limitations may occur due to development on adjacent private or state lands.

Density limitations of one oil and gas or mining location per 640 acres and a 5% disturbance cap within PHMAs (core only) would slow mineral development and could also lead to the relocation of well pads, access roads, pipelines, and ancillary facilities. Relocation of these proposed facilities could cause temporary delays in developing oil and gas resources and limit oil and gas activities in these areas.

Applying BMPs to federal mineral estate where the surface ownership is non-federal could restrict the ability of mineral operators to efficiently develop mineral resources. Depending on the stipulations required, these requirements could increase delays in mineral development.

Avoiding primary and secondary roads within 1.9 miles of the perimeter of occupied GRSG leks and prohibiting other new roads within 0.6 miles of the perimeter of occupied GRSG leks within PHMAs could lead to the relocation of well pads, access roads, pipelines, and ancillary facilities. Relocation of these proposed facilities could cause temporary delays in developing oil and gas resources and could limit oil and gas activities in these areas.

Alternative 2

Rangewide Environmental Consequences

In PHMA management would be the same as Alternative 1, except Colorado has no closed areas. In GHMA, management would be the same as Alternative 1, except Colorado changed the closure areas to NSO.

Mitigation: The BLM in Montana, North Dakota, South Dakota, Nevada, California, and Oregon would apply the same mitigation as Alternative 1. The BLM does not require compensatory mitigation but will enforce state mitigation policies and programs. Colorado and Idaho provide mitigation resulting in no net loss. Utah and Wyoming removed the net conservation gain requirement. Colorado, Idaho, Nevada/California, Oregon, Utah, and Wyoming specify that compensatory mitigation would be voluntary, unless required by laws other than FLPMA or by the State.

The 3% disturbance cap does not include wildfire or agriculture. In Idaho the cap can be exceeded in utility corridors if there is a demonstrated benefit to GRSG. In Utah the disturbance cap can be exceeded if it will benefit GRSG. The cap is applied at the BSU and project scale except in Idaho which just applies it at the BSU scale. In Montana and Wyoming, a 5% disturbance cap which includes disturbance from wildfire and agriculture, is applied at the project area scale in PHMA.

In Colorado, Idaho, Oregon, and Montana and Dakotas field offices, priority will be given to leasing and development of fluid mineral resources, including geothermal, outside of PHMAs and GHMAs, or within the least impactful areas within PHMA and GHMA if avoidance is not possible. In Utah, Nevada/California, and the Lewistown and Butte field offices no similar objective exists.

In Wyoming, leasing would be allowed in PHMA, and if the BLM has a backlog of Expressions of Interest for leasing, the BLM will prioritize work to first process Expressions of Interest in non-habitat, followed by lower

habitat management areas (e.g., GHMA). In Wyoming for fluid mineral development on existing leases that could adversely affect GRSG populations or habitat, the BLM would work with the lessees, operators, or other project proponents to avoid, reduce, and mitigate adverse impacts consistent with lessees' rights.

In Montana/Dakotas, Oregon, and Wyoming no waivers or modifications would be issued. An exception can be considered if the excepted action is an alternative to action on nearby parcels that would be more harmful to GRSG).

In Idaho no waivers or modifications would be issued in PHMA, IHMA or GHMA. An exception can be considered if the excepted action is an alternative to action on nearby parcels that would be more harmful to GRSG, no concurrent approval from other agencies is required.

Colorado, Nevada/California, and Utah developed state-specific exceptions, modifications, and waivers. If a state is not specifically mentioned under environmental consequences, the rangewide consequences would apply.

Colorado Environmental Consequences

In Colorado, the BLM anticipates differing effects for this fluid minerals. Under Alternative 2, approximately 224,200 acres that are closed to fluid mineral leasing under the Alternative 1 would be open for fluid mineral leasing subject to NSO stipulations. Opening the 224,200 acres for fluid mineral leasing means that there is the potential for revenue generation associated with leasing and developing fluid mineral resources.

Approximately 34% of the federal mineral estate in PHMA is currently unleased, including approximately 29% with high potential for oil and gas. There are numerous considerations that operators consider before acquiring and developing leases, including market value of the commodity being produced, operational costs, ease of access to lease minerals, practicality of necessary infrastructure such as roads and pipelines, and technological capabilities. It is difficult to predict if these changes to availability of leases and increased flexibility of the WEMs (Waivers, Modifications, and Exceptions) would lead to additional oil and gas development or a varied approach to the same level of development. In GHMA the closure to leasing under Alternative 1 would change to open to leasing with an NSO stipulation under Alternative 2, this would make more acres available for leasing, potentially resulting in increased production of fluid mineral resources.

Idaho Environmental Consequences

In Idaho, the BLM anticipates differing effects for fluid minerals. PHMA and IHMA not already closed to leasing would be open to oil and gas leasing subject to NSO stipulations. This alternative would maintain Sagebrush Focal Areas (SFAs) from Alternative 1.

Montana Environmental Consequences

Montana did not complete a 2019 Plan Amendment, management and impacts on fluid minerals under this alternative would be the same as described under Alternative 1.

Alternative 3

Rangewide Environmental Consequences

Under alternative 3 all areas managed for GRSG would be PHMA and fluid minerals in these areas would be closed to leasing. Some states are considering expanding HMAs to include areas of adjacent non-habitat, unoccupied historic habitat, or areas with potential to become habitat as PHMA. For valid existing rights the ROW exclusion within PHMA could preclude development of a lease.

ACECs will be considered under this alternative, though because of the restrictive nature of the PHMA management under this alternative, there would be no different allocations between the PHMA and the potential ACEC boundaries.

In areas with development potential for oil and gas resources, closing PHMA to leasing would result in a reduction in oil and gas development and production.

Alternative 4

Rangewide Environmental Consequences

The amount of fluid mineral acreage available for leasing under this alternative is similar to Alternative 1, but the amount that will be leased under Alternative 4 is difficult to predict because leasing in GRSG habitat areas will occur following a process in which parcels for lease are identified by received EOIs and evaluated based on fluid mineral and GRSG habitat criteria in order to determine which parcels are offered for lease. Parcels could be nominated and leased with potentially prohibitive stipulations which could discourage operators from further development. Geothermal leasing would occur following a similar process as described above but evaluation criteria would be adjusted to recognize the differences between geothermal development and petroleum fluid mineral development.

Compared to existing management this alternative would apply similar NSO stipulations to leasing in PHMA and IHMA, and around Leks in GHMA. In some states this alternative would make more acreage available for leasing, but because of the prioritization process for leasing EOIs it is possible that fewer acres could be offered for lease sale. State specific changes for Colorado, Oregon, and Wyoming are discussed below. A 3% disturbance cap would apply at the HAF fine scale habitat selection area in PHMA/IHMA, which could limit development, however very few areas are over or near the disturbance cap at this time. This cap could result in a delay in the timing of future fluid mineral exploration or development; however, the magnitude of the delay would depend on site-specific factors including the current level of habitat assessment that has been conducted to date. If a state is not specifically mentioned under environmental consequences, the rangewide consequences would apply.

Colorado Environmental Consequences

In Colorado, the BLM anticipates differing effects for fluid minerals. Under Alternative 4 more acreage would be available for leasing EOIs and potential leasing than under Alternative 1, this is because under Alternative 4 the plan would no longer apply closures within one mile of leks in GHMA.

Oregon Environmental Consequences

In Oregon, the BLM anticipates differing effects for fluid minerals. Under Alternative 4 more acreage would be available for leasing EOIs and potential leasing than under Alternative 1, this is because under Alternative 4 the plan would no longer apply closures within one mile of leks in GHMA.

Wyoming Environmental Consequences

In Wyoming, the BLM anticipates differing effects for fluid minerals. Unlike in other states, in WY NSO stipulations would be applied to leasing only within 0.6 miles of leks in PHMA and within 0.25 miles of leks in GHMA. Compared to Alternative 1, this alternative would make more acres available for leasing without NSO stipulations.

Alternative 5

Rangewide Environmental Consequences

Impacts on fluid minerals under Alternative 5 would be less than those described for Alternative 4 because fewer acres would be subject to an NSO stipulation (e.g., PHMA in WY would be 0.6-mi NSO around leks with TL stipulations in the rest of PHMA). Under this alternative more flexible WEMs would be considered in all states, allowing compensatory mitigation and the potential for more areas open to leasing with reduced major and minor operational constraints.

Alternative 6

Rangewide Environmental Consequences

Impacts would be the same as those described for Alternative 5 with the additional designation of ACECs. Management of ACECs as open to leasing subject to NSO stipulations with an exception/modification to allow occupancy if there are drainage concerns from adjacent development and if it can be demonstrated that no direct or indirect impacts on GRSG will occur would increase impacts on fluid minerals compared with Alternative 1.

10.10.2 Nonenergy Leasable Minerals

Methodology

Analysis of impacts on nonenergy leasable mineral development from this EIS focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on nonenergy leasable mineral development would result from closure of an area to nonenergy leasable mineral development. An indirect impact would result from removal of a road, which would change the economic feasibility of developing a site. For example, a direct impact of closing lands to nonenergy leasable development would be that those mineral resources are not extracted. An indirect impact would be limited or no traffic into and out of the area since those resources are no longer available to develop. The types of actions that can result in these impacts are discussed in more detail in **Section 4.10.2**, Nature and Type of Effects. Additional actions or conditions that would cause direct or indirect impacts on nonenergy leasable minerals are described under indicators below.

Indicators

Indicators of impacts on nonenergy solid minerals are as follows:

- The number of acres closed to nonenergy solid mineral leasing
- The number of acres closed to new nonenergy leasable surface mining
- The restrictions on surface use or timing placed on nonenergy solid mineral leasing
- The restrictions on surface use or timing placed on prospecting and exploration
- Application of RDFs to nonenergy leasable development for the protection of GRSG

Assumptions

The analysis includes the following assumptions:

- Nonenergy leasable mineral operations on existing federal leases, regardless of surface ownership, could be subject to RDFs by the BLM Authorized Officer and the authorized officer of the surface management agency. Under these circumstances, existing leases would be developed consistent with applicable laws and valid existing rights, using as many of the RDFs and conservation measures as possible while still allowing reasonable access.

Alternative 1

Rangewide Environmental Consequences

Under Alternative 1 most of the PHMA and IHMA in the planning area is closed to new leasing of nonenergy leasable minerals but states can consider expansion of existing leases. In Idaho, all IHMA in Known Phosphate Lease Areas is open to leasing. Wyoming keeps PHMA open subject to occupancy, seasonal limitations, disturbance, and density. Wyoming and Montana are subject to density and disturbance limits. In GHMA most states propose minimization measures to protect GRSG.

Application of the 3% disturbance cap in PHMA and lek buffers in PHMA and GHMA could impact both new and existing nonenergy leasable minerals activities by preventing or restricting new surface development and reducing ultimate recovery of the resource. New nonenergy leasable minerals activities could be precluded if the cap were exceeded in a BSU or a proposed project analysis area. New surface development on existing leases could be restricted if the cap were exceeded. The BLM would not apply the disturbance cap in a manner that would eliminate all reasonable opportunities to develop an existing lease.

Applying lek buffer distances when approving actions could also restrict development of infrastructure related to nonenergy solid leasable mineral development, as could application of RDFs.

Idaho Environmental Consequences

In Idaho, the BLM anticipates differing effects for nonenergy leasable minerals.

Impacts from Nonenergy Solid Leasable Minerals Management

In Idaho, all IHMA in Known Phosphate Lease Areas is open to leasing. No leases are currently on BLM-administered lands in IHMA. All other areas of IHMA would be closed to leasing except for consideration of the expansion of existing leases. Under Alternative 1, 16,270,500 acres, or 59% of the federal nonenergy leasable mineral estate decision area (including all federal nonenergy leasable mineral estate in PHMA outside Known Phosphate Lease Areas) would be closed to prospecting and leasing. Fringe leases and modifications to existing leases would be allowed in PHMA. Approximately 2,899,800 acres, or 10% of federal nonenergy solid leasable mineral estate in the decision area (including all federal nonenergy leasable mineral estate in IHMA outside Known Phosphate Lease Areas), would be open to leasing consideration but only if the Anthropogenic Disturbance Development and Criteria (AD-4) were satisfied (including the requirement that the project would not exceed the 3% disturbance threshold). Development on these acres would also be subject to RDFs, BMPs, and buffers for exploration and initial mine development, and compensatory mitigation once mining commences.

Development of federal nonenergy leasable minerals within GHMA would also be subject to RDFs, BMPs, and buffers on exploration and initial mine development. These limitations could increase costs of federal nonenergy leasable mineral development in the planning area.

Because Known Phosphate Lease Areas in IHMA would remain open to nonenergy solid mineral leasing, which would allow continued development in most of the planning area, impacts on federal nonenergy solid leasable mineral development in Idaho would be lessened compared to a full closure of all IHMA. The areas considered to have moderate potential for future development in the decision area would not be constrained by a closure. RDFs would be applied to phosphate development projects in IHMA. These RDFs could increase the cost of phosphate mining in the decision area.

Impacts from Anthropogenic Disturbance Management, Adaptive Management, and Coordination

Under Alternative 1, anthropogenic disturbance, including nonenergy leasable mineral development, would be limited to 3% of nesting and wintering habitat on new leases and prospecting permits within IHMA within a Conservation Area (BSUs). In BSUs where the 3% cap is already exceeded, new parcels would not be offered for lease until enough habitat was restored to maintain the area under the threshold. New leases for federal nonenergy solid leasable mineral resources that would result in exceedance of the 3% cap in a BSU would also be prohibited. This cap could potentially impact activities on 2,900,100 acres of unleased federal nonenergy solid leasable mineral estate in IHMA, including 400 unleased acres within Known Phosphate Lease Areas. Impacts would be greatest where these caps limited development in unleased portions of Known Phosphate Lease Areas because these areas have the highest potential for nonenergy leasable mineral development. The 16,270,500 acres that would be closed to nonenergy solid mineral leasing under Alternative 1 would not be impacted by the disturbance cap because no new nonenergy leasable solid mineral development could occur in the closed areas.

Nevada Environmental Consequences

In Nevada, the BLM anticipates some differing effects for nonenergy leasable minerals.

Alternative 1 would require a 3% disturbance cap on human surface-disturbing activities in PHMA, and it incorporates RDFs consistent with applicable law in PHMA, GHMA, and OHMA. It would also require all human disturbances to result in a net conservation gain for GRSG and their habitat. Lek buffers would also be required.

Collectively, these GRSG conservation management actions would increase mitigation requirements for land use authorizations. This would result in more complex project designs, potentially excluding infrastructure placement in the most cost-effective locations and potentially resulting in overall greater development costs. A corresponding effect could be a reduction in the number of authorization applications received for activities in PHMA and longer, more complicated review periods for those that are proposed in PHMA.

Management actions for mineral programs other than nonenergy leasable minerals would not impact nonenergy leasable mineral development. Therefore, only the impacts from nonenergy leasable minerals management actions are discussed in the paragraphs below.

Impacts from Nonenergy Leasable Minerals Management

Under the Alternative 1, 10,739,100 acres of the decision area would be closed to nonenergy leasable mineral development. Expanding existing leases would be considered in PHMA. Impacts of this closure would be the same type as those described under Nature and Type of Effects.

Alternative 1 includes applying RDFs on all GRSG habitat, which would mean additional conservation measures for the protection of GRSG consistent with applicable law. Impacts from the RDFs would likely result in higher costs and longer time frames for developing nonenergy leasable minerals. RDFs would require placing operations and facilities as close together as possible, would minimize site disturbance through site analysis and planning, and would phase development with concurrent reclamation.

Oregon Environmental Consequences

Impacts from Lands and Realty Management

Under Alternative 1, all BLM-administered surface in PHMA would be managed as ROW avoidance areas for nonenergy leasable-related activities. All PHMA would be closed to new leases and prospecting permits, so managing PHMA as ROW avoidance areas would have no impact on nonenergy leasable minerals.

BLM-administered surface in GHMA would be managed as ROW avoidance for high voltage transmission lines, major pipelines, but open to other nonenergy leasable mineral-related ROW location under Alternative 1.

Impacts from Nonenergy Leasable Minerals Management

The BLM would close all PHMA to nonenergy solid mineral leasing under Alternative 1. This would result in 7,247,900 acres (51%) of federal mineral estate in the decision area being closed to prospecting and leasing.

Utah Environmental Consequences

Production rates for gilsonite and phosphate are expected to remain steady for the life of the LUPs covered by this LUPA. Total phosphate production in the Utah Sub-region may increase with the possible opening of a new phosphate mine in Utah.

Application of the 3% disturbance cap in PHMA and lek buffers in PHMA and GHMA could impact both new and existing nonenergy leasable minerals activities by preventing or restricting new surface development. New nonenergy leasable minerals activities could be precluded if the cap were exceeded in a BSU or a proposed project analysis area. New surface development on existing leases could be restricted if the cap were exceeded. The BLM would not apply the disturbance cap in a manner that would eliminate all reasonable opportunities to develop an existing lease. Currently there are no population areas where the density of disturbance exceeds the 3% cap. There are areas within 4 miles of a lek in population areas that are near or exceeding the disturbance cap, including in the Uintah Population Area where there is high occurrence and existing development of phosphate.

Applying lek buffer distances when approving actions for linear features, infrastructure related to energy development, surface disturbance, and noise could also restrict development of nonenergy leasable minerals.

RDFs would be applied as under the action alternatives in PHMA and GHMA. In addition to the RDFs, disturbance cap, lek buffers, and density restrictions, additional conservation measures in PHMA would include net conservation gain requirements (also a requirement in GHMA), restrictions on noise, and seasonal restrictions. All of these combined could further restrict nonenergy leasable minerals development. Based on the disturbance cap and these other restrictions, it is unlikely that the existing phosphate and gilsonite mines could expand or that new phosphate or gilsonite mines would be approved on federal mineral estate in the decision area.

All sodium occurrence in the decision area is in PHMA and, under Alternative 1, PHMA would be closed to new nonenergy minerals leases. The occurrence of sodium is largely present outside of GRSG HMAs, so the overall impact on sodium development in Utah would be minimal.

Approximately 673,600 acres (16%) of federal mineral estate in the decision area would be open to leasing consideration for both surface and underground mining, all of which would be in GHMA. In GHMA, development would be subject to mitigation and lek buffers.

Gilsonite. Under Alternative 1, all federal mineral estate with gilsonite potential in the decision area would be within GHMA and would be open to nonenergy leasable mineral leasing. New leases in GHMA would be subject to mitigation and lek buffers. The 2,700 acres of authorized gilsonite leases in mapped occupied habitat would lie within GHMA and would be subject to current lease-specific surface disturbance limitations and/or BMPs included in those leases or approved plans governing the leases.

Phosphate. Under Alternative 1, 186,700 acres (88%) of federal mineral estate with phosphate potential in the decision area would be closed to new nonenergy leasable mineral prospecting and exploration and leasing, including all of federal mineral estate with high phosphate potential in the decision area. New leases adjacent to existing operations would be allowed. This allowance for new leases adjacent to existing operations would reduce impacts on locatable minerals from the closure of PHMA to new nonenergy leasable mineral leasing by allowing continued development around ongoing operations. These new leases would be subject to restrictive management which would likely preclude new surface development associated with new and existing phosphate leases, where existing surface infrastructure could be used for underground development on new leases development would continue, but if that were not feasible operations in PHMA could be forced to close once existing reserves are exhausted.

The mineral potential report for the Vernal RMP identifies continued development of phosphate on nonfederal mineral estate during the period of analysis (through 2017). It does not anticipate any development on federal mineral estate during the period of analysis. Since completion of that report, the phosphate mine in PHMA has changed ownership. Given current mineral holdings on private lands, it is anticipated that mining operations will be able to continue on private lands for 15 years. As the current mine on private lands expands, it is foreseeable that existing mining operations would progress to the edge of the nonfederal mineral estate. Development of federal mineral estate would likely not be consistent with the disturbance cap, so the mine would have to be redirected to other areas with nonfederal minerals or change mining methods

These changes would increase the cost of phosphate mining or, if the cost were deemed too high by the developer, potentially result in phosphate ore being left in place on federal mineral estate. Depending on the size of the federal minerals tract, this could result in either a loss (temporary lack of mining) or waste (permanent lack of mining if the remaining federal mineral resource is not economical to return to develop later) of federal mineral resources. This is because the mine on private lands would be reclaimed, then, if at some future date the federal minerals are available for mining, the minerals on the federal tract would generally not be economical to return to mine. While mining operations would be able to continue, there would be an increase in costs to the mine to use underground mining, move operations around the federal tracts, or redirect to other portions of the private lands. Restricting access to phosphate could hamper the production of fertilizer products needed to produce food.

Sodium. Under Alternative 1, none of the federal mineral estate with sodium occurrence in the decision area would be open to nonenergy leasable mineral leasing. This would reduce the availability and potentially the amount of development of sodium in Utah.

Wyoming Environmental Consequences

In Wyoming PHMA would be managed as open subject to occupancy, seasonal limitations, disturbance, and density. Seasonal restrictions, and density and disturbance limits would be applied to nonenergy leasable mineral development.

Alternative 2

Rangewide Environmental Consequences

In PHMA all states would apply the same management and expect the same resulting impacts on nonenergy leasable minerals as described under Alternative 1 above. The only change is that Nevada would add exception criteria to the closure in PHMA, described under the Nevada Environmental Consequences section below.

In GHMA all states would apply the same management and expect the same resulting impacts on nonenergy leasable minerals as described under Alternative 1 above.

Montana, North Dakota, South Dakota, Nevada/California, and Oregon would apply the same mitigation as Alternative 1. The BLM does not require compensatory mitigation but will enforce state mitigation policies and programs. Colorado and Idaho require mitigation resulting in no net loss. Utah and Wyoming removed the net conservation gain requirement. Colorado, Idaho, Nevada/California, Oregon, Utah, and Wyoming specify that compensatory mitigation would be voluntary unless required by laws other than FLPMA, or by the State.

Under Alternative 2, in all states except Montana and Wyoming, the 3% disturbance cap does not include wildfire or agriculture. In Idaho, the cap can be exceeded in utility corridors if it will benefit GRSG. In Utah the 3% disturbance cap can be exceeded if will benefit GRSG. The cap is applied at the BSU and project scale except in Idaho where it is applied at the BSU scale only. In Montana and Wyoming, a 5% disturbance cap is applied at the project area scale in PHMA, it includes disturbance from wildfire and agriculture.

Nevada Environmental Consequences

Nevada added exception criteria to the closure in PHMA, allowing leasing of nonenergy leasable minerals under certain circumstances. This would improve the availability of nonenergy leasable minerals in the planning areas compared to Alternative 1.

Alternative 3

Rangewide Environmental Consequences

Under this alternative, all PHMA and IHMA, including all proposed ACECs, would be closed to new nonenergy mineral leasing; there would be no GHMA. 100% of the decision area (including acreage already closed) would be closed under Alternative 3, so impacts would increase compared with Alternative 1. COAs would be applied to existing leases where applicable and feasible. These COAs would include no new surface occupancy on existing leases within 1 mile of active leks, and within 2 miles of active leks within PHMA. If the lease is entirely within the active lek buffer, require any development to be placed in the area of the lease least harmful to GRSG based on vegetation, topography, or other habitat features. This Alternative would limit permitted disturbances to 1 disturbance per 640 acres average across the landscape in PHMA. Disturbances may not exceed 3% in PHMA in any biologically significant unit and proposed project analysis area.

Idaho Environmental Consequences

<u>Impacts from Nonenergy Solid Leasable Minerals Management</u>

Impacts under Alternative 3 are the same as those described under Alternative 1, except that more acres would be affected by closures (21,629,700 acres, or 78% of the nonenergy leasable decision area). The magnitude of impacts under this alternative would increase compared with Alternative 1 since 473 acres of existing phosphate leases on BLM-administered lands would occur in PHMA. Less than 1% of the acres closed to leasing would be within Known Phosphate Lease Areas. Because the number of unleased acres within Known Phosphate Lease Areas that are closed would increase compared with Alternative 1, impacts on nonenergy solid leasable minerals would increase under this alternative.

Approximately 5,730 acres of existing unmined federal nonenergy leasable mineral leases in PHMA and GHMA would be subject to RDFs. This would limit surface disturbance, vehicle use, siting, and design of mineral development operations, in addition to imposing reclamation requirements. Application of RDFs

would have the types of impacts described under Nature and Type of Effects**.** Because these RDFs would not be applied under Alternative 1, impacts would increase under Alternative 3.

Under Alternative 3, 19,167,400 acres, or 69% of the federal nonenergy solid leasable mineral estate decision area (including all federal nonenergy solid leasable mineral estate in PHMA), would be closed to prospecting and leasing. New leases to expand existing mines for phosphate would not be permitted in areas managed as closed.

Utah Environmental Consequences

Under Alternative 3 all federal mineral estate in the federal mineral estate decision area (4,008,600 acres) would be closed to new prospecting and exploration and leasing. Management under this alternative would close more federal mineral estate to nonenergy leasable mineral prospecting and exploration and leasing than management under Alternative 1. This allocation decision would impact gilsonite, phosphate, and sodium. New leases to expand existing mines for these minerals also would not be permitted. Closing areas to nonenergy mineral leasing would result in the same type of impacts as those described under *Nature and Type of Effects*.

Under Alternative 3, exploration would be prohibited on all 4,008,600 acres of federal mineral estate within the decision area. Closing the decision area to exploration could reduce the availability of data on nonenergy leasable mineral resources outside the decision area and could increase costs of nonenergy leasable mineral development if it resulted in the need to conduct exploration for resources outside the decision area via less easily accessible locations than the locations within the decision area from which exploration might otherwise occur. Operators with existing leases would still be able to conduct new exploration on those leases.

Alternative 4

Rangewide Environmental Consequences

Under this alternative, nonenergy leasable minerals would be managed the same as under Alternative 1; the impacts would be the same as described under Alternative 1 above, but would be applied to different HMA areas. In Idaho, 1 acre of existing phosphate leases would be within IHMA and 472 acres would be within GHMA.

Nevada and Northeastern California Environmental Consequences

In Nevada and northeastern California, exceptions to the nonenergy leasable mineral closure in PHMA under may allow for increased development of nonenergy leasable minerals in some locations.

Alternative 5

Rangewide Environmental Consequences

Under this alternative, nonenergy leasable minerals would be managed the same as under Alternative 1; the impacts would be the same as described under Alternative 1 above, but would be applied to different HMA areas. In Idaho, no existing phosphate leases would be within HMAs on BLM-administered lands.

Nevada and Northeastern California Environmental Consequences

Impacts would be the same as described for Alternative 4.

Alternative 6

Rangewide Environmental Consequences

Under this alternative, impacts would be the same as described under Alternative 5 except that any existing nonenergy leasable operations within ACECs would not be able to expand on federal mineral estate and no new operations would be permitted in ACECs.

10.10.3 Coal

Methodology

Analysis of impacts on coal development from this EIS focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. The types of actions that can result in these impacts are discussed in more detail in **Section 4.10.3**, Nature and Type of Effects. Additional actions or conditions that would cause direct or indirect impacts on coal are described under indicators below.

Indicators

Indicators of impacts on coal are as follows:

- The amount of acres identified as unacceptable for coal leasing
- The amount of land surface identified as unsuitable for surface coal mining
- Application of siting, surface disturbance, and TL stipulations on both surface and underground coal mining
- Application of surface disturbance limitations and TL stipulations and reclamation requirements for coal exploration.

Assumptions

The analysis includes the following assumptions:

- If an area is leased, it could be developed. Not all leases would be developed within the life of this RMPA; however, pursuant to 43 CFR 3483, coal leases may be terminated if they are not diligently developed.
- Coal operations on existing federal leases, regardless of surface ownership, could be subject to restrictions on surface disturbance. Under these circumstances, existing leases would be developed consistent with applicable laws and valid existing rights, using as many of the restrictions and conservation measures as possible while still allowing reasonable access.
- As the demand for energy increases worldwide, so will the demand for extracting energy resources in areas with potential.

Alternative 1

Rangewide Environmental Consequences

Under Alternative 1, Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming manage PHMA as "essential habitat" for unsuitability evaluation. In GHMA there is no state specified special coal management.

Idaho, Nevada, California, and Oregon did not address coal due to absence of coal mineral in deposits with a reasonably foreseeable possibility of development.

Colorado Environmental Consequences

Under this alternative, the BLM would find coal resources unsuitable for future leasing when GRSG cannot be adequately protected. In addition, the BLM would have flexibility in approving projects with adequate

design and mitigation, subject to a 3% disturbance cap. Restrictions on land use and other authorizations would be included under the Alternative 1, as follows:

- Managing both PHMA and GHMA as ROW avoidance areas
- Prohibiting aboveground structures within 1 mile of active leks
- Restricting surface disturbance to 3% in PHMA

This Alternative provides opportunity for new or expanded mines, subject to restrictions on the amount of surface disturbance in PHMA and ADH areas.

Impacts of the restrictions and authorizations would be as described under *Nature and Type of Effects,* above.

Montana Environmental Consequences

Coal exploration under Alternative 1 would not be allowed on about 93,925 acres of BLM-administered coal mineral estate pursuant to 43 CFR Part 3410.1-1(a)(1) and 43 CFR Part 3465.1(d). About 13,659 acres where exploratory coal drilling would be disallowed fall within the areas designated as coal with development potential.

In areas where coal exploratory drilling would be allowed mitigation such as specialized design features or requiring maintenance of habitat functionality or avoidance would likely be required. These actions would delay permitting and increase the operator's costs for exploratory coal drilling. Requirements for specialized design features or mitigation would allow the operation to occur.

North Dakota Environmental Consequences

There has been no coal development within the planning area. While the Bowman-Gascoyne Known Recoverable Coal Resource Area intersects PHMA and GHMA, no additional development of this field is anticipated within the planning period. This Known Recoverable Coal Resource Area has low development potential, and no interest has been expressed in developing the area.

Lignite is being mined in other areas of the state. The Known Recoverable Coal Resource Area within the planning area was not designated as a Coal Study Area because it was determined not to have sufficient economic coal resources. No coal development is foreseeable in the planning area, coal resources in the planning area are not expected to be impacted by management actions proposed in this RMPA. Potential future surface mining could be precluded as a result of suitability determinations in PHMA (87,443 acres) under Alternative 1.

Utah Environmental Consequences

Measures to protect GRSG and its habitat (disturbance cap, lek buffers, net conservation gain requirements, and restrictions on noise and season) could affect the feasibility of new underground coal leases or the expansion of existing underground operations (e.g., increased costs and development delays due to limits on the timing of activities) but would not preclude them.

Application of a 3.1-mile lek buffer could affect mine placement, though the required buffer distance could be adjusted based on local topography.

Wyoming Environmental Consequences

Consideration of coal leasing within GRSG core, connectivity, and general habitat areas would allow for future development of these resources. Areas available for coal leasing would be dependent on the results of the coal screening process and the application of appropriate mitigation measures. Allowing coal

exploration would enhance the development of these resources. Designating PHMA as "essential habitat" for unsuitability evaluation would impact 338,533 acres which would restrict the ability to develop coal over 2% of GRSG habitat areas.

Alternative 2

Rangewide Environmental Consequences

In all states except Utah management and impacts on coal resources would be the same as described under Alternative 1. Colorado, Montana, North Dakota, South Dakota, and Wyoming all PHMA would be "essential habitat" for unsuitability evaluation. Idaho, Nevada California, and Oregon did not address coal due to absence of coal mineral in deposits with a reasonably foreseeable possibility of development.

Utah Environmental Consequences

In Utah essential habitat would be identified as part of future unsuitability criteria, compared to Alternative 1 where all PHMA would be considered as "essential habitat" for unsuitability evaluation this might give flexibility to consider leasing in small areas that were included in PHMA but do not meet the criteria for essential habitat, such as important connectivity areas. Impacts would likely be minimal because the amount of PHMA that does not meet essential habitat criteria is small. Impacts would otherwise be the same as described under Alternative 1.

Alternative 3

Rangewide Environmental Consequences

All areas managed for GRSG would be PHMA. All essential habitat would be identified as part of future unsuitability criteria. compared to Alternative 1 where all PHMA would be considered as "essential habitat" for unsuitability evaluation, this change in management might give flexibility to consider leasing in small areas that were included in PHMA but do not meet the criteria for essential habitat, such as important connectivity areas. Impacts of this management change would likely be minimal because the amount of PHMA that does not meet essential habitat criteria is small. Impacts of this alternative would otherwise be the same as described under Alternative 1.

Idaho, Nevada, California, and Oregon did not address coal due to absence of coal mineral in deposits with a reasonably foreseeable possibility of development.

Alternative 4

Rangewide Environmental Consequences

Under Alternative 4 the consideration of PHMA as essential habitat for unsuitability evaluation in CO, MT/DK, UT, and WY state that PHMA would be removed as some areas of PHMA do not meet essential habitat criteria. Almost all essential habitat is likely to overlap with PHMA so the impacts would be approximately the same as described under Alternative 1. The plan will not modify any existing suitability and unsuitable determinations. The proposed management under this alternative would apply rangewide, but the planning area in Idaho, Nevada, California, and Oregon does not have coal mineral in deposits with a reasonably foreseeable possibility of development so no impacts on coal would occur in these states.

Alternatives 5 and 6

Rangewide Environmental Consequences

Impacts under Alternatives 5 and 6 would be the same as under Alternative 4.

10.10.4 Locatable Minerals

Methodology

RMP decisions can include those that affect uses related to minerals subject to disposal under the mineral leasing, geothermal leasing, and mineral materials disposal laws; however, no RMP decision can affect the applicability of the US mining laws or uses thereunder. Under section 202(e)(3) of FLPMA, public lands can only be removed from or restored to the operation of the Mining Law of 1872, as amended, by withdrawal action pursuant to section 204 or other action pursuant to applicable law (43 USC 1712(e)(3)). An RMP may recommend an area for withdrawal from location and entry under the U.S. mining laws; however, such recommendation has no legal effect or environmental consequence. Under section 204 of FLPMA, only the Secretary or an individual in the Office of the Secretary who has been appointed by the President, by and with the advice and consent of the Senate, can make, modify, extend, or revoke withdrawals. An RMP recommendation to withdraw an area from location and entry under the U.S. mining laws does not constitute a withdrawal proposal under section 204 of FLPMA, nor does it compel the Secretary to consider such a withdrawal in more detail, or otherwise dictate or limit what areas may be withdrawn.

Despite the lack of legal effect or environmental impact associated with a recommendation in an RMP that the Secretary withdraw any public land from location and entry under the US mining laws, and strictly for the purposes of comparison between the alternatives, this EIS includes a description of the potential environmental consequences of a Secretarial withdrawal of the analysis area from location and entry under the US mining laws. These types of impacts are discussed in more detail in **Section 4.10.4**, Nature and Type of Effects. Should the Secretary propose a withdrawal, such proposal would include a legal land description of the land proposed for withdrawal and would be published in the Federal Register for public review and be subject to appropriate analysis under NEPA and FLPMA, including consideration of any relevant mineral potential data.

Indicators

Indicators of impacts on locatable minerals are as follows:

- The amount of land open to mineral entry
- The amount of land recommended for withdrawal from locatable mineral entry
- The designation of areas as ACECs that would trigger the requirement under 43 C.F.R. § 3809.411(c) to file a plan of operations for any surface disturbing activities in those areas greater than casual use

Assumptions

The analysis includes the following assumptions:

- Restrictions on locatable mineral development could only occur through existing legal avenues such as the BLM's mandate to prevent unnecessary or undue degradation (43 CFR 3809). The management actions analyzed for this RMPA would not interfere with valid existing rights.
- Areas recommended for withdrawal would be withdrawn by a public land order issued by the Secretary of the Interior (5,000 acres or less) or by an act of Congress (over 5,000 acres).

Alternative 1

Rangewide Environmental Consequences

In all states, Alternative 1 recommended the withdrawal of all SFAs from location and entry under the US mining laws. After publication of the RODs in 2015, the BLM applied for these lands to be withdrawn, and the Secretary accepted the application. The BLM then initiated a process to consider the withdrawal,

pursuant to section 204 of FLPMA. If the Secretary decides to withdraw the proposed lands, this would likely result in a decrease in the exploration and development of locatable minerals in these areas. Application of seasonal restrictions, if deemed necessary in other areas, could restrict the timing, feasibility, or costs associated with locatable mineral development.

Colorado Environmental Consequences

Under Alternative 1, locatable minerals operations in PHMA would require appropriate effective mitigation for conservation to the extent necessary to comply with the standards and requirements under 43 CFR Subparts 3715, 3802, and 3809. Seasonal restrictions would be applied if deemed necessary to comply with the standards and requirements under 43 CFR Subparts 3715, 3802, and 3809. In ADH areas and in PHMA where mitigation is not otherwise required to comply with the standards and requirements, operators could be requested to voluntarily agree to suggested design features.

Access roads needed to access claims or mines would be constructed in accordance with 43 CFR Part 3809.420(b) and applicable MSHA or State standards. If it is determined by the authorized officer that an engineered road is warranted, then the BLM would typically require engineered design by the operator. This would also apply where an engineered road is warranted for exploration activities.

Idaho Environmental Consequences

Under Alternative 1, 2,968,200 acres of federal locatable mineral estate (including all acres in the SFA) were recommended for withdrawal from location and entry under the US mining laws. The BLM initiated a separate process for the Secretary to consider whether to withdraw these lands, pursuant to section 204 of FLPMA. If the Secretary ultimately withdraws all of these lands, when combined with the 5,380,200 acres already withdrawn, the acreage of withdrawn federal lands in the decision area would total 8,348,400 acres, or 28% of the federal locatable mineral estate.

Of the 56 plans of operations and notices currently authorized within the decision area for Alternative 1, 7 (13%) are on lands that would be within the SFA under this alternative and therefore within the area previously recommended for withdrawal.

Nevada-California Environmental Consequences

Under Alternative 1, 2,731,600 acres of the decision area were recommended for withdrawal from mineral entry. Pursuant to the separate process currently underway, if the Secretary withdraws all of these lands, when combined with the 521,600 acres already withdrawn, the acreage of withdrawn federal lands in the decision area would total 3,253,200 acres, or 20% of the federal locatable mineral estate, and 80% (13,273,400 acres) are not recommended for withdrawal.

Alternative 1 would require RDFs to all GRSG habitat as additional conservation measures where necessary to comply with the applicable standards and requirements under 43 CFR Subparts 3715, 3802, and 3809.

North Dakota and South Dakota Environmental Consequences

In North Dakota and South Dakota zero acres were recommended for withdrawal from mineral entry.

Oregon Environmental Consequences

Under Alternative 1, 1,835,800 acres of the decision area, specifically land designated as SFA, were recommended for withdrawal from mineral entry. Pursuant to the separate process currently underway, if the Secretary withdraws all of these lands, when combined with the 1,435,900 acres already withdrawn, the

acreage of withdrawn federal lands in the decision area would total 3,271,700 acres, or 23% of the federal mineral estate decision area.

Under this alternative, 117 mining claims, 1 plan of operations, and 9 exploration notices would be in the SFA. As such, all would be in the area that was recommended for withdrawal. This represents 21% of the 609 claims, plans, and notices in occupied GRSG habitat.

Under Alternative 1, 715,049 acres of BLM-administered surface in the decision area would be designated as ACECs. A plan of operations would be required for exploration operations disturbing five acres or less in these ACECs**.**

Utah Environmental Consequences

Under Alternative 1, 235,000 acres (6%) of the decision area, including the SFA, were recommended for withdrawal from mineral entry. Pursuant to the separate process currently underway, if the Secretary withdraws all of these lands, when combined with the 445,900 acres already withdrawn, the acreage of withdrawn federal lands in the decision area would be total 680,900 acres.

Under Alternative 1, 1,800 acres (less than 1%) of federal mineral estate with high potential in the decision area was recommended for withdrawal.

Of the 39 existing authorized locatable mining operations in the decision area, none would be in the SFA under Alternative 1. However, 11 mining claims would be in the SFA. Pursuant to the separate process currently underway, if the Secretary withdraws all lands in SFA, as recommended under Alternative 1, the BLM would not authorize new operations on any existing mining claims in SFA until the BLM confirmed that the mining claim was valid on the date of the withdrawal and remains valid.

Under Alternative 1, the BLM could limit surface-disturbance in PHMA if necessary to comply with the standards and requirements in 43 CFR Parts 3715, 3802, or 3809. The BLM would apply the disturbance cap, minerals/energy density, RDFs, and seasonal restrictions in PHMA and mitigation for net conservation gain and lek buffers in PHMA and GHMA if necessary to comply with the standards and requirements in 43 CFR Parts 3715, 3802, or 3809 and prevent unnecessary or undue degradation.

Wyoming Environmental Consequences

On BLM-administered lands, the BLM previously recommended for withdrawal from mineral entry within SFA portions of PHMA of 1,146,130 acres. Pursuant to the separate process currently underway, if the Secretary withdraws all of the recommendation, these withdrawals in combination with existing withdrawals on 1,761,550 acres, the total acreage of withdrawn federal lands in the decision area would total 2,907,680 acres.

Alternative 2

Rangewide Environmental Consequences

No recommendations for the withdrawal of SFAs from mineral entry are made under this alternative, except in Montana which would continue the recommendation for withdrawal of SFAs as described under Alternative 1. In all states, except Montana, the removal of any recommendation for withdrawal under Alternative 2 would have no impact. Recommendations to withdraw lands from location and entry under the Mining Law of 1872 have no impact. Only the Secretary or her designee may withdraw lands and this is done not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Montana Environmental Consequences

Montana did not remove the recommendation for withdrawal of SFAs from mineral entry as described under Alternative 1. Impacts on locatable minerals in Montana under Alternative 2 would be the same as described under the *Montana Environmental Consequences* section of Alternative 1.

Alternative 3

Rangewide Environmental Consequences

Under Alternative 3, all PHMA including proposed ACECs, would be recommended for withdrawal from mineral entry. Impacts would be similar in nature and type to those described under Alternative 1, but a much larger area would be recommended for withdrawal under this alternative (see **Table 2-3** which shows the acres of PHMA by state). If the Secretary were to decide to withdraw these areas, after the completion of the process outlined in section 204 of FLPMA, there may be limited opportunities for locatable mineral development in the decision area as described in the *Nature and Type of Effects*.

Alternatives 4 and 5

Rangewide Environmental Consequences

Alternatives 4 and 5 would not designate any SFAs and would not recommend any areas for withdrawal from mineral entry. The impacts on locatable minerals under this alternative would be the same as described under Alternative 2.

Montana Environmental Consequences

In Montana under Alternative 4, no SFAs would be designated and no recommendations for withdrawal would be made. Just as in Alternative 1, the removal of any recommendation for withdrawal under this alternative would have no impact.

Alternative 6

Rangewide Environmental Consequences

Alternative 6 would designate ACECs in the same areas as under Alternative 3, along with a requirement (per 43 CFR Part 3809.11(c)(3)) to prepare a plan of operations for exploration operations disturbing five acres or less. Processing plans of operations is more time-consuming than processing an exploration notice. Designation of an ACEC would increase costs to those operators who would otherwise conduct exploration under a notice, and potentially reduce development of locatable mineral resources on BLM-administered mineral estate in the planning area that would have resulted from exploration that could have been done under a notice.

10.10.5 Mineral Materials

Methodology

Analysis of impacts on mineral materials focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact on mineral materials would result from closure of an area to mineral material sales disposal. An indirect impact would result from removal of a road, which could change the economic feasibility of developing a site. The types of actions that can result in these impacts are discussed in more detail in **Section 4.10.5**, Nature and Type of Effects. Additional actions or conditions that might cause direct or indirect impacts on mineral materials are described under Indicators, below.

Indicators

Indicators of impacts on mineral materials are as follows:

- The amount of land closed to mineral material disposal
- Application of disturbance, timing, and other limitations
- The amount of land over which RDFs would be applied to mineral material disposals
- Application of restoration requirements

Assumptions

The analysis includes the following assumptions:

- Future demand for mineral materials will vary depending upon market conditions, which differ according to economic conditions and construction activity. Construction projects within approximately 50 miles of mineral materials deposits may lead to development of these deposits. It is expected that mineral materials activity will continue at roughly the same level for the life of the RMPA.

Alternative 1

Rangewide Environmental Consequences

Under Alternative 1, PHMA would be closed to new mineral material sales, but open for new free use permits, and expansion of existing pits for both free use permits and material sales. This would prevent mineral materials from being sold from new locations but would allow continued use of existing pits. It would also allow new free use permits in both existing and new locations, which would allow state, county, and local governments and non-profit organizations the flexibility to cost-effectively locate mineral material sources. This could result in the displacement of mineral material mining to different areas further from locations where they are needed which would increase costs associated with use. No states would close GHMA to mineral material disposal, but most would apply minimization measures such as RDFs/BMPs and mitigation. Colorado, Idaho and Wyoming would apply state specific management, discussed under the state specific headings for those states below.

Colorado Environmental Consequences

Under this alternative, PHMA would be closed to new mineral material sales, but open to new free use permits and expansion of existing pits where certain criteria are met.

Idaho Environmental Consequences

Under Alternative 1, 15,529,000 acres (56%) of federal mineral material estate in the decision area would be closed to mineral material disposal except for the expansion of existing pits, unlike other states, in Idaho this closure extends to new free use permits. Closing PHMA to new free use permits would result in increased costs to local government road departments for road maintenance and could result in worsening road conditions in these areas. Approximately 3,079,100 acres of federal mineral material estate in the decision area would be open to mineral material disposal but only if the Anthropogenic Disturbance Development and Criteria were satisfied (including the requirement that the project would not exceed the 3% disturbance threshold). Mineral material activities in IHMA and GHMA would also be subject to RDFs, buffers, and seasonal timing restrictions. Mineral material sales from the 47 existing community pits in GRSG habitat would be subject to timing restrictions. These timing restrictions could impact some operations and therefore reduce overall sales of federal materials in the planning area.

Impacts from Anthropogenic Disturbance Management, Adaptive Management, and Coordination

Under the Alternative 1, anthropogenic disturbance, including mineral material development, would be limited to 3% of nesting and wintering habitat within PHMA and IHMA within a Conservation Area (i.e., BSUs). In BSUs where the 3% cap is already exceeded, new development of federal mineral material resources would be prohibited until enough habitat was restored to maintain the area under the threshold. Development of federal mineral material resources that would result in exceedance of the 3% cap in a BSU would also be prohibited. This cap could potentially impact activities on 3,079,100 acres of federal mineral material estate in IHMA.

Nevada Environmental Consequences

Alternative 1 would require a 3% disturbance cap on human surface-disturbing activities in PHMA and would incorporate RDFs consistent with applicable law in PHMA, GHMA, and OHMA. It would also require all human disturbances to result in a net conservation gain for GRSG and their habitat, and lek buffers would be required.

Collectively, these GRSG management actions would result in the impacts described under *Nature and Type of Effects*.

Oregon Environmental Consequences

Application of the 3% disturbance cap and in PHMA and lek buffers in PHMA and GHMA could impact mineral material activities by preventing new surface development. New mineral material pits or expansion of existing pits could be precluded if the cap were exceeded in an Oregon PAC (also known as BSU) and proposed project area. In cases where development was allowed, mitigation requirements would increase the cost of development. Applying lek buffer distances when approving actions would also restrict mineral material development in some areas.

Utah Environmental Consequences

Under Alternative 1, the application of the 3% disturbance cap in PHMA could impact mineral material activities by preventing new surface development. New mineral material pits or expansion of existing pits could be precluded if the cap were exceeded in a BSU or a proposed project analysis area. In cases where development was allowed, mitigation requirements would increase the cost of development.

Applying lek buffer distances when approving actions for surface disturbance could restrict mineral materials development in GHMA and could cause development to move away from desired locations.

Under Alternative 1, all BLM-administered surface within GHMA would be available for ROW location, except for 17,600 acres already managed as exclusion. While these areas would be open, ROW development in GHMA would be subject to lek buffers and net conservation gain requirements, which could impact mineral material development as discussed above. If disturbance is pushed to areas without restrictions, then overall demand for mineral materials will not be affected. However, if the area of new disturbance decreases across the landscape, the demand for mineral materials could be reduced.

Under Alternative 1, PHMA would be closed to mineral material disposal. This includes 1,196,900 acres with mineral material occurrence. Impacts would be somewhat mitigated because new free use permits and expansion of existing pits would be allowed, subject to restrictions. There are approximately 24,000 acres under a mineral material permit within GRSG habitat statewide. Further, with approximately 1,100 acres of existing disturbance associated with those mineral material pits there are opportunities for existing pits to expand within their existing permitted areas. Because less than 5% of the existing permitted area has been

disturbed expansion would fall under the disturbance cap at the project level for most pits. Therefore, while there may be site-specific instances where a new pit in occupied GRSG habitat is denied, the potential for this is low because there is additional development opportunity at existing sites.

Wyoming Environmental Consequences

Under Alternative 1, in Wyoming saleable mineral development (e.g., mineral material exploration, sales and free use permits) would be allowed in GRSG core, connectivity, general habitat areas which would allow for the continued use and development of these resources.

Prohibiting surface disturbing activities on 337,860 acres would result in the same type of impacts on mineral material development as those described under *Nature and Type of Effects*. Restricting surface disturbance on 160,630 acres Density limitations of a 5% disturbance cap within PHMAs (core only) would Prevent the development of new mineral material developments in areas at or above the cap. Prohibiting surface occupancy and disruptive activities within 0.6 miles of occupied leks and seasonal restrictions in GRSG nesting/early brood-rearing habitat and winter concentration areas could result increased cost associated with mineral material development.

Applying RDFs as mandatory stipulations and conservation objectives and applying BMPs to federal mineral estate where the surface ownership is non-federal would result in increased development costs. Avoiding primary and secondary roads within 1.9 miles of the perimeter of occupied GRSG leks and prohibiting other new roads within 0.6 miles of the perimeter of occupied GRSG leks within PHMAs would reduce the area where new roads needed for mineral development could be constructed.

The management of ROW exclusion areas (285,930 acres) within PHMAs and GHMAs would prevent the construction of access roads for mineral material sites, however if mineral material development were otherwise allowed in the area, sites could be constructed along existing roads which could reduce the impacts of this management.

Alternative 2

Rangewide Environmental Consequences

Under Alternative 2 proposed management and impacts would be similar to those described under Alternative 1, except in Idaho and Nevada.

Idaho Environmental Consequences

Under Alternative 2 in PHMA and IHMA managed as closed to mineral material development, Idaho would allow consideration of new free use permits. Compared to Alternative 1 this would reduce impacts on road conditions and high road maintenance costs on local governments which would no longer have to transport mineral materials required for road maintenance from outside these areas. Impacts would otherwise be the same as described under Alternative 1.

Nevada Environmental Consequences

Under Alternative 2 Nevada would exception criteria to the mineral material disposal closure in PHMA. In PHMA, GHMA, and OHMA, the State Director (in coordination with NDOW, Sagebrush Ecosystem Technical Team, and/or CDFW) may grant an exception to the allocations and stipulations proposed if one of the following applies:

i. The location of the proposed activity is determined to be unsuitable (by a biologist with GRSG experience using methods such as (Stiver et al. 2015); lacks the ecological potential to become

marginal or suitable habitat; and would not result in direct, indirect, or cumulative impacts on GRSG and its habitat. Management allocation decisions would not apply to those areas determined to be unsuitable because the area lacks the ecological potential to become marginal or suitable habitat.

ii. The proposed activity's impacts could be offset to result in no adverse impacts on GRSG or its habitat, through use of the mitigation hierarchy consistent with Federal law and the state's mitigation policies and programs. In cases where exceptions may be granted for projects with a residual impact, voluntary compensatory mitigation consistent with the State's management goals could be one mechanism by which a proponent achieves the RMPA goals, objectives, and exception criteria. When a proponent volunteers compensatory mitigation as their chosen approach to address residual impacts, the BLM can incorporate those actions into the rationale used to grant an exception. The final decision to grant a waiver, exception, or modification would be based, in part, on criteria consistent with the state's GRSG management plans and policies.

iii. The proposed activity would be authorized to address public health and safety concerns, specifically as they relate to federal, state, local government and national priorities. iv. Renewals or re-authorizations of existing infrastructure in previously disturbed sites or expansions of existing infrastructure that do not result in direct, indirect, or cumulative impacts on GRSG and its habitat.

iv. The proposed activity would be determined a routine administrative function conducted by federal, state, or local governments, including prior existing uses, authorized uses, existing rights, and existing infrastructure (i.e., rights-of-way for roads) that serve a public purpose and would have no adverse impacts on GRSG and its habitat, consistent with the state's mitigation policies and programs.

v. Exceptions to lands that are identified for retention would be considered for disposal or exchange if they were identified for disposal through previous planning efforts, either as part of the due process of carrying out Congressional Acts (e.g., the respective Lincoln and White Pine County Conservation, Recreation, and Development Acts) or the agency can demonstrate that the disposal, including land exchanges, would have no direct, indirect or cumulative impacts on GRSG and its habitat.

These criteria could increase the time to get approval for new mineral material developments but would also provide certainty about the conditions under which exemptions would be granted.

Alternative 3

Rangewide Environmental Consequences

Under Alternative 3, all areas managed for GRSG would be PHMA and saleable minerals would be closed to disposal in all PHMA. Some states are considering expanding HMAs to include areas of adjacent non-habitat, unoccupied historic habitat, or areas with potential to become habitat as PHMA. Impacts would apply across a much larger area than under Alternative 1, the magnitude of all impacts would increase under this alternative.

ACECs would also be considered under this alternative, though because of the restrictive nature of the PHMA management under this alternative, there would be no different allocations between the PHMA and the potential ACEC boundaries.

Under Alternative 3 all PHMA would be managed as ROW exclusion (outside of designated corridors), however, because all PHMA would be closed to mineral materials disposal under this alternative, the ROW exclusion areas would not impact the mineral materials program.

This alternative has the greatest impacts on saleable minerals because restrictions would be applied to the greatest number of acres, increasing the potential for reduced availability, reduced access, and increased development costs for accessing saleable minerals.

Colorado Environmental Consequences

For existing mineral material disposal sites, no new road construction would be permitted within a 4-mile buffer of a GRSG lek. Road realignments or route upgrades could occur only in certain specified situations, and closing and revegetating unneeded routes to restore GRSG habitat would apply in ADH and PHMA.

Oregon Environmental Consequences

Under Alternative 3, existing mineral materials pits in occupied habitat would also be closed to new sales. Impacts on availability of mineral materials would occur more quickly in Oregon because existing sites in closed areas could not continue to supply mineral materials.

Alternatives 4 and 5

Rangewide Environmental Consequences

Under Alternatives 4 and 5, proposed management and impacts on mineral material development would be the same as described under Alternative 1, except in Idaho as discussed under the state specific heading below.

Idaho Environmental Consequences

In Idaho, exceptions to the mineral material closure in PHMA under Alternative 2 may allow for increased development of mineral materials in some locations.

Alternative 6

Rangewide Environmental Consequences

Under Alternative 6, proposed management and impacts on mineral material development would be the same as described under Alternatives 4 and 5, except that ACECs would also be considered under this alternative. Under Alternative 6, ACECs would be closed to new all new mineral material sales and operations, except for free-use permits issued in order to support maintenance needs for existing local roads to ensure public safety. New mineral material sites for free-use should avoid ACECs, but if avoidance is not possible sites would need to comply with all the minimization measures identified for PHMA.

10.10.6 Oil Shale and Tar Sands

Methodology

Analysis of impacts on oil shale and tar sands focuses on the impacts of conservation measures to protect GRSG. These impacts may be direct or indirect. For example, a direct impact would result from closure of an area to oil shale and tar sand development. An indirect impact would result from removal of a road, which could change the economic feasibility of developing a site. Additional actions or conditions that might cause direct or indirect impacts on mineral materials are described under Indicators, below.

Indicators

Indicators of impacts on oil shale and tar sands are as follows:

- Application of conservation measures for GRSG to existing pending leases
- The amount of land managed as ROW avoidance areas
- The amount of land managed as ROW exclusion areas

Assumptions

There are no assumptions specific to the analysis of oil shale and tar sands.

Alternative 1

Rangewide Environmental Consequences

Colorado, Idaho, Utah, and Wyoming contain significant oil shale resources overlapping the planning area. Colorado, Idaho, and Wyoming manage these resources the same as fluid leasable minerals so management and impacts would be same as described under Fluid Minerals Alternative 1 in **Section 4.10.1**, above.

Proposed management and impacts in Utah are described below. Tar sands resources overlapping the planning area only exist in Utah, management and impacts on tar sands in Utah are described below.

In Utah, the BLM anticipates differing effects for this oil shale and tar sands. See the Utah Environmental Consequences for oil shale and tar sands.

Utah Environmental Consequences

Alternative 1 does not include leasing allocation decisions for oil shale and tar sands in Utah because the ROD for the Allocation of Oil Shale and Tar Sands Resources on Lands Administered by the BLM in Colorado, Utah, and Wyoming closed all mapped occupied GRSG habitat on BLM-administered lands to oil shale and tar sands leasing and development with the exceptions of the pending lease application in the Asphalt Ridge Special Tar Sands Area and the White River Oil Shale Research, Development, and Demonstration site and Preference Lease Right Area (BLM 2013). Within these two areas, leasing and development would be allowed to occur. Management actions and allocation-based decisions being considered could impact the feasibility, amount, and type of development. For example, depending on the alternative selected, GRSG habitat that overlaps the above-mentioned areas may be subject to surface disturbance thresholds, timing restrictions, and other GRSG protection measures. Managing surrounding lands as ROW exclusion or avoidance areas could impact road and facility construction to access and develop those leases.

Under Alternative 1, no disturbance cap would be applied to anthropogenic disturbance in GHMA. The existing and pending leases would be in GHMA under this alternative, soil shale and tar sands development could continue to occur subject to stipulations and other restrictions applied in the Vernal RMP (White River Oil Shale Preference Right Lease Area) and site-specific NEPA analyses.

Oil shale and tar sands development in GHMA would be subject to RDFs, lek buffers, and net conservation gain requirements, which could impact oil shale and tar sands development by restricting new surface development. GHMA would be available for the types of ROW location needed for oil shale and tar sands development. ROW development in GHMA would be subject to lek buffers and net conservation gain requirements. Applying lek buffer distances when approving actions for linear features, infrastructure related to energy development, tall structures, surface disturbance, and noise could also restrict development of infrastructure related to oil shale and tar sands development.

Alternative 2

Rangewide Environmental Consequences

Colorado, Idaho, Utah, and Wyoming contain significant oil shale resources overlapping the planning area. Colorado, Idaho, and Wyoming manage these resources as fluid leasable minerals so management and impacts would be same as described in under Fluid Minerals Alternative 2 in **Section 4.10.1**, above.

Management and impacts in Utah are described below. Tar sands resources overlapping the planning area only exist in Utah, management and impacts on tar sands in Utah are described below.

In Utah, the BLM anticipates differing effects for this oil shale and tar sands. See the Utah Environmental Consequences for oil shale and tar sands.

Utah Environmental Consequences

Alternative 2 does not include leasing allocation decisions for oil shale and tar sands in Utah because the ROD for the Allocation of Oil Shale and Tar Sands Resources on Lands Administered by the BLM in Colorado, Utah, and Wyoming closed all mapped occupied GRSG habitat on BLM-administered lands to oil shale and tar sands leasing and development with the exceptions of the pending lease application in the Asphalt Ridge Special Tar Sands Area and the White River Oil Shale Research, Development, and Demonstration site and Preference Lease Right Area (BLM 2013). Within these two areas, leasing and development would be allowed to occur; however, certain management actions and allocation-based decisions being considered could impact the feasibility, amount, and type of development. Managing surrounding lands as ROW exclusion or avoidance areas could impact road and facility construction to access and develop those leases.

Alternative 2, would allow exceptions for projects to exceed the disturbance and density caps in PHMA, and allow exceptions to avoidance and minimization measures in PHMA if the area is non-habitat and indirect impacts would not occur. Allowing an exceedance to the disturbance and density caps based on site-specific habitat condition, population information, and proponent-volunteered project design elements could allow mineral development to proceed in areas that might otherwise have been precluded by the No-Action Alternative. Allowing consideration or proposed developments that could exceed the 3% disturbance cap or density cap provides the ability to potentially avoid precluding leasing/permitting, development, or consideration of associated infrastructure. Authorizing the exceedances to the disturbance and density caps would only be allowed if voluntarily developed minimization or mitigation improves GRSG habitat. While there is more flexibility and projects may no longer be precluded by the caps, proponents with potential developments may still need to evaluate GRSG conditions or propose habitat improvement projects. While projects may not be precluded by the caps, voluntarily applying the criteria could result in additional costs to implement mitigating measures. This could increase project costs and could make a proposed project uneconomical. Allowing exceptions to avoidance and minimization measures in PHMA if the area is non-habitat and indirect impacts would not occur could allow consideration of leasing/permitting and development for mineral operations.

Alternative 2 would also no longer require proponents to provide for compensatory mitigation on a project-by-project basis to show a net conservation gain. The BLM would cooperate with the State of Utah to analyze applicant-proposed, or state required or recommended compensatory mitigation to offset residual impacts. The BLM may authorize such actions consistent with NEPA analysis and the governing RMP. Not requiring proponents to pay for vegetation and habitat treatments could decrease project costs, providing more opportunities for oil shale and tar sands development projects to move forward in PHMA and former GHMA.

Alternative 3

Rangewide Environmental Consequences

Colorado, Idaho, Utah, and Wyoming contain significant oil shale resources overlapping the planning area. Colorado, Idaho, and Wyoming manage these resources as fluid leasable minerals so management and

impacts would be same as described in under Fluid Minerals Alternative 2 in **Section 4.10.1**, above. Management and impacts in Utah are described below. Tar sands resources overlapping the planning area only exist in Utah, management and impacts on tar sands in Utah are described below.

In Utah, the BLM anticipates differing effects for this oil shale and tar sands. See the Utah Environmental Consequences for oil shale and tar sands.

Utah Environmental Consequences

Under Alternative 3, disturbance in PHMA would be subject to a 3% cap, which would include wildfire. Approximately 2,320 acres of the White River Oil Shale Preference Right Lease Area and all 2,120 acres of the pending federal lease within the Asphalt Ridge Special Tar Sands Area would be in PHMA. The Uintah Population Area, where the White River Oil Shale Preference Right Lease Area is located, is currently just under the 3% disturbance cap. New development could push the area over the cap and prevent new surface disturbance in this portion of the Preference Right Lease Area until areas are reclaimed to the point where disturbance is below the threshold. All BLM-administered surface in PHMA would be managed as exclusion under Alternative 3. There could be indirect impacts resulting from the limits on access and the available means for transporting oil shale and tar sands to processing facilities and markets.

Alternatives 4 and 5

Rangewide Environmental Consequences

Under Alternatives 4 and 5, proposed management and impacts on oil shale and tar sands development would be the same as described under Alternative 1.

Alternative 6

Rangewide Environmental Consequences

Under Alternative 6, proposed management and impacts on oil shale and tar sands development would be the same as described under Alternative 1, except that ACECs would also be considered under this alternative. Under Alternative 6, ACECs would have NSO stipulations applied to leases which could increase the costs of development or prevent the development of some oil shale and tar sands in the planning area.

10.11 SPECIAL DESIGNATIONS

10.11.1 Greater Sage-Grouse ACECs and Key RNAs in Oregon

Impacts of the alternatives on the ACECs proposed for designation under Alternatives 3 and 6 are described in detail in **Appendix 5**, Areas of Critical Environmental Concern for Greater Sage-grouse. Impacts on key RNAs in Oregon are addressed in **Appendix 17**, Proposed RMP Amendment and Analysis for Key Research Natural Areas in Oregon. Management for existing ACECs was determined in the applicable Resource Management Plans to be adequate to support the relevant and important values at the time of their designation. Impacts on these ACECs are not further discussed because the BLM would continue to manage these ACECs to protect their relevant and important values. Management to protect GRSG under the various alternatives could (or would typically) provide additional protections for existing ACECs or provide complementary management. The exception to this is in the High Lakes ACEC in Oregon which would receive PHMA with limited exceptions management direction under the Proposed RMP Amendment. The effects of the alternatives and the Proposed RMP Amendment on the High Lakes ACEC are described in **Appendix 5**, Areas of Critical Environmental Concern for Greater Sage-grouse.

10.12 SOCIAL AND ECONOMIC CONDITIONS (INCLUDING ENVIRONMENTAL JUSTICE)

10.12.1 Methods and Assumptions

Indicators

Fluid Minerals (Oil and Gas)

Potential changes in oil and gas production and development due to the BLM management decisions for the protection of GRSG could impact economic and social conditions. The types of actions that can result in these impacts are discussed in more detail in **Section 4.12.1**, Nature and Type of Effects. The BLM management decisions could change oil and gas production and development by changing the amount of land closed to fluid mineral leasing, the amount of land open to leasing but subject to NSO, CSU, and TL stipulations, and by changing the COAs on fluid mineral exploration and development activities on existing and future leased lands (see **Section 4.9**, Mineral Resources, for more information), and the potential changes in oil and gas production and development could impact economic and social conditions through the following indicators analyzed in this section:

- Change in economic activity, as measured by jobs, income, economic output, and tax revenue and payments to the state and counties.
- Changes to public services associated with potential impacts on tax revenue.
- Changes to way of life, culture, social cohesion, and preservation of nonmarket values, including direct and indirect use and non-use values, for mineral development and production communities of interest, those involved in local governments, local residents, and other communities of interest that may value access to mineral resources.

Nonenergy Leasable Minerals

Potential changes in nonenergy leasable mineral extraction due to the BLM management decisions could impact economic and social conditions through the following indicators:

- Change in economic activity and market conditions associated with impacts on nonenergy leasable minerals due to change in the amount of land closed to mineral leasing and the amount of land open to leasing but subject to NSO, CSU, and TL stipulations.
- Changes to way of life, culture, social cohesion, and preservation of nonmarket values, including direct and indirect use and non-use values, for mineral development and production communities of interest, those involved in local governments, local residents, and other communities of interest that may value access to mineral resources.

Locatable Minerals

Potential changes in locatable mineral exploration and extraction due to the BLM management decisions could impact economic and social conditions through the following indicators:

- Change in economic activity associated with impacts on locatable minerals due to change in the amount of land withdrawn from mineral entry.
- Changes to way of life, culture, social cohesion, and preservation of nonmarket values, including direct and indirect use and non-use values, for mineral development and production communities of interest, those involved in local governments, local residents, and other communities of interest that may value access to mineral resources.

Mineral Materials

Potential changes in mineral materials exploration and extraction due to the BLM management decisions could impact economic and social conditions through the following indicators:

- Change in public access to mineral materials due to changes in the amount of land closed to mineral materials disposal.
- Changes to preservation of nonmarket values, such as access to clean air and water, health and safety impacts, and visitor and viewer enjoyment from changes in air quality associated with potential changes in mineral materials extraction.

Renewable Energy (Geothermal, Wind, and Solar)

Potential changes in renewable energy production and development, including geothermal, wind, and solar, due to the BLM management decisions could impact economic and social conditions through the following indicators:

- Change in economic activity associated with geothermal production and development, as measured by jobs, income, economic output, and tax revenue and payments to the state and counties, that are due to changes in amount of land closed geothermal leasing and open to leasing but subject to NSO, CSU, and TL stipulations and changes in COAs on geothermal development activities on existing and future leased lands for the protection of GRSG.
- Change in economic activity associated with wind and solar due to changes in the amount of land managed as ROW avoidance and exclusion areas.

Change in way of life, culture, visitor and viewer enjoyment, and preservation of nonmarket values, including direct and indirect use and non-use values, for local residents and visitors around renewable energy projects as well as communities of interest that value renewable energy.

Livestock Grazing

Potential changes in livestock grazing due to the BLM management decisions, such as changes in acres of land available for livestock grazing, could impact economic and social conditions through the following indicators:

- Change in economic activity, as measured by jobs, income, and economic output, associated with impacts on billed AUMs.
- Change in economic resilience and stability for ranching and farming communities.
- Changes in way of life, culture, social cohesion, and preservation of nonmarket values, including direct and indirect use and non-use values, associated with livestock grazing for ranchers and farmers and their families, local governments, local residents, and other communities of interest that may value livestock grazing on BLM-administered lands.

Greater Sage Grouse Conservation

Changes in greater sage grouse conservation measures due to the BLM management decisions could impact economic and social conditions through the following indicators:

- Changes to nonmarket values, including direct and indirect use and non-use values, associated with GRSG conservation and healthy sagebrush ecosystems, with particular importance for habitat and resource conservation communities of interest and other communities of interest that value the protection of GRSG for use and non-use values.
- Changes to ecosystem services associated with healthy sagebrush ecosystems.

Environmental Justice

As discussed in Appendix 13, Socioeconomic Baseline Report, and Chapter 3 of this EIS, issues of concern for potential impacts on environmental justice populations were identified (see Appendix 13, Socioeconomic Baseline Report and Section 3.11, Social and Economic Conditions (including Environmental Justice) for more details on the issues of concern). These issues were examined to determine if the BLM-management decisions in each alternative result in adverse and disproportionate impacts on the environment, health, and livelihoods of environmental justice populations.

Assumptions and Methodology

A detailed discussion of the specific methodologies used in the impact analysis is provided in **Appendix 18**, Social and Economic Impact Analysis Methodology. In addition to the assumptions provided in that appendix as well as those provided in **Section 4.1.1**, Analytical Assumptions, this analysis includes the general assumptions described below.

Economic and Social Conditions and Values

- Employment and income (especially labor earnings) would continue to be a driver of economic and population change in the socioeconomic study area.
- Activities and resources available in and around the planning area would continue to be important to the quality of life of current and future residents.
- The pace and timing of mineral development activities is dependent on a variety of factors outside the management decisions of the BLM and Forest Service. These include national and international energy demand and prices, production factors within the planning area, and business strategies of operators. The RFD scenario projects expected rates of well drilling, completion rates, and production decline curves. Together these parameters allow for projection of future oil and gas production volumes for use in the economic impact analysis. Actual economic impacts could vary if development or production deviates from the projections, if prices change, or if the relationships between industry output, intermediate inputs, and labor productivity change.
- The pace and timing of geothermal, wind, and solar energy development activities is also dependent on a variety of factors outside the management decisions of the BLM. These include demand for non-fossil fuel-generated electricity, availability of transmission infrastructure capacity, prices for other energy sources such as coal and natural gas, costs of geothermal, wind and solar energy generation technologies, access and availability of relevant subsidies and incentives, production factors within the planning area, and business strategies of operators. The impacts analysis uses geothermal, wind, and solar deployment scenarios from the RFD. Actual impacts could vary if the rate of development over the study period is different.
- The data collected to calculate projected revenue and well development costs for this impact analysis are based on historical data prior to the passing of the IRA. Revenue and production from new oil and gas leases is expected to change as a result of the changes from the implementation of the IRA, such as the increases in royalty rates and rental rates, which could lead to changes in operational decisions by oil and gas operators.
- While recreation and coal are expected to continue to have impacts on local and regional economic contributions, there are not likely to be impacts on recreation and coal activities and economic contributions across the alternatives from BLM-management decisions related to GRSG. For this reason, economic and social impacts associated with recreation and coal have been dismissed from further analysis. See Section 4.18 and Section 4.9 for more information on BLM-management impacts on recreation and coal, respectively.

- The AMLs for herd management areas are established in RMPs at the outset of planning and adjusted based on monitoring data throughout the life of the RMP. The BLM management decisions could impact wild horses and burros and the ability of herd management areas to support AMLs within the management areas where management options are restricted for the protection of GRSG; however, aside from the initial removal actions of wild horses and burros, there would be no additional impacts to wild horse and burros within herd management areas, under all alternatives. There could be impacts on wild horses and burros outside of herd management areas in OHMA but in adjacent lands that meander in and out of herd management areas and utilize the resources within, because there is potential for removal of resources, particularly water developments. However, these potential changes due to BLM-management decisions are not expected to impact social conditions or access to social values from wild horses through use and non-use values under all alternatives. For this reason, economic and social impacts on wild horses and burros have been dismissed for further analysis. See Section 4.6, Wild Horses, and Burros, for more information on BLM-management impacts on wild horses and burros.
- Economic and social impacts of BLM-management decisions on oil shale and tar sands was dismissed from further analysis due to the limited amount of oil shale and tar sands extraction on federal lands.

Environmental Justice

- Land use planning level decisions do not result directly in development activities. While this analysis looks at impacts on environmental justice populations from potential changes in development activities due to BLM-management decisions, any differences in actual development activities from those included in the discussion below could change the impacts on environmental justice populations. Additional site-specific analyses are required prior to implementation of development activities to determine if and where any disproportionate adverse impacts occur for specific identified environmental justice populations.

10.12.2 Alternative 1

Fluid Minerals (Oil and Gas) Management

Range Wide Environmental Consequences

On annual average, oil and gas production revenue and well development expenditures in the analysis areas is expected to result in a range of about 62,000 to 83,000 total jobs (from 23,000 to 29,000 direct jobs in the drilling oil and gas wells sector and the oil and gas extraction sector), $4.9 billion to $6.7 billion in total labor income (from $2.4 billion to $3.2 billion in direct labor income), and about $26.2 billion to $32.8 billion in economic output (from $18.6 billion to $22.4 billion in direct economic output) combined across 8 states.[2]

A summary of the direct and total average annual number of jobs, labor income, and total economic output that could be supported by projected oil and gas development from 2023 to 2042, under Alternative 1, is provided in **Table 1**, below. **Section 18.4** of **Appendix 18**, Social and Economic Impact and Analysis Methodology and State-Specific Impact Analysis, provides details of the direct and indirect and induced contributions for the analysis area counties combined as well as each state combined, as well as a discussion on the impacts on economic and social conditions for each state in the analysis area with reasonably foreseeable development of oil and gas.

[2] California and Oregon did not have reasonably foreseeable future oil and gas development in the planning area, so they are not included in the discussion.

Table 1. Average Annual Economic Contributions from Oil and Gas, Under Alternative 1

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.

[1] There were no oil and gas developments projected for California and Oregon.

[2] Total impacts include direct, indirect, and induced impacts.

Fiscal revenue is generated on the production of federal minerals at the federal, state, and in some states at the local level. Many western states and local governments are heavily dependent upon these mineral revenues for a significant portion of their annual budgets. For all states in the planning area, BLM decisions on GRSG HMAs, under Alternative 1, are not expected to change tax revenue and public services from current conditions. The total royalty revenue generated from oil and gas production, combined across 8 states, could range from $2.4 billion to $2.8 billion. Oil and gas activity will continue to support revenue from rents and bonus bids, across all states in the analysis area with reasonably foreseeable future oil and gas development. State severance tax revenue could range from about $723 million to $752 million, across 8 states, combined. Local ad valorem taxes could generate a range of about $759 million to $871 million in county revenues, across 3 states with reasonably foreseeable development of oil and gas and that collect ad

valorem taxes, combine. Additionally, revenue from other state-specific fees and taxes, such as Colorado's oil and gas conservation fee, Montana's privilege and license tax, Nevada's Net Proceeds of Minerals Tax, North Dakota's oil extraction tax, Utah's conservation fee, and Wyoming's oil and gas conservation tax, would range from about $25 million to $28 million, consistent with current conditions. Oil and gas activity would also continue to support revenue to state and local governments through sales and use taxes, across all states in the analysis area with reasonably foreseeable future oil and gas development. A quantitative discussion on royalty and state tax revenues for each state is included in **Appendix 18**. For all states in the planning area, BLM decisions on GRSG HMAs, under Alternative 1, are not expected to change social and nonmarket values and conditions such as lifestyles and culture of those communities of interest that value mineral extraction from current conditions.

Under Alternative 1, in most of the planning area PHMA (IHMA in Idaho) fluid mineral leasing would continue to be managed as NSO, except as noted under the state-specific discussion in Appendix 18, for certain areas in Wyoming and GHMA in Idaho, Nevada, and Utah. In the areas managed as NSO, emissions sources and surface disturbing activities would continue to be eliminated, which would reduce impacts on access to clean air, health and safety from changes in air quality and GHG emissions, and visitor and viewer enjoyment from changes in air quality. Fluid mineral development will likely continue in other locations, which would lead to relocation of impacts on the nonmarket and social conditions associated with air quality and GHG emissions.

See **Appendix 18**, Social and Economic Impact Analysis Methodology and State-Specific Impact Analysis, for additional details of impacts for each state in the analysis area with reasonably foreseeable future oil and gas development in the planning area.

Nonenergy Leasable Minerals Management

Under Alternative 1, most of the PHMA and IHMA in the planning area are closed to new leasing of nonenergy leasable minerals but states can consider expansion of existing leases. Across all states in the planning area, there would continue to be economic activity and nonmarket and social values associated with the extraction of federal nonenergy leasable minerals. There could be economic and social impacts, as detailed in **Section 4.2.1**, *Nature and Type of Effects*, due to current BLM decisions regarding access to nonenergy leasable mineral extractions in certain locations, such as Wyoming, where nonenergy leasable minerals are important to the local economies. It is not anticipated that these impacts would be large due to the adaptive management and allowing the Known Sodium Leasing Area to remain open to exploration and consideration for leasing development.

Locatable Minerals Management

Under the 2015 ROD, carried forward as Alternative 1, all states recommended the withdrawal of all SFAs from locatable mineral entry. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA. In 2015, the Secretary proposed to withdraw the SFA lands and a separate process to consider this withdrawal is currently underway. If The Secretary decided to withdraw these lands, there could be impacts on economic activity and social conditions, as discussed in *Nature and Types of Effects*. There could be a decrease in jobs, labor income, and economic output due to the potential decrease in exploration and development. Potential for impacts on access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment from changes in air quality from locatable mineral development would continue in all GHMA and PHMA (IHMA in Idaho), except in all SFAs.

Mineral Materials Management

Under Alternative 1, except in Idaho, as discussed below, PHMA in all other states would be closed to new mineral material sales, but open for new free use permits, and expansion of existing pits for both free use permits and material sales, which would lead to continued impacts on access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment from changes in air quality. Extraction could also take place in other locations outside of GRSG habitat. Given the other opportunities to extract mineral materials in other locations, the impacts on economic activities and social conditions associated with mineral materials is likely to be minimal, under Alternative 1.

Idaho

Under Alternative 1, all PHMA would be closed to mineral material disposal except for the expansion of existing pits, unlike other states, in Idaho this closure extends to new free use permits. Closing PHMA to new free use permits would result in increased costs to local government road departments for road maintenance and could result in worsening road conditions in these areas.

Renewable Energy (Geothermal, Wind, and Solar) Management

Rangewide Environmental Consequences

On annual average, geothermal development, across 7 states in the planning area, is expected to result in about 634 total jobs (about 330 direct jobs), $41.2 million in total labor income (about $20.0 million in direct labor income), and about $120 million in economic output (about $28.4 million in direct economic output).[3]

A summary of impacts on the number of jobs, labor income, and economic output from expenditures on geothermal development for each state in the planning area is included in **Table 2**, below. Details on the direct, indirect, and induced economic contributions as well as a discussion on the impacts on economic and social conditions for each state in the analysis with reasonably foreseeable development of oil and gas are included in **Appendix 18**.

For the 7 states in the planning area that are anticipated to see geothermal development, BLM-management decisions on GRSG HMAs, under Alternative 1, are not expected to change tax revenue and public services from current conditions.

Under Alternative 1, the entire plan area with the exception of Wyoming would limit lands used for ROWs in PHMA (or IHMA in Idaho) and GHMA for Greater Sage-Grouse (see **Appendix 12**, Reasonably Foreseeable Development Scenario, for more detail). These BLM decisions could result in operators relocating development of wind and solar facilities to other locations that are not restricted. If there are constraints on transmission in nearby areas, relocating wind and solar operations might be costly or it might not be possible, because ROW avoidance and exclusion areas would restrict transmission lines as well as renewable energy development. This could result in barriers to development, which could result in impacts on economic contributions of wind and solar. These impacts would more likely occur in Nevada, Oregon, Utah, and Wyoming, where there have been the most wind and solar developed on federal lands. There are various factors that operators use when deciding where to site wind and solar projects that prevent further analysis on state-level impacts on the level of solar and wind development and associated impacts on economic output due to BLM decisions (see **Section 4.9**).

[3] The RFD does not anticipate future geothermal development in Montana, North Dakota, and South Dakota due to limited geothermal potential in the analysis areas.

Table 2. Average Annual Economic Contributions from Geothermal, Under Alternative 1

Source: National Renewable Energy Laboratory 2016
[1]There were no geothermal power plant developments projected for Montana, North Dakota, and South Dakota due to limited geothermal potential in the analysis areas under all alternatives.
[2] Total impacts include direct, indirect, and induced impacts.

Details for impacts on economic and social conditions due to BLM decisions on renewable energy, including geothermal, wind, and solar energy, for each state are included in **Appendix 18**.

Livestock Grazing Management

Rangewide Environmental Consequences

Table 18-7, in **Appendix 18**, shows the average annual number of jobs, labor income, and total economic output that could be supported from projected billed AUMs (total for cattle and sheep), under Alternative 1, for the analysis area counties combined as well as each state combined. On annual average, livestock grazing on allotments where PHMA accounted for at least 15% of the acreage in the analysis areas for all states combined is expected to support about 2,000 total jobs (about 841 direct jobs in the animal production and ranching sectors), $120 million in total labor income (about $67.6 million in direct labor income), and about $380 million in economic output (about $204 million in direct economic output) across all states in the planning area.

Under Alternative 1, PHMA, IHMA, and GHMA would continue to be available for livestock grazing, which would continue to support current levels of economic and social conditions. BLM decisions on GRSG HMAs, under Alternative 1, are not expected to impact social conditions such as lifestyles and culture of ranchers and farmers and those communities of interest that value livestock grazing on public lands, as those impacts described in the *Nature and Types of Effects* (see **Section 4.8**, Livestock Grazing).

A summary of total and direct impacts on the number of jobs, labor income, and economic output from expenditures on livestock grazing for each state in the planning area is included in **Table 3**, below. Details on the direct, indirect, and induced economic contributions as well as a discussion on impacts on economic and social conditions for each state are included in in **Appendix 18**.

[1] Total impacts include direct, indirect, and induced impacts.

Greater Sage Grouse Conservation

Rangewide Environmental Consequences

Management under Alternative 1 to conserve, enhance, and restore sagebrush ecosystems by separating GRSG habitat into SFAs, PHMAs, IHMAs, and GHMAs, would provide protection for GRSG conservation values. BLM decisions would continue to support nonmarket values associated with GRSG conservation, which would especially impact habitat conservation communities of interest (see discussion in *Nature and Type of Effects* and **Section 3.11**, Social and Economic Conditions).

Under Alternative 1, BLM decisions would support the protection of GRSG ecosystems, which would continue to provide value to the surrounding communities through impacts on tribal interests and cultural resources, especially subsistence, from changes in GRSG populations. Habitat conservation could also result in impacts to communities who would benefit from development. Some examples include impacts to road realignment projects near tribal reservations and plans to expand reservation boundaries if the reservation is surrounded by PHMA.

Environmental Justice

Rangewide Environmental Consequences

Under Alternative 1, cultural resources could be impacted by BLM decisions by allowing surface disturbing activities. These impacts on cultural resources would result in disproportionate and adverse impacts on American Indian and Alaska Native populations who value and use these resources. These impacts could occur across all states in the planning area where there are cultural resources and where there are identified environmental justice populations, such as in Colorado, where there are known concentrations of archaeological resources in pinyon-juniper vegetation that provide value to American Indian and Alaska Native populations, and in California and Nevada, where there are traditional pine nutting areas that are valuable to American Indian and Alaska Native populations. Project-specific Section 106 compliance and government-to-government consultation with tribes should mitigate the effects of development on BLM-administered lands outside of sagebrush-dominated areas. See **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Under Alternative 1, surface-disturbing activities could negatively impact subsistence resource availability. This would likely disproportionately impact environmental justice populations due to the importance of subsistence activities to American Indian and Alaska Native populations, low-income populations, and some minority populations. The disturbance cap, under Alternative 1, could help to reduce the impacts to wildlife and subsistence resources, which could reduce impacts on environmental justice populations. These impacts would occur across the planning area. Level of impact would likely vary geographically depending on the level of subsistence use in the region and the location of surface disturbance; a site-specific analysis would be needed to further analyze the impacts. See **Section 4.5**, Fish and Wildlife and **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Under Alternative 1, in most of the planning area PHMA (IHMA in Idaho), except as noted in **Table 4**, below, and discussed under the state-specific subheadings in **Appendix 18** for Idaho, Nevada, Oregon, Utah, and Wyoming, current stipulations and BLM decisions would continue and would likely reduce the impacts on GHG emissions and air quality from particulate matter, risk of wildfire smoke, and surface-disturbing activities. Mineral development will likely continue in other locations, which would lead to relocation of impacts on the nonmarket and social conditions associated with air quality, such as access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment. The impacts on air quality would affect all communities, including environmental justice populations, and the extent to which these impacts would disproportionately affect environmental justice populations would depend on site-specific factors and would require a site-specific analysis. See **Section 4.13**. Air Resources and Climate.

Impacts from BLM-management decisions on environmental justice populations vary by geographic region. Many impacts would require site-specific analyses to determine if BLM decisions would result in disproportionate and adverse impacts on environmental justice populations at a local level. For the purposes of this rangewide EIS, a summary of the number of counties in the analysis area, the number of counties that meet a criteria for containing environmental justice population, and a summary of impacts by state is included in **Table 4**, below, and a more detailed discussion of adverse and disproportionate impacts on environmental justice populations by state is included in **Appendix 18**.[4]

[4] There were no counties in the North Dakota analysis area that met the threshold for environmental justice populations, so North Dakota is not included in the state-by-state discussion.

Table 4. Impacts on Environmental Justice Populations by State, Under Alternative 1

State	Number of Counties in the Analysis Area	Number of Counties that with Populations that meet the Environmental Justice Criteria	Summary of Impacts[1]
California	2	2	Disproportionate and adverse impacts on environmental justice populations could occur from changes in access to subsistence resources.
Colorado	8	7	Disproportionate and adverse impacts on environmental justice populations could occur from changes in access to cultural and subsistence resources.
Idaho	27	25	Same as Colorado. Additionally, disproportionate and adverse impacts on environmental justice populations could occur due to continued impacts on access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment from changes in air quality if there would be an increase in mineral and ROW development and activities in GHMA and IHMA.
Montana	26	18	Same as Colorado.
Nevada	10	10	Similar to Idaho, except disproportionate and adverse impacts could occur if there would be an increase in mineral and ROW development activities in PHMA and GHMA.
Oregon	8	7	Similar to Idaho, except disproportionate and adverse impacts could occur if there would be an increase in mineral and ROW development activities in PHMA, where only utility-scale wind and solar projects would be excluded.
South Dakota	2	1	Same as California.
Utah	23	18	Same as Nevada.
Wyoming	21	15	Same as Nevada.

[1] See Appendix 18 for more details on impacts by state.

10.12.3 Alternative 2

Fluid Minerals (Oil and Gas) Management

Rangewide Environmental Consequences

The number of wells anticipated to be drilled and completed over the planning period would be the same as under Alternative 1 in Montana, Nevada, North Dakota, South Dakota, Utah, and Wyoming, so the market impacts on jobs, labor, income, economic output from oil and gas development and operations would also be the same as described under Alternative 1 for these states (see **Table 5**, below). Under Alternative 2, oil and gas production revenue and well development expenditures are expected to increase in Colorado and Idaho due to BLM-management decisions (see **Section 4.10**, Mineral Resources). On annual average,

this increase is expected to support about 325 more jobs (almost 100 additional direct jobs), about $27 million more in total labor income (about $11.5 million in additional direct labor income), and about $100 million in additional economic output (about $60 million in additional direct economic output) than under Alternative 1, across these two states. Additional details for state-specific direct, indirect, and induced impacts are included in **Appendix 18**.

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.

[1] There were no oil and gas developments projected for California and Oregon.

[2] Total impacts include direct, indirect, and induced impacts.

Mineral development would continue to support federal, state, and local mineral revenues at levels similar to those estimated under Alternative 1, except for impacts in Colorado and Idaho, as described in Appendix 18, which could result in an increase in federal, state, and local revenues, compared with Alternative 1. Changes in mineral revenues available to fund public services and infrastructure in Montana, Nevada, North

Dakota, South Dakota, Utah, and Wyoming would be negligible relative to those under Alternative 1. Across all states in the planning area, compared with Alternative 1, there could be an additional $6.4 to $6.5 million in royalty revenue, $500,000 in state severance tax revenue, $1.7 million in ad valorem tax revenue, and $40,000 in oil and gas conservation fee revenue. Changes in oil and gas activity could lead to an increase in revenue from rents and bonus bids, compared with Alternative 1. Additionally, an increase in oil and gas activity would likely lead to more direct and indirect spending, which would lead to an increase in sales and use tax, compared with Alternative 1.

Under Alternative 2, impacts on nonmarket and social conditions such as impacts on access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment from changes in air quality would be the same as under Alternative 1, except in Colorado as described in **Appendix 18**. Social values in terms of way-of-life, culture, and social cohesion for the communities who value mineral extraction in Montana, Nevada, North Dakota, South Dakota, Utah, and Wyoming would be similar to those described under Alternative 1.

See **Appendix 18** for additional detail of state-level impacts for Colorado and Idaho.

Nonenergy Leasable Minerals Management

Rangewide Environmental Consequences

Under Alternative 2, economic and social impacts from changes in nonenergy leasable minerals due to BLM-management decisions would be the same as under Alternative 1 for all states in the planning area, except Nevada.

Nevada

Nevada added exception criteria to the closure in PHMA, allowing leasing of nonenergy leasable minerals under certain circumstances. This would improve the access of nonenergy leasable minerals in the planning areas compared to Alternative 1, which could improve economic and social conditions associated with nonenergy leasable minerals, such as lifestyle, culture, employment, and economic output, through greater extraction of these mineral resources. However, BLM-management decisions under Alternative 2 could also lead to less access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment from changes in air quality.

Locatable Minerals Management

Rangewide Environmental Consequences

Except for Montana, where recommendation for withdrawal of SFAs language would be as described under Alternative 1, Alternative 2 does not include recommendations for the withdrawal of SFAs from locatable mineral entry. Recommendations for withdrawal have no impact on economic activity.

Under Alternative 2, removing the recommendation for withdrawal of locatable mineral entry in SFA in all states (except in Montana/Dakotas, which did not have a 2019 amendment) would not change impacts on nonmarket and social conditions from changes in air quality and GHG emissions because as discussed under Alternative 1, enacting the recommendation would be separate action and not occur under this RMPA.

Mineral Materials Management

Rangewide Environmental Consequences

Under Alternative 2, impacts on public access to mineral materials and social and nonmarket values associated with mineral material extraction would likely be similar to under Alternative 1, for all states except for Idaho and Nevada.

Under Alternative 2, impacts on nonmarket and social conditions due to changes in air quality and GHG emissions from proposed management of BLM-administered federal mineral estate as closed to or available for saleable mineral sales or disposal in PHMA and GHMA would be the same as under Alternative 1, except in Idaho IHMA and Nevada PHMA as described in the state-specific sub-headings below.

Idaho

Under Alternative 2, PHMA and IHMA would be managed as closed to mineral material sales, however, Idaho would allow consideration of new free use permits. Compared to Alternative 1, this would reduce impacts on road conditions and high road maintenance costs on local governments which would no longer have to transport mineral materials required for road maintenance from outside these areas. Impacts would otherwise be the same as described under Alternative 1.

Under Alternative 2, allowing consideration of new free use permits for saleable minerals in Idaho IHMA, would increase the potential for associated impacts on nonmarket and social conditions due to changes in air quality and GHG emissions compared with Alternative 1. This is because there would be a greater chance for more acres of saleable mineral activities to occur in these areas.

Nevada

Under Alternative 2, Nevada would allow exception criteria to the mineral material disposal closure in PHMA. These criteria could increase the time to get approval for new mineral material sales but would also provide certainty about the conditions under which exemptions would be granted and would reduce social and economic impacts associated with sourcing mineral materials from alternative locations.

Under Alternative 2, adding an exception criterion to saleable and nonenergy mineral closures for Nevada PHMA would increase the potential for associated impacts on nonmarket and social conditions due to changes in air quality and GHG emissions. This is because there would be a greater chance for more area of saleable mineral activities to occur in these areas.

Renewable Energy (Geothermal, Wind, and Solar) Management

Rangewide Environmental Consequences

The number of geothermal plants developed, under Alternative 2, would be the same as those anticipated under Alternative 1 in all states (see **Appendix 12**, Reasonably Foreseeable Development Scenario), so the impacts on economic activity in terms of jobs, labor, income, economic output from future geothermal development would also be the same as those described under Alternative 1 (see **Table 6**, below for a summary of direct and total impacts, and **Table 18-9** in **Appendix 18**, for details on direct, indirect, and induced impacts).

Under Alternative 2, BLM decisions related to ROWs for wind and solar energy would be the same as Alternative 1 for all states, except for Nevada, Utah, and Wyoming). While BLM decisions vary slightly in Nevada, Utah, and Wyoming, the impacts of these decisions on ROWs for wind and solar energy would be minimal due to the projected small change in restricted acres in Nevada and Wyoming and the greater flexibility for infrastructure projects in Utah compared to Alternative 1. This means that for all states, economic contributions from wind and solar energy development would be similar to those under Alternative 1.

Table 6. Average Annual Economic Contributions from Geothermal, Under Alternative 2

State[1]	Type of Impact[2]	Employment	Labor Income	Economic Output
California and Nevada Combined	Direct	276	17,088,024	24,364,445

Source: National Renewable Energy Laboratory 2016
[1]There were no geothermal power plant developments projected for Montana, North Dakota, and South Dakota due to limited geothermal potential in the analysis areas under all alternatives.
[2] Total impacts include direct, indirect, and induced impacts.

Under Alternative 2, impacts on nonmarket and social conditions due to changes in air quality and GHG emissions from changes in GRSG habitat protected from major and minor ROWs and from solar and wind development would be the same as under Alternative 1, except in Nevada for solar energy development and major ROWs, and in Nevada and Utah for wind energy development, as described in the state-specific analysis in **Appendix 18**.

Details for impacts on economic and social conditions due to BLM decisions on renewable energy, including geothermal, wind, and solar energy, by state are included in **Appendix 18**.

Livestock Grazing Management

Rangewide Environmental Consequences

Estimated billed AUMs, under Alternative 2, would be the same as under Alternative 1 for all states and analysis areas, so impacts on economic activity in terms of jobs and income from livestock grazing would also be the same as described under Alternative 1 (see **Table 7**, below, for a summary of direct and total impacts by state, and see **Table 18-10** in **Appendix 18** for direct, indirect, and induced impacts by state). In addition, social impacts in terms of way-of-life, culture, and social cohesion would be similar to those described under Alternative 1.

Impacts on livestock grazing operations and associated non-market values would be similar to those described for Alternative 1.

Table 7. Average Annual Economic Contributions from Livestock Grazing in Allotments where PHMA Accounted for 15% or More of the Acreage, Under Alternative 2

[1] Total impacts include direct, indirect, and induced impacts.

Greater Sage Grouse Conservation

Rangewide Environmental Consequences

Management under Alternative 2 to conserve, enhance, and restore sagebrush ecosystems would have similar impacts on nonmarket and social values of GRSG as those described in Alternative 1. Nonmarket impacts under Alternative 2 would be similar to those described in Alternative 1, with state analysis area specific differences. For GRSG conservation related values, removing SFAs in UT, WY, NV, and ID would reduce protections from development and provide fewer safeguards for nonmarket values associated with self-sustaining populations of GRSG.

Requirements for mitigation that achieves a net conservation gain in all HMA types in MT/DK, NV/CA, and OR, and impacts would be the same as described for Alternative 1. Enforcement of mitigation resulting in no net loss in HMA CO and ID would increase potential impacts to non-market values such as the nonuse values of preserving the species for future generations compared to the net-conservation gain requirements under Alternative 1. In UT and WY, the net conservation gain requirement would be removed, which would increase potential for impacts to conservation related values. Voluntary implementation of compensatory mitigation in CO, ID, NV/CA, OR, UT, and WY HMA, could also increase the potential for impacts on nonmarket values associated with GRSG preservation compared to Alternative 1.

Environmental Justice

Rangewide Environmental Consequences

Impacts on cultural resources under Alternative 2 would be similar to under Alternative 1, except as noted in **Table 8** below for Colorado, Idaho, Nevada, Utah, and Wyoming. **Table 8**, below, provides a summary of the number of counties in the analysis area, the number of counties that meet a criteria for containing environmental justice population, and a summary of impacts by state, and a more detailed discussion of adverse and disproportionate impacts on environmental justice populations by state is included in **Appendix 18**. See **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Table 8. Impacts on Environmental Justice Populations by State, Under Alternative 2

State	Number of Counties in the Analysis Area	Number of Counties that with Populations that meet the Environmental Justice Criteria	Summary of Impacts[1]
Colorado	8	7	Disproportionate and adverse impacts on environmental justice populations could occur from changes in access to cultural resources, due to exposure of PHMAs to potential fluid mineral leasing. Future site-specific implementation analysis would be needed to determine the level and intensity of impacts as well as methods for avoiding, minimizing, and/or compensating for identified impacts. Additionally, disproportionate and adverse impacts on environmental justice populations could occur due to potential impacts on access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment from changes in air quality, compared with Alternative 1.
Idaho	27	25	Similar to Colorado, except the disproportionate and adverse impacts on environmental justice populations could occur from removing SFAs and allowing consideration of new free us permits for saleable minerals. Future site-specific implementation analysis would be needed to determine the level and intensity of impacts as well as methods for avoiding, minimizing, and/or compensating for identified impacts.
Nevada	10	10	Same as Idaho.
Utah	23	18	Same as Idaho. Additionally, disproportionate and adverse impacts on environmental justice populations could occur in areas outside PHMAs that are within 5 miles of leks, which would be avoidance for wind development, due to the potential for impacts on nonmarket and social conditions due to changes in air quality and GHG emissions compared with Alternative 1.
Wyoming	21	15	Same as Idaho. There are protections in place for cultural resources within existing RMPs that would mitigate impacts on environmental justice populations. Future site-specific implementation analysis would be needed to determine the level and intensity of impacts.

Source: US Environmental Protection Agency 2023; US Census Bureau 2023

[1] See Appendix 18 for more details on impacts by state.

Under Alternative 2, impacts on subsistence resources would be similar to those under Alternative 1, except for areas with fewer restrictions on fluid mineral development, and/or more allocable permits for saleable minerals, where subsistence resources would likely be more at risk due to surface disturbance. Impacts on subsistence resources could disproportionately impact environmental justice populations. The extent to which the impacts on subsistence affects environmental justice populations depends on site-specific factors and analysis. See **Section 4.5**, Fish and Wildlife and **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Under Alternative 2, impacts on air quality and GHG emissions would be the same as under Alternative 1, except as noted under the state-specific subheadings below for Colorado, Idaho, Nevada, and Utah. Impacts on air quality from risks of wildfire smoke and fugitive dust, under Alternative 2, would be the same as under Alternative 1. See **Section 4.13**, Air Resources and Climate.

10.12.4 Alternative 3

Fluid Minerals (Oil and Gas) Management

Rangewide Environmental Consequences

On annual average, oil and gas production revenue and well development expenditures in the analysis area for 8 states combined is expected to result in about 17,000 to 29,000 fewer total jobs (about 7,000 to 11,000 fewer direct jobs), about $1.3 billion to $2.3 billion less in total labor income (about $746 million to $1.1 billion less in direct labor income), and about $8.0 billion to $11.6 billion less in economic output (about $6.1 billion to $8.1 billion less in direct economic output) than under Alternative 1. The large changes in economic conditions, under Alternative 3, could lead to higher levels of unemployment and underemployment in some mineral dependent economies. Displaced workers in more diversified economies are likely to have an easier time finding new employment while rural residents may have to commute further for work or may have to consider re-locating out of the area. Those lacking financial resources to either commute further or relocate will be especially impacted.

A summary of the direct and total average annual number of jobs, labor income, and total economic output that could be supported by projected oil and gas development from 2023 to 2042, under Alternative 3, is provided in **Table 9**, below. **Section 18.4.4** of **Appendix 18**, Social and Economic Impact and Analysis Methodology and State-Specific Impact Analysis, provides details of the direct and indirect and induced contributions for the analysis area counties combined as well as each state combined as well as a discussion on the impacts on economic and social conditions for each state in the analysis area with reasonably foreseeable development of oil and gas.

Table 9. Average Annual Economic Contributions from Oil and Gas, Under Alternative 3

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.

[1] There were no oil and gas developments projected for California and Oregon.

[2] Total impacts include direct, indirect, and induced impacts.

Management actions that restrict oil and gas development in PHMA would likely adversely affect fiscal revenues. Under Alternative 3, there could be a reduction in federal royalty revenue by a range of $1.1 billion to $1.4 billion, a reduction in state severance tax revenue by $252 million to $269 million, a reduction in local ad valorem tax revenue by $262 million to $324 million, and a reduction in other state taxes and fees by $4.9 million to $6.4 million (including revenue from Colorado's oil and gas conservation fee, Montana's privilege and license tax, Nevada's Net Proceeds of Minerals Tax, North Dakota's oil extraction tax, Utah's conservation fee, and Wyoming's oil and gas conservation tax). Additionally, the reductions in oil and gas activity due to BLM decisions, under Alternative 3, across all states with reasonably foreseeable future oil and gas developments, could lead to a reduction in revenue from rents and bonus bids, compared with Alternative 1. The reduction in oil and gas activity would also likely lead to less direct and indirect spending, which would lead to a decrease in sales and use tax, compared with Alternative 1. The large decrease in fiscal revenues, under Alternative 3, could contribute to future state and local government budget shortfalls, especially in jurisdictions that rely on the taxation of minerals in place of income taxes or where taxes on mineral production currently represent the single largest source of revenue. These budget shortfalls may affect the ability of states and local governments to maintain infrastructure and provide public services at current levels. Insufficient funding for infrastructure and public services would adversely affect quality of life in affected communities and could further limit rural residents' access to educational opportunities, health care, and social safety net programs.

Under Alternative 3, all PHMA would close all areas in PHMA to mineral and ROW development, and would make PHMA unavailable to livestock grazing, which would reduce potential impacts on nonmarket and social conditions due to changes in air quality and GHG emissions from actions such as surface disturbance from mineral development. Due to closing PHMA, the effects on these nonmarket and social conditions would be the lowest out of the alternatives.

BLM decisions to manage all PHMA as closed to leasing could lead to further impacts on economic and social conditions due to potential changes in oil and gas activity on adjacent nonfederal lands and minerals, as described under the *Nature and Types of Effects*. These impacts would likely occur in areas where the BLM-administered lands are not contiguous, and where it is not economical develop the nonfederal minerals due to limitations on expanding operations across federal and nonfederal minerals, or where pipelines and transmission lines are needed on federal lands to access the nonfederal minerals (see Section 4.10.1, Fluid Minerals (Including Geothermal), for more information on impacts on oil and gas activity on nonfederal minerals and land due to BLM decisions on BLM-administered land). Impacts on economic and social conditions due to changes in oil and gas activity on nonfederal lands include are similar to those described above, and could include reductions in jobs, labor income, economic output, tax revenue, and impacts on social cohesion, way of life, and culture for those communities that rely on mineral development for economic opportunities. If there is a reduction in oil and gas activity on state lands due to BLM decisions on nearby federal lands and minerals, there could be impacts on revenue to the state, which could result in budget shortfalls. Budget shortfalls for the states could adversely impact access and quality of public services, such as education, which is funded by revenue collected from mineral production on state trust lands in states across the analysis area.

See **Appendix 18**, Social and Economic Impact Analysis Methodology and State-Specific Impact Analysis, for additional details of impacts for each state in the analysis area with reasonably foreseeable oil and gas development in the planning area.

Nonenergy Leasable Minerals Management

Rangewide Environmental Consequences

Under Alternative 3, all PHMA would be closed to new nonenergy mineral leasing, which would result in the economic and social impacts. This closure would result in impacts on economic contributions associated with nonenergy mineral extraction, such as reductions in jobs, labor income, economic output, and tax revenue, compared with Alternative 1. The reductions in tax revenues could put strain on local governments' budgets and could impact public services that are offered to the communities. There could be impacts from BLM decisions on lifestyles and culture for those in mineral development communities of interest, especially for those individuals who rely on mineral extraction for employment. These impacts would have a larger effect on communities in northwestern Colorado, in Caribou County, Idaho, central Utah, and southwestern Wyoming, where the local economies have relied on nonenergy leasable mineral extraction on federal estate.

Closures in land to new nonenergy mineral leasing could result in increases in prices in the short term of household products, such as products made from trona due to an increase in cost that would likely occur to mining operators. Restrictions on mineral leasing will likely not result in immediate closures of mines. If restrictions on nonenergy leasing continue in the long term, there could be impacts on the availability of household products made from trona due to the potential continued constraints on nonenergy leasable mineral extractions. Increases in prices and decreases in availability of household products can put large strains on households, especially those with limited resources for alternative products or those with low income, where the products already make up a larger percentage of disposable income. If closures in mines

continue to put pressure on prices and limit availability, it could cause even more stress on the surrounding communities, including increases in conflicts and decreases in social cohesion and health and safety. See **Section 4.10.2**, Nonenergy Leasable Minerals, for more information regarding impacts on trona and other nonenergy leasable minerals due to BLM-Management decisions.

Under Alternative 3, all PHMA would be closed to nonenergy mineral leasing, which would reduce potential impacts on nonmarket and social conditions due to changes in air quality and GHG emissions from actions such as surface disturbance from mineral development, as described under the *Nature and Types of Effects*. Due to closing PHMA, the effects on these nonmarket and social conditions would be the lowest out of the alternatives.

Locatable Minerals Management

Rangewide Environmental Consequences

Under Alternative 3, all lands in PHMA would be recommended for withdrawal from locatable mineral entry. Recommending areas for closure to the mining laws for locatable exploration or development does not restrict any activities and therefore, such recommendation does not have any impacts. However, the BLM could ask the Secretary of the Interior to propose and make a withdrawal of the land from location and entry under the Mining Law of 1872 pursuant to Section 204(a) of FLPMA. Proposing and making a withdrawal is not a land use planning process. Should the Secretary propose a withdrawal, the proposal would require environmental and other analysis under NEPA and other applicable authorities before the land could be withdrawn. For purposes of this planning initiative, the alternatives analysis includes a description of the likely environmental effects should the Secretary propose and make a withdrawal in the future. If the Secretary decided to withdraw the land, such a withdrawal would likely result in a reduction of economic activity in mining sectors, compared with under Alternative 1, as described in the *Nature and Type of Effects*. The reduction in economic activity could result in impacts on market and nonmarket conditions, such as reductions in jobs, labor income, economic output, tax revenue, public services, access to lifestyles and culture associated with mining. For mining operators with existing mining claims that might survive a withdrawal, costs could increase due to the additional requirement to verify mining claim validity before the BLM will approve a notice or plan of operations. These impacts could put strain on communities, especially those that are dependent on the mining industry. These impacts would likely be larger in areas with high potential for locatable mineral development, assuming that there are existing mining claims on those lands as of the date of withdrawal. Such a withdrawal, if made by the Secretary, would not impact nonmarket and social conditions associated with changes in air quality and GHG emissions.

Mineral Materials Management

Rangewide Environmental Consequences

Under Alternative 3, all areas managed for GRSG would be PHMA and would be closed to mineral materials disposal. This would reduce federal, state, territorial, municipality, and non-profit access to mineral materials through free use permits and would increase costs for these users by relocating mineral materials operations to nonpublic lands or to public lands that are further away from where the minerals are going to be used, which would increase transportation costs. The increases in cost of mineral materials extraction could cause delays or cancelations of public projects that use mineral materials, such as road maintenance and construction of infrastructure by states and municipalities. Delays and cancelations in construction and maintenance projects would impact surrounding communities who rely on the roads and infrastructures and could increase public safety concerns and residents' frustration with road construction and repairs. These impacts would likely be larger in areas with high potential for mineral materials extraction. If historical

extraction is an indication of potential, then the analysis areas in Colorado, Idaho, Montana, Nevada, and Wyoming would likely be impacted more by BLM decisions on lands closed to mineral materials disposal.

Under Alternative 3, closing PHMA to mineral materials disposal could reduce potential impacts on nonmarket and social conditions due to changes in air quality and GHG emissions from actions such as surface disturbance, associated with mineral development. However, if mineral materials operations shift to state or private lands due to closing PHMA to mineral materials disposal, then impacts on social conditions and access and quality of nonmarket values would shift to these locations as well and there would be no overall change in impacts on nonmarket and social conditions, compared with Alternative 1.

Renewable Energy (Geothermal, Wind, and Solar) Management

Rangewide Environmental Consequences

Impacts on economic activity from BLM-management decisions that could impact geothermal development, under Alternative 3, are discussed each state with reasonably foreseeable development in **Appendix 18**. Montana, North Dakota, and South Dakota did not have any projected geothermal development in the analysis areas due to the limited geothermal potential. On annual average, across the 7 states with projected geothermal development, geothermal development is expected to result in about 76 fewer total jobs (about 43 fewer direct jobs), $4.3 million less in total labor income (about $2.4 million less in direct labor income), and about $11.5 million less in economic output (about $3.3 million less in direct economic output), compared with Alternative 1 (see **Table 10**, below, for a summary of direct and total impacts by state, and see **Appendix 18** for a more detailed discussion of impacts, including direct, indirect, and induced impacts by state).

Table 10. Average Annual Economic Contributions from Geothermal, Under Alternative 3

State[1]	Type of Impact[2]	Employment	Labor Income	Economic Output
California and Nevada Combined	Direct	276	17,088,024	24,364,445

	Total	558	36,885,507	108,748,475

Source: National Renewable Energy Laboratory 2016

[1]There were no geothermal power plant developments projected for Montana, North Dakota, and South Dakota due to limited geothermal potential in the analysis areas under all alternatives.

[2] Total impacts include direct, indirect, and induced impacts.

Under Alternative 3, there would be the most restrictions on ROWs for wind and solar development out of all alternatives (see **Appendix 12**, Reasonably Foreseeable Development Scenario, for more detail). These BLM decisions could result in operators relocating development of wind and solar facilities to other

non-federal locations. Relocating wind and solar operations might not be feasible in certain locations due to constraints on transmission line availability, and it could be very costly or not possible to develop transmission lines to the nearby area, because ROW avoidance and exclusion areas would apply to transmission lines as well. If additional lines of transmission are needed, this could result in impacts on economic contributions of wind and solar. Under Alternative 3, impacts on economic conditions may be increased compared to Alternative 1 due to the highest level of restrictions on solar and wind site development. There are many factors that operators consider when siting solar and wind development that are not influenced by BLM-management decisions, including resource potential, electricity prices, business decisions, among others. These factors can vary by site, operator, and technology, so a site-specific analysis would need to be conducted to further understand the economic impacts from changes in wind and solar development due to BLM decisions (see **Section 4.9**, Lands and Realty).

Under Alternative 3, all PHMAs would be managed as exclusion areas for major ROWs and wind or solar energy. Prohibiting development of wind, solar, and other major ROWs would eliminate the likelihood for impacts on nonmarket and social conditions from changes in air quality and GHG emissions from surface-disturbing activities in these areas.

Details for impacts on economic and social conditions due to BLM decisions on renewable energy, including geothermal, wind, and solar energy, by state are included in **Appendix 18**.

Livestock Grazing Management

Rangewide Environmental Consequences

Under Alternative 3, all HMA (PHMA) would be unavailable for domestic livestock grazing, which would result in a substantial reduction in forage availability on federal lands. This reduction in forage availability would adversely affect ranching activity, including reducing billed AUMs, market, nonmarket, and social impacts associated with livestock grazing on public lands across communities. On annual average, livestock grazing on allotments where PHMA accounted for at least 15% of the acreage in the analysis areas for all 10 states combined is expected to result in about 2,000 fewer total jobs (about 841 fewer direct jobs), $120 million less in total labor income (about $67.6 million less in direct labor income), and about $380 million less in economic output (about $204 million less in direct economic output), compared with Alternative 1 (see **Table 11**, below, for a summary of direct and total impacts by state, and see **Appendix 18** for a more detailed discussion of impacts, including direct, indirect, and induced impacts by state).

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.
[1] Total impacts include direct, indirect, and induced impacts.

The restrictions on livestock grazing in large portions of federal allotments would impact the economic resilience of ranching and farming communities, as discussed in *Nature and Type of Effects,* especially in areas that are also reliant on mineral development due to the boom and bust economic cycle of the resources.

In many cases, BLM lands may have importance for a broader level of ranch operations, for example when providing important seasonal rotation pastures, and impacts limiting access to livestock grazing on BLM lands can result in large economic and social impacts for affected ranchers. Making PHMA unavailable to livestock grazing could result in increases in costs to ranchers and farmers who would have to find alternatives for federal forage for their livestock. The cost increases may lead to increases in meat prices if passed on to consumers and, in the long term, decreases in availability of meat and animal products. Increases in prices and decreases in availability of meat and animal products could put additional strain on households, especially those with lower incomes in rural areas, where food prices tend to be higher and a larger percentage of their disposable income goes towards food purchases.

Under Alternative 3, BLM decisions to restrict livestock grazing would likely have large market and nonmarket impacts on the local communities and economies across the analysis areas. There could be higher potential for closures of ranches or ranches selling lands to create ranchettes, which could have substantial impacts on social and economic conditions in some surrounding communities. These impacts include impacts on communities' well-being and social cohesion and impacts on access and quality of the ranching lifestyle, culture, and sense of place for those who rely on access to forage from federal land for their farming and ranching operations as well as for those who are part of the farming and ranching communities of interest and value livestock grazing on public lands. The regions that would be disproportionately affected include those communities and economies that rely on the agriculture industry and that have large quantities of small and midsize family farms and ranches where the operators' primary occupation is farming or ranching.[5] These

[5] Small family ranches are those with annual gross cash farm income less than $350,000 and midsize family ranches are those with annual gross cash farm income of at least $350,000 but less than $1 million. See **Section 3.11**, Social and Economic Conditions (Including Environmental Justice) and **Appendix 13**, Socioeconomic Baseline Report for more information on the types of ranches in the analysis area).

small and midsize ranches are located across most of the analysis area in each state of the planning area (see **Section 3.11**, Social and Economic Conditions) and **Appendix 13**, Socioeconomic Baseline Report).

Details for impacts on economic and social conditions due to BLM decisions on livestock grazing by state are included in **Appendix 18**.

Greater Sage Grouse Conservation

Rangewide Environmental Consequences

Alternative 3 would have the highest level of restrictions on development in all HMAs, including the fewest acres open and the most stringent restrictions for mineral extraction. Alternative 3 would also provide the most protection for wildlife and habitat within GRSG management areas because of increased restrictions, and in some cases the prohibition of surface disturbing activities (including mineral development, renewable energy development, and ROW development). Alternative 3 would provide the highest level of support for conservation related values.

BLM decisions, under Alternative 3, would support the protection of GRSG ecosystems, which would continue to provide value to the surrounding communities through impacts on tribal interests and cultural resources, especially subsistence, from changes in GRSG populations. Conversely, habitat conservation could negatively impact road realignment projects near tribal reservations and plans to expand reservation boundaries if the reservation is surrounded by PHMA.

Environmental Justice

Rangewide Environmental Consequences

Alternative 3 would offer the highest level of protection to cultural resources in GRSG habitat across all alternatives. This would result in reduced impacts on environmental justice populations, as those described in Nature and Type of Effects. See **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Adverse impacts on subsistence resource availability, under Alternative 3, would be minimal due to the highest level of restrictions for mineral development and other surface-disturbing activities, compared with Alternative 1. See **Section 4.5**, Fish and Wildlife and **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

The impacts on nonmarket and social conditions due to changes in air quality from mineral exploration and development and surface disturbing activities would substantially reduce, compared with Alternative 1, due to the increase in restrictions on mineral development. This would reduce the impacts on environmental justice populations. Due to restrictions in vegetation management, impacts on air quality from increased wildfire risk could increase. These impacts could disproportionately impact environmental justice populations, but the impacts would depend on site-specific factors such as location of changes in air quality compared with the locations of environmental justice populations that cannot be determined in this analysis. See **Section 4.13**, Air Resources and Climate.

Large swaths of public land would be unavailable for livestock grazing and closed to mineral leasing, which would likely increase production costs to ranchers and nonenergy leasable mineral operators as they use alternative lands for forage and mining operations, if available. Depending on the ability of the affected permittees and mining leases to adapt and mitigate to the loss of public land forage and public lands for mineral leasing, the increases in costs could lead to either higher prices of meat and household products if the costs are passed on to consumers or closures in ranching and mining operations, which would lead to a decrease in availability of meat and household products. These impacts would disproportionately affect low-

income environmental justice populations, because marginal increases in prices of meat and household products make up a larger percentage of the disposable income from low-income households than the general public and low-income households tend to have fewer alternatives if meat and household products become unavailable. The restrictions in livestock grazing and nonenergy leasable mineral development that could lead to impacts on prices and availability are localized and vary across geographic regions. The impacts of meat and household product prices and availability would likely be observed regionally and nationally, especially in areas with higher low-income populations. See subsections in this section on *Nonenergy Leasable Minerals* and *Livestock Grazing* as well as **Section 4.10.2**, Nonenergy Leasable Minerals, and **Section 4.8**, Livestock Grazing.

Restrictions on mineral development in PHMA under Alternative 3 could contribute to budget shortfalls for state and local governments that are highly dependent on mineral revenues, like many counties in Wyoming, and may affect their ability to provide public services. Reductions in public services could adversely affect the quality of life in affected communities. Since some public services are more heavily used by low-income individuals and families, insufficient funding for programs may disproportionately adversely impact low-income populations if access to those services was reduced.

Economic impacts, such as impacts on environmental justice populations from greater restrictions in livestock grazing and mineral and oil and gas development are not included in the discussion on environmental justice. This issue was dismissed from the discussion because, at the time of this analysis, there is a lack of evidence that the types of operations that are most likely to impacted by BLM management decisions (such as mining, renewable energy, and small family-owned ranching and livestock operations) employ a higher percentage of people who meet the criteria for environmental justice. Therefore, there is not evidence that impacts on economic conditions due to BLM decisions will lead to disproportionate impacts on environmental justice populations. Impacts on economic conditions may occur across the analysis area, and these impacts on economic output, jobs, and labor income from changes in livestock grazing, mineral, oil and gas, and renewable energy development activity are discussed and analyzed in other subsections in this section, as it relates to all populations in the analysis area (see the *Fluid Minerals (Oil and Gas), Renewable Energy (Geothermal, Wind, and Solar),* and *Livestock Grazing* subsections). Additional screening and consideration of environmental justice populations and analysis of any disproportionate and adverse impacts will occur at the implementation stage at a scale commensurate with the scope and scale of management actions being considered to provide additional protections for local GRSG populations. Depending on conditions at that time, communities with environmental justice concerns may change.

10.12.5 Alternative 4

Fluid Minerals (Oil and Gas) Management

Rangewide Environmental Consequences

The number of wells drilled and completed would be the same as under Alternative 1 in Montana, Nevada, North Dakota, South Dakota, Utah, and Wyoming, so the impacts on jobs, labor, income, economic output from oil and gas development and operations would also be the same as described under Alternative 1 for these states (see **Table 12**, below). Under Alternative 4, oil and gas production revenue and well development expenditures are expected to increase in Colorado and Idaho due to more areas available for leasing and addition of more exceptions and waivers and oil and gas production revenue and well development expenditures are expected to decrease in Wyoming due to all land in PHMA managed as NSO (see **Section 4.6**, Mineral Resources). On annual average, this change is expected to result in about 5,000 to 6,000 fewer total jobs (about 3,000 fewer direct jobs), about $375 million to $435 million less in total labor income (about $250 million to $274 million less in direct labor income), and about $3.1 million to $2.9

million less in economic output (about $2.4 to $2.5 million less in direct economic output) than under Alternative 1, across these three states. Additional details for state-specific direct, indirect, and induced impacts are included in **Appendix 18**.

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.

[1] There were no oil and gas developments projected for California and Oregon.

[2] Total impacts include direct, indirect, and induced impacts.

Mineral development would continue to support federal, state, and local mineral revenues at levels similar to those estimated under Alternative 1, except for impacts in Colorado, Idaho, and Wyoming, as described in **Appendix 18**, which could lead to an overall decrease in federal, state, and local revenues, compared with Alternative 1. Changes in mineral revenues available to fund public services and infrastructure in Montana, Nevada, North Dakota, South Dakota, and Utah would be negligible relative to those under Alternative 1. Across Colorado, Idaho, and Wyoming, there could be a reduction in royalty revenue by $295

million to $312 million, in state severance tax revenue by $120 million to $121 million, ad valorem tax revenue by $117 million to $121 million, and other taxes and fees by $720,000 to $829,000. Overall changes in oil and gas activity, across the 3 states, could lead to a decrease in revenue from rents and bonus bids, compared with Alternative 1. Additionally, the reduction in oil and gas activity would likely lead to less direct and indirect spending, which would lead to a decrease in sales and use tax, compared with Alternative 1.

Impacts on nonmarket and social conditions associated with changes in air quality and GHG emissions from fluid mineral leasing would be similar to Alternative 1, except in Colorado and Wyoming, as discussed in **Appendix 18**. Alternative 4 would minimize impacts on nonmarket and social conditions associated with air quality and GHG emissions by promoting project designs that avoid, minimize, reduce, rectify, and mitigate for direct and indirect impacts. Social impacts from way-of-life, culture, and social cohesion for the communities who value mineral extraction in Idaho, Montana, Nevada, North Dakota, South Dakota, and Utah would be similar to those described under Alternative 1.

See **Appendix 18** for additional detail of state-level impacts for Colorado Idaho, and Wyoming.

Nonenergy Leasable Minerals Management

Rangewide Environmental Consequences

Under Alternative 4, many of the economic and social impacts from changes in nonenergy leasable minerals due to BLM-management decisions would be the same as under Alternative 1 for all states in the planning area.

Under Alternative 4, the BLM would manage minerals to minimize land use conflict and associated impacts from subsequent development through project designs that avoid, minimize, reduce, rectify, and mitigate for indirect impacts. The BLM would take a more adaptive approach to management and consider existing data and best available science to determine if conservation measures are reasonable. While the impacts on nonmarket and social conditions related to air quality and GHG emissions would be reduced or removed in some cases, compared with Alternative 1, impacts could increase due to an increase in development and surface disturbing activities, compared with Alternative 1.

Nevada/California

In Nevada and northeastern California, exceptions to the nonenergy leasable mineral closure in PHMA under Alternative 1 may allow for increased development of nonenergy leasable minerals, which could lead to impacts on nonmarket and social conditions such as access to clean air, health and safety from changes in air quality and GHG emissions, and reduced visitor and viewer enjoyment from changes in air quality, in some locations.

Locatable Minerals Management

Rangewide Environmental Consequences

Under Alternative 4, there would be no areas recommend for withdrawal from locatable mineral entry. As noted above, recommendations for withdrawal do not restrict any activities; therefore, they have no effects. Similarly, not recommending an area for withdrawal does not have any effects. There would be no impact to jobs, income, economic output and social conditions, as discussed in *Nature and Types of Effects*, under Alternative 4 different from those under Alternative 1.

Mineral Materials Management

Rangewide Environmental Consequences

Under Alternative 4, impacts on public access to mineral materials and social and nonmarket values of mineral material extraction would likely be similar to under Alternative 1, for all states, except for Idaho.

Idaho

In Idaho, under Alternative 4, economic and social impacts from proposed management and impacts on mineral material development would be the same as described under the Alternative 2 *Idaho* section.

Renewable Energy (Geothermal, Wind, and Solar) Management

Rangewide Environmental Consequences

The number of geothermal plants developed would be the same as under Alternative 1 in all states (see **Appendix 12**, Reasonably Foreseeable Development Scenario, for more detail), so the impacts on jobs, labor, income, economic output from geothermal development would also be the same as described under Alternative 1 (see **Table 13**, below, for a summary of direct and total impacts by state, and see **Table 18-15** in **Appendix 18** for direct, indirect, and induced impacts by state).

Table 13. Average Annual Economic Contributions from Geothermal, Under Alternative 4

State[1]	Type of Impact[2]	Employment	Labor Income	Economic Output
California and Nevada Combined	Direct	276	17,088,024	24,364,445
	Total	540	35,982,758	106,272,068

Source: National Renewable Energy Laboratory 2016

[1]There were no geothermal power plant developments projected for Montana, North Dakota, and South Dakota due to limited geothermal potential in the analysis areas under all alternatives.

[2] Total impacts include direct, indirect, and induced impacts.

Utility scale wind and solar projects in PHMA would be managed as ROW exclusion areas, under Alternative 4 (see **Appendix 12**, Reasonably Foreseeable Development Scenario, for more detail). These BLM-management decisions could result in operators relocating development of wind and solar facilities to other locations that are not restricted. However, relocating wind and solar operations might not be possible or feasible, if access to transmission lines is limited, due to the high costs associated with building transmission lines and because ROW avoidance and exclusion areas would impact transmission lines as well. As noted in Alternative 1 discussion, if additional lines of transmission are needed, this could result in impacts on

economic contributions of wind and solar. Under Alternative 4, impacts may be increased compared to the Alternative 1 due to increased restrictions on solar and wind site development due to ROW exclusion areas.

Livestock Grazing Management

Rangewide Environmental Consequences

Estimated billed AUMs, under Alternative 4, would be the same as under Alternative 1 for all states and analysis areas, so market impacts on jobs and income from livestock grazing would also be the same as described under Alternative 1 (see **Table 14**, below, for a summary of direct and total impacts by state, and see **Table 18-16** in **Appendix 18** for direct, indirect, and induced impacts by state). In addition, social impacts from way-of-life, culture, and social cohesion would be similar to those described under Alternative 1.

Impacts on livestock grazing operations and associated non-market values from designating GRSG habitat as HMAs would be similar to those described for Alternative 1.

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.

[1] Total impacts include direct, indirect, and induced impacts.

Greater Sage Grouse Conservation

Rangewide Environmental Consequences

Impacts would be similar to that described in Alternative 1, with some additional state analysis area variation in level of protection for GRSG and associated impacts on those groups prioritizing development or conservation values. The level of impacts to non-market values associated with GRSG would therefore vary by area based on the determination of site-specific development restrictions determined by state.

Environmental Justice

Rangewide Environmental Consequences

Impacts from BLM-management decisions on environmental justice populations through cultural resource disturbance would be similar to Alternative 1. See **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Impacts on subsistence resource availability, could be reduced due to minerals management strategies that reduce possibilities of consequences from potential development in GRSG habitats or giving preference to lands that would not obstruct the suitability and proper operation of GRSG habitats. See **Section 4.5**, Fish and Wildlife and **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Impacts on nonmarket and social conditions from changes in air quality and GHG emissions from mineral development may increase compared with Alternative 1 due to the wavers, exceptions, and modifications that would be allowed under Alternative 4, which could increase mineral extraction. This would likely result in adverse and disproportionate impacts on environmental justice populations. See **Section 4.13**, Air Resources and Climate.

10.12.6 Alternative 5

Fluid Minerals (Oil and Gas) Management

Rangewide Environmental Consequences

The number of wells drilled and completed would be the same as under Alternative 1 in Montana, Nevada, North Dakota, South Dakota, and Utah, so the impacts on jobs, labor, income, economic output from oil and gas development and operations would also be the same as described under Alternative 1 for these states (see **Table 15**, below). Under Alternative 5, oil and gas production revenue and well development expenditures are expected to increase in Colorado and Idaho due to more areas available for leasing and addition of more exceptions and waivers and oil and gas production revenue and well development expenditures are expected to decrease in Wyoming due to all land in PHMA managed as NSO, relative to Alternative 1 (see **Section 4.6**, Mineral Resources). On annual average, this change is expected to result in about 130 to 840 more total jobs (about 150 fewer direct jobs to 50 more direct jobs), about $20 million to $81 million more in total labor income (about $8.5 million less in direct labor income to $15.3 million more in direct labor income), and about $179 million less in total economic output to $46.6 million more in total economic output (about $106 million to $231 million less in direct economic output) than under Alternative 1, across these three states. Additional details for state-specific direct, indirect, and induced impacts are included in **Appendix 18**.

Table 15. Average Annual Economic Contributions from Oil and Gas, Under Alternative 5

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.

[1] There were no oil and gas developments projected for California and Oregon.

[2] Total impacts include direct, indirect, and induced impacts.

Mineral development would continue to support federal, state, and local mineral revenues at levels similar to those estimated under Alternative 1, except for impacts in Colorado, Idaho, and Wyoming, as described in **Appendix 18**. Changes in mineral revenues available to fund public services and infrastructure in Montana, Nevada, North Dakota, South Dakota, and Utah would be negligible relative to those under Alternative 1. Across Colorado, Idaho, and Wyoming, compared with Alternative 1, there could be an reduction in royalty revenue by $11 million to $28 million, a decrease in state severance tax revenue by $17 million to $19 million, a reduction in ad valorem tax revenue ranging from $10 million to $14 million, and an increase in other fees and taxes on oil and gas production by $22,000 to $131,000. Changes in oil and gas activity, under Alternative 5, could lead to a change in revenue from rents, bonus bids, and sales and use tax, compared with Alternative 1. The magnitude and direction of the change in revenue from rents, bonus bids

and sales and use tax depend on state- and site-specific factors (see Appendix 18 for more discussion on these revenues by state for Colorado, Idaho, and Wyoming).

Impacts on nonmarket and social conditions associated with air quality and climate change to the surrounding communities and regions would be similar as described under Alternative 1. Social impacts from way-of-life, culture, and social cohesion for the communities who value mineral extraction in Montana, Nevada, North Dakota, South Dakota, and Utah would be similar to those described under Alternative 1.

See **Appendix 18** for additional detail of state-level impacts for Colorado Idaho, and Wyoming.

Nonenergy Leasable Minerals Management

Rangewide Environmental Consequences

Economic and social impacts from changes in nonenergy leasable minerals due to BLM-management decisions would be the same as under Alternative 1 for all states in the planning area.

Locatable Minerals Management

Rangewide Environmental Consequences

The impacts on the economic activities and social conditions associated with locatable mineral resources would be the same as described under Alternative 4 above.

Mineral Materials Management

Rangewide Environmental Consequences

Impacts on public access to mineral materials and social and nonmarket values of mineral material extraction would likely be the same as under Alternative 4.

Renewable Energy (Geothermal, Wind, and Solar) Management

Rangewide Environmental Consequences

The number of geothermal plants developed would be the same as under Alternative 1 in all states (see **Appendix 12**, Reasonably Foreseeable Development Scenario), so the impacts on jobs, labor, income, economic output from geothermal development would also be the same as described under Alternative 1 (see **Table 16**, below, for a summary of direct and total impacts by state, and see **Table 18-18** in **Appendix 18** for direct, indirect, and induced impacts by state).

Lands encompassing major ROWs and utility scale wind and solar in PHMA would be managed as ROW avoidance areas, while in GHMA they would be managed as open to ROWs. The impacts of BLM decisions on economic activity and market conditions from wind, solar, and transmission line development across all states would be the same as under Alternative 4.

Table 16. Average Annual Economic Contributions from Geothermal, Under Alternative 5

State[1]	Type of Impact[2]	Employment	Labor Income	Economic Output
California and Nevada Combined	Direct	276	17,088,024	24,364,445

Source: National Renewable Energy Laboratory 2016
[1]There were no geothermal power plant developments projected for Montana, North Dakota, and South Dakota due to limited geothermal potential in the analysis areas under all alternatives.
[2] Total impacts include direct, indirect, and induced impacts.

Livestock Grazing Management

Rangewide Environmental Consequences

Estimated billed AUMs, under Alternative 5, would be the same as under Alternative 1 for all states and analysis areas, so impacts on jobs and income from livestock grazing would also be the same as described under Alternative 1 (see **Table 17**, below, for a summary of direct and total impacts by state, and see **Table 18-19** in **Appendix 18** for direct, indirect, and induced impacts by state). Social impacts from way-of-life, culture, and social cohesion would be similar to those described under Alternative 1.

Impacts on livestock grazing operations and associated non-market values from designating GRSG habitat as HMAs would be similar to those described for Alternative 1.

Table 17. Average Annual Economic Contributions from Livestock Grazing in Allotments where PHMA Accounted for 15% or More of the Acreage, Under Alternative 5

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.
[1] Total impacts include direct, indirect, and induced impacts.

Greater Sage Grouse Conservation

Rangewide Environmental Consequences

Impacts would be similar to that described in Alternative 1, with some additional state analysis area variation in level of protection for GRSG and associated impacts on those groups prioritizing development or conservation values. The level of impacts to non-market values associated with GRSG would therefore vary by area based on the determination of site-specific development restrictions determined by state.

Environmental Justice

Rangewide Environmental Consequences

Iimpacts from BLM-management decisions on environmental justice populations through cultural resource disturbance would be similar to Alternative 1. See **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Impacts on environmental justice populations from changes in subsistence resource availability, under Alternative 5, would be similar to Alternative 1. See **Section 4.5**, Fish and Wildlife and **Section 4.17**, Tribal Interests and **Section 4.16**, Cultural Resources.

Impacts on nonmarket and social conditions due to changes in air quality and GHG emissions from mineral development would be minimized by promoting project designs that avoid, minimize, reduce, rectify, and mitigate for indirect impacts. This would reduce the impacts on environmental justice populations, compared with Alternative 1. See **Section 4.13**, Air Resources and Climate.

10.12.7 Alternative 6

All impacts would be the same as described for Alternative 5 except for the impacts described below.

Fluid Minerals (Oil and Gas) Management

The number of wells anticipated to be drilled and completed over the planning period would be the same as under Alternative 5 in all states except for Wyoming, so the market impacts on jobs, labor, income, economic output from oil and gas development and operations would also be the same as described under Alternative 5 for these states (see **Table 18**, below). Under Alternative 6, compared with Alternative 1, oil and gas production revenue and well development expenditures are expected to decrease in Wyoming (see **Section 4.10**, Mineral Resources). On annual average, oil and gas production revenue and well development expenditures in the Wyoming analysis area is expected to result in about 1,400 fewer total jobs (about 600 fewer direct jobs), about $110 million less in total labor income (about $64 million less in direct labor income), and about $717 million less in economic output (about $559 million less in direct economic output),

than under Alternative 1, throughout the state. Additional details for state-specific direct, indirect, and induced impacts are included in **Appendix 18**.

Table 18. Average Annual Economic Contributions from Oil and Gas, Under Alternative 6

State[1]	Type of Impact[2]	Employment		Labor Income		Economic Output	
		Analysis Area	State	Analysis Area	State	Analysis Area	State
Colorado (Low Scenario)	Direct	6,948	6,948	835,579,681	835,579,681	4,210,876,842	4,210,876,842
	Total	19,116	23,572	1,572,945,903	1,999,834,792	6,469,461,097	7,437,254,132
Colorado (High Scenario)	Direct	13,366	13,366	1,607,628,515	1,607,628,515	8,094,956,453	8,094,956,453
	Total	36,759	45,318	3,024,814,147	3,844,614,938	12,436,843,453	14,296,431,664
Idaho	Direct	10	10	576,005	576,005	2,998,007	2,998,007
	Total	20	22	1,128,152	1,214,830	4,871,080	5,178,863
Montana	Direct	1,922	1,922	284,762,972	284,762,972	1,318,085,631	1,318,085,631
	Total	5,046	5,299	467,912,653	484,846,192	1,893,586,767	1,939,453,416
Nevada	Direct	18	18	249,165	249,165	6,374,761	6,374,761
	Total	41	42	2,133,031	2,182,516	11,445,990	11,681,292

	Total	72,726	83,463	5,774,526,641	6,759,888,606	30,474,089,534	32,720,307,858

Source: IMPLAN 2021 Data for model region including counties in the socioeconomic analysis area in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming as well as for all counties in the state using the multi-regional input-output analysis.

[1] There were no oil and gas developments projected for California and Oregon.

[2] Total impacts include direct, indirect, and induced impacts.

The decrease in projected oil and gas activity in Wyoming, under Alternative 6, would result in reductions in tax revenues by about $69 million in royalty revenue, $25 million in state severance tax revenue, $26 million in ad valorem tax revenue, and $208,000 in and gas conservation tax revenue, compared with Alternative 1. Additionally, a reduction in oil and gas activity, in Wyoming, under Alternative 6, could lead to a decrease in revenue from rents, bonus bids, and sales and use taxes, compared with Alternative 1. The reductions in tax revenues could put strain on local governments' budgets and could impact public services that are offered to the communities, including education. There could be impacts from BLM decisions on

lifestyles and culture for those in mineral development communities of interest, especially for those individuals who rely on oil and gas extraction for employment.

The reduction in the acreage available for fluid mineral leasing, in Wyoming, could reduce the development-related impacts on nonmarket and social conditions associate with changes in air and GHG emissions, compared with Alternative 1.

Nonenergy Leasable Minerals Management

Impacts would be the same as described under Alternative 5 except that any existing nonenergy leasable operations within ACECs would not be able to expand on federal mineral estate and no new operations would be permitted in ACECs. This limitation on expansion and new operations would result in the economic and social impacts. The impacts would be limited to areas within ACECs.

Locatable Minerals Management

Under Alternative 6, requiring a plan of operations for exploration operations disturbing five acres or less in ACECs would increase administrative process and cost for operators conducting exploration. This could result in a reduction in exploration in ACECs which could lead to a reduction in development and production in these areas as well. If this results in a reduction development, there could be impacts on economic and social conditions in the surrounding communities.

Mineral Materials Management

Restrictions on mineral material development in ACECs could result in impacts on economic and social conditions. Due to mineral materials being available in other locations, the impacts are not anticipated to be large.

10.13 Air Resources and Climate

10.13.1 Air Quality

Methodology

Implementation of GRSG conservation measures may indirectly impact air quality, following the assumption that existing operations would remain unchanged and could continue to affect air quality. Future air impacts will be directly evaluated during their individual NEPA processes and air quality impacts will remain unchanged until a project is implemented. The air quality impact analysis focuses on how changes in allowable uses under each alternative would impact air pollution. The types of actions that can result in impacts on air quality are discussed in more detail in **Section 4.13.1**, Nature and Type of Effects.

The analysis assumes that oil and gas development would be the dominant source of criteria air pollutant and HAP emissions and impacts on air quality from BLM-authorized activity in the planning area; therefore, overall impacts are assessed using emission estimates from oil and gas development. The BLM has conducted the 2032 Western US Photochemical Air Quality Modeling study to assess the impacts of fossil fuel development and production and other cumulative sources on air quality and air quality related values in BLM-administered lands in the seven US intermountain western states (Colorado, Montana, New Mexico, North Dakota, South Dakota, Utah, and Wyoming. Modeling results represent emission sources for year 2032 based on anticipated future oil, gas, and coal development, other human-caused (anthropogenic) emissions, and natural sources on air quality and air quality related values such as visibility and deposition (Ramboll 2023). Quantitative estimate of average annual emissions under each alternative from federal oil and gas development are shown in **Table 4-1**; these were estimated by scaling circa 2032 modeled emissions in states that overlap with the planning area (Ramboll 2023; see **Appendix 12, Section 12.11**, Air Pollutant and Greenhouse Gas Emission Calculation).

Analysis of impacts from other activities including from other mineral development (saleable and locatable minerals), solar and wind energy development, ROWs, traffic and road construction, and livestock grazing is discussed qualitatively. Potential impacts on air quality from implementing Alternatives 2, 3, 4, 5, and 6 are qualitatively compared to Alternative 1, as the No Action Alternative, to determine what changes, if any, can be expected to air quality under each alternative.

Indicators

Indicators of impacts on air quality are as follows:

- Tons of annual criteria air pollutant emission changes from oil and gas development.
- Acres closed to nonenergy solid mineral leasing, mineral entry, and sale or disposal of mineral material resources.
- Area of land with the potential for disturbance due to solar and wind energy development and associated facilities, and from other major and minor ROWs.
- Amount of road traffic from construction, daily operation, and road maintenance.
- Changes in the level of livestock grazing, supporting activities, and range maintenance.
- A substantial change in the likelihood or severity of wildland fire (based on level of restrictions on uses that may introduce sources of ignition)

Assumptions

In addition to the assumptions in **Section 4.1.1**, Analytical Assumptions, this analysis includes the following assumptions:

- Air resource impacts can be localized or regional.
- Weather-related events and wildfires may cause or contribute to local or regional air resource impacts.

Alternative 1

Rangewide Environmental Consequences

Under Alternative 1, in most of the planning area PHMA (IHMA in Idaho), except as noted under the state-specific sub-headings below, fluid mineral leasing would continue to be managed as NSO. While this would continue to eliminate emission sources in PHMA (IHMA in Idaho), impacts could be relocated within the planning area, and continue to impact air quality as described in the *Nature and Types of Effects*. Fluid mineral development and production would continue to be the primary source of emissions from BLM-authorized activity in the planning area. Under Alternative 1, potential emissions from oil and gas development in the Greater Sage-Grouse planning area represent 0.19% of annual carbon monoxide, 3.11% of nitrogen oxide, 0.03% of PM_{10}, 0.08% of $PM_{2.5}$, 3.15% of sulfur dioxide, and 1.49% of VOC emissions from the planning area counties. For more detail on average annual emission estimates for each state see **Table 4-1.**

Under Alternative 1, except as noted under the state-specific sub-headings below, potential impacts on air quality from proposed management of BLM-administered federal mineral estate as closed to or available for saleable mineral sales or disposal within the planning area GHMA where there is no specific allocation, and within PHMA (IHMA in Idaho) from new free use permits and expansion of existing leases would continue.

Under Alternative I, potential for impacts on air quality from locatable mineral development would continue in all GHMA and PHMA (IHMA in Idaho).

Under Alternative 1, except as noted under the state specific sub-heading below, potential impacts on air quality from major and minor ROWs in PHMA/IHMA and GHMA, where it would continue to be managed as avoidance for major ROWs and open to minor ROWs, would continue. Under Alternative 1, except as noted under the state-specific sub-headings below, wind and solar development would continue to be managed as avoidance in GHMA and as exclusion in PHMA (IHMA in Idaho). This would continue to reduce potential impacts on air quality associated with emissions and surface-disturbing activities in GHMA and eliminate sources of impacts on air quality in PHMA, as described in the *Nature and Types of Effects*.

Under Alternative 1, impacts on air quality from changes in livestock grazing would continue in PHMA (IHMA in Idaho) and GHMA across the planning area. Impacts would continue to largely be determined by variations in site-specific management actions that minimize surface-disturbing actions. These management actions would continue to indirectly reduce impacts on air quality from changes in livestock grazing described in the *Nature and Types of Effects*.

Colorado Environmental Consequences

Under Alternative 1, Colorado GHMA would continue to be managed as closed to fluid mineral leasing within 1 mile of leks, NSO within 2 miles of leks, and seasonal limitations elsewhere, and PHMA would continue to be closed to fluid mineral leasing within 1 mile of leks. While in areas that remain as closed or as open with NSO stipulations for fluid mineral leasing, sources of impacts on air quality would be removed, impacts may be relocated to elsewhere within the planning area where fewer restrictions on fluid mineral leasing exists.

Idaho Environmental Consequences

Under Alternative 1, fluid mineral leasing would continue to be managed as NSO in Idaho IHMA and as CSU in GHMA. Within GHMA, potential for impacts on air quality from fluid mineral leasing would continue to exist while in areas that remain designated NSO for fluid mineral leasing, emissions sources would be eliminated. However, the potential for displacement of impacts to elsewhere within the planning area where fewer restrictions on fluid mineral leasing exist would continue.

Under Alternative 1, potential impacts on air quality from proposed management of BLM-administered federal mineral estate as closed to or available for saleable mineral sales or disposal would continue to exclude impacts from new free use permits and continue to be limited to impacts from expansion of existing permits.

Under Alternative 1, potential for impacts on air quality from wind, solar, and other major ROWs would continue within GHMA in Idaho where it would continue to be open to such use. Potential for impacts on air quality from solar and wind development in Idaho IHMA, where it would continue to be managed as avoidance for solar and wind development and only excluded for utility scale projects, would continue to be higher compared with PHMA in other planning area states.

Nevada/California Environmental Consequences

Under Alternative 1, potential for impacts on air quality from fluid mineral leasing would continue in Nevada and California GHMA where it would continue to be open to fluid mineral leasing, subject to CSU stipulations.

Under Alternative 1, potential for impacts on air quality from solar and wind projects would continue to exist in Nevada and California PHMA from non-utility-scale solar and wind, and from major ROWs or wind projects in GHMA, which would continue to be managed as avoidance. No air quality impacts from solar

development within the Nevada and California PHMA would occur, where it would continue to be managed as exclusion for solar projects.

Oregon Environmental Consequences

Under Alternative 1, while potential for impacts on air quality from fluid mineral leasing within 1 mile of leks would continue to be eliminated, potential for impacts outside of the 1-mile radius, where it would continue to be open to fluid mineral leasing and subject to CSU stipulations, would continue to exit.

Under Alternative 1, potential for impacts on air quality from solar and wind projects would continue in Oregon PHMA, where it would continue to be managed as avoidance for solar and wind development and only excluded for utility scale projects (except in Lake, Harney, and Malheur Counties where it is avoidance and impacts could occur within PHMA).

Utah Environmental Consequences

Under Alternative 1, potential impacts on air quality from fluid mineral leasing in Utah GHMA would continue, where it would continue to be managed as NSO near leks or CSU based on allocations in plans that predated the 2015 amendment. While in areas that remain designated as NSO for fluid mineral leasing, sources of impacts on air quality would be removed, impacts may be relocated to elsewhere within the planning area, where fewer restrictions on fluid mineral leasing exists. In areas open to fluid mineral leasing with CSU stipulations, potential for impacts on air quality would continue to exist.

Under Alternative 1, GHMA in Utah would continue to be open to wind and other major ROWs (subject to minimization and mitigation), which would continue to result in air quality impacts that are associated with emissions and surface-disturbing activities. Under Alternative 1, potential for impacts on air quality from wind projects would continue to exist in PHMA in Utah to within 5 miles of leks.

Wyoming Environmental Consequences

Under Alternative 1, in Wyoming, GHMA would be managed as NSO within 0.25 miles of leks, and seasonal limitations within 2 miles of leks, while PHMA would continue to be managed as NSO within 0.6 miles of leks and as CSU or with timing limitations outside. While in areas that remain designated as NSO for fluid mineral leasing, sources of impacts on air quality would be removed, impacts may be relocated to elsewhere within the planning area, where fewer restrictions on fluid mineral leasing exists. In areas open to fluid mineral leasing with CSU stipulations or timing limitations, potential for impacts on air quality would continue to exist.

Under Alternative 1, potential impacts on air quality from proposed management of BLM-administered federal mineral estate as closed to or available for saleable sales or disposal would continue to exist within PHMA in Wyoming, where it would continue to be managed as open, subject to occupancy, seasonal limitations, disturbance, and density for such use.

Under Alternative 1, potential impacts on air quality would continue to exist from major and minor ROWs, and from solar and wind development, in Wyoming PHMA, where it would be open to such use.

Alternative 2

Rangewide Environmental Consequences

Under Alternative 2, impacts on air quality from closure to leasing or stipulations applied to fluid mineral leasing in PHMA and GHMA would be the same as under Alternative 1, except in Colorado as described under the state-specific sub-heading below.

Under Alternative 2, impacts on air quality from proposed management of BLM-administered federal mineral estate as closed to or available for saleable mineral sales or disposal in PHMA and GHMA would be the same as under Alternative 1, except in Idaho IHMA and Nevada PHMA as described in the state-specific sub-headings below.

Under Alternative 2, removing the recommendation for withdrawal of locatable mineral entry in SFA in all states (except in Montana/Dakotas, which did not have a 2019 amendment) would not change impacts on air quality because as discussed under Alternative 1, recommending areas for closure to the mining laws for locatable exploration or development does not restrict any activities and therefore, such recommendation does not have any impacts. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Under Alternative 2, impacts on air quality from changes in GRSG habitat protected from major and minor ROWs and from solar and wind development would be the same as under Alternative 1, except in Nevada for solar energy development and major ROWs, and in Nevada and Utah for wind energy development, as described in the state-specific sub-headings below.

Under Alternative 2, impacts on air quality from changes in livestock grazing would be similar to those described under Alternative 1. However, there would be more exceptions to restrictions on livestock grazing than under Alternative 1, which could result in increased potential localized impacts on air quality in PHMA or IHMA.

Colorado Environmental Consequences

Under Alternative 2, PHMAs in Colorado would be designated as NSO for fluid mineral development. Compared with Alternative 1, under which areas within 1 mile of leks would remain closed to fluid mineral leasing, this would increase potential impacts on air quality. Compared with Alternative 1, changing GHMA from closed to fluid mineral leasing within 1 mile of leks and NSO within 2 miles of leks under Alternative 1 to NSO within 1 mile of leks under this alternative would likely result in an increase in air emissions because the amount of federal mineral estate available for leasing and development would be greater under this alternative. Under Alternative 2, annual emissions from fluid mineral leasing would increase on average by 0.7% compared with Alternative 1.

Idaho Environmental Consequences

Under Alternative 2, allowing consideration of new free use permits for saleable minerals in Idaho IHMA, would increase the potential for associated impacts on air quality compared with Alternative 1. This is because there would be a greater chance for more acres of saleable mineral activities to occur in these areas.

Nevada/California Environmental Consequences

Under Alternative 2, adding an exception criterion to saleable and nonenergy mineral closures for Nevada PHMA would increase the potential for associated impacts on air quality. This is because there would be a greater chance for more area of saleable mineral activities to occur in these areas.

Under Alternative 2, there would be an exception criterion avoidance for ROWs and to the closure to wind and solar development in Nevada PHMA and to wind development in Nevada/California GHMA. Compared with Alternative 1, this could increase the potential for impacts on air quality associated with changes in land protected from or open to renewable energy development because there would be a higher chance of development. However, the exception criteria would likely avoid impacts on air quality.

Utah Environmental Consequences

Under Alternative 2, areas outside PHMAs that are within 5 miles of leks in Utah would be avoidance for wind development. This could increase the potential for impacts on air quality associated with changes in land protected from wind development compared with Alternative 1. This is because there would be a higher chance of development in an avoidance area as opposed to an exclusion area that includes an exception criterion to closure.

Alternative 3

Rangewide Environmental Consequences

Under Alternative 3, closing PHMA to fluid mineral leasing, saleable mineral sales and disposal, and nonenergy mineral leasing would reduce potential impacts on air quality from actions such as surface disturbance, associated with mineral development as described under the *Nature and Types of Effects*. Effects would be reduced compared with Alternative 1. The recommendation to withdraw all PHMA from location and entry under the US mining laws would not impact air quality because considering whether to withdraw certain lands is a separate action with its own NEPA analysis.

New infrastructure development would be substantially limited compared with Alternative 1. Under Alternative 3, prohibiting development of wind, solar, and other major ROWs would eliminate the likelihood for impacts on air quality from changes in land protected from or open to such surface-disturbing activities in these areas.

Compared with Alternative 1, Alternative 3 contains greater restrictions on other resources and would most greatly reduce the potential for impacts on air quality from changes in land protected from or open to livestock grazing as described under the *Nature and Type of Effects*. However, removing grazing may result in the accumulation of fine fuels, potentially leading to wildfires that could impact air quality.

Colorado Environmental Consequences

Under Alternative 3, annual emissions from fluid mineral leasing in Colorado would on average decrease by 27.7%, compared with Alternative 1.

Montana Environmental Consequences

Under Alternative 3, annual emissions from fluid mineral leasing in Montana would on average decrease by 40.5%, compared with Alternative 1.

North Dakota Environmental Consequences

Under Alternative 3, annual emissions from fluid mineral leasing in North Dakota would on average decrease by 15.4%, compared with Alternative 1.

South Dakota Environmental Consequences

Under Alternative 3, annual emissions from fluid mineral leasing in South Dakota would on average decrease by 1.2%, compared with Alternative 1.

Utah Environmental Consequences

Under Alternative 3, annual emissions from fluid mineral leasing in Utah would on average decrease by 9.8%, compared with Alternative 1.

Wyoming Environmental Consequences

Under Alternative 3, annual emissions from fluid mineral leasing in Wyoming would on average decrease by 38.0%, compared with Alternative 1.

Alternative 4

Rangewide Environmental Consequences

Under Alternative 4, impacts on air quality from fluid mineral leasing would be similar to Alternative 1. Under Alternative 4, impacts on air quality from management of BLM-administered federal mineral estate as closed to or available for saleable mineral sales or disposal, would be the same as under Alternative 1, except in some states as discussed under state-specific subheadings below.

Under Alternative 4, PHMA in all states, and IHMA to within 3.1 miles from active leks, would be managed as exclusion for utility-scale wind and solar energy projects. Therefore, no air quality impacts from utility-scale wind or solar projects would be expected in those areas, similar to IHMA in Idaho, and PHMA in Nevada/California and Oregon (except in Lake, Harney, and Malheur Counites where potential for impacts remain, because it would be managed as avoidance under Alternative 1). Under Alternative 4, potential for impacts on air quality from utility-scale solar or wind development would be less than the potential for impacts from construction of such projects in Wyoming and Utah under Alternative 1, where the management action is either avoidance, or exclusion with exception criterion.

Under Alternative 4, site-specific management actions would continue to have impacts on air quality resulting from changes in livestock grazing as described under the *Nature and Type of Effects*. The emphasized flexibility under Alternative 4, compared to Alternative 1, would help ensure that grazing practices remain in compliance with established guidelines, reducing impacts on air quality compared with Alternative 1.

Colorado Environmental Consequences

Under Alternative 4, annual emissions from fluid mineral leasing in Colorado would on average increase by 4.1%, compared with Alternative 1.

Wyoming Environmental Consequences

Under Alternative 4, annual emissions from fluid mineral leasing in Wyoming would on average decrease by 19.9%, compared with Alternative 1.

Alternative 5

Rangewide Environmental Consequences

Under Alternative 5, impacts on air quality from mineral development would be similar to Alternative 1, except in some states as discussed under state-specific subheadings below. Under Alternative 5, PHMA would be designated as avoidance for utility-scale wind and solar projects, prioritizing the protection of GRSG habitat and, in turn, reducing the impacts on air quality as described under the *Nature and Type of Effects*. In contrast, GHMA would remain open for utility-scale wind and solar development, accompanied by specific minimization measures to mitigate potential impacts on air quality as described under the *Nature and Type of Effects*.

The measures under Alternative 5, compared with Alternative 1, would improve disturbance management and mitigate potential degradation, which could have long-term benefits on air quality conditions for GRSG's sagebrush habitat across different states and specific boundaries.

Under Alternative 5, like Alternative 1, livestock grazing would generally remain available in PHMA, IHMA, and GHMA for GRSG, except for certain RNAs in Oregon that may be partially or entirely unavailable for grazing. Changes in livestock grazing would be determined by site-specific management actions aiming to decrease surface disturbance activities which would have impacts on air quality as described under the *Nature and Types of Effects*.

Alternative 5 introduces a targeted approach for the inclusion of thresholds and responses. which, compared with Alternative 1, would focus efforts on the priority areas, promoting the establishment of suitable habitat and thus minimizing impacts on air quality by reducing land disturbance as described under the *Nature and Type of Effects*.

Colorado Environmental Consequences

Under Alternative 5, annual emissions from fluid mineral leasing in Colorado would be the same as Alternative 4.

Wyoming Environmental Consequences

Under Alternative 5, annual emissions from fluid mineral leasing in Wyoming would on average decrease by 3.3%, compared with Alternative 1.

Alternative 6

Rangewide Environmental Consequences

Under Alternative 6, impacts on air quality would be similar to Alternative 5, except in some states as discussed under state-specific subheadings below. ACECs under Alternative 6 would restrict some uses, in accordance with the ACEC boundaries and restrictions under Alternative 3, which could reduce potential sources of pollutants.

Wyoming Environmental Consequences

Under Alternative 6, annual emissions from fluid mineral leasing in Wyoming would on average decrease by 3.9%, compared with Alternative 1.

10.13.2 Climate Change and Greenhouse Gases

Methodology

Impacts to climate change depend on changes in emission of GHGs and carbon sequestration of the land. GHG emissions from oil and gas development (**Table 4-2**) was estimated by scaling the circa 2032 modeled emissions for states that overlap with the planning area (Ramboll 2023; see **Appendix 12, Section 12.11**, Air Pollutant and Greenhouse Gas Emission Calculation). Grazing emissions were estimated by evaluating methane emissions from enteric fermentation and manure management, and nitrous oxide emissions from manure deposited on rangeland according to methodologies included in USDA guidelines (USDA 2023), and the 2019 Refinement to the 2006 IPCC Guidelines for National Greenhous Gas Inventories, Volume 4, Agriculture, Forestry and Other Land Use (IPCC 2019). Grazing emissions were based on the 5-year averaged billed AUM values in each state (see Table 3-10 in **Appendix 14**, Socioeconomic Baseline Report). Potential impacts on climate change from implementing Alternatives 2, 3, 4, 5, and 6 are compared to Alternative 1, as the No Action Alternative, to determine what changes, if any, can be expected to GHG emissions or carbon sequestration under each alternative.

Indicators

Indicators of impacts of climate change include:

- Acres closed or subject to stipulations on fluid mineral leasing, and potential changes in oil and gas production.
- Acres closed to nonenergy solid mineral leasing, locatable mineral entry, and sale or disposal of mineral material resources.
- Area of land managed as open, exclusion, or avoidance areas for renewable energy development and ROWs (e.g., transmission lines).
- Level of road traffic from daily travel and amount of road maintenance and construction activities.
- Changes in permitted AUMs and level of livestock grazing supporting activities (e.g., rangeland improvement or livestock transportation).
- A substantial change in the likelihood or severity of wildland fire (based on level of restrictions on uses that may introduce sources of ignition)

Assumptions

In addition to the assumptions in **Section 4.1.1**, Analytical Assumptions, this analysis assumes wild horses and burros, wild ungulates, livestock, and wildlife species all contribute similar GHG emissions.

Alternative 1

Rangewide Environmental Consequences

Except as noted under the state-specific subheading below, in most of the planning area PHMA (IHMA in Idaho), fluid mineral leasing would continue to be managed as NSO. While this would continue to eliminate emission sources and improve carbon sequestration in PHMA (IHMA in Idaho), development could be relocated within the planning area, and continue to result in increased GHG emissions and changes to carbon sequestration.

Under Alternative 1, potential emissions from oil and gas development in the Greater Sage-Grouse planning area represent 0.03% of state-wide GHG emissions in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming (29,436 million metric tons of CO_2e; **Table 3-18**). Social cost of GHGs from oil and gas development for the 20-year life of the project would be 2,263 million dollars (2020 dollars) at the 5% discount rate and 7,179 million dollars at 3% discount rate calculated using methodology developed by the Interagency Working Group on Social Cost of Greenhouse Gases (IWG 2021).

Except as noted below, potential impacts on GHG emissions and carbon sequestration from management of BLM-administered federal mineral estate as closed to or available for saleable mineral sales or disposal within the planning area GHMA where there is no specific allocation, and within PHMA (IHMA in Idaho) from new free use permits and expansion of existing leases would continue.

Potential for impacts on GHG emissions and carbon sequestration from locatable mineral development would continue in all GHMA and PHMA (IHMA in Idaho).

Most states would continue to manage PHMAs (or IHMA in Idaho) as avoidance areas for major ROWs, and exclusion for wind and solar ROWs (Idaho, Nevada/California, and Oregon have exclusion for utility scale solar and wind projects only). In most states, GHMAs would continue to be managed as either avoidance or open for major ROWS, wind, and solar projects. In exclusion areas which do not allow for ROWs, there would be no impacts on GHG emissions or changes to carbon sequestration. In avoidance

areas, while the potential for impacts would remain, this would be less than the potential for impacts in areas that would remain open to ROWs or have fewer restrictions.

Restrictions on surface-disturbing activities on BLM lands, including mineral development and ROWs, might push development onto private land, which could result in indirect impacts as described under *Nature and Types of Effects*.

Impacts on GHG emissions and carbon sequestration from changes in livestock grazing would continue to largely be determined by variations in AUMs and site-specific management actions that involve surface-disturbing actions. Under Alternative 1, livestock grazing would result in 24,400 metric tons of methane and from enteric fermentation and manure management and 19,782,000 metric tons of nitrous oxide from direct and indirect emissions due to manure deposited on rangeland. This would result in 5,401 million metric tons of 100-year CO_2e and 5,402 million metric tons of 20-year CO_2e, representing 18% of total GHG emissions from state-wide grazing emissions in California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming. Social cost of GHGs for the 20-year life of the project would be 1,960,000 million dollars at the 5% discount rate and 6,886,000 million dollars at 3% discount rate (IWG 2021).

Management actions that would continue to indirectly reduce impacts on climate change from changes in livestock grazing include managing for riparian vegetation, applying the principles of prescriptive livestock grazing to control time and timing of grazing during the hot season, and retiring grazing privileges on a voluntary basis.

Impacts on GHG emissions and carbon sequestration from changes in wild horse and burro management would continue to largely be determined by variations in AMLs and site-specific management actions that involve surface-disturbing actions. Management actions that would continue to indirectly reduce impacts on climate change from changes in wild horse and burro management include implementing wild horse and burro gathers and fertility treatments.

Colorado Environmental Consequences

Colorado GHMA would continue to be managed as closed to fluid mineral leasing within 1 mile of leks, NSO within 2 miles of leks, and seasonal limitations elsewhere, while PHMA would continue to be closed to fluid mineral leasing within 1 mile of leks. Emission sources and impacts to carbon sequestration could be displaced and would continue to result in overall impacts on climate change.

Idaho Environmental Consequences

Fluid mineral leasing would continue to be managed as NSO in Idaho IHMA and as CSU in GHMA. Within GHMA. Emission sources and impacts to carbon sequestration could be displaced and would continue to result in overall impacts on climate change.

Potential impacts on GHG emissions and carbon sequestration from management of BLM-administered federal mineral estate as closed to or available for saleable mineral sales or disposal would continue to exclude impacts from new free use permits and continue to be limited to impacts from expansion of existing permits.

Potential for impacts on GHG emission and carbon sequestration from wind, solar, and other major ROWs would continue within GHMA in Idaho where it would continue to be open to such use. Potential for impacts on GHG emissions and carbon sequestration from solar and wind development in Idaho IHMA, where it

would continue to be managed as avoidance for solar and wind development and only excluded for utility scale projects, would continue to be higher compared with PHMA in other planning area states.

Nevada/California Environmental Consequences

Potential for impacts on GHG emissions and carbon sequestration from fluid mineral leasing would continue in Nevada and California GHMA where it would continue to be open to fluid mineral leasing, subject to CSU stipulations.

Potential for impacts on GHG emissions and carbon sequestration from solar and wind projects would continue to exist in Nevada and California PHMA from non-utility-scale solar and wind, and from major ROWs or wind projects in GHMA, which would continue to be managed as avoidance. No impacts from solar development within the Nevada and California PHMA would occur, where it would continue to be managed as exclusion for solar projects.

Oregon Environmental Consequences

While potential for impacts on GHG emissions and carbon sequestration from fluid mineral leasing within 1 mile of leks would continue to be eliminated, potential for impacts outside of the 1-mile radius, where it would continue to be open to fluid mineral leasing and subject to CSU stipulations, would continue to exit.

Potential for impacts on GHG emissions and carbon sequestration from solar and wind projects would continue in Oregon PHMA, where it would continue to be managed as avoidance for solar and wind development and only excluded for utility scale projects (except in Lake, Harney, and Malheur Counties where it is avoidance and impacts could occur within PHMA).

Utah Environmental Consequences

Potential impacts on GHG emissions and carbon sequestration from fluid mineral leasing in Utah GHMA would continue, where it would continue to be managed as NSO near leks or CSU based on allocations in plans that predated the 2015 amendment. Emission sources and impacts to carbon sequestration would be displaced and would continue to result in overall impacts on climate change.

GHMA in Utah would continue to be open to wind and other major ROWs (subject to minimization and mitigation), which would continue to result in GHG emissions and carbon sequestration impacts that are associated with emissions and surface-disturbing activities. Under Alternative 1, potential for impacts on climate change from development of wind projects would continue to exist in PHMA in Utah to within 5 miles of leks.

Wyoming Environmental Consequences

Wyoming, GHMA would be managed as NSO within 0.25 miles of leks, and seasonal limitations within 2 miles of leks, while PHMA would continue to be managed as NSO within 0.6 miles of leks and as CSU or with timing limitations outside. While in areas that remain designated as NSO for fluid mineral leasing, emission sources and impacts on carbon sequestration would be removed, impacts may be relocated to elsewhere within the planning area, where fewer restrictions on fluid mineral leasing exists. In areas open to fluid mineral leasing with CSU stipulations or timing limitations, potential for impacts on GHG emissions and carbon sequestration would continue to exist.

Potential impacts on GHG emissions and carbon sequestration from proposed management of BLM-administered federal mineral estate as closed to or available for saleable sales or disposal would continue to

exist within PHMA in Wyoming, where it would continue to be managed as open, subject to occupancy, seasonal limitations, disturbance, and density for such use.

Potential impacts on GHG emissions and carbon sequestration would continue to exist from major and minor ROWs, and from solar and wind development, in Wyoming PHMA, where it would be open to such use.

Alternative 2

Rangewide Environmental Consequences

Impacts on GHG emissions and carbon sequestration from changes in land protected from or open to fluid minerals in PHMA and GHMA would be the same as under Alternative 1, except as described below. Under Alternative 2, the social cost of GHGs from oil and gas development for the 20-year life of the project would be 2,269 million dollars at the 5% discount rate and 7,199 million dollars at 3% discount rate (IWG 2021).

Impacts on GHG emissions and carbon sequestration from changes in land protected from or open to saleable minerals in PHMA and GHMA would be same as under Alternative 1, except in Idaho IHMA and Nevada PHMA as described in the state-specific sub-headings below.

Impacts on GHG emissions and carbon sequestration from nonenergy mineral management in PHMA and GHMA would be the same as under Alternative 1, except in Nevada PHMA as described in the state-specific sub-headings below.

Removing the recommendation for withdrawal of locatable mineral entry in SFA in all states (except in Montana/Dakotas, which did not have a 2019 amendment) would not change impacts on GHG emissions and carbon sequestration compared with Alternative 1, because as discussed under Alternative 1, recommending areas for closure to the mining laws for locatable exploration or development does not restrict any activities and therefore, such recommendation does not have any impacts. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Impacts on GHG emissions and carbon sequestration from changes in land protected from or open to renewable energy management would be the same as under Alternative 1, except in Nevada and Utah as described in the state-specific sub-headings below.

Impacts on GHG emissions and carbon sequestration from changes in livestock grazing would be similar to those described under Alternative 1. There would be more exceptions to restrictions on livestock grazing than under Alternative 1, which could have increased potential impacts on climate change in PHMA or IHMA.

Impacts on GHG emissions and carbon sequestration from changes in wild horse and burro management would be the same as those described under Alternative 1.

Colorado Environmental Consequences

PHMAs in Colorado would be designated as NSO for fluid mineral development. Compared with Alternative 1, under which areas within 1 mile of leks would remain closed to fluid mineral leasing. Under Alternative 2, annual GHG emissions from fluid mineral leasing would increase by 0.7, compared with Alternative 1. This would increase potential impacts on climate change from increased emissions and surface disturbance.

Idaho Environmental Consequences

Allowing consideration of new free use permits for saleable minerals in Idaho IHMA, would increase the potential for associated impacts on GHG emissions and carbon sequestration. This is because there would be a greater chance for more area of saleable and/or nonenergy mineral open to activities to occur, increasing potential GHG emissions and reducing carbon storage in the land from surface disturbance.

Nevada/California Environmental Consequences

Adding an exception criterion to saleable and nonenergy mineral closures for Nevada PHMA would increase the potential for associated impacts on GHG emissions and carbon sequestration as described in the Nature and Types of Effects. This is because there would be a greater chance for more area of saleable and/or nonenergy mineral open to activities to occur in these areas, increasing potential GHG emissions and reducing carbon storage in the landscape from surface disturbance.

There would be additional exception criteria for areas open to wind/solar development in Nevada PHMA and for wind development in Nevada/California GHMA. Compared with Alternative 1, this could increase the potential for development, increasing impacts on GHG emissions and carbon sequestration associated with changes in land protected from or open to renewable energy development because there would be a higher chance of development.

Utah Environmental Consequences

Areas outside PHMAs in Utah would be avoidance for wind development. This could increase the potential for impacts on GHG emissions and carbon sequestration associated with changes in land protected from wind development compared with Alternative 1. This is because there would be a higher chance of development in avoidance areas as opposed to exclusion areas under Alternative 1, which would not allow any development.

Alternative 3

All GRSG management areas would be managed as PHMAs which would be closed to fluid mineral leasing, saleable minerals, and nonenergy minerals and would be recommended for withdrawal from locatable mineral entry. Under Alternative 3, the social cost of GHGs from oil and gas development for the 20-year life of the project would be 1,535 million dollars at the 5% discount rate and 4,915 million dollars at the 3% discount rate (IWG 2021).

All PHMAs would be managed as exclusion areas for major ROWs and wind or solar energy, unavailable to livestock grazing, and wild horses and burros would be removed. ROW exclusion would preclude development of Class VI projects. Under Alternative 3, GHG emissions from livestock grazing would be reduced to zero. Due to a reduction in the level of use from added restrictions, including removal of most major surface disturbing activities, livestock grazing, and wild horse and burros, Alternative 3 would result in the least amount of GHG emissions and surface disturbance on BLM-administered lands, compared with all alternatives. However, such restrictions could shift such development and associated impacts to state, tribal, or private lands, where GHG emissions and surface disturbance would still occur. Any reduction in development of minerals under the Mining Law of 1872 would only occur if the Secretary were to propose and make a withdrawal pursuant to section 204 of FLPMA.

Colorado Environmental Consequences

Under Alternative 3, annual GHG emissions from fluid mineral leasing in Colorado would decrease by 27.3% compared with Alternative 1.

Montana Environmental Consequences
Under Alternative 3, annual GHG emissions from fluid mineral leasing in Montana would decrease by 41.6% compared with Alternative 1.

North Dakota Environmental Consequences
Under Alternative 3, annual GHG emissions from fluid mineral leasing in North Dakota would decrease by 15.4% compared with Alternative 1.

South Dakota Environmental Consequences
Under Alternative 3, annual GHG emissions from fluid mineral leasing in South Dakota would decrease by 1.1% compared with Alternative 1.

Utah Environmental Consequences
Under Alternative 3, annual GHG emissions from fluid mineral leasing in Utah would decrease by 9.8% compared with Alternative 1.

Wyoming Environmental Consequences
Under Alternative 3, annual GHG emissions from fluid mineral leasing in Wyoming would decrease by 36.7% compared with Alternative 1.

Alternative 4
Impacts on GHG emissions and carbon sequestration would be the same as those described for Alternative 1 except as discussed below. The BLM would manage minerals to minimize land use conflict and associated impacts from subsequent development through project designs that avoid, minimize, reduce, rectify, and mitigate for indirect impacts. Under Alternative 4, the social cost of GHGs from oil and gas development for the 20-year life of the project would be 2,135 million dollars at the 5% discount rate and 6,777 million dollars at the 3% discount rate.

PHMAs and IHMAs would be managed as avoidance for major ROWs within 0.5-mile buffer zone. GHMA would be managed as avoidance areas within breeding, nesting, and limited-seasonal habitats where mapped. Under this alternative, the BLM would take a more adaptive approach to management and consider existing data and best available science to determine if conservation measures are reasonable. While the impacts on climate change would be reduced or removed in some cases, under the scenario which management would allow more development, impacts would include an increase in GHG emissions and reduction of carbon sequestration would increase compared with Alternative 1.

Colorado Environmental Consequences
Under Alternative 4, annual emissions from fluid mineral leasing in Colorado would increase by 4.0%, compared with Alternative 1.

Wyoming Environmental Consequences
Under Alternative 4, annual emissions from fluid mineral leasing in Wyoming would decrease by 19.3%, compared with Alternative 1.

Alternative 5
Impacts on GHG emissions and carbon sequestration would be the same as those described for Alternative 1 except as discussed below. The BLM would apply a balanced approach to development by managing to minimize potential for conflict in important habitat. This would result in an increase in GHG emissions and

carbon sequestration in situations where more development would occur while can result in a reduction in impacts where less development would occur. Under Alternative 5, the social cost of GHGs from oil and gas development for the 20-year life of the project would be 2,271 million dollars at the 5% discount rate and 7,208 million dollars at the 3% discount rate.

Alternative 5 would be less restrictive than Alternative 4 in terms of allowing for mineral and renewable energy development. Alterations in impacts, wherein a decrease in development is anticipated under Alternative 4 compared to Alternative 1, would likely result in a greater reduction of impacts under Alternative 5.

Colorado Environmental Consequences

Under Alternative 5, annual emissions from fluid mineral leasing in Colorado would be the same as Alternative 4.

Wyoming Environmental Consequences

Under Alternative 5, annual emissions from fluid mineral leasing in Wyoming would decrease by 3.2%, compared with Alternative 1.

Alternative 6

Impacts on GHG emissions and carbon sequestration would be the same as described for Alternative 5, except in Wyoming where there would be an increase in oil and gas emissions. ACECs under Alternative 6 would restrict some uses, in accordance with the ACEC boundaries and restrictions under Alternative 3, which could reduce surface disturbance and potential sources of GHGs. Similar to Alternative 3, such restrictions in ACECs could shift surface disturbance and development and associated impacts to state, tribal, or private lands. Under Alternative 6, the social cost of GHGs from oil and gas development for the 20-year life of the project would be 2,266 million dollars at the 5% discount rate and 7,193 million dollars at the 3% discount rate.

Wyoming Environmental Consequences

Under Alternative 6, annual emissions from fluid mineral leasing in Wyoming would decrease by 3.7%, compared with Alternative 1.

10.14 SOIL RESOURCES

10.14.1 Methods and Assumptions

Methodology

The types of actions that can result in impacts on soil resources are discussed in more detail in **Section 4.14.1**, Nature and Type of Effects. Wide ranging impacts are described because the nature and type of impacts would not change at different levels, though they may be concentrated in different areas based on how surface-disturbing activities are distributed across the landscape and area-specific soil resources. The following activities are considered surface-disturbing and would have similar impacts on soils: minerals development, renewable energy development, and ROW development.

Indicators

Indicators of impacts on soil resources are as follows for assessing soil productivity and erosion:

- Changes in livestock grazing
- Changes in surface-disturbing activities (minerals development, renewable energy development, and ROW development)

- Changes in vegetation treatments, prescribed burns, and potential for wildfire
- Changes in wild horse and burro management

Assumptions

This analysis is based on the assumptions in **Section 4.1.1**. The analysis also includes the following assumptions:

- Soils on BLM-administered lands will be managed to maintain inherent productivity and promote sustained yields, while keeping erosional mechanism at minimal and acceptable levels thus preventing physical or chemical degradation. Proposed surface-disturbing projects will be analyzed to determine suitability of soils to support or sustain such projects and will be designed to minimize soil loss.
- Achieving or maintaining Standards for Rangeland Health and Guidelines for Livestock Grazing Management (described in **Section 3.7**, Livestock Grazing) generally are effective in managing the effects on soils from livestock grazing when properly implemented and monitored. Grazing authorizations will be adjusted on a case-by-case basis when site-specific studies indicate changes in management are needed.
- BLM management actions and objectives will be consistent with soil resource capabilities.
- Vegetation treatment projects and planned or unplanned wildland fires that contribute to establishing a more natural fire regime would have long-term benefits to soil health. However, wildfire can have detrimental soil health impacts (e.g. in high intensity or sensitive soil types) in some locations or when the disturbance leads to the establishment of invasive plant species.
- Wild horses and burros exceeding AML can degrade soil resources. However, wild horse and burro management would reduce the impacts on soils.

10.14.2 Alternative 1

Livestock Grazing Management

Under Alternative 1, PHMA, IHMA (Idaho only), and GHMA would continue to be available for livestock grazing, except in Oregon where all or portions of 13 key RNAs would be unavailable. The BLM would continue to prioritize monitoring and permit renewal of grazing per IM 2018-024 or subsequent updated policy. SFAs and PHMA outside of SFAs should be considered high priority areas to assess. Impacts on soil productivity and erosion from changes in livestock grazing would be determined by variations in site-specific management actions that strive to minimize concentrated compaction and aim to maintain or improve soil conditions. Within the areas available for livestock grazing, the BLM Authorized Officer may include or adjust permit terms and conditions needed to meet land health standards and GRSG habitat objectives. In turn, these management actions would continue to help minimize local impacts on soil productivity and erosion from the changes in livestock grazing, which would continue to also help minimize rangewide impacts for long-term soil productivity as described in the *Nature and Types of Effects*.

Wild Horse and Burro Management

Under Alternative 1, wild horses and burros would be managed within their established AML levels with priority of wild horse and burro management actions occurring within PHMA and where herd management areas or herd areas overlap GRSG habitat. Soil health would improve under Alternative 1 since a reduction in the current population of wild horses and burros within the planning would reduce soil impacts caused by trampling and excessive forage use by wild horses and burros. Forage and plant community conditions would improve under Alternative 1 allow for soil productivity to increase and erosion to be reduced.

Management of Surface-disturbing Activities

Management actions proposed in this alternative that minimize, preclude, or stipulate surface disturbance would help maintain or improve soil productivity, such as the 3% disturbance cap. Management of fluid minerals, saleable minerals, and nonenergy mineral development in PHMA, GHMA, and IHMA varies by state and includes areas that are open, closed, and withdrawn (see **Chapter 2** alternatives for minerals management).These various restrictions on land protected from surface-disturbing activities and areas closed to surface-disturbing activities from mineral activities within PHMA, IHMA, and GHMA would continue to help minimize impacts on soil productivity and erosion as described under the *Nature and Types of Effects*.

PHMA and IHMA in all states would continue to be identified as ROW avoidance areas to allow for management flexibility, except for minor ROWs in Wyoming. PHMA would continue to be designated as ROW exclusion for wind and solar (utility scale solar only in Idaho, Nevada/California, and Oregon) development, with exceptions in Wyoming, Oregon, and Idaho. Classifying PHMA as exclusion or avoidance areas would decrease the potential for impacts on soil productivity and erosion associated with ROW development, such as the surface-disturbing activities described in the *Nature and Types of Effects*. This is because development of ROWs would be prohibited in exclusion areas and would be considered on a case-by-case basis in avoidance areas.

New ROWs in PHMA would continue to not be allowed except in accordance with the Anthropogenic Disturbance Screening Criteria. In IHMA, new ROWs could be considered if in accordance with the IHMA Anthropogenic Disturbance Development Criteria. The BLM would continue to collocate new ROWs with existing infrastructure when possible. The BLM would retain management flexibility to route ROWs to minimize overall impacts on soil productivity and erosion. Existing ROW corridors are preferred for collocation of new ROWs but could not be widened more than 50% greater than the original footprint. These measures would continue to reduce negative impact to soil productivity from the surface-disturbing activities as described in *Nature and Types of Effects*. GHMA in all states would be open to minor ROWs with mitigation measures, except Wyoming would not require mitigation. Impacts on soil productivity and erosion associated with these surface-disturbing activities could occur in these areas if developed, but mitigation measures would help to lessen the impacts.

10.14.3 Alternative 2

Livestock Grazing Management

Under Alternative 2, impacts from changes in livestock grazing would be similar to those described above under Alternative 1.

Wild Horse and Burro Management

Under Alternative 2, references to management within SFA's would be removed in some states with the reference removed for GHMA in Utah. Management of wild horses and burros in herd management areas and AMLs would be the same as described in Alternative 1. Impacts to soil resources from wild horse and burro actions would be the same as Alternative 1, except for areas where SFA references are removed. This could cause forage and other vegetation to be removed in areas that were once references as SFAs. Soil productivity would be reduced and soil erosion could be increased in these areas under Alternative 2.

Management of Surface-disturbing Activities

Changes to the disturbance cap would apply and include allowing the cap to be exceeded in all states except Oregon under certain circumstances. This action could impact soil productivity and erosion as described in the *Nature and Type of Effects*.

Under Alternative 2, impacts from changes in land open to fluid minerals in PHMA and GHMA would be similar to those described above under Alternative 1, except in Colorado PHMA and Colorado GHMA where fluid mineral development would be open and would increase potential for surface-disturbing impacts on soil productivity and erosion, as compared to Alternative 1. This is because mineral development activities could occur in previously closed areas and cause negative impacts as described under *Nature and Types of Effects*. Changing GHMA from closed to fluid mineral development to NSO would likely not change impacts on soil resources because the NSO stipulation would avoid potential for land available to surface-disturbing activities.

Impacts from changes in land open to saleable mineral management in PHMA and GHMA would be similar to those described under Alternative 1, except in Idaho IHMA and Nevada PHMA. Impacts from changes in land open to nonenergy mineral management in PHMA and GHMA would be similar to those described under Alternative 1, except in Nevada PHMA. As compared with Alternative 1, the additional exception criterion to saleable and nonenergy mineral closures for Nevada PHMA and allowing consideration of new free use permits for saleable minerals in Idaho IHMA would increase the potential for associated impacts on soil productivity and erosion as described under the *Nature and Types of Effects*. This is because there would be a greater chance for saleable and/or nonenergy mineral activities to occur in these areas.

Removing the recommendation for locatable mineral withdrawal in SFAs in all states (except in MT/DK, which did not have a 2019 amendment) has no impact. This is because a recommendation to withdraw lands under the Mining Law of 1872 has no impact. Withdrawals are considered through a separate process pursuant to section 204 of FLPMA.

Impacts from changes in land protected from or open to ROW and renewable energy management would be similar to those described under Alternative 1, with additional exception criteria in Nevada/California. Under Alternative 2, there would be an additional exception criterion for ROW and wind and solar development in Nevada PHMA and for wind development in Nevada/California GHMA. As compared to Alternative 1, this could increase the potential for impacts on soil productivity and erosion associated with ROW and renewable energy development because there would be a higher chance of development. However, the exception criteria would likely avoid major impacts on soil productivity and erosion as described under the *Nature and Type of Effects*.

Under Alternative 2, removing the prioritization objective for PHMA and GHMA, which involves determining the order or preference for leasing decisions, would not directly impact soil productivity and erosion because prioritization does not permit or preclude leasing in PHMA.As compared with Alternative 1, the NSO stipulations and conservation measures in place for PHMA would protect soil resources; however, the prioritization objective could potentially result in temporarily deferring a parcel in PHMA from leasing to a later sale, but only in instances of large lease sales where staff capacity would be incapable to analyzing all the nominated parcels. In an area with high levels of disturbance, such a delay could provide time for vegetation conditions and soil productivity to improve before new developments are implemented. As the amount of development increases in former GHMA, the consecutive effects of mitigating disturbances in PHMA could mount and could possibly affect soil productivity and erosion as described in the *Nature and Type of Effects*. Site-specific planning and other management from local resource management plans, and adhering to the land health standards, would reduce impacts on soil productivity and erosion in former GHMA with the use of BMP and other project mitigation design features.

10.14.4 Alternative 3

Livestock Grazing Management

Management of PHMA as unavailable for livestock grazing would eliminate the possibility of the short-term, site-specific impacts from changes in livestock grazing and the associated impacts on soil productivity and erosion as described under the *Nature and Types of Effects*. Compared with Alternative 1, Alternative 3 contains greater restrictions on livestock grazing and would be more protective of soil productivity from impacts related to livestock grazing.

Wild Horse and Burro Management

Under Alternative 3, there would be no new designation of herd management area in any herd areas that overlap with PHMA unless the area outside of the PHMA boundary could still support a herd management area. All wild horse and burros would be removed from existing PHMA. Soils in the planning area would experience short term impacts from wild horse and burro round up activities (i.e, off road vehicular travel and temporary corrals) that could cause soil erosion. The long terms impacts to soil resources in the planning area in comparison to Alternative 1 would be more beneficial because all wild horse and burro activity that impacts soils would be eliminated from PHMA.

Management of Surface-disturbing Activities

Application of a 3% disturbance cap and calculating disturbance at the project scale and HAF fine scale habitat selection area may prevent some development, and therefore reduce impacts to soil productivity and erosion. Compared with Alternative 1, Alternative 3 would have greater restrictions on new areas of land protected from or open to ROWs, fluid mineral leasing, and other mineral development and thus on development in these areas that would otherwise have the potential to impact soil productivity and erosion. PHMA in all states would be closed to fluid mineral leasing, saleable minerals, and nonenergy minerals would reduce potential impacts on soil productivity and erosion, such as areas available to surface-disturbance activities associated with mineral development as described under the *Nature and Types of Effects*. Effects would be reduced to a greater extent than under Alternative 1. This is because areas closed to leasing could not be developed at any point. Recommendation to withdraw PHMA from location and entry under the US mining laws does not restrict any activities and therefore would not have any impact on soil productivity and erosion. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

New infrastructure development would be substantially limited as compared with Alternative 1. All PHMA would be excluded from new ROW authorizations. New linear ROWs would be allowed only in designated ROW corridors. The inability to site ROWs in PHMA would decrease the potential for impacts on soil productivity and erosion associated with ROW development and as described under the *Nature and Type of Effects*. The inability to site ROWs in PHMA could lead to longer ROW routes to bypass closed areas. Longer routes would increase surface disturbance and other impacts of ROW siting on soil productivity and erosion outside of PHMA and may result in increased impacts on soil productivity and erosion on adjacent state, tribal, or private lands.

Under Alternative 3, PHMA would be ROW exclusion for wind and solar energy development. Prohibiting wind energy development would eliminate impacts on soil productivity and erosion from changes in land protected from or open to this type of surface-disturbing activity in these areas. However, these prohibitions could result in the shifting of surface-disturbing activity and impacts on soil productivity and erosion to state, tribal or private lands.

10.14.5 Alternative 4

Livestock Grazing Management

Under Alternative 4, same as Alternative 1, livestock grazing would remain available in PHMA, IHMA, and GHMA, with the exception of 13 key RNAs in Oregon that may be fully or partially unavailable for grazing. Site-specific management actions would play a crucial role in determining the impacts on soil productivity and erosion resulting from changes in livestock grazing as described under the *Nature and Type of Effects*. These actions would minimize concentrated compaction and aim to maintain or improve soil productivity and minimize erosion, thereby mitigating effects on soil productivity and erosion as described under the *Nature and Type of Effects*. The BLM Authorized Officer would retain the authority to include or adjust permit terms and conditions within the areas available for livestock grazing. As compared with Alternative 1, the emphasized flexibility under Alternative 4 would ensure that grazing practices comply with existing land health standards under 43 CFR Part 4180 (or subsequent changes to regulations or policy) and contributes to minimizing local and implementation level impacts on soil productivity and erosion resulting from changes in livestock grazing as described in the *Nature and Types of Effects*.

Wild Horse and Burro Management

Under Alternative 4, wild horse and burro impacts would be similar to Alternative 1 with the direction to remove SFAs. Impacts to soil resources from wild horse and burro would be similar to was described in Alternative 1 and Alternative 2 with the exception of having reference to GHMA in Utah not being removed.

Management of Surface-disturbing Activities

Alternative 4 would include a 3% cap within the HAF fine scale habitat selection area in PHMA. Additionally, Alternative 4 would address habitat loss from wildfire and agriculture through existing sagebrush availability and habitat objectives. These measures under Alternative 4 would aim to manage and minimize disturbance, preserve vegetation communities, and mitigate the potential for further degradation while balancing impacts on soil productivity and erosion as described under the *Nature and Types of Effects*.

Under Alternative 4, additional management actions would be included compared with Alternative 1, specifically addressing fluid mineral leasing and development within GRSG PHMA, IHMA, and GHMA. Under Alternative 4, the proposed measures would include evaluating parcels identified in Expressions of Interest within GRSG habitat management areas giving preference to lands that would not result in impairing habitat suitability and proper function. Alternative 4 would consider the management of areas already leased for fluid minerals, emphasizing the application of lease stipulations, minimization measures, and compliance with NEPA. With that, under Alternative 4 and similar to Alternative 1, the BLM would aim to minimize impacts on soil productivity and erosion by promoting project designs that avoid, minimize, reduce, rectify, and mitigate for direct and indirect impacts, while considering site-specific considerations and project specific COAs. However, a blanket NSO restriction on new leases in an area with existing leases complicates the effectiveness of the described efforts. Alternative 4 would also include enhanced collaboration with project proponents and state wildlife agencies to promote effective conservation and connectivity of habitats, while reducing impacts on soil productivity and erosion.

Alternative 4 would maintain the exclusion of PHMA for utility-scale wind and solar projects and would designate IHMA as exclusion within 3.1 miles from active leks, while the remaining IHMA areas are avoidance. Avoidance areas would also be designated within 0.5 miles of PHMA/IHMA to address indirect impacts. GHMA would be avoidance for utility-scale wind/solar projects. PHMA/IHMA would be avoidance for major ROWs, and areas within 0.5 miles of PHMA/IHMA would also be avoidance. GHMA would be avoidance

within breeding/nesting/limited-seasonal habitats or entirely if not mapped, and designated corridors remain open. These modifications in Alternative 4, compared with Alternative 1, would help reduce impacts on soil productivity and erosion, as described under the *Nature and Types of Effects*, while allowing for managed development in specific areas.

10.14.6 Alternatives 5 and 6

Livestock Grazing Management

Under Alternatives 5 and 6, similar to Alternative 1, livestock grazing would generally remain available in PHMA, IHMA, and GHMA, with the exception of certain RNAs in Oregon that may be partially or entirely unavailable for grazing (pending final determinations). The impacts on soil productivity and erosion resulting from changes in livestock grazing would be determined by variations in site-specific management actions. These actions would strive to minimize concentrated compaction and aim to maintain or improve soil productivity and erosion as described under the *Nature and Type of Effects*.

Under Alternatives 5 and 6, livestock grazing within GRSG PHMA, IHMA, and GHMA would be managed to meet land health standards, informed by the site-scale HAF suitability. The BLM Authorized Officer would have the flexibility to include or adjust permit terms and conditions within the available livestock grazing areas, ensuring compliance with land health standards and GRSG habitat objectives. Under Alternatives 5 and 6, construction of range infrastructure, such as water sources, structures, and fences, would be guided by guidelines that minimize impacts on GRSG and soil productivity and erosion as described under the *Nature and Type of Effects*, similar to the consolidation and simplification efforts of Alternative 1.

While Alternative 1 does not specify the areas where thresholds and responses would be required, Alternatives 5 and 6 would introduce a targeted approach. Under Alternatives 5 and 6, areas with the greatest potential to impact GRSG if suitable habitat conditions were not met would be prioritized for the inclusion of thresholds and responses. Accordingly, by focusing efforts on these priority areas, proactive conservation measures would be implemented, promoting the establishment of suitable habitat and minimizing impacts on soil productivity and erosion as described under the *Nature and Type of Effects*.

Wild Horse and Burro Management

Under Alternatives 5 and 6, wild horse and burro impacts to soil resources within the decision area would be similar to what is described in Alternative 1.

Management of Surface-disturbing Activities

Alternatives 5 and 6 include varying caps on disturbance at the project scale within PHMA, depending on the state. These measures under Alternatives 5 and 6 would aim to manage disturbance, protect vegetation communities, and mitigate potential degradation while reducing impacts on soil productivity and erosion, as described under the *Nature and Type of Effects*, across states and specific boundaries.

Alternatives 5 and 6 would include additional management actions compared to Alternative 1, specifically addressing fluid mineral leasing and development within GRSG PHMA, IHMA, and GHMA. The proposed measures under Alternatives 5 and 6 would include evaluating parcels identified in Expressions of Interest within GRSG habitat management areas giving preference to lands that would not result in impairing habitat suitability and proper function. Additionally, Alternatives 5 and 6 would consider the management of areas already leased for fluid minerals, emphasizing the application of lease stipulations, minimization measures, and compliance with NEPA. Under Alternatives 5 and 6, the BLM would aim to minimize impacts to soil productivity and erosion as described under the *Nature and Type of Effects* by promoting project designs that avoid, minimize, reduce, rectify, and mitigate for direct and indirect impacts, while considering site-specific

considerations and project specific COAs. Collaboration with project proponents and state wildlife agencies would be encouraged to promote effective conservation and connectivity of habitats while reducing impacts to soil productivity and erosion.

Alternatives 5 and 6 would include notable changes compared to Alternative 1 for wind and solar development and major transmission ROW. Specifically, PHMA would be designated as avoidance for utility-scale wind and solar projects as well as major ROWs, prioritizing the protection of soil productivity. In contrast, GHMA would be open for utility-scale wind and solar development with the implementation of specific minimization measures to mitigate potential impacts on soil productivity and erosion. The designated corridors would remain open to accommodate transmission infrastructure. These modifications in Alternatives 5 and 6 would strike a balance between facilitating renewable energy development, ensuring transmission infrastructure access, and safeguarding the impacts on soil productivity and erosion as described under the *Nature and Type of Effects.*

10.15 WATER RESOURCES

10.15.1 Methods and Assumptions

Methodology

The types of actions that can result in impacts on water resources are discussed in more detail in **Section 4.15.1**, Nature and Type of Effects. Wide ranging impacts are described because the nature and type of impacts would not change at different levels, though they may be concentrated in different areas based on how surface-disturbing activities are distributed across the landscape and watershed resources. The following activities are considered surface-disturbing and would have similar impacts on water resources: minerals development, renewable energy development, and ROW development.

Indicators

Indicators of impacts on water resources are as follows for assessing water resource conditions, and water quality and quantity:

- Changes in livestock grazing
- Changes in surface-disturbing activities (minerals development, renewable energy development, and ROW development)
- Changes in vegetation treatments, prescribed burns, and potential for wildfire
- Changes in wild horse and burro management

Assumptions

This analysis is based on the assumptions in **Section 10.1.3**. Also, the analysis includes the following assumptions:

- Projects that help restore watersheds, desirable vegetation communities, or wildlife habitats (including surface disturbance associated with these efforts) would benefit water resources over the long term.
- The degree of impact attributed to any one disturbance or series of disturbances would be influenced by several factors. These are proximity to running streams, drainages and groundwater wells, location within the watershed, time and degree of disturbance, reclamation potential of the affected area, vegetation present, precipitation, and mitigating actions applied to the disturbance.
- Areas closed to ROWs, mineral resource development, or with NSO stipulations would result in less potential for water erosion and sedimentation to surface water.

- Surface-disturbing actions related to fluid mineral development would comply with Gold Book (BLM 2007) surface operating standards (and subsequent updates), and all federal and state water quality standards.
- Fluid mineral operations on existing federal leases, regardless of surface ownership, would be subject to COAs by the BLM Authorized Officer. The BLM can deny surface occupancy on portions of leases with COAs to avoid or minimize resource conflicts if this action does not eliminate reasonable opportunities to develop the lease or does not affect lease rights.
- The quantity of water stored in the landscape either as surface water or groundwater varies over time depending upon precipitation and human extractions of that water. Management measures that reduce or prevent water use involving mineral development, livestock grazing, wild horses and burros, and pinyon-juniper vegetation would have a net benefit on the quantities of water stored in the landscape.

10.15.2 Alternative 1

Livestock Grazing Management

Under Alternative 1, PHMA, IHMA, and GHMA would continue to be available for livestock grazing. In Oregon all or portions of 13 key RNAs would be unavailable to livestock grazing. The BLM would continue to prioritize monitoring and renewal of grazing in SFAs and PHMA outside of SFAs. This prioritization includes permit renewals in SFAs and PHMA, with the exception of cases outlined in IM 2018-024. These exceptions may encompass areas that have never undergone assessment or that comply with court orders. Impacts on water resource conditions from changes in livestock grazing would continue to largely be determined by variations in site-specific management actions. Some of the management actions could minimize surface-disturbing actions. In turn, these management actions would continue to help minimize local impacts on water resource conditions from changes in livestock grazing, which would also continue to help minimize rangewide impacts for long-term benefits to water resource conditions as described in the *Nature and Types of Effects*.

Wild Horse and Burro Management

Under Alternative 1, wild horse and burro would be managed within their established AML levels with priority of wild horse and burro management actions occurring within PHMA and where herd management areas or herd areas overlap GRSG habitat. These management actions would address overpopulated wild horse and burro areas, which are crucial for reducing strain on water quality, as these animals contribute to overgrazing and contamination, further impacting water resource conditions Water resources would improve under Alternative 1 as that a reduction in the current population of wild horse and burro within the planning area would reduce direct impacts wild horses and burros have on water resources.

Management of Surface-disturbing Activities

Within the rangewide planning area, impacts on water resource conditions are largely a result of variations in management actions. Management actions proposed in this action that minimize, preclude, or stipulate surface disturbance would help maintain or improve water resource conditions. Management of fluid minerals, saleable minerals, and nonenergy mineral development in PHMA, GHMA, and IHMA varies by state and includes areas that are open, closed, and withdrawn (see **Chapter 2** alternatives for minerals management). These various restrictions land protected from or open to surface disturbing activities within PHMA and GHMA would continue to help reduce impacts on water resource conditions as described under the *Nature and Types of Effects*. However, water flows across jurisdictional boundaries and such restrictions

could potentially shift such surface disturbance and associated impacts on water resource conditions from BLM lands to state, tribal, or private lands

PHMA and IHMA in all states would continue to be identified as ROW avoidance areas to allow for management flexibility, except for minor ROWs in Wyoming. PHMA would continue to be designated exclusion for wind and solar (utility scale solar only in Idaho, Nevada/California and Oregon) development, with exceptions in Wyoming, Oregon, and Idaho IHMA. Classifying PHMA as exclusion or avoidance areas would continue to decrease the potential for impacts on water resource conditions associated with changes in land open to ROW development, such as the surface-disturbing activities as described in the *Nature and Types of Effects*. This is because development of ROWs would continue to be prohibited in exclusion areas and would be considered on a case by-case basis in avoidance areas.

New ROWs in PHMA would continue to not be allowed except in accordance with the Anthropogenic Disturbance Screening Criteria outlined in the 2015 approved plan. In IHMA, new ROWs could be considered if in accordance with the IHMA Anthropogenic Disturbance Development Criteria. The BLM would continue to collocate new ROWs with existing infrastructure when possible. The BLM would continue to retain management flexibility to route ROWs to minimize overall impacts on water resource conditions. Existing ROW corridors are preferred for collocation of new ROWs but could not be widened more than 50% greater than the original footprint. These measures would continue to reduce negative impact to water resource conditions from surface-disturbing impacts described in the *Nature and Types of Effects*. However, water flows across jurisdictional boundaries, so BLM restrictions could potentially shift surface disturbance and associated impacts on water resources from BLM lands to state, tribal, or private lands. GHMA in all states would continue to be open to minor ROWs with mitigation measures, except Wyoming does not require mitigation. Impacts on water resource conditions associated with changes in land open to ROW development, such as surface disturbance could occur in these areas if developed, but mitigation measures, such as erosion control practices and revegetation, would help to lessen the impacts.

GRSG Management

Watershed health would continue to be affected by reducing water infiltration rates, increase overland flow and sediment loading, which could affect turbidity, temperature, and nutrient loading in water systems.

10.15.3 Alternative 2

Livestock Grazing Management

Under Alternative 2, impacts on water resource conditions from changes in livestock grazing would be similar to those described under Alternative 1. In Oregon, all or portions of the 13 key RNAs would be available to livestock grazing.

Wild Horse and Burro Management

Under Alternative 2, references to management within SFA's would be removed in some states with the reference removed for GHMA in Utah. Management of wild horses and burros in herd management areas and AMLs would be the same as described in Alternative 1. Impacts to water resources from wild horse and burro management actions would be the same as Alternative 1, except for areas where SFA references are removed. This could cause degradation of water resources that are present in areas that were once references as SFAs. Water quality would be reduced and competition between wildlife and wild horses and burros for water resources would increase under Alternative 2.

Management of Surface-disturbing Activities

Impacts on water resource conditions from changes in land protected from or open to fluid minerals in PHMA and GHMA would be the similar to those described under Alternative 1, except in Colorado PHMA and Colorado GHMA. Removing the closure of Colorado PHMA to fluid mineral development would increase potential for surface-disturbing impacts on water resource conditions. This is because fluid mineral development activities could occur in previously closed areas and cause impacts on water resource conditions as described under the *Nature and Types of Effects*. Compared with Alternative 1, changing GHMA from closed to fluid mineral development to NSO would likely not change impacts on water resource conditions because the NSO stipulation would avoid potential for these surface-disturbing activities.

Impacts on water resource conditions from changes in land protected from or open to saleable minerals in PHMA and GHMA would be similar to those described for Alternative 1, except in Idaho IHMA and Nevada PHMA. Impacts from nonenergy mineral management in PHMA and GHMA would be similar to those described under Alternative 1, except in Nevada PHMA. Under Alternative 2, adding an exception criterion to saleable and nonenergy mineral closures for Nevada PHMA, and allowing consideration of new free use permits for saleable minerals in Idaho IHMA, would increase the potential for associated impacts on water resource conditions as described in the *Nature and Types of Effects*. This is because there would be a greater chance for more area of saleable and/or nonenergy mineral open to activities to occur in these areas.

Under Alternative 2, removing the recommendation for locatable minerals in SFA in all states (except in Montana/Dakotas, which did not have a 2019 amendment, and Oregon, which retained SFA designation through a plan maintenance action and not an amendment.) would increase the potential for impacts on water resource conditions compared with Alternative 1. This is because locatable mineral activities could occur and cause impacts as described under the *Nature and Types of Effects*.

Impacts on water resource conditions from changes in land protected from or open to renewable energy management would be the similar to those described under Alternative 1, with additional exception criteria in Nevada/California. Under Alternative 2, there would be additional exception criteria for areas land open to wind/solar development in Nevada PHMA and for wind development in Nevada/California GHMA. Compared with Alternative 1, this could increase the potential for impacts on water resource conditions, as described under the *Nature and Type of Effects*, associated with changes in land protected from or open to renewable energy development because there would be a higher chance of development. However, the exception criteria would likely avoid impacts on water resource conditions.

Impacts on water resource conditions from changes in land protected from or open to ROW would be the similar to those described under Alternative 1, with additional exception criteria in Nevada/California. Under Alternative 2, there would be additional exception criteria for areas land open to ROW in Nevada PHMA and for wind development in Nevada/California GHMA. Compared with Alternative 1, this could increase the potential for impacts on water resource conditions, as described under the *Nature and Type of Effects*, associated with changes in land protected from or open to ROW development because there would be a higher chance of development. However, the exception criteria would likely avoid impacts on water resource conditions.

GRSG Management

Impacts on water resource conditions from changes in potential for wildfire would be the same as those described under Alternative 1 and as described under the *Nature and Type of Effects*.

10.15.4 Alternative 3

Livestock Grazing Management

All areas managed for GRSG would be PHMA. Compared with Alternative 1, Alternative 3 contains greater restrictions on other resources and would most greatly reduce the potential for impacts on water resource conditions as described under the *Nature and Type of Effects*. However, while Alternative 3 would be more protective of water resource conditions from impacts related to changes in land protected from or open to livestock grazing compared with Alternative 1, it could also make BLM lands more susceptible to wildfire. This increased wildfire risk could negatively impact water resources, as detailed in **Section 4.4**, which describes the increased likelihood of fire in greater detail.

Management of PHMA as unavailable for livestock grazing would eliminate the possibility of the short-term, site-specific impacts from changes in land protected from or open to livestock grazing and the associated impacts on water resource conditions as described under the *Nature and Type of Effects*. Alternative 3 would be more protective of water resource conditions from impacts related to changes in land protected from or open to livestock grazing compared with Alternative 1.

Wild Horse and Burro Management

Under Alternative 3, there would be no new designation of herd management area in any herd areas that overlap with PHMA unless the area outside of the PHMA boundary could still support a herd management area. All wild horse and burros would be removed from existing PHMA. Water resources within PHMA would improve with the direct impacts of wild horses and burros on water resources being eliminated.

Management of Surface-disturbing Activities

Compared with Alternative 1, Alternative 3 would have greater restrictions on new ROWs, fluid mineral leasing, and other mineral development and thus on areas land open to development in these areas that would otherwise have the potential to impact water resource conditions. Under Alternative 3, closing PHMA to fluid mineral leasing, saleable minerals, and nonenergy minerals would reduce potential impacts on water resource conditions, such as surface disturbance, associated with mineral development as described under the *Nature and Types of Effects*. Effects would be reduced to a greater extent than those under Alternative 1. This is because areas closed to leasing could not be developed at any point. Recommendation to withdraw PHMA from location and entry under the US mining laws would not restrict any activities and therefore would have no impact on water resource conditions. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Under Alternative 3, PHMA would be designated ROW exclusion for wind and solar energy development. Prohibiting wind energy development would eliminate the likelihood for impacts on water resource conditions from changes in land protected from or open to these surface-disturbing activities in these areas.

Because many water-consuming activities would be restricted, Alternative 3 is also likely to result in increased water retention through improved infiltration across the landscape. Restrictions from Alternative 3 would reduce surface disturbances that cause runoff and erosion, improving the likelihood of more waters fully supporting beneficial uses and maintaining or increasing the stream miles meeting state and federal water quality standards and designated beneficial uses.

New infrastructure development would be substantially limited compared with Alternative 1. All PHMA would be excluded from new ROW authorizations. New linear ROWs would be allowed only in designated ROW corridors. The inability to site ROWs in PHMA would decrease the potential for impacts on water resource conditions associated with changes in land open to ROW development as described under the

Nature and Type of Effects. However, the inability to site ROWs in PHMAs could lead to longer ROW routes to bypass closed areas. Longer routes would increase surface disturbance and other impacts of ROW siting on water resource conditions outside of PHMA and may result in increased impacts on water resource conditions on adjacent state, tribal, or private lands.

GRSG Management

Alternative 3 would have more restrictions and result in fewer areas treated when compared with Alternative 1. Under these restrictions, impacts on water resource conditions as described under the *Nature and Type of Effects* would be more prone to impacts from potential wildfires in those areas.

10.15.5 Alternative 4

Livestock Grazing Management

Under Alternative 4, same as Alternative 1, livestock grazing would generally remain available in PHMA, IHMA, and GHMA, except for all or portions of 13 key RNAs in Oregon that may be fully or partially unavailable for grazing. Under Alternative 4, same as Alternative 1, the BLM would maintain its focus on monitoring and renewing grazing activities in PHMA areas. Under Alternative 4, site-specific management actions would continue to play a crucial role in determining the impacts on water resource conditions resulting from changes in livestock grazing as described under the *Nature and Type of Effects*. These actions would strive to minimize concentrated compaction and aim to maintain or improve water resource conditions, thereby mitigating effects on water resource conditions as described under the *Nature and Type of Effects*. Under Alternative 4, to align with land health standards and GRSG habitat objectives, the BLM Authorized Officer would retain the authority to include or adjust permit terms and conditions within the areas available for livestock grazing. The emphasized flexibility under Alternative 4, compared with Alternative 1, would help ensure that grazing practices remain in compliance with established guidelines and contribute to minimizing local impacts on water resource conditions resulting from changes in livestock grazing as described under the *Nature and Types of Effects*.

Wild Horse and Burro Management

Under Alternative 4, wild horse and burro impacts would be similar to Alternative 1 with the direction to remove SFAs. Impacts to water resources from wild horses and burros would be similar to was described in Alternative 1 and Alternative 2 with the exception of having reference to GHMA in Utah not being removed. Site-specific management actions would also address the impacts on water resource conditions from overpopulated wild horse and burro areas, which affect water quality through overgrazing and contamination.

Management of Surface-disturbing Activities

Alternative 4, compared with Alternative 1, would introduce additional management actions specifically addressing fluid mineral leasing and development within GRSG Habitat Management Areas (PHMA, GHMA, IHMA). Under Alternative 4, the BLM would evaluate parcels identified in Expressions of Interest within GRSG habitat management areas giving preference to lands that would not result in impairing habitat suitability and proper function. Furthermore, Alternative 4 emphasizes the management of already leased areas for fluid minerals, including the application of lease stipulations, minimization measures, and compliance with NEPA. Alternative 4 would minimize impacts on water resource conditions as describes under the *Nature and Type of Effects* by promoting project designs that avoid, minimize, reduce, rectify, and mitigate for direct and indirect impacts.

Alternative 4 would direct the exclusion of PHMA for utility-scale wind and solar projects and designate IHMA as exclusion within 3.1 miles from active leks, with the remaining IHMA areas being avoidance. Avoidance areas would also be designated within 0.5 miles of PHMA/IHMA to address indirect impacts. GHMA would be avoidance for utility-scale wind/solar projects.

Under Alternative 4, PHMA/IHMA would be avoidance for major ROWs, and areas within 0.5 miles of PHMA/IHMA would also be avoidance. GHMA would be avoidance within breeding/nesting/limited-seasonal habitats, or entirely if not mapped, while designated corridors remain open. These modifications aim to protect water resource conditions and the GRSG habitat while allowing for managed development in specific areas, considering the impacts described under the *Nature and Types of Effects*.

GRSG Management

Alternative 4 would introduce specific provisions that differ from Alternative 1 regarding potential for wildfire, focusing on the impacts on water resource conditions for GRSG. That is, under Alternative 4, there would be a 3% cap within the HAF fine scale habitat selection area in PHMA. These measures under Alternative 4 aim to manage and minimize disturbance, preserve vegetation communities, and mitigate the potential for further degradation, while ensuring the conservation of water resource conditions and considering the impacts described under the *Nature and Types of Effects*.

10.15.6 Alternatives 5 and 6

Livestock Grazing Management

Under Alternatives 5 and 6, same as Alternative 1, livestock grazing would generally remain available in PHMA, IHMA, and GHMA for GRSG, except for certain RNAs in Oregon that may be partially or entirely unavailable for grazing pending final determinations. This precautionary measure aims to maintain critical GRSG habitat and associated water resource conditions in Oregon so that impacts described under the *Nature and Types of Effects* would be minimized.

In contrast to Alternative 1, Alternatives 5 and 6 introduce a targeted approach for the inclusion of thresholds and responses. Priority areas with the greatest potential to impact GRSG if suitable habitat conditions were not met would be identified for the implementation of thresholds and responses. This proactive conservation approach, compared with Alternative 1, would focus efforts on these priority areas, promoting the establishment of suitable habitat and thus minimizing impacts on water resource conditions as described under the *Nature and Type of Effects*.

Wild Horse and Burro Management

Under Alternatives 5 and 6, wild horse and burro impacts to water resources within the decision area would be similar to what is described in Alternative 1.

Management of Surface-disturbing Activities

Alternatives 5 and 6 introduce additional management actions compared with Alternative 1, specifically focusing on fluid mineral leasing and development within GRSG HMAs. The BLM would evaluate parcels identified in Expressions of Interest within GRSG habitat management areas giving preference to lands that would not result in impairing habitat suitability and proper function. Alternatives 5 and 6 would include management of areas already leased for fluid minerals, emphasizing the application of lease stipulations, minimization measures, and compliance with NEPA. Alternatives 5 and 6, compared with Alternative 1, would help minimize impacts on water resource conditions as described under the *Nature and Type of Effects* by promoting project designs that avoid, minimize, reduce, rectify, and mitigate for direct and indirect impacts, while considering site-specific considerations and project specific COAs. Moreover, Alternative 5

would expand upon the management actions in Alternative 1 to strike a balance between resource development and the conservation of GRSG habitat, connectivity, and impacts on water resource conditions.

Regarding wind and solar development, Alternatives 5 and 6 would introduce notable changes compared with Alternative 1. PHMA would be designated as avoidance for utility-scale wind and solar projects, prioritizing the protection of GRSG habitat and, in turn, reducing the impacts on water resource conditions as described under the *Nature and Type of Effects*. In contrast, GHMA would remain open for utility-scale wind and solar development, accompanied by specific minimization measures to mitigate potential impacts on water resource conditions as described under the *Nature and Type of Effects*. The designated corridors would be retained to accommodate transmission infrastructure. These modifications in Alternative 5 aim to conserve the GRSG habitat and strike a balance between renewable energy development and the preservation of water resource conditions.

Regarding major transmission ROWs, Alternatives 5 and 6 would introduce notable changes compared with Alternative 1. PHMA would be designated as avoidance for major ROWs, prioritizing the protection of GRSG habitat and, in turn, reducing the impacts on water resource conditions as described under the *Nature and Type of Effects*. In contrast, GHMA would remain open for major ROW development, accompanied by specific minimization measures to mitigate potential impacts on water resource conditions as described under the *Nature and Type of Effects*. The designated corridors would be retained to accommodate transmission infrastructure. These modifications in Alternative 5 aim to conserve the GRSG habitat and strike a balance between ROW development and the preservation of water resource conditions.

GRSG Management

Alternatives 5 and 6 would introduce provisions that slightly deviate from Alternative 1 concerning the potential for wildfire in relation to impacts on water resource conditions as described under the *Nature and Type of Effects*. That is, Alternatives 5 and 6 would entail different disturbance caps within the project analysis area of PHMA, depending on the state. In Wyoming and Montana, the cap would be set at 5%, while in other states, the cap would be 3%, limited to infrastructure only. Furthermore, a 3% cap on infrastructure would be implemented within the HAF fine scale habitat selection area in PHMA. Moreover, there would be no additional disturbance cap, but there are two scales of analysis. These measures under Alternatives 5 and 6, compared with Alternative 1, would aim to improve disturbance management, preserve vegetation communities, and mitigate potential degradation, while ensuring the conservation of water resource conditions for the GRSG across different states and specific boundaries.

10.16 CULTURAL RESOURCES

10.16.1 Methods and Assumptions

Methodology

This section focuses on qualitatively describing the impacts that would result from implementing the alternatives. Impacts are described across the entire planning area because the nature and type of impacts would not change at various levels, though they may be concentrated in different areas based on how potentially surface-disturbing and setting-altering activities and actions that increase use or access are distributed across the landscape.

Impacts on cultural resources would primarily be the product of management actions described in **Chapter 2** that result in surface disturbance or alterations in setting, and actions that result in increased resource use or access. There is overlap between them, and impacts can only be described qualitatively and generally

without site-specific project details. The types of actions that can result in these impacts are discussed in more detail in **Section 4.15.2**, Nature and Type of Effects.

Indicators

Indicators of impacts on cultural resources are as follows:

- Changes in potential for ground disturbance, including erosion and soil removal.
- Changes in potential for vandalism and collection of cultural resources through changes in access or recreation.
- Changes in potential for impacts to site setting, such as landscape fragmentation, visual disturbance, and noise.

Assumptions

This analysis is based on the assumptions in **Section 4.1.1**. and the following additional assumptions:

- The BLM will follow existing regulatory procedures for the consideration of impacts on cultural resources (for example, Section 106 of the National Historic Preservation Act or relevant program alternatives).
- Nondiscretionary mining notices are not federal undertakings, but 43 CFR 3809 specifically provides for the protection of cultural properties by prohibiting mining operators on claims of any size from knowingly disturbing or damaging these properties.
- Many more sites and resources exist in the planning area than are currently inventoried; this includes traditional cultural properties and other data sets outside existing inventoried cultural data, including but not limited to, knowledge of sites from communities in the planning area.
- Areas of high potential for cultural resource site locations have not been modeled throughout the entire planning area.
- Many sites, inventoried or not, are likely significant for regional and national history, including indigenous sites; however, they have never been evaluated for listing on the National Register of Historic Places.
- This analysis assumes all sites are eligible until evaluated, and they are subject to the impacts discussed.
- Any ground-disturbing activity would be considered a potential threat to cultural resources. Cultural sites are nonrenewable resources, adverse impacts are permanent, and beneficial impacts cannot reverse adverse impacts. Even minor impacts accrue over time, resulting in deteriorating site condition and loss of important scientific data and cultural values.
- Recreation levels and future demand in the planning area are likely to continue increasing (See Section 10.19, Recreation and Visitor Services).
- Implementing the management actions for GRSG would have mostly negligible or beneficial impacts on cultural resources. Impacts from resource use actions would tend to have negligible detrimental effects.
- Degradation of known and undiscovered cultural resources from natural processes (e.g., erosion) would continue regardless of avoidance of human caused impacts.
- Unauthorized or unplanned activities, wildland fire, dispersed recreation, natural processes and unauthorized collection, excavation, and vandalism would lead to impacts that would be difficult to monitor and mitigate. Impacts on traditional cultural properties, sacred sites, historic trails, and

some other cultural resources that are significant for reasons other than data potential would be difficult or impossible to mitigate unless the resources and associated settings were avoided.

- Traditional cultural property locations, importance, and nature of use are defined by the communities associated with them. Maintaining access to and reducing impacts on them are responsibilities of the BLM and are important objectives of cultural resource management.

10.16.2 Impacts Common to All Alternatives

Under all alternatives, the BLM would continue to adhere to the existing laws, such as the National Historic Preservation Act, and cultural resource related policy like that found in the BLM manuals and handbooks, such as Manual 8100 The Foundations for Managing Cultural Resources (BLM 2004b). This would generally act to protect culturally significant resources from impacts related to ground-disturbing activities, alterations to setting, and vandalism or unauthorized collection. It would also contribute to mitigating unavoidable impacts to cultural resources through various strategies. These might involve the collection of scientific data during cultural resource inventories or excavations, as well as in situ preservation to minimize physical disturbance and avoidance measures to guide activities away from sensitive areas. The BLM would continue to identify and manage cultural resources on a programmatic and project specific level. Additionally, continued consultation and cooperation with State Historic Preservation Offices and Native American Tribes would allow information on cultural properties and cultural landscapes to continue to be compiled and concerns regarding sensitive cultural resources such as TCPs to be addressed. This would enable better future management and protection of the integrity of these resources.

10.16.3 Alternative 1

GRSG Management

Under Alternative 1, HMAs and SFAs would be designated in GRSG habitat. In all states, a disturbance cap ranging from 3 to 5% would be implemented within PHMA. In Wyoming, a 5% cap is made at the project area scale and includes disturbance from wildfire and agriculture. In all other states (Colorado, Montana, Idaho, Nevada, California, Oregon, Utah, North Dakota, and South Dakota) a 3% cap would not include wildfire or agriculture and the cap would apply not only at the project area scale but also at the biologically significant unit scale within PHMA. In Idaho the cap could be exceeded in utility corridors if it is a benefit to GRSG.

Management related to HMAs and SFAs under Alternative 1, including disturbance caps, would protect cultural resources in these areas from disturbance related impacts to varying degrees depending on the activity and location. While this would continue to reduce potential for impacts on cultural resources in HMAs, it is likely at least some of the development related impacts would be displaced to locations outside of HMA, exposing cultural resources in other areas to greater potential for impacts.

Minerals Management

Under Alternative 1, leasing of fluid minerals would be permitted within PHMAs (and IHMAs in Idaho), with NSO) stipulations. The NSO stipulations would reduce potential for ground disturbing activities, changes to site setting, and increases in access due to development activities within PHMAs and IHMAs.

Under Alternative 1, closure of PHMA and IHMA to saleable and nonenergy mineral development (with some limited exceptions) would reduce potential within PHMAs and IHMAs for ground disturbing activities, changes to site setting, and increases in access due to development activities.

Under Alternative 1, the BLM previously recommended that all SFAs be withdrawn from location and entry under US mining laws. Recommending areas for withdrawal from location and entry under the Mining Law

of 1872 does not restrict any activities and therefore, such recommendation does not have any impacts. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Under Alternative 1 fluid, saleable, and nonenergy mineral development in GHMAs would be subject to a mixture of management measures intended to minimize impacts on GRSG including designation as open, controlled surface use, closed, or NSO within varying distance of GRSG leks. These measures would reduce potential for ground disturbing activities, changes to site setting, and increases in access to impact cultural resources within GHMAs, though not to the degree that the management described above for PHMAs and IHMAs would.

While restrictions from minerals management under Alternative 1 would reduce potential for impacts on cultural resources within HMAs and SFAs, it would also likely result in a shift of some of these activities to suitable areas outside of them where possible, increasing potential for impacts on cultural resources outside of HMAs and SFAs. Overall, restrictions from minerals management under Alternative 1 could make development more costly and difficult or prevent development that could not be relocated to a suitable area. This would continue to be generally protective of cultural resources across the planning area.

Renewable Energy Management

Under Alternative 1, PHMA would be excluded from wind energy development except in some Oregon counties where PHMA would be designated as avoidance and Wyoming, where all PHMA would be designated as avoidance or open if there would be no impact to GRSG. IHMA in Idaho would be designated as avoidance for wind energy development.

Under Alternative 1, PHMA would be excluded from solar energy development, except in Wyoming where solar energy development would not be addressed and in Oregon, where it would be designated as avoidance. IHMA would be designated as avoidance for solar energy development.

Under Alternative 1, GHMAs would be a mix of open, avoidance, and exclusion for wind and solar that would vary by state. Exclusion or avoidance of wind and solar energy development would reduce potential within these areas for ground disturbing activities, changes to site setting, and increases in access due to development.

Impacts on cultural resources from ground disturbance, alteration of setting, and increased access related to renewable energy development would be the same as those described under Nature and Type of effects. While excluding or avoiding renewable energy development within HMAs under Alternative 1 would reduce potential for impacts on cultural resources within these areas, it would likely result in a shift of these activities to suitable areas outside of HMAs, negatively impacting cultural resources outside of them. Overall, the restrictions on renewable energy development under Alternative 1 could make development more costly and difficult or prevent any uses that could not be relocated to a suitable area. This would continue to be generally protective of cultural resources across the planning area.

Lands and Realty Management

Under Alternative 1, all states would designate PHMA/IHMAs as avoidance for major and minor ROWs, except for Wyoming which would be open to minor ROWs with buffers and mitigation. This would reduce potential within designated PHMAs and IHMAs for ground disturbing activities, changes to site setting, and increases in access due to ROW development.

Under Alternative 1, GHMAs would be designated as avoidance for major ROW development in Colorado, California, Nevada, and Oregon. In Idaho and Utah GHMAs would be open to major ROWs with minimization measures, and Wyoming is open to major ROWs. All states would be open to minor ROW development with mitigation, except for Wyoming which would not require mitigation. This would reduce potential within GHMAs for ground disturbing activities, changes to site setting, and increases in access due to ROW development, though to a much lesser degree than ROW related management for PHMAs and IHMAs.

While excluding or avoiding ROW development within HMAs under Alternative 1 would continue to reduce potential for impacts on cultural resources within these areas, it would likely result in a shift of these activities to suitable areas outside of HMAs, negatively impacting cultural resources outside of them.

Livestock Grazing Management

Under Alternative 1, all PHMAs, IHMAs, and GHMAs would be available for livestock grazing except for in Oregon where some or all of RNAs would be unavailable. Livestock grazing would continue to create potential for impacts on cultural resources within these areas from ground disturbance like trampling and changes to site setting through vegetation changes.

Wild Horse and Burro Management

Under Alternative 1, in all states where wild horses and burros overlap with GRSG habitat, the BLM would continue to manage wild horse and burro populations within established AMLs and incorporate GRSG objectives into wild horse and burro management. Keeping wild horse and burro populations at established AMLs, and prioritized gathers to accommodate GRSG habitat objectives would keep wild horse and burro populations from increasing. Any reduction in AMLs from incorporation of GRSG objectives into wild horse and burro management could decrease wild horse and burro populations. Restrictions on wild horses and burros under Alternative 1 would maintain or decrease the current potential for surface disturbance and changes to site setting from wild horse and burro grazing, extending protection to cultural resources.

10.16.4 Alternative 2

GRSG Management

Under Alternative 2, the impacts on cultural resources from designating SFAs and HMAs within GRSG habitat would be similar to those described under Alternative 1, although SFAs in Utah, Wyoming, Nevada and Idaho would not be designated under Alternative 2. Under Alternative 2, the impacts on cultural resources from instituting a disturbance cap in GRSG habitat would be very similar to those described under Alternative 1, relevant differences being that in Utah the cap can be exceeded if it is a benefit to GRSG, and in Idaho the cap only applies at the BSU-scale, both of which could result in additional impacts from development beyond what would be seen under Alternative 1.

Similar to Alternative 1, management related to HMAs and SFAs under Alternative 2 would protect cultural resources in these areas from disturbance related impacts to varying degrees depending on the activity and location. The differences in GRSG management under Alternative 2 would reduce GRSG related restrictions in these areas that are protective of cultural resources.

Minerals Management

Under Alternative 2, impacts from fluid mineral management in PHMAs and GHMAs would be similar to those described for Alternative 1, except in Colorado PHMAs would not be closed to fluid mineral leasing and GHMAs would have NSO stipulations instead of closure. The increased potential for fluid mineral leasing

and associated activities in Colorado GRSG habitat from these changes would increase the potential for related impacts on cultural resources in these areas.

Under Alternative 2, impacts from saleable and nonenergy mineral management in PHMAs and GHMAs would be similar to those described for Alternative 1, except that in Idaho consideration of new free use permits would be allowed and in Nevada there would be exception criteria added to closure. The increased potential for saleable and nonenergy mineral development in Idaho and Nevada GRSG habitat would increase the potential for related impacts on cultural resources in these areas.

Under Alternative 2, the recommendation that all SFAs be withdrawn from location and entry under US mining laws (except in Montana, North Dakota, and South Dakota) would be removed. This removal would have no impact because withdrawals are initiated and considered not through land use planning but through a separate process outlined in section 204 of FLPMA. Only the Secretary may withdraw lands through a Public Land Order.

Under Alternative 2, restrictions from minerals management would reduce potential for impacts on cultural resources within HMAs and SFAs and would also likely result in a shift of some of these activities to suitable areas outside of them where possible. This would increase potential for impacts on cultural resources outside of HMAs and SFAs. Overall, restrictions from minerals management under Alternative 2 could make development more costly and difficult or prevent uses that could not be relocated to a suitable area. This would be generally protective of cultural resources across the planning area.

Renewable Energy Management

Under Alternative 2, the impacts from solar and wind energy management in PHMAs and GHMAs would be the similar to those described for Alternative 1, with some additional exception criteria added to exclusion and avoidance of HMAs in Nevada and California. These exception criteria would increase potential for ground disturbing activities, changes to site setting, and increases in access related to renewable energy development in these areas.

Lands and Realty Management

Under Alternative 2, the impacts from ROW management would be similar to those described for Alternative 1, with the addition of exception criteria for ROWs in PHMAs in Nevada. These exception criteria would increase potential for ground disturbing activities, changes to site setting, and increases in access related to ROW development in these areas.

Livestock Grazing Management

Under Alternative 2, the impacts from livestock grazing management would be similar to those described for Alternative 1. In Utah, Wyoming, and Nevada, the prioritization for review and processing of grazing permits in SFAs and PHMAs was removed; however, the BLM would still have the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value.

Wild Horse and Burro Management

Under Alternative 2, the impacts from wild horse and burro management would be the same as those described for Alternative 1.

10.16.5 Alternative 3

GRSG Management

Under Alternative 3, all areas managed for GRSG would be designated PHMAs, with some states considering expanding HMA boundaries to include areas of adjacent non-habitat, unoccupied historic GRSG habitat, or areas with potential to become GRSG habitat as PHMAs. Under Alternative 3, The disturbance cap is 3%, applies at the project scale, and in accordance with the HAF (Stiver et al. 2015) Fine Scale boundaries range wide. Of note, under Alternative 3, the disturbance cap would include wildfire and agriculture as well as infrastructure, greatly increasing the amount of potential disturbance included in the disturbance calculation for those states that do not do so under Alternative 1 (all but Montana and Wyoming)

Under Alternative 3, the HMA designation scheme would create the highest acreage of PHMA, and along with the most robust version of the disturbance cap, offers the highest level of protection to cultural resources in HMAs from GRSG related restrictions among the alternatives.

Minerals Management

Under Alternative 3, closure of PHMAs to fluid minerals, saleable minerals, and nonenergy minerals related development offers the highest level of related protections to cultural resources from GRSG related restrictions among the alternatives.

Under Alternative 3, the recommendation that all PHMAs be withdrawn from location and entry under US mining laws would be made. This recommendation would have no impact on ground disturbing activities, changes to site setting, or access due to related locatable mineral development because withdrawals are initiated and considered not through land use planning but through a separate process outlined in section 204 of FLPMA. Only the Secretary may withdraw lands through a Public Land Order.

Renewable Energy Management

Under Alternative 3, impacts on cultural resources from ground disturbance, alteration of setting, and increased access related to renewable energy development would be the same as those described under Nature and Type of effects. Only PHMA would be designated under Alternative 3, and all designated PHMA would be excluded from solar and wind energy development without exceptions. These exclusions would decrease potential in designated HMAs for ground disturbing activities, changes to site setting, and increases in access due to solar and wind energy related development the most among alternatives.

Lands and Realty Management

Under Alternative 3, PHMA would be excluded from ROW development outside of designated corridors. These exclusions would decrease potential for ground disturbing activities, changes to site setting, and increases in access due to ROW related development inside PHMAs, and would designate the most acreage of PHMA among alternatives. However, the exclusion of ROW development in PHMAs could lead to creation of longer ROW routes to get around closed areas. Longer ROW routes would increase potential for ground disturbing activities, changes to site setting, and increases in access outside of PHMAs.

Livestock Grazing Management

The management of PHMA as unavailable for livestock grazing would cause the greatest decrease in potential for related impacts on cultural resources among alternatives. However, removal of all grazing could reduce the removal of fine fuels across the landscape, making the decision area potentially at higher risk of a large-scale wildfire that could damage or destroy cultural resources located at or near the surface.

Wild Horse and Burro Management

The removal of wild horses and burros would decrease the potential for related impacts on cultural resources within PHMAs the most among alternatives.

10.16.6 Alternative 4

GRSG Management

Under Alternative 4, the BLM would consider adjustments to HMA boundaries from the 2015 and 2019 amendments based on new information such as updated science and mapping that could result in expansion of HMAs, removal of current HMA designation, or re-categorization of HMAs. Under Alternative 4, the impacts on cultural resources from designating HMAs within GRSG habitat would likely be similar to those described under Alternative 1, although SFAs would not be designated under Alternative 4.

Under Alternative 4, the disturbance cap in PHMA (and IHMA in Idaho) for all states would be 3% for new and pre-existing authorizations at the project scale and also within HAF fine scale habitat selection area, and would apply only to infrastructure (not to wildfire or agriculture). Impacts from the disturbance cap as instituted under Alternative 4 would be similar to those under Alternative 1.

Minerals Management

Similar to Alternative 1, under Alternative 4 fluid mineral leasing management would seek to minimize impacts on GRSG through reduction of habitat fragmentation and loss, which would be generally protective of cultural resources in GRSG habitat. Under Alternative 4 a greater number of waivers, exceptions, and modifications for fluid minerals leasing applied across a larger portion of the planning area could enable a greater degree of development in HMAs than would be seen under Alternative 1, leading to increased potential for impacts on cultural resources related to mineral development, as described in *Nature and Type of Effects*.

Renewable Energy Management

Under Alternative 4, PHMA would be managed as exclusion for utility scale wind and solar development while IHMA would be managed as exclusion for utility scale wind and solar development within 3.1 miles of active leks, with the rest of IHMA managed as avoidance. Unique to Alternative 4, all areas within 0.5 miles of PHMA or IHMA would be managed as avoidance for utility scale wind and solar development. Under Alternative 4, the overall impacts on cultural resources from managing HMAs as exclusion and avoidance areas for wind and solar energy development would be similar to those described for Alternative 3.

Lands and Realty Management

Under Alternative 4, PHMA and IHMA as well as a 0.5 mile buffer around them would be designated as avoidance for major transmission ROWs. GHMA would also contain at least some areas designated as ROW avoidance, depending on habitat mapping at the state level. Despite the addition of a 0.5-mile ROW avoidance buffer on PHMA and IHMA, the lack of major ROW exclusions under Alternative 4 could result in shorter ROWs, reducing the overall acreage where cultural resources would potentially be impacted across the planning area compared to Alternative 1.

Livestock Grazing Management

Impacts from livestock grazing management would be the same as described under Alternative 1.

Wild Horse and Burro Management

Impacts from wild horse and burro management would be the same as described under Alternative 1.

10.16.7 Alternative 5

GRSG Management

Under Alternative 5, the BLM would consider adjustments to HMA boundaries from the 2015 and 2019 amendments based on new information such as updated science and mapping that could result in expansion of HMAs, removal of current HMA designation, or re-categorization of HMAs. Under Alternative 5, the impacts on cultural resources from designating HMAs within GRSG habitat would likely be similar to those described under Alternative 1, although SFAs would not be designated under Alternative 5.

Under Alternative 5, the disturbance cap in PHMA (and IHMA in Idaho) for all states would be 3% for new and pre-existing authorizations within HAF fine scale habitat selection area, and would apply only to infrastructure (not to wildfire or agriculture). In Wyoming and Montana, a 5% cap is made in PHMA at the project scale and includes disturbance from wildfire and agriculture. In all other states (Colorado, Montana, Idaho, Nevada, California, Oregon, Utah, North Dakota, and South Dakota) a 3% cap at the project scale would not include wildfire or agriculture related disturbance. Impacts on cultural resources from the disturbance cap as instituted under Alternative 4 would be similar to those under Alternative 1.

Minerals Management

Under Alternative 5, impacts on cultural resources from fluid mineral management would be similar to those described under Alternative 4. The management of fewer acres as NSO under Alternative 5 could make some cultural resources more susceptible to impacts from fluid mineral exploration and development as described in the *Nature and Type of Effects*.

Renewable Energy Management

Under Alternative 5, Impacts on cultural resources related to renewable energy development would be the same as those described under Nature and Type of Effects. Under Alternative 5, PHMA and IHMA would be managed as avoidance for utility scale wind and solar development while GHMA would be open to it. Impacts on cultural resources within HMAs would be greater than under Alternative 1 due to the lack of HMA designated as solar and wind energy exclusion areas, however overall likelihood of these impacts within the planning area are likely to be the similar to that under Alternative 1, since impacts on cultural resources due to renewable energy development may only be displaced instead of avoided entirely.

Lands and Realty Management

Under Alternative 5, impacts on cultural resources related to ROW avoidance would be the same as those described under Nature and Type of effects. The designation of GHMA as open to major ROWs and lack of major ROW exclusions under Alternative 5 could result in shorter ROWs compared to management under all the other alternatives, since all other alternatives include greater ROW avoidance or exclusion designations. Shorter ROWS would reduce the overall area where cultural resources could potentially be impacted by ROWs across the planning area compared to all other alternatives.

Livestock Grazing Management

Under Alternative 5, the impacts from livestock grazing management would be the same as those described for Alternative 1.

Wild Horse and Burro Management

Impacts from wild horse and burro management under Alternative 5 would be the same as those described for Alternative 1.

10.16.8 Alternative 6

Impacts on cultural resources under Alternative 6 would be similar to impacts under Alternative 5 except for the designation of ACECs. ACECs designated for the benefit of GRSG under Alternative 6 would have greater restrictions on mineral exploration, including fluid minerals, nonenergy minerals, saleable minerals and mineral materials as well as development of major ROWs, wind and solar within the ACECs, which would be protective of cultural resources inside these areas. The overall likelihood of impacts on cultural resources from various types of development within the planning area would be similar to that under Alternative 5 since impacts on cultural resources may only be displaced outside of ACECs instead of avoided entirely.

10.17 TRIBAL INTERESTS

10.17.1 Methods and Assumptions

Indicators

The use of indicators in NEPA analysis should provide information on determining the extent or degree to which a tribal interest, resource, or setting is damaged, its physical integrity is lost, or its physical integrity is otherwise adversely affected by a proposed action. However, unlike cultural resources, which have legal criteria for determining the impacts, the impacts on areas or resources of tribal interest and the severity of impacts are dependent upon the perspective and context of the tribe or affected group. In other words, significant impacts would be determined by Indian tribes defining what is culturally or spiritually important to them. When assessing whether the action would have significant impact, the following level-of-effect indicators are carefully considered and consulted upon with tribal representatives:

- Magnitude: The amount of physical alteration or destruction that can be expected. The resultant loss of tribal value is not measurable in quantitative terms, but is described in qualitative summary.
- Severity: The irreversibility of an impact. Impacts that result in an irreversible and irretrievable loss of value are of the highest severity.
- Duration: The length of time an impact persists. Impacts may have short-term or temporary effects, or conversely, more persistent, long-term effects on tribal values.
- Range: The spatial distribution, whether widespread or site-specific, of an impact.
- Frequency: The number of times an impact can be expected. For example, an impact of variable magnitude and severity may occur only once. An impact such as that resulting from annual activities, such as road maintenance, may be of recurring or ongoing nature.

Assumptions

In addition to the assumptions in **Section 4.1.1**. this analysis includes the following assumptions:

- Native Americans or other traditional communities may have concerns about federal impacts on cultural resources, religious practices, or natural resource gathering that may occur because of federal actions. In cases where these concerns may be present, consultation would occur with the potentially affected Indian tribes.
- There may be areas of importance to contemporary Native Americans that are not readily identifiable outside of those communities.
- Consultation would continue with Indian tribes to identify any traditional cultural properties or resource uses and address impacts. Through this process, effects would be minimized or eliminated, although residual effects would be possible.

10.17.2 Impacts Common to All Alternatives

Under all alternatives the BLM would continue to manage BLM-administered lands in a manner that accommodates Native American religious traditions, practices, and beliefs as guided by directives contained in the BLM Manual 1780, BLM Handbook 1780-1, American Indian Religious Freedom Act (42 USC 1996), Native American Graves Protection and Repatriation Act (25 USC 3001), Executive Order 13007 (Indian Sacred Sites), and Executive Order 13084 (Tribal Consultation), Secretarial Order 3317, DOI Policy on Consultation with Indian Tribes (December 1, 2011), and Joint Secretarial Order 3403, on Fulfilling the Trust Responsibility to Indian Tribes in the Stewardship of Federal Lands and Waters (November 21, 2022). All alternatives allow for the appropriate tribal governments to consult on a case-by-case basis on undertakings on BLM-administered lands that could affect Native American concerns. The BLM would continue to identify, protect, and preserve tribal assets, treaty rights, sacred/religious sites, or special use areas through site- and project-specific modification or mitigation on a case-by-case or project-by-project consultation basis that could affect Native American concerns.

Under all alternatives, actions that provide protections for GRSG or its habitat by limiting access into areas or excluding surface-disturbing activities, such as NSO and restrictions on surface and vehicle use would protect cultural resources from effects due to surface disturbance, erosion, effects on setting and access leading to vandalism, inadvertent damage, and unauthorized collection of cultural resources. These actions could also increase tribal opportunities to maintain specific traditional practices and values such as traditional plant gathering, hunting animals including GRSG, and the role played by GRSG in oral traditions and cultural practices such as observing lekking behavior as described in the Nevada and Northeastern California Greater Sage-Grouse Proposed Land Use Plan Amendment and Final Environmental Impact Statement (BLM 2015) if the current leasing of nonenergy minerals has led to decreases in GRSG populations.

10.17.3 Alternative 1

GRSG Management

Under Alternative 1, GRSG habitat would be separated into SFAs, PHMAs, IHMAs, and GHMAs. Restrictions to land use and surface-disturbing activities would occur within each HMA and SFA, depending on the classification. Corresponding management actions, including lek buffers, required design features, fluid mineral leasing prioritization, and habitat objectives, would provide a hierarchy of potential conditions to minimize effects in HMAs which could stabilize or increase GRSG populations in the future. These management goals and objectives could lead to increased opportunities for tribes to maintain traditional cultural practices and values, such as observing lekking behavior. However, use of Sagebrush Focal Areas (SFAs) and sagebrush-dominated vegetation areas in HMAs to the restrict development has the potential to push development into other vegetation regimes where cultural resources and areas of tribal interest may also exist. For example, in northwest Colorado, there are known concentrations of archaeological resources in pinyon-juniper vegetation areas that could face increased potential for impacts if ground-disturbing activities are directed into those areas when sagebrush-dominated areas are more restrictive. In Nevada and California, tribes have expressed concern for access to traditional pine nutting areas that could be similarly impacted if development is pushed to other vegetative areas in preference for SFA conservation. However, project-specific Section 106 compliance and tribal consultation should mitigate the effects of development on BLM-administered lands outside of sagebrush-dominated areas.

Lands and Realty Management

Under Alternative 1, the BLM would manage and minimize effects of land use actions on PHMA and GHMA; however, it would allow for corridors and ROWs that result in a net conservation gain for GRSG. Tribes would be able to maintain traditional practices by accessing pine nutting areas and observing lekking behavior.

Restricting new development and land use authorizations near leks would likely maintain traditional tribal cultural practices and values. Cultural resources important to tribes could be impacted by the development of transmission lines within new and existing utility corridors, specifically surface disturbances from construction of poles, roads, and ancillary features, and visual impacts to the setting.

All states would have a 3% disturbance cap applied to land use activities other than wildfire and agriculture, except MT and WY, which would have a 5% cap that would include wildfire and agriculture. The 3% cap would be calculated at both the BSU-scale and at proposed project analysis area within PHMA, though in ID, the cap could be exceeded in utility corridors. Including caps at both project and BSU scales in the 3% states would reduce disturbance on both the local and landscape scales, therefore, provide protection for resources of tribal interest. A higher disturbance cap in MT and WY calculated at only the project-scale could lead to greater levels of disturbance within a project area, and therefore greater potential direct disturbances to tribally-important resources and the potential for greater cumulative disturbances across multiple projects.

Renewable Energy development is excluded in PHMAs in all states except WY where PHMAs are avoidance or open if there is no impact to GRSG. IHMAs and certain areas in OR would use GRSG avoidance rather than exclusion. GHMAs would be a mix of open, avoidance, and exclusion for wind and solar by state. Allowing renewable energy development within certain GRSG core habitat areas could adversely impact cultural resources and access for tribal cultural practices in those areas.

Minerals Management

Leasing of fluid minerals would be allowed in PHMAs and ID IHMAs, subject to NSO stipulations and/or seasonal restrictions. Allowing fluid mineral leasing would create surface disturbance that could impact cultural resources important to tribes in those areas. However, NSO stipulations on new leases would protect PHMAs from surface-disturbing activities, which could protect cultural resources and increase the opportunities for tribes to participate in traditional cultural practices, if the NSO stipulations were to increase or stabilize GRSG populations.

Closing PHMA to saleable and nonenergy minerals would protect cultural resources important to tribes and increase the opportunities for tribes to participate in traditional cultural practices if the closures were to increase or stabilize GRSG populations.

Livestock Grazing

Management of livestock grazing in PHMA and GHMA could decrease tribal opportunities to maintain specific traditional practices and values such as observing lekking behavior if those current management practices have led to decreases in GRSG populations.

Wild Horse and Burro Management

Management of wild horses and burros in PHMA and GHMA could decrease tribal opportunities to maintain specific traditional practices and values such as observing lekking behavior if those current management practices have led to decreases in GRSG populations.

10.17.4 Alternative 2

GRSG Management

Impacts from designating GRSG habitat as SFAs, PHMAs, IHMAs, and GHMAs would be similar as to those described for Alternative 1. However, some SFAs would be removed in UT, WY, NV, and ID. Removing SFAs in UT, WY, NV, and ID would reduce protections to GRSG and habitat, which could lead to decreased

opportunities for tribes to maintain traditional cultural practices and values, such as observing lekking behavior.

Lands and Realty Management

Impacts from ROW management would be the same as described for Alternative 1 (with additional exception criteria in NV/CA). The additional exception criteria for ROW and renewable energy in NV/CA could increase the potential for impacts to cultural resources and traditional uses from surface-disturbing activities, though the criteria would likely avoid impacts to GRSG. Impacts from disturbance caps at 3%, and 5% in MT and WY, would be similar to Alternative, though the caps could be exceeded in both ID and UT under certain conditions which could pose a higher risk of potential impacts to resources of tribal interest in those states.

Minerals Management

Impacts from fluid mineral management in PHMAs and GHMAs would be the same as described for Alternative 1, except in CO PHMAs would have no closed areas and CO GHMAs would have NSO in place of closed areas. The exposure of areas in CO to fluid mineral leasing could increase the risk of potential impacts to cultural resources and decrease opportunities for tribes to maintain traditional cultural practices and values in areas where fluid mineral leasing occurs.

Impacts from saleable and nonenergy mineral management in PHMAs and GHMAs would be the same as described for Alternative 1, except in ID IHMAs where new free use permits for saleable minerals would be considered and NV PHMAs would include exception criteria to closure for both saleable and nonenergy minerals. These actions could expose cultural resources to increased risk of potential impacts from surface-disturbing activities and decrease opportunities for tribes to maintain traditional cultural practices and values.

Removing the recommendation for withdrawal of the SFAs from location and entry under the Mining Law of 1872 in all states (except in MT/DK, which did not have a 2019 amendment) would have no impact on how surface-disturbing activities would impact cultural resources and would not impact GRSG disturbance and habitat alterations/degradation, nor would it impact opportunities for tribes to maintain traditional cultural practices and values. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Livestock Grazing Management

Impacts from domestic livestock grazing management would be the same as described for Alternative 1. In UT, WY, and NV, the prioritization for review and processing of grazing permits was removed; however, the BLM would still have the authority to prioritize staff time and budget to identify areas that aren't meeting land health standards and implement corrective actions in areas with the greatest GRSG habitat value.

Wild Horse and Burro Management

Impacts from wild horse and burro management would be the same as described for Alternative 1.

10.17.5 Alternative 3

GRSG Management

Under Alternative 3, the highest level of conservation for GRSG would be adopted with all areas managed for GRSG as PHMAs and establish management goals and objectives for specific resources in PHMA that could stabilize or increase GRSG populations in the future. If successful, these management goals and objectives could lead to increased opportunities for tribes to maintain traditional cultural practices and values such as observing lekking behavior.

Lands and Realty Management

New development would be substantially limited compared with Alternatives 1 and 2. All PHMAs would be excluded from new ROW authorizations. New linear ROWs would be allowed only in designated corridors. The potential for habitat degradation and fragmentation within the PHMAs would be reduced and this would result in increased opportunities for tribes to maintain traditional practices as well as increase protection of cultural resources important to tribes in those areas from surface-disturbing activities by reducing travel and access, which in, turn could reduce vandalism and collection. However, the inability to site ROWs in PHMAs could lead to longer ROW routes in order to bypass closed areas. Longer routes would increase surface disturbance and other impacts of ROW siting, resulting in more areas that would be exposed to ground disturbance, erosion, and impacts from increased access outside of PHMAs. A 3% disturbance cap would be applied to pre-existing land-use authorization including wildfire and agriculture at multiple scales and with now exceptions, offering a higher level of protection to resources of tribal interest than alternatives 1 and 2.

Under Alternative 3, PHMAs in all states would be ROW exclusion areas for wind and solar energy development. Alternative 3 would offer more protection from renewable energy development than under Alternatives 1 and 2 because more areas would be excluded from renewable energy development with no exceptions. Excluding wind energy development in GRSG priority and general habitat areas would reduce surface disturbance and visual impacts to cultural resources important to tribes in those areas as well as preserving opportunities for tribes to maintain traditional cultural practices.

Minerals Management

Closing PHMAs in all states to fluid mineral leasing, saleable minerals, and nonenergy minerals would reduce potential for impacts to GRSG and habitat to a greater extent than Alternatives 1 and 2. This is because areas closed to leasing could not be developed at any point. Closing PHMAs to mineral leasing and development would protect cultural resources important to tribes from surface-disturbing activities as well as subsurface activities (e.g., directional drilling). GRSG would not be exposed to disruption that is often associated with the noise and human activity that accompanies construction, development, or production activities, preserving opportunities for tribes to maintain traditional cultural practices.

Recommending PHMAs for withdrawal from location and entry under the US mining laws would have no impact on tribal opportunities to practice traditional cultural behavior and values such as observing lekking behavior if this management strategy stabilizes or increases GRSG populations. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA.

Livestock Grazing Management

Under Alternative 3, all PHMA would be unavailable for domestic livestock grazing that would increase opportunities for tribes to maintain traditional practices, such as observing lekking behavior, if this grazing strategy stabilizes or increases future GRSG populations. Prohibiting livestock grazing within GRSG priority habitat could also protect cultural resources important to tribes in these areas from damage by livestock trampling. However, removal of all grazing could reduce the removal of fine fuels across the landscape, making the decision area potentially at higher risk of a large-scale wildfire that could damage or destroy tribal interests. Additionally, this alternative may decrease economic revenue to tribes holding grazing permits if their current AUMs are reduced.

Wild Horse and Burro Management

Removing wild horses and burros in those PHMAs with existing herd management areas in all states would increase habitat quality for wildlife, including GRSG, as described in **Section 4.2**. This increase in GRSG habitat quality would increase opportunities for tribes to maintain traditional practices.

10.17.6 Alternative 4

GRSG Management

Under Alternative 4, the BLM would consider adjustments to HMA boundaries from the 2015 and 2019 amendments based on new information such as updated science and mapping that could result in expansion of HMAs, removal of areas currently in HMA, or re-categorization of HMA prioritization. Impacts to resources of tribal interest from HMA designations under Alternative 4 are expected to be similar to alternatives 1 and 2.

Lands and Realty Management

Under Alternative 4, impacts from managing PHMAs in all states and ID IHMAs as ROW avoidance areas would be similar to those described for Alternative 1.

Impacts from applying a 3% disturbance cap under Alternative 4 would be similar as to those described for Alternative 3, however, the cap would apply to both existing and proposed infrastructure authorizations and wildfire and agriculture would not be included in the disturbance calculation. As a result, the level of possible disturbance to resources of tribal interest from other sources (energy development, roads, RPWs, etc.) would be relatively higher than if wildfire and agriculture were included in the disturbance calculation.

Impacts from managing PHMAs in all states as ROW exclusion areas for utility-scale wind and solar energy development would be similar to those described for Alternative 3. Unique to Alternative 4, all areas within 0.5 miles of PHMA or IHMA would be managed as avoidance for utility scale wind and solar development. However, since PHMAs would apply to a smaller area under this alternative, the extent of protection from disturbance associated with from renewable energy development would be less.

Minerals Management

Under Alternative 4, fluid mineral leasing management would seek to minimize impacts on GRSG through reduction of habitat fragmentation and loss, which would be generally protective of cultural resources and other tribal interests in GRSG habitat. Under Alternative 4 a greater number of waivers, exceptions, and modifications for fluid minerals leasing applied across a larger portion of the planning area could enable a greater degree of development in HMAs than would be seen under Alternative 1.

Livestock Grazing Management

Impacts under Alternative 4 would be the same as those described under Alternative 1.

Wild Horse and Burro Management

Impacts under Alternative 4 would be the same as those described under Alternative 1.

10.17.7 Alternative 5

GRSG Management

Under Alternative 5, impacts to tribal interests would be similar to Alternative 4 with the additional consideration of adjustments to HMAs to balance multi-use opportunities, which has the potential to produce impacts on tribal interests since HMAs would cover a smaller area under Alternative 5.

Lands and Realty Management

Under Alternative 5, impacts from managing PHMAs in all states and ID IHMAs as ROW avoidance areas and applying minimization measures where major ROWs cannot be avoided would be similar to those described for Alternative 4. GHMA would be open to major ROW development with minimization measures of managing the severity of a project impact at a specific location. Potential impacts on areas of tribal interest would be similar to those as described under Alternative 4, but greater in magnitude due to GHMA being managed as open to major ROW development.

Impacts from applying a 3% disturbance cap under Alternative 5 would be the same as described for Alternative 4, except in WY and MT that would have a 5% disturbance cap at the project scale. Impacts from exceeding the 3% disturbance cap under certain conditions would be similar to those described for Alternative 4, but more exceptions would be allowed, which may result in increased development and potential disturbance to resources of tribal interest.

Minerals Management

Under Alternative 5, impacts on areas of tribal interest from fluid mineral management would be identical to those described under Alternative 4.

Livestock Grazing Management

Impacts under Alternative 5 would be the same as those described under Alternative 1.

Wild Horse and Burro Management

Impacts from wild horse and burro management under Alternative 5 would be similar to those described for Alternative 1. Management within established AMLs could increase in GRSG habitat quality, which could increase opportunities for tribes to maintain traditional practices in some areas.

10.17.8 Alternative 6

Impacts on areas of tribal interest under Alternative 6 would be similar to impacts under Alternative 5 except for the designation of ACECs. ACECs designated for the benefit of GRSG under Alternative 6 would have greater restrictions on mineral exploration, including fluid minerals, nonenergy minerals, saleable minerals and mineral materials as well as development of major ROWs, wind and solar within the ACECs, which would lessen the potential for impacts to areas of cultural interests in these areas.

10.18 LANDS WITH WILDERNESS CHARACTERISTICS

10.18.1 Methods and Assumptions

Indicators

Any change in the existing conditions of lands with wilderness characteristics is an indicator of impacts to the inventoried characteristics. Changes in existing conditions could be positive or negative, such as, impacts affecting preservation or degradation of inventoried characteristics. The types of actions that can result in these impacts are discussed in more detail in **Section 4.18.1**, Nature and Type of Effects.

Indicators of inventoried wilderness characteristics are as follows:

- Size—Projects or management actions that bisect a lands with wilderness characteristics unit so that there are no longer 5,000 acres or more of contiguous BLM lands would change the boundary of the unit and cause the unit to not meet the size requirements. Examples include issuing rights of way and/or constructing or improving roads that would create a wilderness inventory boundary and potentially reduce the size of lands with wilderness characteristics inventoried units.

- Naturalness—Impacts would result from new or a lack of human developments, surface disturbances, or vegetation manipulations that make the area appear to the casual visitor as more or less affected primarily by the forces of nature.
- Outstanding opportunities for solitude or a primitive, unconfined type of recreation—Indicators of impacts that may influence a visitor's solitude include distance between areas of frequent visitation, vegetative screening around the proposed action, topography of the area around the proposed action, attraction of significant additional public visitation, and the ability of visitors to avoid the proposed action and find seclusion in other parts of the inventoried unit. Indicators of impacts that may influence a visitor's opportunity for primitive and unconfined recreation include impairment to the qualities of the primitive and unconfined recreation opportunities to the degree that they would no longer be outstanding. Some examples of primitive and unconfined types of recreation include: hiking, backpacking, fishing, hunting, spelunking, horseback riding, climbing, river running, cross-country skiing, snowshoeing, dog sledding, photography, bird watching, canoeing, kayaking, sailing, and sightseeing for botanical, zoological, or geological features.

Assumptions

The analysis includes the following assumptions:

- All units identified as possessing wilderness characteristics were determined by the BLM to meet the inventory criteria outlined in the BLM Manual 6310 (i.e., size, apparent naturalness, and contain outstanding opportunities for solitude or a primitive and unconfined type of recreation).
- All wilderness characteristics inventories will be maintained and will be updated whenever actions are proposed that could impact BLM-administered lands determined to possess wilderness characteristics.
- The BLM can choose to manage lands with wilderness characters for multiple use rather than the preservation of wilderness character. This analysis addresses the impacts on wilderness characteristics.

10.18.2 Alternative 1

Under Alternative 1, fluid minerals would be managed within PHMA and IHMA as open with an NSO stipulation in most states with the exception that PHMA in Colorado would be closed to fluid mineral leasing within 1 mile of leks. Fluid mineral leasing in PHMA within Wyoming and Montana would also be subject to density and disturbance limits. Fluid mineral leasing within GHMA would be managed as closed within one mile of leks in Colorado and Oregon. Fluid minerals would be managed with an NSO stipulation in GHMA with varying distances from leks depending on the state. Fluid minerals would also be managed within GHMA as controlled surface use in California, Idaho, Nevada, Oregon, and Wyoming. Areas open to fluid minerals leasing and development would not provide protection to wilderness characteristics because development and infrastructure related to those actions would impact wilderness characteristics as discussed above under *Nature and Type of Effects*.

PHMA and IHMA would be managed as closed to saleable minerals in most states and closed to new development of nonenergy leasable minerals. These closures would protect the naturalness of the lands with wilderness characteristics. Lands in GHMA would have minimization measures for saleable mineral and nonenergy leasable mineral development, which would minimize impacts, but would not prevent impacts from saleable mineral development on lands with wilderness characteristics.

SFAs were recommended for withdrawal from mineral location and entry within PHMA. Recommending areas for closure to the mining laws for locatable exploration or development does not restrict any activities and therefore, such recommendation does not have any impacts. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA. Where lands with wilderness characteristics intersect with the areas open for mineral development, there is no certainty for protection of these wilderness characteristics.

PHMA and IHMA would be managed as ROW avoidance areas for major and minor ROWs. However, Wyoming would be open to ROWs with buffers and mitigation. Major ROW development within GHMA would vary by state. For minor ROWs, GHMA would remain open to ROW development with mitigation for all states, except for Wyoming, which does not require mitigation. ROW activities and associated development can reduce the size of lands with wilderness characteristics and can impair the apparent naturalness of the area and the experience of solitude, as described above under *Nature and Type of Effects*. Due to screening criteria, conditions for development, and required mitigation, applicants may find it easier to site their development outside of GRSG habitat, thereby leading to some additional protection of lands with wilderness characteristics within GRSG habitat.

Livestock grazing would be available in GRSG HMAs, except in Oregon where all or portions of 13 key RNAs would be unavailable. Impacts to wilderness characteristics would be the same as those described under *Nature and Type of Effects*.

10.18.3 Alternative 2

Under Alternative 2, impacts from management of fluid minerals on lands with wilderness characteristics would be similar as those described under Alternative 1. However, under Alternative 2, PHMA and GHMA within Colorado would not be managed as closed to fluid minerals, rather these areas would be managed as NSO within 1 mile of leks which would effectively provide the same protection to wilderness characteristics due to the lack of surface disturbance with this type of development.

Impacts from saleable minerals on lands with wilderness characteristics within PHMA and IHMA would be similar as those described under Alternative 1. However, under Alternative 2, Idaho would allow for consideration of new free use permits and Nevada would have exception criteria to the closed areas. Compared with Alternative 1, the free use permits, and exception criteria would allow for more impacts on lands with wilderness characteristics within PHMA and IHMA due to more areas allowing this surface disturbing activity. Impacts from saleable minerals and nonenergy minerals on lands with wilderness characteristics within GHMA would be the same as those described under Alternative 1.

The BLM would not recommend lands for withdrawal from locatable mineral entry within GHMA or PHMA. Recommending areas for closure to the mining laws for locatable exploration or development does not restrict any activities and therefore, such recommendation does not have any impacts. The Secretary proposes and makes withdrawals not through BLM land use planning but according to a separate process pursuant to section 204 of FLPMA. Where lands with wilderness characteristics intersect with the areas open for mineral development, impacts in these areas would be greater under this alternative compared with Alternative 1 due to no certainty for protection of wilderness characteristics.

PHMA would be managed similar to Alternative 1 for ROWs, except Nevada would have added exception criteria added which could allow for more impacts to wilderness characteristics under this alternative as described under *Nature and Type of Effects*. Impacts from ROWs on lands with wilderness characteristics would be the same as those described under Alternative 1 for GHMA.

Impacts from livestock grazing on lands with wilderness characteristics would be the same as those described under Alternative 1. In Oregon, livestock grazing would be available in all or portions of 13 key RNAs.

10.18.4 Alternative 3

Under Alternative 3, PHMA would be closed to fluid mineral leasing, saleable minerals, nonenergy leasable minerals, and recommended for withdrawal from locatable mineral entry providing the most protection from impacts described under *Nature and Type of Effects* to lands with wilderness characteristics than under any other alternative. However, a recommendation for withdrawal provides no protection to habitat. Withdrawals are initiated and considered not through land use planning but through a separate process outlined in section 204 of FLPMA.

PHMA would be managed as ROW exclusion areas which would result in the most protection of lands with wilderness characteristics compared to all other alternatives. ROW activities and associated development can reduce the size of lands with wilderness characteristics and can impair the apparent naturalness of the area and the experience of solitude, as described under *Nature and Type of Effects*. Precluding these types of activities would help protect wilderness characteristics.

Livestock grazing would be unavailable in PHMA which would result in the most indirect protection of lands with wilderness characteristics of all the other alternatives because lands with wilderness characteristics would not be subject to the types of impacts from livestock grazing that could reduce naturalness. In Oregon, key RNAs within PHMA would be unavailable for grazing with the same direct and indirect impacts as described under *Nature and Type of Effects*. However, removal of all grazing could reduce the removal of fine fuels across the landscape, making the decision area potentially at higher risk of a large-scale wildfire that could damage wilderness characteristics.

Management actions under Alternative 3 would have the overall greatest potential to maintain wilderness characteristics on lands with wilderness characteristics within PHMA when compared to all other alternatives. However, these management actions could lead to a buildup of fuels and increase the risk of wildfire. Wildfire would make affected areas less desirable for primitive recreation.

10.18.5 Alternative 4

Under Alternative 4, no changes to mineral resource use allocations would be made, but fluid mineral leasing would be managed to minimize potential for conflict and associated impacts from subsequent development in important habitats or connectivity areas. The evaluation of parcels and the consideration of development proximity, habitat significance, and potential would contribute to the preservation of naturalness in lands with wilderness characteristics as described under *Nature and Types of Effects.*

PHMA and IHMA would be managed as avoidance areas for major ROWs under this alternative. All areas within 0.5 miles of PHMA and IHMA would be managed as avoidance areas for ROWs to address indirect impacts to adjacent PHMA and IHMA. GHMA would be managed as avoidance areas within breeding, nesting, and limited-seasonal habitats where mapped. Impacts on lands with wilderness characteristics would be similar to those as described under Alternative 1, but lesser in magnitude due to the additional areas adjacent to HMAs being managed as avoidance areas for ROWs.

All GRSG HMAs would be available for livestock grazing, except in Oregon, where all or portions of 13 key RNAs would be unavailable. Livestock grazing would be managed toward meeting land health standards, which are informed by GRSG habitat objectives for Special Status Species. This alternative does not provide additional protections to lands with wilderness characteristics, as these lands were designated under existing

livestock grazing management. The purpose of livestock grazing is not to provide protection to lands with wilderness characteristics, and land health standards already exist under 43 CFR 4100, independent of such designations. New range improvement projects would be designed to enhance livestock distribution, and new structural range improvements would be placed in a way that minimizes impacts on GRSG and their habitat. This would limit the impacts on lands with wilderness characteristics from new range improvement projects as described under *Nature and Type of Effects*.

10.18.6 Alternative 5

Under Alternative 5, impacts from mineral resource use allocations on lands with wilderness characteristics would be the same as those described under Alternative 4.

PHMA and IHMA would be managed as avoidance areas for major ROWs under this alternative, but GHMA would be open to major ROW development with minimization measures of managing the severity of a project impact at a specific location. Impacts on lands with wilderness characteristics would be similar to those as described under Alternative 4, but greater in magnitude due to GHMA being managed as open to major ROW development.

Impacts from livestock grazing on lands with wilderness characteristics would be the same as those described under Alternative 4.

10.18.7 Alternative 6

Where lands maintained for wilderness characteristics overlap ACECs, management of these other areas could also indirectly protect wilderness characteristics due to the protective measures proposed for the other areas. These protective measures would include complementary management objectives, where lands with wilderness characteristics would be managed to protect them. This could offer some indirect protection of wilderness characteristics for units managed primarily for other resource considerations.

Under Alternative 6, ACECs would be open to fluid mineral leasing subject to NSO stipulations. Where ACECs overlap inventoried areas found to possess wilderness characteristics, impacts to the indicators of lands with wilderness characteristics would occur due to the surface disturbance and facility development associated with locatable and fluid mineral development. Closure of ACECs to new nonenergy minerals and saleable minerals operations would protect overlapping lands with wilderness characteristics from this type of surface disturbing development.

Management of ACECs as ROW exclusion areas would result in the protection of overlapping lands with wilderness characteristics. ROW activities and associated development can reduce the size of lands with wilderness characteristics and can impair the apparent naturalness of the area and the experience of solitude, as described under *Nature and Type of Effects*. Precluding these types of activities would help protect wilderness characteristics.

10.19 Recreation and Visitor Services

10.19.1 Methods and Assumptions

Methodology

This discussion analyzes the impacts that proposed management decisions would have on managing recreation, recreation opportunities, and the SRP program. Visitor use patterns are difficult to estimate and depend on many factors beyond the scope of management (e.g., recreation trends and economy). For this reason, qualitative language—for example, "increase" or "decrease"—is used to describe anticipated

impacts. For information on qualitative socioeconomic impacts on recreation, refer to **Section 4.11**, Social and Economic Conditions (Including Environmental Justice).

Indicators

Indicators of impacts on recreation resources are as follows:

- Change in the types of recreation activities, experiences, and benefits in the decision area
- Restrictions on the number and type of SRPs issued on an annual basis within the decision area

Assumptions

This analysis includes the following assumptions:

- Recreational OHV use will continue to be a recreation activity.
- Recreation activity, particularly recreational OHV use and mountain biking, is expected to increase throughout the life of current RMPs.
- Outside areas where recreation is the management focus, the BLM will manage recreation activities that consist mostly of dispersed activities where users participate in activities individually or in small groups.
- The potential for resource impacts and conflicts between all types of users, but particularly between motorized and nonmotorized users, will increase with increasing use.
- BLM management of areas unsuitable for public utilities (i.e., ROW exclusion areas) preserves recreation opportunities.
- Closure of areas to mineral development decreases the likelihood for conflict with recreation users and maintains desired recreation settings in those areas.
- Outdoor recreation will continue to be an important component of local economies.
- Demand for SRPs will remain steady or gradually increase.
- The BLM will continue to issue SRPs on a discretionary basis.

10.19.2 Impacts Common to All Alternatives

Under all alternatives, the BLM would continue to review and approve SRPs on a case-by-case basis within the planning area, and the overall number of large group and commercial SRPs would remain consistent. There would be no direct impacts on recreation through changes to the number and types of SRPs issued annually within the decision area. Any indirect impacts on SRPs would be related to the impacts on the change in the types of recreation activities, experiences, and benefits in the decision area.

Under all alternatives, disturbance caps which restrict the construction of recreation infrastructure would decrease access for recreation experiences that depend on road and trail development and could inhibit management objectives where developments are part of the desired conditions. If future recreation projects would exceed the disturbance cap in a particular area, the disturbance cap would prohibit construction of new recreation facilities such as campground, day-use areas, and trailheads in PHMA and GHMA. However, these disturbance caps would also limit development in some areas, thereby increasing remoteness and naturalness in areas managed for those objectives and enhancing the recreational user experience of primitive backcountry recreation activities and experiences over the long-term (BLM 2014).

10.19.3 Alternative 1

Under Alternative 1, existing restrictions on other resource uses, such as seasonal restrictions on fluid mineral development and disturbance caps, would indirectly affect recreation by reducing resource conflicts

in PHMA, IHMA, or GHMA (**Table 2-3**) as described in **Chapter 2**. Reducing resource conflicts with recreation enhances and preserves the recreational experiences in those areas. These restrictions would reduce the impacts on recreation from the general trend of resource conflict with increasing energy development on BLM-administered lands in those management areas over the long-term. Additionally, other key drivers of change, such as growing public demand for outdoor recreation and technological advances, would also shape future recreational opportunities.

Management of major ROW avoidance areas including those for power lines, pipelines, access roads, and communication sites in PHMA and IHMA and in GHMA in some states (CO, NV/CA, OR), would continue to improve recreation experiences over the long-term as these diminish the naturalness of the physical setting and the opportunities for recreation activities, experiences, and outcomes that require more remote and natural settings. These avoidance areas would not apply to existing roads and facilities.

10.19.4 Alternative 2

Under Alternative 2, there would be more exceptions to restrictions on other resource uses compared with Alternative 1, such as no closed areas for fluid mineral development in Colorado and additional exceptions to the disturbance cap. These exceptions would indirectly increase recreation conflicts with other resources in PHMA, IHMA, and GHMA compared with Alternative 1. While some forms of recreation, such as motorized recreation, may benefit from the expansion of roads associated with energy and mineral development, other forms of recreation, such as primitive recreation and solitude-seeking activities, could experience diminished user experiences due to increased noise, traffic, and industrial infrastructure. Over the long term, these exceptions could contribute to the broader trend of increased energy development on BLM-administered lands, further intensifying the impacts on recreational experiences, particularly for activities dependent on undisturbed landscapes. However, for OHV users, the increase in roads may provide enhanced access to recreation areas.

Management of ROW avoidance areas under Alternative 2 would be similar to Alternative 1, except in Nevada where additional exception criteria would allow for more ROWs to be constructed. This would diminish the naturalness of the physical setting and opportunities for recreation experiences in those areas over time for recreation activities that require more remote and natural settings; however, this exception criteria would only occur in Nevada. Some ROWs, such as for road maintenance and trail development, would enhance other recreational activities by providing better access to recreational activities.

Under Alternative 2, there would be fewer acres of PHMA and GHMA when compared to Alternative 1 (**Table 2-3**). This would restrict fewer acres of land subject to disturbance caps when compared to Alternative 1. Therefore, if future recreation projects would exceed the disturbance cap in a particular area, the disturbance cap would have the potential to restrict fewer acres than Alternative 1.

10.19.5 Alternative 3

Alternative 3 would impose the greatest restrictions on other resources, including closing fluid mineral leasing in PHMA, and would most greatly reduce the potential for resource conflict with recreation. Reducing resource conflicts with recreation would enhance and preserve recreation which requires specific physical setting characteristics, such as remoteness. This would counter the trend of increased energy development on BLM-administered lands and its impact on recreation resources in PHMA to a greater extent than Alternative 1. These restrictions would also reduce the degradation of physical setting characteristics within the planning area, which would enhance the recreational user experience more than Alternative 1.

By managing more acres of ROW exclusion compared to Alternative 1, Alternative 3 would prohibit such developments over a greater area and would thus maintain the naturalness and remoteness for recreation experiences in these areas (BLM 2014).

Alternative 3 has the greatest acreage of PHMA, which would be subject the greatest acreage to disturbance caps. Therefore, if future recreation would have the potential exceed the disturbance cap in a particular area, the disturbance cap would have the potential to prohibit the construction of new recreation facilities over the largest area when compared with the other alternatives. There would be over double the acres of PHMA when compared to Alternative 1 (**Table 2-3**). Although Alternative 3 offers the greatest protection for primitive recreation and opportunities for solitude, it does so at the expense of motorized recreation users or those unable to participate in primitive activities, compared with Alternative 1.

10.19.6 Alternative 4

Similar to Alternative 1, under Alternative 4, existing restrictions on other resource uses such as fluid mineral leasing, would have an indirect effect on recreation by reducing resource conflicts in PHMA, IHMA, or GHMA. Reducing resource conflicts with recreation enhances and preserves the recreational experiences in those areas.

Under Alternative 4, ROWs would have additional criteria for avoidance of GRSG when compared to Alternative 1, which would limit such developments over a greater area and would thus indirectly affect recreation by maintaining the naturalness and remoteness for recreation experiences in these areas (BLM 2014).

Under Alternative 4, there would be more acres of PHMA and fewer acres of GHMA when compared to Alternative 1 (**Table 2-3**), which would subject fewer acres of land to disturbance caps. Therefore, if future recreation projects would exceed the disturbance cap in a particular area, the disturbance cap would have the potential to restrict fewer acres of land against the construction of new recreation facilities when compared to Alternative 1.

10.19.7 Alternative 5

Similar to Alternative 1, existing restrictions on other resource uses such as fluid mineral leasing, would have an indirect effect on recreation by reducing resource conflicts in PHMA, IHMA, or GHMA. Under Alternative 5, all states would be avoidance for utility scale wind and solar energy development. This would be less restrictive on energy development than Alternative 1, which could indirectly affect recreation by leading to the potential for great resource conflicts with energy development. Increasing resource conflicts with recreation diminishes the recreational experiences in those areas.

Under Alternative 5, ROWs would have less restrictive criteria for avoidance of GRSG when compared to Alternative 1. This would indirectly affect recreation when compared to Alternative 1 by decreasing the naturalness and remoteness for recreation experiences in these areas (BLM 2014).

Under Alternative 5, there would be more acres of PHMA when compared to Alternative 1 (**Table 2-3**). This would restrict more acres of land to disturbance caps when compared to Alternative 1. Therefore, if future recreation projects would exceed the disturbance cap in a particular area, this would have the potential to restrict more acres against the construction of new recreation facilities when compared to Alternative 1.

10.19.8 Alternative 6

Impacts to recreation under Alternative 6 would be similar to impacts under Alternative 5 except in ACECs. Alternative 6 would have greater restrictions on mineral exploration, including fluid minerals, nonenergy minerals, and mineral materials as well as major ROWs, wind and solar. These would indirectly decrease the resource conflicts that also affect recreation resources when compared to Alternative 1.

10.20 TRANSPORTATION AND TRAVEL MANAGEMENT

10.20.1 Methods and Assumptions

Methodology

The analysis of impacts on transportation and travel management is a comparison of the acres that would move from open to limited based on changes to HMA designations under each alternative.

Indicators

The indicator of impacts on transportation and travel management are the acres managed as open, and limited to OHV use because existing OHV allocations under the 2015 RMP Amendment are not proposed for change under this RMP Amendment under any alternatives and the 2015 RMP Amendment management direction limits OHV use to designated routes in GHMA and PHMA and does not close any areas to OHV use.

Assumptions

There are no assumptions specific to transportation and travel management.

10.20.2 Impacts Common to All Alternatives

Through Resource Management Plans (RMPs), the BLM designates lands in one of three Off Highway Vehicle (OHV) designation categories: open to cross country vehicle use, limited to existing routes, or closed to OHV use. None of the action alternatives, including the Proposed RMP Amendment, propose changes to the existing 2015 GRSG travel and transportation allocations or management direction. Therefore, under all alternatives, in PHMA and GHMA, OHV travel is limited to existing routes and no cross-country travel is allowed.

The changing HMA allocations occurring across the alternatives could, however, result in changes to areas moving from open to cross country travel to limited to existing routes due to areas moving from non-habitat to either PHMA or GHMA and, conversely, areas could move from limited to open if previously identified habitat (GHMA or PHMA) is no longer identified as habitat and the areas are not otherwise limited or closed under an existing RMP decision. Per the existing 2015 management direction under Alternative 1, PHMA and GHMA that do not have designated routes in a Travel Management Plan will be managed as limited to existing routes until a Travel Management Plan designates routes (unless they are already designated as limited to designated routes or closed to OHV use). As noted, this decision will not change by alternative, but since HMAs change by alternative, areas that were open and not designated as open under Alternatives 1 and 2 could, under each alternative, move to a limited designation because areas once considered non-habitat could be identified as either GHMA or PHMA and in GHMA and in PHMA these areas are managed as limited. **Table 4-4 – Table 4-7** illustrate the acres that have changed in open and limited categories based on changes in the HMA boundaries.

10.20.3 Comparison of Alternatives

The HMA allocations in Colorado, Idaho, Montana, and Wyoming would not change the OHV allocations currently in place under any of the alternatives, and, therefore, there are no anticipated effects to by alternative and thus no effects are expected in those states (**Table 4-4**).

In Nevada/California there is an increase in open areas when compared with the existing condition under Alternative 1 in all alternatives except Alternative 3, where there is a decrease in open areas (refer to Table 4-5 in Appendix 9). The increase in open areas is greatest under Alternative 4. Alternatives 5 and 6 both increase open areas by approximately two million acres (refer to Table 4-5 in Appendix 9). From a travel and transportation perspective, this increase in open areas could allow for more recreation associated with off-highway vehicle use. These increases could also increase resource impacts associated with off-highway vehicle travel.In Oregon, there is decrease in open areas and corresponding increase in limited areas from the existing acres in Alternative 1 in all of the alternatives except Alternative 2 (refer to Table 4-6). The largest decrease in open areas occurs under Alternatives 5 and 6 with approximately 600,000 fewer acres allocated as open. Under Alternatives 3 and 4, there are approximately 465,000 fewer acres allocated as open. From a travel and transportation perspective, these changes could reduce recreation opportunities associated with off-highway vehicle use. These decreases would also reduce resource impacts associated with off-highway vehicle travel.

In Utah, like Oregon, there is a decrease in the amount of OHV areas that are open and a corresponding increase in areas that are limited as a result of changes in HMA allocations. The decrease in open areas is greatest under Alternative 3 followed by Alternative 4 (refer to Table 4-7 in Appendix 9). Under Alternatives 5 and 6 the decrease is approximately 88,000 acres, under Alternative 4 the decrease is approximately 376,000 acres, and under Alternative 3 the decrease is approximately 464,000 acres. From a travel and transportation perspective, these changes could reduce recreation opportunities associated with off-highway vehicle use. These decreases would also reduce resource impacts associated with off-highway vehicle travel.

Appendix 11

Special Status Species

This page intentionally left blank.

Appendix 11. Special Status Species

This appendix presents the Endangered Species Act-listed species, candidate and proposed species for Endangered Species Act listing, and the BLM sensitive species that may potentially occur in the planning area as well as their habitat associations. See **Chapter 3**, **Section 3.6**, Special Status Species for a description of the affected environment related to special status species.

Taxa	Common Name	Scientific Name	Habitat Associations
Amphibians	Boreal toad (western toad)	*Anaxyrus boreas*	Boreal toads use wet habitats in foothill, montane, sagebrush and subalpine areas and are seldom far from water. Causes of population decline are not well understood but include chytrid fungus (*Batrachochytrium dendrobatidis*) infections, wetland habitat alteration due to recreation, grazing, reservoir construction, timber harvest, fire management, environmental pollutants, and non-native species introduction and climate change.
Amphibians	Great Plains toad	*Anaxyrus cognatus*	Great Plains toads inhabit deserts, grasslands, semidesert shrublands, open floodplains, and agricultural areas, typically in stream valleys. When not active on the surface they usually occupy underground burrows. Breeding sites include rain pools, flooded areas, and ponds and reservoirs that fluctuate in size. Eggs and larvae develop in shallow water (usually clear). Calling males sit along the shoreline or brace themselves on submerged plants.
Amphibians	Hot Creek toad	*Anaxyrus monfontanus*	Inhabits marsh habitats fed by hot springs. Extremely restricted and remote habitat surrounded otherwise by sagebrush steppe, restricting toad dispersal. Only found in Hot Creek Canyon in Nye County, Nevada.
Amphibians	Railroad Valley toad	*Anaxyrus nevadensis*	Endemic to the spring-fed wetlands of Lockes Ranch in Railroad Valley, Nye County, Nevada. Restricted and remote habitat surrounded otherwise by sagebrush steppe, restricting toad dispersal.
Amphibians	Dixie Valley toad	*Anaxyrus williamsi ssp.*	Found in springs, seeps, streams, and similar inundated areas. Presently thought to be endemic to Dixie Valley, NV and potentially a distinct species of western toad.

Taxa	Common Name	Scientific Name	Habitat Associations
Amphibians	Woodhouse's toad	*Anaxyrus woodhousii*	Inhabits grasslands, desert and semi-desert shrublands, river valleys and floodplains, and agricultural areas, usually in areas with deep friable soils. When inactive, they burrow underground or hide under rocks, plants, or other cover. These toads live on land except during the brief breeding season. Breeding occurs in marshes, rain pools, ponds, lakes, reservoirs, flooded areas, stream pools or backwaters, and other bodies of water with a shallow margin lacking a strong current, including both permanent and temporary pools, generally in sites with few if any fishes.
Amphibians	Rocky Mountain tailed frog	*Ascaphus montanus*	Rocky Mountain tailed frogs are present year-round in and near perennial streams associated with cold, clear, rocky streams in mature forests.
Amphibians	Boreal toad	*Bufo boreas boreas*	Inhabit wet habitats in foothills, montane and subalpine streams. Uses both aquatic and terrestrial habitats to meet all seasonal habitat requirements.
Amphibians	Yellow-blotched salamander	*Ensatina eschscholtzii croceator*	Inhabits cool, moist places, under the soil, under debris, or near water.
Amphibians	Shasta salamander	*Hydromantes shastae*	Found around cliff faces, vertical cavern walls and level ground in mixed forests of Douglas fir, pines, and oaks. Lives in moist caves and rock cracks. Mostly associated with limestone outcrops, but one population has been found in a volcanic outcrop, and others in forest areas with no rock outcrops.
Amphibians	Northern leopard frog	*Lithobates pipiens*	Northern leopard frogs live in the vicinity of springs, slow streams, marshes, bogs, ponds, canals, flood plains, reservoirs, and lakes; usually they are in or near permanent water with rooted aquatic vegetation. In summer, they commonly inhabit wet meadows and fields. Threats include commercial overexploitation, and, in some areas, probably competition/predation by bullfrogs or other introduced species. Habitat alteration and loss including flood-control measures and diversion of water for irrigation have probably reduced the availability of breeding habitat along floodplains in lowland segments of some streams. Decline in populations in the Rocky Mountains has been documented.
Amphibians	Foothill yellow-legged frog	*Rana boylii*	The foothill yellow-legged frog is found in or near rocky streams in a variety of habitats.
Amphibians	Columbia spotted frog	*Rana luteiventris*	Closely associated with clear or slow-moving or ponded surface waters, with little shade, and relatively constant water temperatures; breeding and egg-laying occurs in waters with floating vegetation and larger ponds, such as oxbows, lakes, stock ponds, and beaver-created ponds.
Amphibians	Southern Mountain yellow-legged frog	*Rana muscosa*	California's Sierra Nevada mountains in lakes, ponds, marshes, meadows and streams at elevations ranging from 4,500 to 12,000 feet (1,370 to 3,660 meters).

Taxa	Common Name	Scientific Name	Habitat Associations
Amphibians	Sierra Nevada yellow-legged frog	*Rana sierrae*	Occur in lakes, ponds, marshes, meadows and streams at elevations ranging from 4,500 to 12,000 feet (1,370 to 3,660 meters).
Amphibians	Oregon spotted frog	*Rana pretiosa*	Rarely found far from water. Breeding habitat is in seasonally flooded margins of wetlands and areas of extensive shallows (approximately 6 to 8 inches deep).
Amphibians	Western spadefoot toad	*Spea hammondii*	Occurs primarily in grasslands, but occasional populations also occur in valley-foothill hardwood woodlands.
Amphibians	Great Basin spadefoot	*Spea intermontana*	Mainly sagebrush flats, semi-desert shrublands, pinyon-juniper woodland. Digs its own burrow in loose soil or uses those of small mammals. Breeds in temporary or permanent water, including rain pools, pools in intermittent streams, and flooded areas along streams. Eggs are attached to vegetation in water or placed on bottom of pool.
Birds	Northern goshawk	*Accipiter gentilis*	Inhabits both deciduous and coniferous forests with various ages, structural conditions and successional stages.
Birds	Tricolored blackbird	*Agelaius tricolor*	Prefers wetlands but will use agricultural fields for nesting. Have also been found nesting in patches of Himalayan blackberry near stock ponds or irrigated pastures in the foothills of the Sierra Nevada, California. Foraging habitats include cultivated fields, feedlots associated with dairy farms, and wetlands.
Birds	Baird's sparrow	*Ammodramus bairdii*	Grassland specialist requiring large landscapes for breeding.
Birds	Grasshopper sparrow	*Ammodramus savannarum*	Breeding habitat includes grasslands of intermediate height and are often associated with clumped vegetation interspersed with patches of bare ground or moderately deep litter and sparse coverage of woody vegetation.
Birds	Sage sparrow	*Amphispiza bella*	Prefers large and undisturbed tracts of tall and dense sagebrush.
Birds	Black-throated sparrow	*Amphispiza bilineata*	Not closely associated with particular plant species or communities, but favors sparsely vegetated desert scrub, including thorn brush, cacti, chaparral, mesquite and juniper. It is most often found on desert uplands, alluvial fans, and hillsides where thorny xeric brush dominates, and sometimes also in dry shrubby washes, but avoids desert valley floors.
Birds	Sprague's pipit	*Anthus spragueii*	Endemic species of the northern Great Plains, breeding in mixed-prairie grasses.
Birds	Golden eagle	*Aquila chrysaetos*	Golden eagles generally inhabit open and semi-open country such as prairies, sagebrush, arctic and alpine tundra, savannah or sparse woodland, and barren areas, especially in hilly or mountainous regions, in areas with sufficient mammalian prey base and near suitable nesting sites.
Birds	Sagebrush sparrow	*Artemisiospiza nevadensis*	This species found in shrubby, open flats and sagebrush plains, with nesting sites usually in or under low shrubs like sagebrush or saltbush.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	Short-eared owl	*Asio flammeus*	This species is found in large, open areas with low vegetation, including prairie and coastal grasslands, heathlands, meadows, shrubsteppe, savanna, tundra, marshes, dunes, and agricultural areas; winter habitat is similar, but is more likely to include large open areas within woodlots, stubble fields, fresh and saltwater marshes, weedy fields, dumps, gravel pits, rock quarries, and shrub thickets.; if food is plentiful, winter areas often become breeding areas
Birds	Long-eared owl	*Asio otus*	Roosts in dense vegetation and forages in open grasslands or shrublands and open coniferous or deciduous woodlands. They occur at elevations ranging from near sea level to above 6,500 feet.
Birds	Burrowing owl	*Athene cunicularia*	Optimum habitat typified by short vegetation and presence of fresh small mammal burrows. Found in open grasslands, sagebrush, and sagebrush-steppe, sometimes in open areas such as vacant lots near human habitation. Spends much time on the ground or on low perches such as fence posts or dirt mounds.
Birds	Upland sandpiper	*Bartramia longicauda*	Restricted primarily to extensive, open tracts of short grassland habitat. Nest in native prairie, dry meadows, pastures, domestic hayfields, short-grass savanna, plowed fields, along highway rights-of-way and on airfields, and (in the north) peatlands and scattered woodlands near timberline. Nesting is also known to occur in dry patches of wet meadows and in blueberry barrens. A survey of nesting habitats in Wisconsin suggests that upland sandpipers favor a level topography with a minimum of tall vegetation edges and proportionately high acreages of agricultural crops which duplicate prairie grasslands in terms of structure.
Birds	Ferruginous hawk	*Buteo regalis*	Open country, primarily prairies, plains and badlands; sagebrush, saltbush-greasewood shrubland, periphery of pinyon-juniper and other woodland, desert. In the southern Great Plains, common at black-tailed prairie dog colonies in winter. Nests in tall trees or willows along streams or on steep slopes, in junipers (Utah), on cliff ledges, river-cut banks, hillsides, on power line towers, sometimes on sloped ground on the plains or on mounds in open desert. Generally, avoids areas of intensive agriculture or human activity.
Birds	Swainson's hawk	*Buteo swainsoni*	This species favors open habitats for foraging; hay and alfalfa fields, pastures, grain crops, and row crops, or perched atop adjacent fence posts and overhead sprinkler systems; they rely on scattered stands of trees near agricultural fields and grasslands for nesting sites.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	Cassin's finch	*Carpodacus cassinii*	Open coniferous forest; in migration and winter also in deciduous woodland, second growth, scrub, brushy areas, partly open situations with scattered trees, and sometimes suburbs near mountains. Usually nests in conifer, 3-25 m above ground, on outer end of limb; may sometimes nest in deciduous tree or in shrub. May return to same nesting area in successive years, though this may be unusual.
Birds	Veery	*Catharus fuscescens*	Nesting habitat includes swampy forest, especially in more open areas with shrubby understory, as well as second growth, willow or alder shrubbery near water; large tracts of forest are most suitable. Nests usually are on or near the ground, at the base of a shrub, in a clump of herbaceous vegetation, or in a shrub or low tree. In migration and winter this species occurs also in lowland forest, woodland, and scrub.
Birds	Greater sage-grouse	*Centrocercus urophasianus*	Habitat includes sagebrush steppe; nest in areas with relatively dense cover from big sagebrush; may use areas with rabbitbrush, greasewood, and grassy areas; leks are located in clear areas such as broad ridgetops, grassy swales, dry lakebeds, and sometimes recently burned areas. chick rearing areas include irrigated pastures, wet meadows, and alfalfa fields, in addition to sagebrush.
Birds	Vaux's swift	*Chaetura vauxi*	Mature and old-growth coniferous and mixed forests for nesting, especially those with plenty of hollow trees.
Birds	Western snowy plover	*Charadrius alexandrines nivosus*	Barren to sparsely vegetated sand beaches, dry salt flats in lagoons, dredge spoils deposited on beach or dune habitat, levees and flats at salt-evaporation areas.
Birds	Mountain plover	*Charadrius montanus*	Nesting habitat includes high plains/shortgrass prairie and desert tablelands, commonly prairie dog towns in some areas, such as sagebrush/blue grama habitats in central Montana. In central and southwestern Montana, southeastern Wyoming, and northeastern Colorado, nesting often occurs in shortgrass prairie with a history of heavy grazing or in low shrub semideserts. Nesting areas are characterized by very short vegetation, significant areas of bare ground, and flat or gentle slopes. Commonly, nesting takes place in barren fields that subsequently are planted with millet or sunflowers, resulting in losses of eggs and chicks. Nests are on the ground in shallow depressions that may be lined with plant material and/or adjacent to dried cattle dung. Adults often take chicks to windmill/water tank areas to forage, but site around tank must be dry. This bird generally avoids moist soils.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	Common nighthawk	*Chordeiles minor*	Nest in both rural and urban habitats including coastal sand dunes and beaches, logged forest, recently burned forest, woodland clearings, prairies, plains, sagebrush, grasslands, open forests, and rock outcrops.
Birds	Yellow-billed cuckoo	*Coccyzus americanus*	Large stands of cottonwood-willow habitat below 7,000 feet. Riparian obligates requiring low, dense shrubby vegetation for nesting.
Birds	Black-billed cuckoo	*Coccyzus erythropthalmus*	Elusive cuckoo that lives in woodlands, including aspen and willows.
Birds	Olive-sided flycatcher	*Contopus cooperi*	Boreal forest and western coniferous forests, from sea level to over 10,000 feet elevation. Here they are found in forests of spruce, fir, Douglas-fir, hemlock, western redcedar, and tamarack or larch. Use openings or edges in the forest and are rarely found in deep, closed forest.
Birds	Trumpeter swan	*Cygnus buccinator*	Nest in clear and quiet water bodies with relative static water levels and shallow margins.
Birds	Black swift	*Cypseloides niger*	Colonial breed on cliff faces near waterfalls or in caves and forage over forests and open areas.
Birds	Bobolink	*Dolichonyx oryzivorus*	This species generally selects habitat with moderate to tall vegetation, moderate to dense vegetation, and moderately deep litter. Breeding habitat includes tall grass areas, flooded meadows, prairie, deep cultivated grains, and hayfields.
Birds	White-headed woodpecker	*Dryobates albolarvatus*	Habitat consists of montane coniferous forests dominated by pines.
Birds	Snowy egret	*Egretta thula*	Nests in riparian, marsh, and tree habitats.
Birds	Willow flycatcher	*Empidonax traillii*	Breeding habitat is strongly tied to brushy areas of willow and similar shrubs. Found in thickets, open second growth with brush, swamps, wetlands, streamsides, and open woodland. Common in mountain meadows and along streams; also in brushy upland pastures (especially hawthorn) and orchards. The presence of water such as running water, pools, or saturated soils and willow, alder, or other deciduous riparian shrubs are essential habitat elements.
Birds	Great Basin willow flycatcher	*Empidonax traillii adastus*	Breeds in moist, shrubby areas with standing or running water, such as deciduous thickets and woodland edges.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	Gray flycatcher	*Empidonax wrightii*	Arid woodland and brushy areas. Most commonly associated with pinyon-juniper woodland. In Wyoming, strongly associated with the presence of pinyon pine and higher than expected juniper overstory cover. In western Great Basin, nests in tall, big sagebrush shrublands. Less frequently found in open ponderosa pine or pine-oak woodland. In the last three decades has expanded its range northward into Washington and British Columbia, where it uses open stands of small to medium ponderosa pines exclusively; these stands usually have a scattered shrub or young pine understory. Usually builds nest in fork or branch of a shrub or juniper. In migration and winter also in arid scrub, riparian woodland, and mesquite.
Birds	Prairie falcon	*Falco mexicanus*	Primarily open situations, especially in mountainous areas, steppe, plains or prairies. Typically nests in pothole or well-sheltered ledge on rocky cliff or steep earth embankment, 10 to more than 100 meters above base.
Birds	American peregrine falcon	*Falco peregrinus anatum*	Various open situations from tundra, moorlands, steppe, and seacoasts, especially where there are suitable nesting cliffs, to mountains, open forested regions, and human population centers. When not breeding, occurs in areas where prey concentrate, including farmlands, marshes, lakeshores, river mouths, tidal flats, dunes and beaches, broad river valleys, cities, and airports.
Birds	Pinyon jay	*Gymnorhinus cyanocephalus*	Pinyon-juniper woodland, less frequently pine; in nonbreeding season, also occurs in scrub oak and sagebrush. Nests in shrubs or trees (e.g., pine, oak, or juniper), about 1.5-9 m above ground.
Birds	Cassin's finch	*Haemorhous cassinii*	Often live in mature forests of lodgepole pine and ponderosa pine, but are also found in Jeffrey pine, Douglas-fir, limber pine, Engelmann spruce, subalpine fir, grand fir, red fir, pinyon pine, bristlecone pine, and quaking aspen. Some Cassin's Finches breed in open sagebrush shrubland with scattered western junipers.
Birds	Bald eagle	*Haliaeetus leucocephalus*	Breeding habitat most commonly includes areas close to (within 4 km) coastal areas, bays, rivers, lakes, reservoirs, or other bodies of water that reflect the general availability of primary food sources including fish, waterfowl, or seabirds.
Birds	Harlequin duck	*Histrionicus histrionicus*	Most common in fast-flowing sections of rivers early in the breeding season, but move to slower-moving stretches of rivers and lakes once the chicks have hatched. Use streams and rivers with small islands and sandbars for resting. In the winter, they are found almost exclusively on rocky coastal shorelines.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	Scott's oriole	*Icterus parisorum*	Inhabits arid foothills and mountains down to deserts, preferring higher slopes with abundant yucca, agave, pinyon pine, juniper, and live oak, usually between about 980 and 8,200 feet elevation.
Birds	Least bittern	*Ixobrychus exilis*	Freshwater and brackish marshes with tall, dense emergent vegetation such as cattails, sedges, and rushes that are interspersed with clumps of woody shrubs and open water.
Birds	Loggerhead shrike	*Lanius ludovicianus*	Found in open country with short vegetation and well-spaced shrubs or low trees, particularly those with spines or thorns; frequent agricultural fields, pastures, old orchards, riparian areas, desert scrublands, savannas, prairies, golf courses, and cemeteries; are often seen along mowed roadsides with access to fence lines and utility poles.
Birds	Virginia's warbler	*Leiothylpis virginiae*	Breed in open pinyon-juniper and oak woodlands often on steep slopes with shrubby ravines throughout most of their range. They also use dense thickets of mountain mahogany in southern Idaho.
Birds	Franklin's gull	*Leucophaeus pipixcan*	Franklin's gulls nest in large prairie marshes with lots of emergent vegetation and open water.
Birds	Black rosy-finch	*Leucosticte atrata*	Breed above treeline in areas with cliffs and rock slides. During the nonbreeding season, they often move to lower elevations especially when heavy snow covers foraging areas to forage in open parks and valleys with little snow cover.
Birds	Brown-capped rosy-finch	*Leucosticte australis*	Brown-capped rosy-finch breed almost exclusively in alpine tundra at or above ~11,000 feet elevation. They remain at high elevations throughout the year but outside of the breeding season they will move down in elevation into areas with thinner snowpacks such as high parks, meadows, and open grassland valleys between mountain ranges.
Birds	Gray-crowned rosy-finch	*Leucosticte tephrocotis*	Inhabit alpine areas above treeline nesting near glaciers, talus, rock piles, and cliffs, at very high elevations. Move in response to snow levels, usually descending to lower elevations in late fall and winter as snows accumulate.
Birds	Wallowa rosy finch	*Leucosticte tephrocotis wallowa*	This subspecies has a small breeding range in alpine zone of Wallowa Mountains, northeastern Oregon.
Birds	Lewis's woodpecker	*Melanerpes lewis*	Individuals require snags in advanced stages of decay or trees with softer wood (*e.g.*, *Populus* spp.) for nest sites because they are not a strong excavator compared with other woodpecker species. They most often nest in riparian areas dominated by cottonwoods.
Birds	Ash-throated flycatcher	*Myiarchus cinerascens*	Desert scrub, pinyon-juniper and oak woodland, chaparral, thorn scrub and riparian woodland; in winter also in open deciduous woodland. Usually nests in a tree cavity, a hole in a cactus, in an abandoned woodpecker hole or Cactus Wren nest.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	Long-billed curlew	*Numenius americanus*	Occurs in a variety of grasslands communities including sagebrush-grasslands.
Birds	Sage thrasher	*Oreoscoptes montanus*	Sagebrush plains, primarily in arid or semi-arid situations, rarely around towns. Usually breeds between 1300 and 2000 meters above sea level.
Birds	Mountain quail	*Oreortyx pictus*	Live in dense brush in wooded foothills and mountains; most common in pine-oak woodland, coniferous forest, and chaparral; sometimes in pinyon-juniper woods or in scrub at lower elevations; may be common in areas of second-growth brush after fires or clearcuts; requires dense low thickets for cover; during hot weather, rarely found more than a mile from water.
Birds	American white pelican	*Pelecanus erythrorhynchos*	Habitat includes rivers, lakes, reservoirs, estuaries, bays, and open marshes, sometimes inshore marine habitats. Pelicans rest/roost on islands and peninsulas. Nests usually are on islands or peninsulas (natural or dredge spoils) in brackish or freshwater lakes, or on ephemeral islands in shallower wetlands as in the northern Great Plains or on the Texas coast. Nest sites usually are in open areas but often near vegetation, driftwood, or large rocks. Habitats used in winter are mainly coastal but also include also inland waters such as the Salton Sea and some rivers with open water. Suitable sand bars and similar sites for roosting or loafing are important components of winter habitat
Birds	White-headed woodpecker	*Picoides albolarvatus*	Associated with old-growth ponderosa pine and sugar pine, ideally with partly open canopies, limited understory, and an abundant pine seed crop. They're also often found in recently burned forests.
Birds	American three-toed woodpecker	*Picoides dorsalis*	Inhabit coniferous forest, both the boreal forest (mostly spruce and fir) and mountain forests. Most numerous in mature and old-growth forests that have been damaged in some way, such as by wind storms, floods, or fire.
Birds	Green-tailed towhee	*Pipilo chlorurus*	Breeds in thickets, chaparral, shrublands, riparian scrub, and especially sagebrush. Habitat varies with elevation. Primarily in mountains. Found on mountain slopes, plateaus, and higher valleys of arid West, associated with dense shrubs 0.5 to 1.5 m in height; most commonly uses dry shrubby hillsides and post-disturbance shrubby second growth. Attracted to dwarf mistletoe as a nest, roost or foraging site in southwestern Ponderosa pine forests. Nests on or near ground in shrubby habitat; nest is usually under cover of brush or plant tufts; built by the female.
Birds	White-faced ibis	*Plegadis chihi*	White-faced Ibises forage in shallow wetlands, usually among short plants such as sedges, spikerush, glasswort, saltgrass, and greasewood. Salt, brackish, and freshwater marshes all provide foraging habitat. They also frequent wet agricultural fields with low plant cover, including alfalfa, barley, wheat, oats, and rice, along with livestock pastures and hayfields.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	Horned grebe	*Podiceps auratus*	Small, shallow, freshwater ponds with emergent vegetation such as rushes, sedges, and reeds.
Birds	Blue-gray gnatcatcher	*Polioptila caerulea*	Blue-gray Gnatcatchers nest and forage in a broad range of wooded habitats. They use a range of broadleaf and mixed woodlands from chaparral to mature forests, preferring moist areas, often near habitat edges. In the west, oak and pinon-juniper woodlands, chaparral, and willow and cottonwood woodlands near water all provide habitat.
Birds	Purple martin	*Progne subis*	A wide variety of open and partly open situations, frequently near water or around towns. In west and formerly in east nests in tree cavities, abandoned woodpecker holes (including those in saguaro cacti), crevices in rocks.
Birds	Flammulated owl	*Psiloscops flammeolus*	Breeds in dry mature mountain forests of ponderosa pine or other large coniferous trees, often interspersed with aspen or oak. Occurs on middle and upper slopes, avoiding lower elevations and valleys.
Birds	Bank swallow	*Riparia riparia*	Habitat includes open and partly open situations, frequently near flowing water. Nests are in steep sand, dirt, or gravel banks, in burrows dug near the top of the bank, along the edge of inland water, or along the coast, or in gravel pits, road embankments, etc. Both sexes construct the nest burrow. Pairs usually dig a new burrow each year, but sometimes they use old bank swallow burrows or abandoned cavities of the belted kingfisher. Individuals tends to return to same nesting area in successive years, though they may move several kilometers away, especially if nesting was unsuccessful the previous year; yearlings often return to the natal area or nearby.
Birds	Thick-billed longspur	*Rhychophanes mccownii*	This species breeds in the Great Plains of Canada through Montana and Wyoming and barely into Colorado. Ideal nesting habitat consists of blue grama and buffalo grass, with scattered purple three-awn, western wheatgrass, needle-and-thread grass, and taller vegetation such as opuntia cacti, broom snakeweed, rabbitbrush, and prairie sagebrush.
Birds	Broad-tailed hummingbird	*Selasaphorus platycercus*	Habitat includes open woodland, especially pine, pine-oak, pinyon-juniper, and conifer-aspen associations, brushy hillsides, montane scrub, and thickets; in migration and winter, broad-tailed hummingbirds also inhabit open situations in lowlands where flowering shrubs are present.
Birds	Black-throated gray warbler	*Setophaga nigrescens*	Open pine forests, pine-oak woodlands, and pinyon-juniper forests with a brushy understory.
Birds	Brewer's sparrow	*Spizella breweri*	Brewer's Sparrows depend almost exclusively on the sagebrush ecosystem when breeding typically dominated by big sagebrush (*Artemisia tridentata*) and similar species, interspersed with bunchgrasses and bare ground. Some also use large clearings in pinyon-juniper woodlands.

Taxa	Common Name	Scientific Name	Habitat Associations
Birds	California spotted owl	*Strix occidentalis occidentalis*	Lives in mid-elevation forests of the Sierra Nevada, which consist primarily of ponderosa pine (*Pinus ponderosa*), mixed-conifer, and white fir (*Abies concolor).*
Birds	Bendire's thrasher	*Toxostoma bendirei*	Desert habitats including arid grasslands, shrublands, and even some agricultural habitats. In the northern parts of the range they also breed in sage-juniper desert.
Birds	Sharp-tailed grouse	*Tympanuchus phasianellus*	Requires a mosaic of dense grass and shrubs with rich forb and insect foods during nesting and brood-rearing. During winter often relies on riparian areas and other sites that support deciduous trees and shrub for feeding, roosting, and escape cover; also utilizes non-native cultivated grains and hedgerow species. Natural succession of grasslands and shrublands to forests, accelerated or expanded geographically by artificial fire regimes, have influenced habitat quality and populations in several regions. Habitat and distribution is constrained in regions where fire suppression has reduced early and mid-successional vegetation communities.
Birds	Columbian sharp-tailed grouse	*Tympanuchus phasianellus columbianus*	Native bunchgrass and shrub-steppe communities. In western Idaho, preferred big sagebrush habitats with moderate vegetative cover, high plant species diversity, and high structural diversity; in general, selected vegetative communities that were least modified by livestock grazing. Deciduous shrubs are critical for winter food and escape cover. Bunchgrasses and perennial forbs are important components of nesting and brood-rearing habitat.
Birds	Virginia's warbler	*Vermivora virginiae*	Breeding habitat includes arid montane woodlands, oak thickets, pinyon-juniper, coniferous scrub, chaparral. Brushy steep mountain slopes within or near dry coniferous woodlands. In northern part of breeding range, generally use scrubby habitat below pine woodlands; in southern part of range use scrubby habitat islands with coniferous woodlands. Will inhabit ravines or rocky slopes with dense scrub oaks or mountain mahogany. Also found along mountain streams in sagebrush, or cottonwood and willow.
Birds	Gray vireo	*Vireo vicinior*	Breeding habitats include warm/hot, semi-arid, shrubby habitats, especially mesquite and brushy pinyon-juniper woodlands; also chaparral and desert scrub. Thorn scrub, oak-juniper woodland, pinyon-juniper, juniper-cholla, mesquite, dry chaparral.
Conifers and Cycads	Ground cedar	*Diphasiastrum complanatum*	Circum-boreal species that occurs in most coniferous forests.

Taxa	Common Name	Scientific Name	Habitat Associations
Conifers and Cycads	White-bark pine	*Pinus albicaulis*	Populations of whitebark pine in Montana and across most of western North America have been severely impacted by past mountain pine beetle outbreaks and by the introduced pathogen, white pine blister rust. The results of which have been major declines in whitebark pine populations across large areas of its range. Occurs in Subalpine and krummholtz habitats in most mountain ranges.
Conifers and Cycads	Lodgepole pine	*Pinus contorta*	Thrives in mostly well drained soils but may be found in peat bogs, muskegs or on dry sandy sites.
Conifers and Cycads	Limber pine	*Pinus flexilis*	Limber pine dominates on dry rocky sites at many elevations (1500-3600m) within its range. It can occur scattered throughout forested regions on more mesic sites, especially in low density, open areas. At higher elevations, Pinus flexilis can define the boundary of the treeline; occurring in high montane forests, often at the timberline). In these areas (i.e., Utah and the West) it is often very long-lived and slow growing, occurring on dry, harsh sites. In the northern half of its distribution, limber pine is generally found near lower tree line and on dry sites in the montane forests.
Conifers and Cycads	Bristlecone pine	*Pinus longaeva*	Grow in the mountains of Utah, Nevada, and California, in exposed, dry, rocky areas at elevations between 6,500 and 11,000 feet.
Fishes	White sturgeon	*Acipenser transmontanus*	White sturgeon primarily inhabits estuaries of large rivers and move into freshwater to spawn.
Fishes	Bluehead sucker	*Catostomus discobolus*	Occurs in low elevation mainstem rivers and tributaries.
Fishes	Flannelmouth sucker	*Catostomus latipinnis*	Prefers large rivers with deep riffles and runs but will inhabit small tributaries.
Fishes	Modoc sucker	*Catostomus microps*	Inhabit cool (<25°C) pools of headwater streams that usually have high spring flows and low summer flows. Favorable streams have moderate gradients with large mud or rock bottomed pools where the Suckers can seek refuge during summer.
Fishes	Wall Canyon sucker	*Catostomus murivallis*	Known from only one stream in northwestern Nevada.
Fishes	Goose Lake sucker	*Catostomus occidentalis lacusanserinus*	This taxon is endemic to the Goose Lake basin of Northern California and Southern Oregon.
Fishes	Mountain sucker	*Catostomus platyrhynchus*	This species can range in elevation up to 9,000 feet but is generally found in cool, clean water mid elevation mountain streams with cobble, sand, or gravel substrate, and favors pools.
Fishes	Tahoe sucker	*Catostomus tahoensis*	Native to the Lahontan Basin in southeastern Oregon, Nevada, and northeastern California. They are commonly found in large lakes and reservoirs, such as Lake Tahoe and Pyramid Lake, but can also be found in ponds in lower reaches of streams.
Fishes	Cui-ui	*Chasmistes cujus*	Restricted to Pyramid Lake, Nevada.

Taxa	Common Name	Scientific Name	Habitat Associations
Fishes	Northern redbelly X finescale dace	*Chrosomus eos X C. neogaeus*	These hybrid dace are found in clear, cool, slow-flowing creeks, ponds and lakes with aquatic vegetation, including filamentous algae, and sandy or gravelly bottoms interspersed with silt. In Montana, this species is an indicator species of the Northern Glaciated Prairie Stream Ecological System and may occur in the intermittent prairie stream systems.
Fishes	Rough sculpin	*Cottus asperrimus*	Occurs in vegetated runs and riffles of creeks and small to medium rivers, usually over mud in clear, fairly deep water (1-2 m).
Fishes	Shorthead sculpin	*Cottus confusus*	Habitat includes fast riffles of cold headwaters, creeks, and small to large rivers - also sometimes large rivers with slow-moving water.
Fishes	Bear Lake sculpin	*Cottus extensus*	Occur throughout Bear Lake in UT and ID, with adults spawning in littoral areas on rocky substrate, and juveniles found throughout the lake in benthic habitats.
Fishes	Shoshone sculpin	*Cottus greenei*	Generally found in cool, well-oxygenated, low velocity waters with abundant benthic structure and aquatic vegetation.
Fishes	Wood River sculpin	*Cottus leiopomus*	Small to medium-sized streams that are cool and have swift currents. endemic to the Big Wood and Little Wood rivers and their tributaries upstream of Magic Reservoir in Blaine County, Idaho.
Fishes	Preston White River springfish	*Crenichthys baileyi albivallis*	Inhabits warm water springs extending from east central Nevada to the Colorado River system.
Fishes	White River springfish	*Crenichthys baileyi baileyi*	Inhabits warm springs and their effluents in the White River drainage of eastern Nevada.
Fishes	Hiko White River springfish	*Crenichthys baileyi grandis*	Springs and remnants of the White River system in eastern Nevada
Fishes	Moorman WhiteRiver springfish	*Crenichthys baileyi thermophilus*	Endemic to three small springs, the Moorman, Moon River and Hot Creek Spring in Nevada.
Fishes	Railroad Valley springfish	*Crenichthys nevadae*	Live in six thermal springs, including Chimney Spring, North Spring, Hay Corral Spring, Reynolds Springs, Big Spring, Big Warm Spring, and Little Warm Spring.
Fishes	Lost River sucker	*Deltistes luxatus*	Spawn in rivers, streams, or springs associated with lake habitat. After hatching, migrate to lakes. Need shoreline river and lake habitat with vegetative structure during larval and juvenile rearing.
Fishes	Desert dace	*Eremichthys acros*	Lives in thermal springs and outflows in Soldier Meadows in Humboldt County, Nevada. Has the highest temperature tolerance of any minnow in western North America and can live in waters as warm as 104 degrees Fahrenheit.
Fishes	Iowa darter	*Etheostoma exile*	Iowa Darters prefer clear slow-flowing streams with solid bottoms, although they have a wide range of tolerance for changes in water flow rates. They are also found in lakes and reservoirs.

Taxa	Common Name	Scientific Name	Habitat Associations
Fishes	Borax lake chub	*Gila boraxobius*	Small minnow found only in Borax Lake in the Alvord Basin of southeastern Oregon. Borax Lake is fed by geothermal hot springs rich in dissolved mineral and heavy metals that most fish could not tolerate
Fishes	Cow head tui chub	*Gila bicolor vaccaceps*	Found in springs, ponds, lakes, large sluggish streams, and in the shelter of small swiftwater streams.
Fishes	Roundtail chub	*Gila robusta*	Found in large, swift rivers in tributaries to the Green River and several lakes in the upper portion of the basin.
Fishes	Pit roach	*Lavinia symmetricus mitrulus*	Predominately found in small warm streams but are capable of thriving in larger colder streams with diverse conditions. They may actually occupy several different habitat types within a single drainage.
Fishes	White River spinedace	*Leidomeda albivallis*	Lives in the springs and outflows of the upper White River in Nevada. Habitat characterized by shallow, cool and clear water over sand and gravel.
Fishes	Northern leatherside chub	*Lepidomeda copei*	Inhabits streams with a broad range of temperatures and requires habitats with health riparian vegetation and intact streambanks.
Fishes	Big spring spinedace	*Lepidomeda mollispinis pratensis*	Known only from Condor Canyon section of upper Meadow Valley Wash in Lincoln County, Nevada. Uses clear, clean shallow streams.
Fishes	Northern pearl dace	*Margariscus nachtriebi*	The Pearl Dace is a small, native minnow of both the eastern and northern drainages within the Glaciated Plains ecoregion of Montana, and is an indicator species of the complete Coolwater Northern Glaciated Plains Fish Assemblage
Fishes	Hornyhead chub	*Nocomis biguttatus*	Isolated populations occur within the Missouri River drainage. Usually occur in small to medium-sized streams with gravel bottoms.
Fishes	Fine-spotted Snake River cutthroat trout	*Oncorhyncus clarkia behnkei*	Occurs in large rivers with swift current and requires clear, cool, well-oxygenated water.
Fishes	Yellowstone cutthroat trout	*Oncorhynchus clarkia bouvieri*	Yellowstone Cutthroat Trout are native to the Yellowstone and Snake River watersheds. In pre-European settlement, Yellowstone Cutthroat Trout were present in an estimated 17,800 miles of stream. This distribution included large parts of Wyoming, Montana, Idaho, with a few streams supporting Yellowstone Cutthroat Trout extending into small portions of Utah and Nevada.
Fishes	Lahontan cutthroat trout	*Oncorhynchus clarkia henshawi*	Found in cold, high-elevation mountain streams and lower-elevation desert lakes. They are obligate stream spawners, and the distance they travel to spawn depends on the stream size and strain.

Taxa	Common Name	Scientific Name	Habitat Associations
Fishes	Westslope cutthroat trout	*Oncorhynchus clarkia lewisi*	Westslope Cutthroat Trout are common in both headwaters lake and stream environments. They feed primarily on aquatic insect life and zooplankton. Newborn fry frequently migrate back to lakes to rear after 1 to 2 years in their native stream. Spawning and rearing streams tend to be cold and nutrient poor.
Fishes	Colorado River cutthroat trout	*Oncorhynchus clarkii pleuriticus*	Requires cool, clear water and well-vegetated streambanks for cover and bank stability; instream cover in the form of deep pools and boulders and logs also is important; adapted to relatively cold water, thrives at high elevations. Most remaining populations are fluvial or resident. Occurs also in lakes (Trappers Lake in Colorado formerly had the largest pure population; now hybridized with rainbow trout). Adfluvial populations largely have been eliminated, though reestablished lacustrine stocks have been reported in Wyoming and in Rocky Mountain National Park in Colorado
Fishes	Bonneville cutthroat trout	*Oncorhynchus clarkii utah*	Ranges from high-elevation streams with coniferous and deciduous riparian trees to low-elevation streams in sage-steppe grasslands containing herbaceous riparian zones to lakes; in winter, streams may have instream ice that reduces trout habitat; high flows occur in spring from melting snowpack, low flows occur in mid- to late summer, when lethal and sublethal water temperatures may be common. Occurs primarily in small headwater streams; optimum habitat includes areas with a 1:1 pool to riffle ratio and slow, deep water with vegetated streambanks for shade, bank stability, and cover; prefers summer water temperatures of about 55 F but can survive in water up to 70 F; in lakes (e.g., Bear Lake), the littoral and pelagic zones are typically used during most of the year. Beaver ponds likely are important as both summer and winter holding habitat for adults.
Fishes	Steelhead	*Oncorhynchus mykiss*	Gravel-bottomed, fast-flowing, well-oxygenated rivers and streams. They migrate to the ocean then return to freshwater to spawn.
Fishes	Redband trout	*Oncorhynchus mykiss gairdneri*	Clean, cool, relatively small and low gradient streams, but are capable of enduring higher water temperatures (75–80 °F; 24–27 °C) than other trout that may co-habit the same streams.
Fishes	Sockeye salmon	*Oncorhynchus nerka*	Freshwater lakes, streams, estuaries, and associated wetlands provide vital nursery grounds for sockeye salmon
Fishes	Chinook salmon	*Oncorhynchus tshawytscha*	Spend their early life growing and feeding in freshwater streams, estuaries, and associated wetlands. Spend the remainder of their life foraging in the ocean before returning to the streams and tributaries where they were born to spawn.
Fishes	White River desert sucker	*Pantosteus clarkia intermedius*	Inhabits rapids and fast-flowing streams with gravelly bottoms.

Taxa	Common Name	Scientific Name	Habitat Associations
Fishes	Paddlefish	*Polyodon spathula*	The Paddlefish is an ancient, mostly cartilaginous fish with a smooth skin. Habitat includes slow or quiet waters of large rivers or impoundments. They spawn on the gravel bars of large rivers during spring high water. Paddlefish tolerate, or perhaps seek, turbid water. In Montana, paddlefish are found in the Yellowstone and Missouri Rivers.
Fishes	Bear Lake whitefish	*Prosopium abyssicola*	Lives in the cold, deeper waters of Bear Lake in Utah and Idaho.
Fishes	Bonneville cisco	*Prosopium gemmifer*	Endemic to Bear Lake on the Utah-Idaho border. Bonneville cisco generally inhabit deep cool water.
Fishes	Bonneville whitefish	*Prosopium spilonotus*	Found only in Bear Lake on the Utah-Idaho border. Bonneville whitefish prefer cold water and stay in cool deep areas of the lake during the summer months.
Fishes	Mountain whitefish	*Prosopium williamsoni*	Primarily a stream-dwelling species, but populations are also found in reservoirs and lakes. Prefers cold mountain lakes and streams with highly oxygenated water.
Fishes	Relict dace	*Relictus solitarius*	A small fish that lives in a few isolated habitats in eastern Nevada. Habitat includes springs, spring-fed streams, ponds, intermittent lakes and marshes, with mud or stone bottoms.
Fishes	Longnose dace	*Rhinichthys cataractae*	Found in the riffles of small to medium rivers and creeks, and in headwater streams with steep gradients. They prefer moderate currents and areas with overhanging cover.
Fishes	Independence Valley speckled dace	*Rhinichthys osculus lethoporus*	Inhabits a temperate desert stream and marsh in Neveada that is fed by many springs.
Fishes	Clover Valley speckled dace	*Rhinichthys osculus oligoporus*	Found in three springs and outflows in the Clover Valley in Elko County, Nevada.
Fishes	Foskett speckled dace	*Rhinichthys osculus ssp. nov*	Found only in desert springs of Lake County, Oregon including Foskett Spring and Dace Spring
Fishes	Monitor Valley speckled dace	*Rhinichthys osculus ssp. 5*	Inhabits freshwater, riparian, and herbaceous wetland habitats
Fishes	White river speckled dace	*Rhinichthys osculus ssp. 7*	Found in springs in the upper White River drainage, White Pine County, Nevada, US
Fishes	Lahontan redside shiner	*Richardsonius egregius*	Stream populations shoal near the surface of quiet pools, where they catch drifting insects, while in lakes they form groups in the littoral zone, generally preferring to stay over rocky bottoms, and eat a combination of surface insects, insect larvae, and planktonic crustacea.
Fishes	Bull trout	*Salvelinus confluentus*	Bull trout have exacting habitat demands, requiring water temperatures generally below 55 °F (13 °C), gravel beds, deep pools, complex cover such as snags and cut banks, and large systems of interconnected waterways to accommodate spawning migrations.

Taxa	Common Name	Scientific Name	Habitat Associations
Fishes	Sauger	*Sander canadensis*	Sauger inhabit the larger turbid rivers and the muddy shallows of lakes and reservoirs. They spawn in gravelly or rocky areas in shallow water and seem to prefer turbid water.
Fishes	Alvord chub	*Siphateles alvordensis*	Inhabits springs and spring-fed streams, and impoundments in Alvord basin.
Fishes	Fish Creek Springs tui chub	*Siphateles bicolor euchila*	Endemic species restricted to springs and outflows of Fish Creek Springs in southeastern Eureka County, NV. Typically found in slow-moving water with lots of aquatic vegetation.
Fishes	Independence Valley tui chub	*Siphateles bicolor isolata*	A subspecies of tui chub endemic to the drainage of the Independence Valley in Elko County, Nevada. The highest concentration of this species are found in water temperature between 11 and 20 degree Celsius (51.8 and 68 degree Fahrenheit) and water depth between 200 and 400 mm (7.8 and 15.7 in). T
Fishes	Newark Valley tui chub	*Siphateles bicolor newarkensis*	Inhabits freshwater springs and small ponds in Newark Valley, Nevada.
Fishes	Oregon lakes tui chub	*Siphateles bicolor oregonensis*	This subspecies is endemic to the endorheic Abert Lake basin in south-central Oregon.
Fishes	Duckwater Creek tui chub	*Siphateles bicolor ssp. 3*	Most comfortable in slow-moving water with lots of vegetation.
Fishes	Fish Lake Valley tui chub	*Siphateles bicolor ssp. 4*	Subspecies of tui chub found in Fish Lake Valley, Esmeralda County, Nevada. Its current distribution is limited to a single spring and outflow system.
Fishes	Hot Creek Valley tui chub	*Siphateles bicolor ssp. 5*	This subspecies occurs in riparian wetlands..
Fishes	Little Fish Lake Valley tui chub	*Siphateles bicolor ssp. 6*	This subspecies occurs in riparian wetlands.
Fishes	Railroad Valley tui chub	*Siphateles bicolor ssp. 7*	A freshwater fish that lives in shallow water.
Fishes	Dixie Valley tui chub	*Siphateles bicolor ssp. 9*	Known from two sites in Dixie Valley, Nevada. One site is an impoundment supplied from an artesian well.
Fishes	Goose Lake tui chub	*Siphateles bicolor thalassina*	Endemic fish species that lives in the Goose Lake watershed in Oregon and California.
Fishes	Arctic grayling	*Thymallus arcticus montanus*	Arctic Grayling are found primarily small, cold, clear lakes with tributaries suitable for spawning. They do not coexist well with other fishes except cutthroat trout and others with which they evolved. Arctic grayling are common in lakes across the western half of Montana. Historically, river-dwelling Arctic graylings were widespread throughout the Missouri River drainage, but now are reduced to a single, native population in the Big Hole River, in MT.
Flowering Plants	Trans montane abronia	*Abronia turbinata*	This species occurs in sandy soils of desert scrub at elevations ranging from 900 to 2500 m.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Henderson's ricegrass	*Achnatherum hendersonii*	Dry, rocky, shallow soil. Often associated with Artemisia rigida and occasionally with Pinus ponderosa. Also found in *Eriogonum thymoides/Poa secunda* community type.
Flowering Plants	Nevada needlegrass	*Achnatherum nevadense*	This species is found in open woodlands and sagebrush.
Flowering Plants	Richardson's ricegrass	*Achnatherum richardsonii*	Sandy and gravelly sites in grassland, open forest, and sagebrush grassland.
Flowering Plants	Wallowa ricegrass	*Achnatherum wallowaense*	Dry, shallow rocky soil. Restricted to non-forested, rocky, shallow soils, dominated by Poa secunda, other bunchgrasses and forbs. Rigid sagebrush (Artemisia rigida) is often present. These communities, often referred to as "scablands", are commonly found on topographic high ground and are particularly exposed to summer heat and dryness. During winter and early spring, the shallow scabland soils are subject to severe water saturation and frost heaving.
Flowering Plants	Cusick's giant-hyssop	*Agastache cusickii*	Associated with western juniper (*Juniperus occidentalis*), curlleaf mountain-mahogany (*Cercocarpus ledifolius*), quaking aspen (*Populus tremuloides*), or high-elevation sagebrush-grasslands
Flowering Plants	Tall agoseris	*Agoseris elata*	Meadows, prairies, open woods, and exposed rocky ridges with various aspects, from low elevations to timberline.
Flowering Plants	Mill Creek agoseris	*Agoseris lackschewitzii*	Grows in well-draining soils that are rich in organic matter in full sun to partial shade.
Flowering Plants	Rabbit Valley gilia	*Aliciella caespitosa*	On Navajo and Wingate sandstone in crevices, Carmel Limestone formations, detrital slopes, and (infrequently) in sandy wash bottoms. Found within open pinyon-juniper communities, often mixed with mountain brush, sagebrush, or ponderosa pine, at 1554 to 2743 m elevation.
Flowering Plants	Narrow-stem gilia	*Aliciella stenothyrsa*	Found in open places often in hills of pinyon-juniper, salt desert shrub, sagebrush, and mountain-mahogany communities from 5,003 to 9,318 feet (1,525 to 2,840 meters) elevation. Soils are typically silty to gravelly loams and sandy or clay alkaline, sandstone and siltstone shale or clay barrens all of the Green River and Uinta Formation. Presumed extinct.
Flowering Plants	Mussentuchit gilia	*Aliciella tenuis*	A Navajo Basin endemic growing in various mixed-desert shrub communities, commonly associated with Shadscale, ephedra, Wyethia, Indian-ricegrass, pinyon-juniper, and mountain mahogany communities at 1585 to 2170 m.
Flowering Plants	Iodinebush	*Allenrolfea occidentalis*	Grows in sandy, often salty, distinctly alkaline soils, such as desert washes and saline dry lakebeds.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Asse's onion	*Allium aaseae*	Aase's onion is restricted to a narrow range of habitat conditions. It occurs on open, relatively barren, xeric, gentle to very steep, sandy slopes, generally with a southerly aspect, but ranging from east to west. It is usually associated with relatively sparsely vegetated bitterbrush (*Purshia tridentata*) or bitterbrush/sagebrush (*Artemisia tridentata*) communities.
Flowering Plants	Two-headed onion	*Allium anceps*	High elevation plant that thrives under damp and shady conditions or open meadows.
Flowering Plants	Blue mountain onion	*Allium dictuon*	Open, fairly dry, rocky areas at low to middle elevations.
Flowering Plants	Geyer's onion	*Allium geyeri var. geyeri*	Moist, open slopes, meadows, or stream banks in mountains.
Flowering Plants	Nevius' onion	*Allium nevii*	Found in grasslands, sagebrush desert, and ponderosa pine forests in shallow, winter wet soils.
Flowering Plants	Tolmiei's onion	*Allium tolmiei var. persimile*	Occurs on mountains and scrublands at elevations of 1,300–9,200 feet (400–2,800 m).
Flowering Plants	Candystick	*Allotropa virgata*	Grows in deep humus of mature, usually lodgepole pine forests in the montane zone.
Flowering Plants	Malheur valley fiddleneck	*Amsinckia carinata*	Occurs in the Malheur River Valley in eastern Oregon, where it grows on slopes of talus and gravel.
Flowering Plants	Jones' bluestar	*Amsonia jonesii*	This species is growing in dry, gravelly, sandy, loam, or clay soils of washes in pinyon- juniper, desert shrub, mountain brush, blackbrush, semi-desert grasslands, and sandy sagebrush deserts communities at 1,200 to 2,150 m.
Flowering Plants	Long-fruit anemone	*Anemone cylindrica*	Native to sandy and rocky fields, hillsides and woodlands.
Flowering Plants	Bog anemone	*Anemone organa var. felix*	Found in Oregon in sphagnum bogs and marshes in Lincoln and Tillamook counties, and in the Cascade foothills of Linn county.
Flowering Plants	Great Basin angelica	*Angelica kingii*	This species grows in a variety of sites with moist soils including montane or subalpine riparian areas, in wet meadows and seeps within pinyon-juniper woodland and Great Basin scrub.
Flowering Plants	Meadow pussytoes	*Antennaria arcuata*	Moist meadows, often on hummocks of sedges and rushes that stay drier than the surrounding areas, or at the edges of these meadows. 1500-2400 m. The wet meadows are usually surrounded by sagebrush grassland communities.
Flowering Plants	King snapdragon	*Antirrhinum kingii*	This species is found in washes, as well as on rocky slopes and scree at elevations ranging from 500 to 2,300 meters.
Flowering Plants	Laramie columbine	*Aquilegia laramiensis*	Endemic to the Laramie Mountains in Wyoming and occurs in shaded microsites associates with outcrops and boulders at 6,300 feet to 10,100 feet.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Goodrich's columbine	*Aquilegia scopulorum var. goodrichii*	This species is associated with pine, juniper, and mountain brush communities on Green River Shale Formation.
Flowering Plants	Goodrich eared rockcress	*Arabis goodrichii*	Occurs on rocky slopes in sagebrush, pinyon-juniper woodlands, oak thicket.
Flowering Plants	Fremont County Rockcress	*Arabis pusilla*	This species occurs in coarse soil that has accumulated in cracks and crevices of sparsely vegetated granite-pegmatite outcrops at about 2,350 m elevation. The surrounding plant community is sagebrush grassland. The habitat is exposed to high winds and extreme cold conditions with as few as 30 frost free days annually.
Flowering Plants	Park rockcress	*Arabis vivariensis*	Low elevations in the mountains. Granitic soil at upper limit of sagebrush and sandy soils at the bases of cliffs.
Flowering Plants	Prickly-poppy	*Argemone munita ssp. rotundata*	Grows in open slopes and foothills in full sun.
Flowering Plants	Rock tansy	*Artemisia capitata*	This species grows on dry, rocky hills, in shallow, silt loams that are typically limestone-derived overlying rock outcrops. It can be found in exposed sagebrush grassland, desert shrubland, and juniper woodland in the valley and foothill zones.
Flowering Plants	Owyhee sagebrush	*Artemisia papposa*	This species grows in meadows, alkaline flats, and sagebrush-juniper slopes.
Flowering Plants	Porter's sagebrush	*Artemisia porteri*	Very sparsely vegetated badlands of pale, ashy or tufaceous (volcanic) mudstones and clay slopes. 1615-1980 m elevation.
Flowering Plants	Eastwood milkweed	*Asclepias eastwoodiana*	Desert shrub and pinyon-juniper communities on calcareous, tuffaceous, and sedimentary substrates at 3500-7000 feet.
Flowering Plants	Dwarf milkweed	*Asclepias uncialis*	This species is often associated with Juniper Woodland and Savanna ecological systems, but it is always found in the prairie or grassland components of these systems.
Flowering Plants	Green spleenwort	*Asplenium viride*	Cliff crevices, especially on limestone, often near or above timberline.
Flowering Plants	Boise milkvetch	*Astragalus adanus*	Occurs on brushy slopes, terraces and benches along canyons or along dry flats and gently rolling hill country among sagebrush in alluvial clays and gravels.
Flowering Plants	Field milk-vetch	*Astragalus agrestis*	Moist spots in sagebrush plains, and mountain meadows to alpine slopes.
Flowering Plants	Challis milkvetch	*Astragalus amblytropis*	Grows in soft clay, mobile shale, clay detritus, and volcanic ash deposits of sagebrush or shadescale covered slopes at 4600-5600 feet.
Flowering Plants	Rattlepod	*Astragalus americanus*	Open forest, woodlands, thickets, moist meadows, often along streams; valleys to lower subalpine

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Lost River milkvetch	*Astragalus amnis-amissi*	Grows in cracks and ledges on, or near vertical limestone cliffs, and in talus at the base of cliffs
Flowering Plants	Gunnison mikvetch	*Astragalus anisus*	This species is found within Sagebrush Shrubland (dominated by *Artemisia tridentata* ssp. *tridentata, Artemisia tridentata* ssp. *vaseyana, Artemisia tridentata* ssp. *wyomingensis*, or *Artemisia cana*) and Sagebrush Shrub Steppe ecological system types; primarily within the Dry Sagebrush Shrubland type. It is usually found in fairly open sites where sagebrush shrubs do not form a closed canopy, but sometimes shelters under low sagebrush plants. Sites are characterized by the absence of trees, moderate shrub cover, moderate understory cover, and extensive bare ground.
Flowering Plants	Goose Creek milkvetch	*Astragalus anserinus*	Confined to deeply weathered, sandy, white rhyolitic ash of the Salt Lake Formation, sometimes overlain by a thin veneer of black glassy sinter gravel of apparent volcanic origin. It occurs in drainage bottoms, lower to upper slope and crest positions, typically within open Utah juniper, Wyoming big sagebrush, or rabbitbrush communities with Sandberg's bluegrass, and needle and thread grass as well.
Flowering Plants	Ash Valley milkvetch	*Astragalus anxius*	Gravelly volcanic soil among pines, sagebrush; 1550 m altitude.
Flowering Plants	Lemhi milkvetch	*Astragalus aquilonius*	Shale or clay washes of gullied clay bluffs, on steep eroded canyon banks or on sand bars within the shrub-steppe zones at lower elevations.
Flowering Plants	Silverleaf milk-vetch	*Astragalus argophyllus var. argophyllus*	Occurs usually in wetlands, occasionally in non wetlands and in meadows and plays. Found in alkali sink areas.
Flowering Plants	Palouse milkvetch	*Astragalus arrectus*	Grows on grassy hillsides, sagebrush flats, river bluffs, and grassy or shrub-dominated openings of ponderosa pine (*Pinus ponderosa*) and Douglas-fir (*Pseudotsuga menziesii*) forests.
Flowering Plants	Mourning milkvetch	*Astragalus atratus var. inseptus*	Endemic to the Snake River Plain where it grows on sparsely vegetated ridge crests.
Flowering Plants	Barr's milkvetch	*Astragalus barrii*	In southeastern Montana, this species is restricted to heavy clay knobs, buttes, and barren hilltops. Often only a sparse shrub cover of *Artemisia tridentata* and/or *Atriplex confertifolia* is present. Also occurs in silty to sandy, calcareous soils. When an upper overstory is present, usually consists of a sparse cover of *Pinus ponderosa* and *Juniperus scopulorum*. Populations of this plant are associated with the harsh edaphic and environmental conditions of badlands areas. Buttes, bluffs, clay hills or sandstone, open barren ground; 900-1450 m.
Flowering Plants	Two-grooved milkvetch	*Astragalus bisculcatus var. bisulcatus*	Grows in upland meadows, prairies, grasslands, roadsides, dry hillsides, gullied bluffs, and over-grazed pastures.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	California milkvetch	*Astragalus californicus*	Dry hillsides, stony ridges, and canyon benches, among sagebrush, in open oak woods or in openings of coniferous forests.
Flowering Plants	Callaway milkvetch	*Astragalus callithrix*	Deep, sandy soil on the valley floor or on dunes in barren openings with *Atriplex, Grayia, Chrysothamnus*, and *Artemisia* at elevations of 1550 - 1710 m.
Flowering Plants	King's rattleweed	*Astragalus calycosus*	Occurs on dry, open hillsides, knolls and ridges in grassland and sagebrush desert to drier slopes of lower mountains. Sandy or gravelly clay soils.
Flowering Plants	One-leaflet Torrey's milkvetch	*Astragalus calycosus var. monophyllidius*	Occurs in sagebrush or pinyon-juniper communities on lower foothills and valley habitats on dry, stony, or otherwise barren place.
Flowering Plants	Painted milkvetch	*Astragalus ceramicus var. apus*	The species is associated with early successional habitats in sandhills. It is found in sandy, well-drained blowout areas and sandy flats or draws of old sand dunes at elevations of 6650-6700 feet, on moderately steep (20-30%), south- and west-facing slopes. Much of the vegetative cover consists of *Artemisia tripartita*, *Phacelia hastata*, *Agropyron dasystachyum, Stipa comata* and *Tetradymia canescens*.
Flowering Plants	Cima milkvetch	*Astragalus cimae var. cimae*	Mesas and stony hillsides in calcareous soils, commonly among sagebrush. Habitats include Great Basin scrub, Joshua tree woodland, and pinyon and juniper woodland.
Flowering Plants	Inflated cima milkvetch	*Astragalus cimae var. sufflatus*	This variety occurs among sagebrush on gentle slopes and flats, open pinon forest, and in calcareous, clay soil at elevations ranging from 5,000 to 6,000 feet.
Flowering Plants	Four-wing milkvetch	*Astragalus cinerascens*	Found in deserts, forests, sands, and disturbed areas.
Flowering Plants	Stiff milkvetch	*Astragalus conjunctus var. conjunctus*	This variety occurs in grassland and meadows, stony hilltops, canyon benches, brushy hillsides, sagebrush desert, and rarely into the edge of xeric pine forest on basaltic bedrock at elevations ranging from 2,000 feet to 5,100 feet.
Flowering Plants	Margaret Rushy milkvetch	*Astragalus convallarius var. margaretiae*	Grows on rocky slopes and flats beneath sagebrush (Artemisia tridentata) in pinyon-juniper woodland. Associated species include *Pinus monophylla, Purshia tridentata, Artemisia tridentata* ssp. *wyomingensis, Ribes velutinum, Poa secunda, Juniperus osteosperma, Leymus cinereus, Elymus elymoides*, and *Tetradymia canescens.*
Flowering Plants	Cusick's horse-mint	*Astragalus cusickii*	The species is associated with early successional habitats in sandhills and is found in sandy, well-drained blowout areas and sandy flats or draws of old sand dunes at elevations of 6650-6700 feet, on moderately steep (20-30%), south- and west-facing slopes. Much of the vegetative cover consists of *Artemisia tripartite*.
Flowering Plants	Barren milkvetch	*Astragalus cusickii var. sterilis*	Inhabits dry, barren ashy areas on gravelly and sandy clay bluffs and knolls at elevations ranging from 823-1460 m (2700-4800 ft).

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Debeque milkvetch	*Astragalus debequaeus*	Found in varicolored, fine-textured, seleniferous, saline soils of the Atwell Gulch Member of the Wasatch Formation, in areas surrounded by pinyon-juniper woodlands and desert shrub. Plants are mostly clustered on toe slopes and along drainages, but many occur on steep sideslopes. Soils are clayey but littered with sandstone fragments.
Flowering Plants	Rimrock milkvetch	*Astragalus desperatus var. neeseae*	Plants are found growing in desert scrub and salt-desert scrub communities, frequently associated with juniper, blackbrush, and horsebrush as well as shadscale and sagebrush. Known primarily from the Uinta Basin in Utah with the Colorado portion of the distribution considered disjunct.
Flowering Plants	Debris milkvetch	*Astragalus detritalis*	Found in pinyon-juniper and mixed desert shrub communities associated with Artemisia, Stipa, Phlox, Trifolium, and cactus species. Often in rocky soils ranging from sandy clays to sandy loams, and on alluvial terraces with cobbles from 5,400 to 7,200 feet (1,646 to 2,195 meters) elevation.
Flowering Plants	South fork John Day milk-vetch	*Asragalus diaphanous var. diurnus*	Endemic to Oregon. Occurs on barren rocky slopes and in sagebrush-juniper communities.
Flowering Plants	Meadow milkvetch	*Astragalus diversifolius*	Halophyte species restricted to low topographic positions within sagebrush valleys and closed-basin drainages in moist alkaline meadows.
Flowering Plants	Duchesne milkvetch	*Astragalus duchesnensis*	Found in salt desert shrub and pinon-juniper communities on sandy and gravelly pediments such as sandy mesas or around sandstone or shale outcrops (Goodrich, 1986) from 1430 to 1830 m.
Flowering Plants	Horseshoe milkvetch	*Astragalus equisolensis*	Grows on sand and sandy silt soils and is a component of the salt-desert shrub vegetative community. This species occurs on river terrace sand and gravel. Habitat is sagebrush, shadscale, horsebrush, and other mixed desert shrub.
Flowering Plants	Geyer's milkvetch	*Astragalus geyeri var. geyeri*	Habitat includes sandy desert areas, especially dunes, gullies, and washes, depressions in mobile or stabilized dunes, sandy flats, and valley floors.
Flowering Plants	Threeleaf or plans milkvetch	*Astragalus gilviflorus*	Barren knolls, stony hilltops, gullied bluffs and badlands, on limestone, shale or sandstone in sagebrush communities at 5340-6590 feet.
Flowering Plants	Dubois milkvetch	*Astragalus gilviforus var. purpureus*	Endemic to the Dubois Badlands in Wyoming. Found in sparsely vegetated cushion plant/bunchgrass communities on sandy-clay souls with abundant surface gravel.
Flowering Plant	Hamilton's milkvetch	*Astagalus hamiltonii*	This species grows on gullied bluffs and barren hilltops in desert shrub and juniper communities in the Uinta Basin, Utah.
Flowering Plants	Hyattville milkvetch	*Astragalus jejunus var. articulates*	Occurs in sparsely vegetated cushion plant/bunchgrass/low shrub communities. Endemic to the eastern rim of the Bighorn Basin in Wyoming.
Flowering Plants	Starveling milkvetch	*Astragalus jejunus var. jejunus*	Found in the rolling hills of Wyoming big sagebrush and mixed grasslands.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Lemmon's milkvetch	*Astragalus lemmonii*	Grows in meadows and flats along streams in or on the margins of ponderosa pine forest, and the shore of small ephemeral lakes.
Flowering Plants	Lens-pod milkvetch	*Astragalus lentiformis*	Dry sandy soil among sagebrush; sometimes with Jeffrey pines, Great Basin scrub.
Flowering Plants	Broad-pod freckled milkvetch	*Astragalus lentiginosus var. latus*	Occurs on open, gravelly slopes in the timber belt from 7,500 to 9,500 feet, on limestone. It occurs on gravelly or sandy calcareous soils, generally on moderate to steep slopes. Associated plants include pinyon-juniper and sagebrush. It is endemic to Nevada and known from several ranges in White Pine County and the Monitor Range in Eureka County.
Flowering Plants	Pohl's milkvetch	*Astragalus lentiginosus var. pohlii*	This species can be found growing in greasewood, shadescale, horsebrush, big sagebrush communities and vegetated sand dunes at 1330-1650 m.
Flowering Plants	Sodaville milkvetch	*Astragalus lentiginosus var. sesuimetralis*	Occurs on moist, open, alkaline hummocks and drainages near cool springs.
Flowering Plants	Park milkvetch	*Astragalus leptaleus*	Grows in moist or wet, often alkaline meadows in the valley, foothills, and montane zones.
Flowering Plants	Grand Junction milkvetch	*Astragalus linifolius*	Found in rocky soil on dry hillsides. Many populations occur on the Chinle and Morrison Formations with pinyon-juniper and sagebrush. Often found in drainages and along benches of perennial streams.
Flowering Plants	Loa milkvetch	*Astragalus loanus*	Volcanic gravels at 1650-2075 m elevation in sagebrush and pinyon-juniper communities.
Flowering Plants	Stiff milkvetch	*Astragalus microcymbus*	Open sagebrush or juniper-sagebrush communities on moderately steep to steep slopes. Often found in rocky areas with a variety of soil conditions from clay to cobbles, gray to reddish in color.
Flowering Plants	Least bladdery milkvetch	*Astragalus microcystis*	This species is found in alpine and subalpine areas on limestone and dry, gravelly soils and sandy areas, as well as on riverbanks and in open woods.
Flowering Plants	Pauper milkvetch	*Astragalus misellus var. misellus*	Habitat is stony hills and pastures and gravelly clay banks, on basaltic bedrock, with sagebrush and juniper.
Flowering Plants	Mulford's milkvetch	*Astragalus mulfordiae*	Mulford's milkvetch occurs on loose, sandy substrates derived from lacustrine and alluvial sediments, including unconsolidated sands, decomposed sandstone, and oolithic limestone. It occurs predominantly on south to west-facing aspects. The slopes may be prone to high rates of erosion. It occurs at elevations between 670 - 1100 meters (2200 -3600 feet). It is found mainly in shrub-steppe and desert shrub communities.
Flowering Plants	Ferron's milkvetch	*Astragalus musiniensis*	Gullied knolls and stony clay benches among junipers, on shale, sandstone, or gravelly alluvia, 4700-7000 feet. Weber and Wittmann report the Colorado habitat as sagebrush hills.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Naturita milkvetch	*Astragalus naturitensis*	This species grows in the cracks and ledges of sandstone cliffs and rim rocks and flat bedrock areas with shallow soil development within pinyon-juniper woodlands at elevations of 1,650 to 2,050 m.
Flowering Plants	Newberry's milkvetch	*Astragalus newberryi var. castoreus*	Found in sagebrush and pinyon-juniper woodlands in the plains, foothills, bluffs and badlands.
Flowering Plants	Nye milkvetch	*Astragalus nyensis*	Occurs in the foothills of desert mountains, outwash fans, and gravelly flats, sometimes in sandy soil.
Flowering Plants	Picabo milkvetch	*Astragalus oniciformis*	Occurs almost exclusively on the *Artemisia tridentata* var. *wyomingensis*/*Stipa comata* habitat type, an edaphically controlled habitat type restricted to sandy loam soils.
Flowering Plants	Pink egg milkvetch	*Astragalus oophorus var. lonchocalyx*	Pinyon-juniper, sagebrush, and mixed desert shrub communities at 1,770 to 2,300 m. Dry gravelly hillsides and stony flats, associated with sagebrush, on limestone.
Flowering Plants	Payson's milkvetch	*Astragalus paysonii*	Grows in open places in the timber belt, burned-over forests, on decomposed granites, or other open disturbed mountainous sites on silty and ashy soils.
Flowering Plants	Peck's milkvetch	*Astragalus peckii*	Occurs on very dry sites, on loose sandy soil or pumice at ca. 900-1500 m; it is often found in dry water-courses. This species is usually found in barren openings in juniper/sagebrush communities or in openings in lodgepole pine forests. Plants also occur in the forest ecotone and occasionally beneath forest canopy.
Flowering Plants	Broad-keeled milk-vetch	*Astragalus platytropis*	Found in rocky alpine and subalpine plant communities at elevations ranging from 6,000 to 12,000 feet. Often in dry waterways, and on sagebrush flats on dry, sandy soils or pumice.
Flowering Plants	Lahontan milkvetch	*Astragalus porrectus*	Localized and restricted to the bed of Pleistocene Lake Lahontan. It inhabits open, calcareous or alkaline, sandy to gravelly washes, alluvium, or gullies on clay badlands, knolls, or playa edges in the shadscale zone.
Flowering Plants	Precocious milkvetch	*Astragalus proimanthus*	Occurs in cushion plant/bunchgrass communities on dry, thin, rocky clay soils of benches and bluffs at 6,400-7,200 feet. Restricted to a small are in the southern Green River Basin in Wyoming.
Flowering Plants	Tonopah milkvetch	*Astragalus pseudiodanthus*	Occurs on deep, loose, sandy soils of stabilized and active dune margins, old beaches, valley floors, or drainages, with black greasewood and other salt desert shrub taxa.
Flowering Plants	Rams Horn Spring milkvetch	*Astragalus pulsiferae var. coronensis*	Occurs in Great Basin scrub, lower montane coniferous forest, pinyon and juniper woodland.
Flowering Plants	Ames milkvetch	*Astragalus pulsiferae var. pulsiferae*	Sandy or rocky soils (frequently granitic), often occurring with pines or sagebrush. Elevation: 1300-1900 m.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Suksdorf's milkvetch	*Astragalus pulsiferae var. suksdorfii*	Rocky ledges and arid gravelly hillsides in the Creosote Bush Scrub community, Joshua tree woodland, carbonate soil. Great Basin scrub, lower montane coniferous forests, pinyon and juniper woodlands, dry flats in open pine forest and on stony plains, in loose volcanic soils, 1290 m.
Flowering Plants	Hare's-foot milkvetch	*Astragalus purshii var. lagopinus*	This variety occurs on dry slopes and plains usually with sagebrush on basalt or pumice.
Flowering Plants	Snake River milkvetch	*Astragalus purshii var. ophiogenes*	This variety is found in loosely aggregated sand and gravelly sand deposits on bluffs, talus, dunes and volcanic ash beds with big sagebrush, Indian ricegrass, needle-and-thread grass, and four-wing satlbush, at elevations ranging from 700 to 1,075 meters.
Flowering Plants	Racemose milkvetch	*Astragalus racemosus var. treleasei*	Occurs on shale derived substrates on outwash flats and slopes along river valleys. Elevation 6500-7500 (8300) ft. Frequently occurs with thickspike wheatgrass, rubber rabbitbrush, green rabbitbrush and shadscale.
Flowering Plants	Bitterroot milkvetch	*Astragalus scaphoides*	Sagebrush-grassland communities on dry slopes at mid- elevations (5000-6000 feet).
Flowering Plants	Weak milkvetch	*Astragalus solitarius*	Stiff clays of valley floors and mesas, usually in close association with Artemesia arbuscula (Nevada, Oregon) & Sacrobatus (in Oregon).
Flowering Plants	Bastard kentrophyta	*Astragalus tegetarioides*	Dry sandy soil, in Ponderosa pine forests at elevations of 1300–1700 m.
Flowering Plants	Railhead milkvetch	*Astragalus terminalis*	Sagebrush steppe and sparsely vegetated grasslands in the valley, foothills, montane, and alpine zones; 1524-2914 m.
Flowering Plants	Tiehm's milkvetch	*Astragalus tiehmii*	Grows in desert habitats, specifically in basalt mesa country with white ash deposits at elevations of 1,600–1,700 meters.
Flowering Plants	Currant milkvetch	*Astragalus uncialis*	Dry alkaline soils derived from limestone. With sagebrush in gullied foothills at 1,600-1,825 m in Nevada and in shadscale at 1,400-1,600 m on Sevier Desert in Utah.
Flowering Plants	Webber's milk-vetch	*Astragalus webberi*	Grows at forest edges in openings on well-drained soils.
Flowering Plants	Welsh's milkvetch	*Astragalus welshii*	This species occurs exclusively on igneous gravels, in sagebrush, pinyon-juniper, and sagebrush-aspen communities at elevations of 2,000-2,810 m.
Flowering Plants	Mudflat milkvetch	*Astragalus yoder-williamsii*	Grows in shrubland/chaparral habitats on dry, cold ridge crests, stony flats, and disturbed roadbeds.
Flowering Plants	Dunes four-wing saltbush	*Atriplex canescens var. gigantea*	Grows in habitats of interdune valleys with scurfpea, anomalous sunflower, and other sand-loving plants. Found at elevations between 1450 to 1600 meters.
Flowering Plants	King's desert grass	*Blepharidachne kingii*	Grows in pinyon-juniper woodlands.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Sickle-pod rockcress	*Boechera atrorubens*	This species occurs on rocky summits, and sagebrush slopes on sandy loam.
Flowering Plants	Bodie Hills rockcress	*Boechera bodiensi*	Occurs at high elevations on rolling to steep topography; found on dry, open, rocky, high or north-facing slopes (often in rock crevices) and exposed rocky ridges and summits. Occurs on granitic, rhyolitic, or andesitic substrates. Occurs in high elevation Great Basin scrub, pinyon and juniper woodland, and subalpine lodgepole pine and whitebark pine forests. Preferred microsites include moisture-accumulating microsites in sagebrush associations, under shrubs, and on disturbed soils of prospector's diggings.
Flowering Plants	Davidson's rockcress	*Boechera davidsonii*	Ledges and rock outcrops in lodgepole forests, subalpine forests, and alpine fell-fields.
Flowering Plants	Elko rockcress	*Boechera falcifructa*	Endemic to Nevada, predominantly in Elko County with one disjunct population in the Shoshone Mountains in Lander County. Occurs on gently north-sloping, sagebrush-dominated slopes with a high moss/cryptogamic cover over silty substrates.
Flowering Plants	Sapphire rockcress	*Boechera fecunda*	This species occurs in the ecotone between lower treeline (associated species include *Pseudotsuga menziesii*, *Juniperus scopulorum* and/or *Pinus ponderosa*) and shrub/grasslands (associated species include Artemisia tridentata and/or *Cercocarpus ledifolius* and *Agropyron* spicatum. Soils are highly calcareous, sandy to coarsely gravelly, derived from metamorphosed calcium silicate parent materials. Sites are usually sparsely vegetated and on south to west-facing steep, eroding slopes (erosion and a dry, warm microclimate probably help maintain the open habitat).
Flowering Plants	Hells canyon rockcress	*Boechera hastatula*	Endemic to Oregon where it is found in subalpine or subarctic areas on shallow gravel of igneous rock outcrops.
Flowering Plants	Mt. Adams rockcress	*Boechera paddoensis*	Known only from the mountains of central Washington and northeastern Oregon where it grows on alpine slopes and talus.
Flowering Plants	Small rock cress	*Boechera pusilla*	Endemic to the southern Wind River Range in Wyoming. Occurs in creices and sparsely vegetated, occurs granite soil in outcrops surrounded by sagebrush grasslands.
Flowering Plants	Upward-lobed moonwort	*Botrychium ascendens*	Occurs in open habitats and microsites with evidence of slight to moderate disturbances, such as lower montane mesic coniferous forest, open subalpine slopes, and mountain and riparian meadows.
Flowering Plants	Prairie moonwort	*Botrychium campestre*	Rangewide, this species is reported from sandy grasslands and limestone prairies.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Dainty moonwort	*Botrychium crenulatum*	Occurs in very moist sites with saturated soil and dense, herbaceous vegetation. Usually found at higher elevations in southern areas (most of Nevada). Probably has some affinity for limestone or other calcareous substrates.
Flowering Plants	Western moonwort	*Botrychium hesperium*	Found in upper montane to subalpine elevations in open, mesic meadows with low, herbaceous cover including sagebrush shrublands, moist and dry meadows and forest edges on dry, gravelly, or sandy loam soils.
Flowering Plants	Slender moonwort	*Botrychium lineare*	Early- to mid-succession species in a wide variety of habitats including mid-height grasslands, grazed rangelands, a limestone shelves, woodlands, roadside gravels and in grass under conifers.
Flowering Plants	Moonwort	*Botrychium lunaria*	Generally occurs on calcareous soils in the sunlight of open fields, wood edges, and occasionally forests in the southern parts of its range.
Flowering Plants	Mountain grap-fern	*Botrychium montanum*	Moist duff around seeps or streams under mature *Thuja plicata* or, rarely, *Picea engelmannii,* at mid-montane elevations. Occasional in fen-like seeps or in moist to wet meadows with moss or lush herbaceous cover at subalpine elevations.
Flowering Plants	Peculiar moonwort	*Botrychium paradoxum*	A small perennial fern with a single above ground frond. Found in mesic meadows associated with spruce and lodgepole pine forests in the montane and subalpine zones; also found in springy western red cedar forests.
Flowering Plants	Stalked moonwort	*Botrychium pedunculosum*	Mesic meadows with low, herbaceous or grassy cover, gravelly soil, brushy areas, and in duff under mature *Thuja plicata*, at upper montane to subalpine elevations.
Flowering Plants	Blue gramma	*Bouteloua gracilis*	Grows pure stands in mixed prairie associations and disturbed habitats, usually on rocky or clay soils and mainly at elevations of 300-3000 m.
Flowering Plants	American thorowax	*Bupleurum americanum*	Found in stony soil of grasslands, meadows, turf, fellfields, montane to alpine elevations.
Flowering Plants	Brewer's reedgrass	*Calamagrostis breweri*	Occurs n moist subalpine and alpine meadows, lake margins, and stream banks. 1400–2800m.
Flowering Plants	Cascade reedgrass	*Calamagrostis tweedyi*	Grows in seral stages of Douglas-fir and subalpine fir forests in the montane zone.
Flowering Plants	Winged water-starwort	*Callitriche marginata*	Aquatic plant that grows in wet areas and vernal pools.
Flowering Plants	Wheel fruited water-starwort	*Callitriche trochlearis*	Found in western central to northern California (below about 500 meters) and western Oregon, occurring in shallow water or mud, near the margin or free-floating in ponds and marshes.
Flowering Plants	Howell's mariposa-lily	*Calochortus howellii*	Found in the Illinois River Valley of southern Oregon in dry, rocky, serpentine outcrops in open woodlands and brush-covered slopes at elevations of 300–800 meters.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Long-haired star-tulip	*Calochortus longebarbatus var. longebartatus*	Found in grassy margins of wet meadows and under pines at elevations of 1600--1800 m.
Flowering Plants	Peck's mariposa-lily	*Calochortus longebarbatus var. peckii*	Found in meadow margins, intermittent streambeds, and semi-moist areas in ponderosa pine forests.
Flowering Plants	Green-brand mariposa-lily	*Calochortus macrocarpus var. maculosus*	Dry plains, rocky slopes, sagebrush scrub, and in pine forests. Usually occurring in volcanic soils.
Flowering Plants	Booth's evening primrose	*Camissonia boothii ssp. boothii*	Most abundant in arid areas such as deserts.
Flowering Plants	Cusick's camas	*Camassia cusickii*	Occurs at low to mid elevations on steep, rocky hillsides and ridgetops in moist soils, usually along or near creeks. Often found in sagebrush scrub and among scattered ponderosa pine.
Flowering Plants	Grand Junction Chylismia	*Camissonia eastwoodiae*	Plants are annuals and generally found in low densities on barren clay soils of the Mancos Formation often alongside Gardner's saltbush (*Atriplex gardneri*).
Flowering Plants	Lewis' River suncup	*Camissonia parvula*	This species is found in areas with sagebrush scrub and sandy soils at elevations ranging from 100 to 2,700 meters.
Flowering Plants	Pygmy suncup	*Camissonia pterosperma*	This species occurs on well-drained slopes, often of volcanic origin, with sagebrush and pinyon-juniper, at elevations of 700 to 2600 m, but at 1400 to 2400 m elevation in California.
Flowering Plants	Washoe suncup	*Camissonia pusilla*	Dry, open to branchy slopes, flats, and roadsides on sandy soil with Artemisia to pinyon-juniper. Commonly found growing sympatrically with *Camissonia parvula* and *Camissonia pubens* (Kartesz 1988). Mixed desert shrub, sagebrush, and mountain brush communities at ca. 1220 to 1830 m.
Flowering Plants	Indian Valley sedge	*Carex aboriginum*	Grows primarily in sagebrush steppe, dominated by *Artemisia tridentata*, *Purshia tridentata,* and *Pseudoroegneria spicata*.
Flowering Plants	Blackened sedge	*Carex atrosquama*	Moist to dry subalpine and alpine meadows, fellfields, rocky slopes, swales, and shores.
Flowering Plants	Hairlike sedge	*Carex capillaris*	Moss mats in moist areas; bogs, marshes, stream banks, wet meadows, moist woods, usually on limestone substrates at elevations of 1600–2800 m.
Flowering Plants	Capitate sedge	*Carex capitata*	Found in wet to seasonally wet alpine or subalpine meadows on calcareous substrates, or at lower elevations in cold air drainages. Also found along shores, boreal forest heaths and mires.
Flowering Plants	Cordilleran sedge	*Carex cordillerana*	Found in mesic forests, disturbed open grassy slopes, and disturbed rocky soils with organic layers, often near streams.
Flowering Plants	Idaho sedge	*Carex idahoa*	Idaho sedge is a regional endemic known from several dozen sites in Montana. It inhabits moist alkaline meadows, often along streams. It most often occupies ecotonal areas between wet meadow and sagebrush steppe.
Flowering Plants	Slender sedge	*Carex lasiocarpa var. americana*	Fens, bogs, lake shores, and wet meadows, sometimes forming floating mats, in deep, organic, acidic soils with low to moderate nutrient levels.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Intermediat sedge	*Carex media*	Grows in drier habitats above timberline
Flowering Plants	Pyrenaean sedge	*Carex micropoda*	In dry or moist, rocky meadows and slopes, ledges, talus, and scree; also in washes, arid or very dry desert areas and disturbed habitats along roads, railroads, burned areas, vacant lots, and similar places.
Flowering Plants	Spikenard sedge	*Carex nardina*	Grows on dry alpine ridges and slopes, abrasion plateaus, heaths and fellfields at elevations of 2300–3000 m.
Flowering Plants	Western sedge	*Carex occidentalis*	Frequently found in dry grasslands and forests, generally at mid-elevations, but extending upward to sulalpine or alpine areas from 1,200 to 3,500 meters in elevation.
Flowering Plants	New sedge	*Carex pelocarpa*	Grows in alpine areas, often above the timberline in dry sites and barren slopes.
Flowering Plants	Retrorse sedge	*Carex retrorsa*	Grows along stream shores, lake shores, marshes, graminoid meadows, openings in swamps.
Flowering Plants	Russet sedge	*Carex saxatilis*	Grows in fens, bogs, and lake shores at high elevations (1800–2400 m).
Flowering Plants	Alaskan single-spiked sedge	*Carex scirpoidea ssp. stenochlaena*	Moist meadows, stream banks, and rocky slopes, the more southerly populations on waterfalls and seepy cliffs on somewhat acidic substrates.
Flowering Plants	Dark alpine sedge	*Carex subnigricans*	Moist, rocky, alpine to subalpine slopes and meadows at elevations of 2300–2800 m.
Flowering Plants	Many-headed sedge	*Carex sychnocephala*	Moist or wet ground adjacent to marshes or lakes, on a wide variety of substrates: rocky, sandy, silty, and at least moderately alkaline soils.
Flowering Plants	Tahoe sedge	*Carex tahoensis*	This species occurs in grasslands, sagebrush as well as open, rocky and sandy slopes, subalpine and alpine meadows, at elevations ranging from 600 to 3,700 meters.
Flowering Plants	Tioga Pass sedge	*Carex tiogana*	Found in meadows and on terraces next to lakes.
Flowering Plants	Foothill sedge	*Carex tumulicola*	Occurs in upland prairies, dry to moist meadows, and in openings in Garry Oak woodlands.
Flowering Plants	Native sedge	*Carex vernacula*	Alpine and subalpine wet meadows, rocky slopes that receive snowmelt, edges of headwater streams, and lake shores at elevations of 2300–2800 m.
Flowering Plants	Rural paintbrush	*Castilleja flava var. rustica*	This variety is mostly found in montane sagebrush habitats with dry soils at elevations ranging from 1,100 to 2,300 meters.
Flowering Plants	Fraternal paintbrush	*Castilleja fraterna*	Narrow endemic found only in the Wallowa Mountains of Oregon. Occurs on moist or dry rocky slopes and flats, ridges and talus, and in dwarf willow mats.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Peck's Indian paintbrush	*Castilleja peckiana*	Open conifer forests, sagebrush slopes, riparian meadows, shores, dry areas, sandy or gravelly soil, pine forests, deserts, grasslands, and rocky areas
Flowering Plants	Purple alpine paintbrush	*Castilleja rubida*	Rocky, open ground on alpine summits at elevations of 2240-3000 m. Found in the Wallowa Mountains, Oregon.
Flowering Plants	Monte Neva paintbrush	*Castilleja salsuginosa*	Endemic to Nevada; it is limited to alkaline soils of travertine hot springs in two areas: one in White Pine County (Monte Neva Hot Springs in the Steptoe Valley) and one in Eureka County (Hot Spring Hill). It occurs in damp, open, alkaline to saline, clay soils of hummocks and drainages on travertine hot spring mounds.
Flowering Plants	Thompson's painbrush	*Castilleja thompsonii*	Dry soil, frequently associated with sagebrush. Local on open slopes and bald summits of the surrounding mountains to about 7000 ft.
Flowering Plants	Sticky paintbrush	*Castilleja viscidula*	Found in dry to mesic sagebrush steppes, rocky slopes, ledges, and open woodlands.
Flowering Plants	Smooth wild cabbage	*Caulanthus crassicaulis var. glaber*	This variety is found in pinyon-juniper woodland and sagebrush scrub at elevations ranging from 1,200 to 2,900 meters.
Flowering Plants	Alexander wild cabbage	*Caulanthus major*	Grows in dry mountain slopes and similar habitats in the Great Basin.
Flowering Plants	Hairy wild cabbage	*Caulanthus pilosus*	Open, dry habitat in the Great Basin of Nevada, the Eastern slope of the Sierra Nevada to 9,000 ft (2,700 m) and surrounding regions of the United States northward to the SE corner of Oregon.
Flowering Plants	Prostrate ceanothus	*Ceanothus prostratus*	Occurs on well-drained soils and thrives in the acidic, granitic soils of the Sierra Nevada Mountains. It is commonly found as an understory beneath Douglas-fir, Jeffery pine, and ponderosa pine.
Flowering Plants	Birchleaf Mountain mahogany	*Cercocarpus montanus*	This species is found on sandstone, granite, limestone ridges, rocky slopes, and valley floors, as well as grasslands, savannahs, juniper-oak, pinyon-juniper, yellow pine woodlands, aspen, and pine-fir forests, at elevations ranging from 800 to 3,000 meters.
Flowering Plants	Cusick's pincushion	*Chaenactis cusickii*	A regional endemic that is locally abundant on ash-clay soils in southwestern Idaho and southeastern Oregon.
Flowering Plants	Desert or broadflower pincushion	*Chaenactis stevioides*	This species is found in arid or semiarid, gravelly, or sandy, open slopes, flats, and shrublands at elevations ranging from -30 to 2,300 meters.
Flowering Plants	Desert Chaenactis	*Chaenactis xantiana*	Arid and semiarid shrublands and chaparral, and prefers sandy soils.
Flowering Plants	Wheeler's skeleton-weed	*Chaetadelpha wheeleri*	This species is found in dunes, sandy soils and alkali flats in sagebrush scrub and creosote bush scrub, at elevations ranging from 800 to 1,800 meters.
Flowering Plants	Fee's lip fern	*Cheilanthes feei*	In arid climates, on limestone or sandstone cliff crevices, outcrops, rocky areas, and steep slopes.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Spearhed	*Chlorocrambe hastata*	Mountain slopes and canyons, thickets, shady damp areas, stony and brushy hillsides.
Flowering Plants	Naked-stemmed evening-primrose	*Chylismia scapoidea ssp. scapoidea*	This subspecies occurs in shrublands and rocky, gravelly, or sandy slopes.
Flowering Plants	Bulbous water hemlock	*Cicuta bulbifera*	Lives in sunny areas in swamps, fens, along shores, and in slow moving water.
Flowering Plants	Cedar Rim thistle	*Cirsium aridum*	Endemic to the Green River Basin, Beaver Rim, Sweetwater River Valley and Flaming Gorge area in Wyoming. Occurs in sparsely vegetated openings within Wyoming sagebrush grasslands at 5,80-7,500 feet.
Flowering Plants	Palouse thistle	*Cirsium brevifolium*	Lives in Palouse grassland remnants, dry rocky slopes, and roadsides.
Flowering Plants	Mojave thistle	*Cirsium mohavense*	Occurs in damp soils around desert springs, streams, and ditches from 1,500 to 9,000 feet.
Flowering Plants	Ownbey's thistle	*Cirsium ownbeyi*	Juniper, sagebrush, and riparian communities. Usually on limestone, talus, or sandy slopes. Weber and Morgan formations.
Flowering Plants	Slender-lobed clematis	*Clematis columbiana var. tenuiloba*	Rock faces and peaks, typically in exposed areas or thin pine woodlands
Flowering Plants	Many-stemmed spider flower	*Cleome multicaulis*	Found on alkaline soils at the margins of spring-fed playa lakes and dried lakebeds.
Flowering Plants	Hillman's stickweed	*Cleomellas hillmanii var. goodrichii*	Grows in dry, open, often alkaline meadows and flats.
Flowering Plants	Alkali cleomella	*Cleomella plocasperma*	Grows mainly in wet, alkaline soils such as those around hot springs.
Flowering Plants	Barren Valley collomia	*Collomia renacta*	This species occurs on rocky soils (rocks average less than 5-10 cm wide) on south-facing slopes.
Flowering Plants	Slender gentian	*Comostoma tenellum*	Grows in alpine areas, typically where moist.
Flowering Plants	Solieri's pygmyweed	*Crassula solieri*	Grows in vernal pools, along the shores of lakes and streams, and at elevations below 2,100 meters.
Flowering Plants	Barneby's cryptanth	*Cryptantha barnebyi*	Locally abundant on the domed or gently sloping white shale knolls of the Green River Formation, mostly in shadscale and pinyon-juniper communities at 1850-2400 m elevation.
Flowering Plants	Tufted cryptantha	*Cryptantha caespitosa*	Populations are usually restricted to rocky or chalky ridgetops in cushion plant communities. Forb-grass, pinyon-juniper, mountain brush, limber pine, and spruce-fir forests at 1950 to 3120 meters.
Flowering Plants	Silver-mounded candleflower	*Cryptantha cana*	This species occurs on open slopes in juniper woodlands and valleys, in sandy, calcareous soil, and on sandstone outcroppings and bluffs, at 1219 - 2300 m elevation.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Cocks-comb cat's-eye	*Cryptantha celosioides*	Stony or sandy, often sparsely vegetated soil of grasslands, sagebrush steppe; plains, valleys, montane.
Flowering Plants	Mound catseye	*Cryptantha compacta*	Occurs in salt desert shrub and mixed desert shrub communities, mostly on Devonian Sevy dolomite; on shallow, stony loam; rocky slopes; and summits of desert ranges.
Flowering Plants	Creutzfeldt-flower	*Cryptantha creutzfeldtii*	Known only from Carbon County and Emery County, Utah where it is a Navajo Basin endemic found in the San Rafael Swell. Grows in barren clay knolls and shaley slopes, in shadscale and mat-atriplex communities.
Flowering Plants	Fendler cat's-eye	*Cryptantha fendleri*	Widespread in the western U.S. Grows in open areas of sand dunes, and occupies a range of sparsely vegetated sites and successional stages.
Flowering Plants	Narrow-stem cryptantha	*Cryptantha gracilis*	This species is found in joshua tree and pinyon-juniper woodlands, as well as dry slopes, mesas, creosote bush scrub, all in sandy to rocky soils.
Flowering Plants	Clearwater cryptantha	*Cryptantha grandiflora*	Grows in grasslands, open conifer forest, scree slopes, and volcanic-based substrates.
Flowering Plants	Gray cryptantha	*Cryptantha leucophaea*	Sandy substrates, especially sand dunes that have not been completely stabilized.
Flowering Plants	Malheur cryptantha	*Cryptantha propria*	Native Habitat includes clay hillsides, sandy bluffs, rocky outcrops.
Flowering Plants	Schoolcraft catseye	*Cryptantha schoolcraftii*	In sagebrush scrub, on white-colored volcanic ash deposits at 837 - 1750 m, most locations are in a basalt mesa area along the west side of Black Rock Desert.
Flowering Plants	Silky cryptantha	*Cryptantha sericea*	This species occurs in open pine-juniper woodlands and fir-mountain brush communities, in sandy to gravelly soils, shaley slopes and sandstone outcrops.
Flowering Plants	Pine Woods cryptantha	*Cryptantha simulans*	This species found in open conifer forests and shrublands, as well as dry, gravelly sites, slopes, and disturbed areas.
Flowering Plants	Snake River cryptanthea	*Cryptantha spiculifera*	This species occurs in dry, open slopes and flats in plains and grasslands, sandy or stony ridges, foothills, valleys, and sagebrush steppe.
Flowering Plants	Owl Creek miner's candle	*Cryptantha subcapitata*	Endemic to Owl Creek and Bridger Mountains and northern Wind River Basin in Wyoming. Occurs on sandy-gravelly slopes and desert ridges in sparsely vegetation cushion plan communities.
Flowering Plants	Torrey's cryptantha	*Cryptantha torreyana*	An annual that grows in sparsely-vegetated soil, talus of woodlands, open forest, grasslands, sagebrush steppe, often in partial shade around the base of trees.
Flowering Plants	Steller's rockbrake	*Cryptogramma stelleri*	Moist, shaded cliffs sand ledges, often on calcareous rocks, middle elevations to the subalpine.
Flowering Plants	Greeley's wavewing	*Cymopterus aculis var. greeleyorum*	Occurs in desert communities, including desert scrub, sagebrush, blackbrush, pinyon-juniper, dry plains, and prairies.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Intermountain wavewing	*Cymopterus basalticus*	Reported to occur on bare basaltic, but more often dolomite rocks, barren clays, dolomite outcrops, gravelly hills and alluvial fans, at elevations of 1705 - 2134 meters (5600 - 7000 feet) in desert shrub, pinyon-juniper and sagebrush communities.
Flowering Plants	Pinnate spring-parsley	*Cymopterus beckii*	Sandy or stony crevices, ledges, and cliff bases on Navajo Sandstone in pinyon-juniper, mountain brush, and ponderosa pine-manzanita conifer-oak, and Douglas fir communities between 1700-2635 m elevation.
Flowering Plants	Uintah Basin springparsley	*Cymopterus duchesnensis*	Found in cold desert shrub, sagebrush, and juniper communities on sandy clay and clay semi-barrens of the Mancos and Morrison shales (Morrison, Uintah, Wasatch and Green River formations) from 4,700 to 6,800 feet (1,433 to 2,073 meters) elevation.
Flowering Plants	Evert's wafer-parsnip	*Cymopterus evertii*	Montane populations in Wyoming are on dry, rocky, often disturbed ridges and in meadows with volcanic substrates at 2200-3300 m elevation. Other Wyoming populations are along sandstone ridges with scattered Limber pine (Pinus flexilis) and Utah juniper (Juniperus osteosperma) at elevations of 1770-1800 m. The Utah plants are growing in gravelly soils on limestone outcrops at 2620 m.
Flowering Plants	Goodrich biscuitroot	*Cymopterus goodrichii*	Endemic to the Toiyabe and Humboldt ranges of Nevada on steep scree and talus slopes of slate or limestone.
Flowering Plants	Henderson's wavewing	*Cymopterus hendersonii*	Occurs in dry talus or skeletal soil of upper slopes and ridge crests at 2620-3000 m (8,600- 9600 ft.) in elevation. Associated vegetation is sparse and dominated by cushion plants.
Flowering Plants	Ibapah wavewing	*Cymopterus ibapensis*	This species occurs in alkaline, clay soil in valleys, rocky hillsides and flats.
Flowering Plants	Snowline spring-parsley	*Cymopterus nivalis*	Dry alpine meadows, high rocky ridges, under alpine conifers, and dry meadows. Typically found at elevations between 2,700–3,300 meters.
Flowering Plants	Purple cymopterus	*Cymopterus purpurascens*	This species occurs on shrubby slopes.
Flowering Plants	Wiliams' wafer-parsnip	*Cymopterus williamsii*	Endemic to the Bighorn Mountains in Wyoming. Occurs on open ridgetops and upper slopes with exposed limestone outcrops or talus.
Flowering Plants	Clustered lady's-slipper	*Cypripedium fasciculatum*	Predominantly occurs within the Klamath mountain region in coniferous forests with steep slopes and dense canopy cover.
Flowering Plants	Hole-in-the-rock prairie-clover	*Dalea flavescens var. epica*	Endemic to Utah. It grows on sandstone bedrock and sand among blackbrush and mixed desert shrub communities at 4,700 to 5,000 feet elevation.
Flowering Plants	Ordate dalea	*Dalea ornata*	Dry sand, shaley barrens, rocky ridges, gullied bluffs, knolls, and canyon washes with Artemisia to yellow pine.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Fringed waterplantain	*Damasonium californicum*	Damp ground, in and near water of shallow ponds, vernal pools, intermittent streams, sloughs, and mud flats at low elevations.
Flowering Plants	Poverty oatgrass	*Danthonia spicata*	Open woods, dry prairies, limestone and sandstone glades, balds, thinly wooded bluffs, rocky slopes, and roadsides.
Flowering Plants	Wyoming tansymustard	*Descurainia torulosa*	Endemic to the southern Absaroka Range in Wyoming. Gound at the base of steep cliffs at 7,700-10,500 feet.
Flowering Plants	Dimeresia	*Dimeresia howellii*	Grows in dry volcanic sand, scree or barren ridges, at high elevations.
Flowering Plants	Cusick's monkeyflower	*Diplacus cusickii*	This species occurs in canyons, ditches, washes, black volcanic gravel, volcanic ash and sand, sagebrush areas, as well as on sand talus, diatomaceous slopes, and basalt outcrops, at elevations ranging from 800 to 1,000 meters.
Flowering Plants	Steamboat monkeyflower	*Diplacus ovatus*	Dry to somewhat moist, often barren, loose, sandy to gravelly slopes derived from siliceous sinter deposited by hot springs in the sagebrush zone, or from highly acidic hydrothermally altered andesite or rhyolite deposits supporting sparse yellow pine woodlands within the pinyon-juniper zone, or possibly on sandy alkaline valley floor deposits in the sagebrush zone, sometimes on adjacent roadsides or washes.
Flowering Plants	Darkthroat shootingstar	*Dodecatheon pulchellum var. shoshonense*	Found in widely scattered, nearly always alkaline meadows mainly in the valley bottoms. Can be locally abundant at the bases of limestone cliffs.
Flowering Plants	Bacigalupi's downingia	*Downingia bacigalupii*	Found in moist meadows and vernal pools.
Flowering Plants	Harlequin calicoflower	*Downingia insignis*	Found in vernal pools, roadside ditches, playas, lakeside margins and stream margins.
Flowering Plants	Pointed draba	*Draba globosa*	Found above treeline in remote alpine meadows, snow flushes and talus slopes.
Flowering Plants	Lost River whitlow-grass	*Draba hitchcockii*	Endemic to Idaho, found in gravelly soil and limestone outcrops.
Flowering Plants	Yellowstone whitlow-grass	*Draba incerta*	Found in stony soil of fellfields, turf, cliffs, exposed slopes; alpine, occasionally lower on exposed calcareous sites.
Flowering Plants	Subalpine whitlow-grass	*Draba oreibata var. oreibata*	Found on rock outcrops, gravelly soil, and talus in mixed conifer and subalpine meadow communities.
Flowering Plants	Pennell draba	*Draba pennellii*	Restricted to White Pine County, Nevada and Juab County, Utah. Occurs in remote and inaccessible crevices and ledges of carbonate or quartzite cliffs and rock faces.
Flowering Plants	American dragonhead	*Dracocephalum parviflorum*	Found in open, moist areas in Oregon at low to middle elevations east of the Cascades crest in open, rocky, moist riparian and woodland areas.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	False tickhead	*Eatonella nivea*	This small annual is native to the western United States, particularly the Great Basin, where it grows in sandy soils or gravelly soils in barrens or shrubland/chaparral or often sagebrush scrub.
Flowering Plants	Short seeded waterwort	*Elatine brachysperma*	Found in open, rocky, moist riparian and woodland areas in Oregon at low to middle elevations east of the Cascades crest.
Flowering Plants	Bolander's spikerush	*Eleocharis bolanderi*	Found in a variety of wet habitats in Oregon, including: mountain meadows, springs, seeps, and stream margins.
Flowering Plants	Dune wildrye	*Elymus simplex var. luxurians*	Sparsely vegetation slopes and flats, most common in swales of choppy dune landscapes. Only known from a few locations in Wyoming.
Flowering Plants	Nevada willowherb	*Epilobium nevadense*	Grows in Pinyon-juniper and oak-mountain mahogany communities, at 1560-2685 m elevation.
Flowering Plants	Swamp willow-herb	*Epilobium palustre*	Mesic to wet meadows, stream banks, and talus, from middle to high elevations in the mountains.
Flowering Plants	Chatterbox	*Epipactis gigantea*	This orchid favors the shoreline of streams, lakes, seeps, and the sandy soil of marshes and riparian areas.
Flowering Plants	Yellow lovegrass	*Eragrostis lutescens*	Found on sandy banks of lakes and streams, moist alkaline flats, in canyons and disturbed grounds.
Flowering Plants	Nevada suncup	*Eremothera nevadensis*	Endemic to central-western Nevada, from 3,900 to 5,400 feet in elevation. It grows in various soils in dry, open places in valleys and foothills. It occurs on open, sandy, gravelly, or clay slopes and flats in the salt desert, shadscale, and lower sagebrush zones.
Flowering Plants	Dwarf evening-primrose	*Eremothera pygmaea*	Endemic to Oregon. Found on dry plains and slopes with unstable soils or on gravel in steep talus, dry washes, banks and roadcuts.
Flowering Plants	Bloomers goldenweed	*Ericameria bloomeri*	Grows on dry, rocky slopes, and in open woods, coniferous forests, open gravelly or rocky places, mixed forests, pine woods, shrublands, open slopes, ridges, and roadsides
Flowering Plants	Greenwood's goldenbush	*Ericameria lingnumviridis*	A Utah Great Basin endemic, where it is found in riparian areas of the Utah Great Basin region.
Flowering Plants	Dwarf gray rabbitbrush	*Ericameria nauseosa var. nana*	Found in shrublands, grassy meadows, and conifer woods.
Flowering Plants	Winward's narrow leaf goldenweed	*Ericameria winwardii*	Rare species only know in Wyoming and Idaho. Occurs on unstable substrates susceptible to erosion from disturbances.
Flowering Plants	White cushion erigeron	*Erigeron disparipilus*	This species occurs on rocky and gravelly substrates of ridges and slopes, in grassland and sagebrush, at elevations ranging from 600 to 2,200 meters.
Flowering Plants	Fan-leaved fleabane	*Erigeron flabellifolius*	Grows on scree and talus.
Flowering Plants	Broad fleabane	*Erigeron latus*	Thin, volcanic soils on gravelly or rocky hillsides and outcrops in the sagebrush zone, near juniper woodlands. 1600-2000 meters elevation.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Cliff daisy	*Erigeron petrophilus*	Grows in forest and woodland, often, as its name suggests, in rocky habitat, sometimes on serpentine soils.
Flowering Plants	Tender fleabane	*Erigeron tener*	Grows in rocky or gravelly areas, such as talus, cliff ledges, and crevices at elevations of 1700–3200m. Is often associated with *Atriplex*, sagebrush, pinyon-juniper, yellow pine, bristlecone pine, limber pine, or spruce.
Flowering Plants	Limestone daisy	*Erigeron uncialis var. uncialis*	This taxon grows in crevices and cracks of limestone outcrops or at the base of cliffs within Great Basin sagebrush scrub, subalpine coniferous forest, or pinyon and juniper woodland at altitudes of 1,900 to 2,900 meters.
Flowering Plants	Untermann's daisy	*Erigeron untermannii*	Calcareous shales and sandstones, mainly of the Uinta and Green River formations, in various plant communities at elevations ranging from 2073 to 2890 meters. Pinyon-juniper, mountain mahogany, limber and bristlecone pine, and sagebrush communities on calcareous shales and sandstones of the Uinta and Green River Formations between 7,000 and 9,400 feet elevation
Flowering Plants	Single-stem buckwheat	*Eriogonum acaule*	Endemic to the Wyoming Basin. Plants exhibit a low mat-forming habit in barren areas of fine soils often with sagebrush and saltbrush.
Flowering Plants	Alexander's buckwheat	*Eriogonum alexanderae*	Occurs on light-colored clay outcrops, hillsides, and badlands in the shadscale, sagebrush, and pinyon-juniper zones.
Flowering Plants	Ibex buckwheat	*Eriogonum ammophilum*	This taxon occurs in sandy washes, flats, and dunes and stabilized sand in shadscale, horsebrush, winterfat, rabbitbrush, ephedra, and pinyon-juniper communities at 1460 to 1890 meters elevation.
Flowering Plants	Windloving buckwheat	*Eriogonum anemophilum*	Wind-loving Buckwheat occurs on bleak, exposed, windswept summits, ridges, and exposed rocky slopes on loose, gravelly to rocky limestone and on volcanic tuff outcrops, and at low elevations on barren clay hills. It occurs in saltbush and sagebrush communities, pinyon-juniper woodlands, and in barren areas, at elevations of 1400-2600 meters.
Flowering Plants	Kaye H. Throne's buckwheat	*Eriogonum artificis*	This species occurs in sandy to gravelly soil, on volcanic slows, mixed grassland, sagebrush and juniper woodland communities.
Flowering Plants	Beatley buckwheat	*Eriogonum beatleyae*	Dry volcanic outcrops (Reveal 1989). Volcanic tuffaceous soils, sagebrush communities, pinyon-juniper woodlands at 1,700-2,800 meters elevation.
Flowering Plants	Short-flowered eriogonium	*Eriogonum brachyanthum*	Creosote bush, other warm desert shrub & shad-scale communities
Flowering Plants	Lost Creek wild buckwheat	*Eriogonum brevicaule var. mitophyllum*	Grows in clay flats and slopes, saltbush communities and juniper woodlands at 1700-1800 m.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Golden buckwheat	*Eriogonum chrysops*	This species is found within the cold desert environment of the Owyhee uplands, typically within the Artemisia arbuscula-Poa sandbergii lithosolic association in rocky scabland areas. It occurs in relatively open sites, on flats, gently sloping ridges, and outcrops. The substrate is dry, barren, shallow, gravelly to rocky soil overlying basalt or rhyolite flows.
Flowering Plants	Grand buckwheat	*Eriogonum contortum*	Plants are found growing on badlands composed of Mancos Formation shales with vegetative components of the salt desert scrub community.
Flowering Plants	Crosbys buckwheat	*Eriogonum crosbyae var. crosbyae*	Light colored, tuffaceous sandstones and (in Nevada) clay outcrops. Typically, on rolling hills dominated by big sagebrush (Artemisia tridentata). 1650-1700 meters elevation.
Flowering Plants	Pueblo Mountains buckwheat	*Eriogonum crosbyae var. mystrium*	Alpine plant that grows on thin gravelly soils on ridgelines and high convex slopes.
Flowering Plants	Cusick's buckwheat	*Eriogonum cusickii*	Occurs on barren flats and hills with dry soil over weathered basalt and welded tuff. Plants in surrounding areas include dwarf sagebrush (*Artemesia arbuscula*) and western juniper (Juniperus occidentalis). It occurs from 1200 to 1600 m (3940 to 5250 feet) elevation.
Flowering Plants	Churchill Narrows buckwheat	*Eriogonum diatomaceum*	Dry, relatively barren and undisturbed, white to yellowish tan, often gysiferous, clay to silty diatomaceous deposits of the Coal Valley Formation, with a variable volcanic cobble overburden, on rounded knolls, low ridges, slopes, and especially small drainages on all aspects at elevations of 1300-1410 m, with *Atriplex confertifolia, Stanleya pinnata, Sarcobatus baileyi, Artemisia spinescens*, *Kochia americana, Tetradymia glabrata*, and other shadscale zone associates.
Flowering Plants	Tall buckwheat	*Eriogonum elatum var. elatum*	Sand and gravel slopes and flats, grasslands, sagebrush desert, ponderosa pine forest openings, and montane ridges.
Flowering Plants	Ephedra buckwheat	*Eriogonum ephedroides*	Found in juniper and sagebrush-grass communities on white shale of the Green River Shale Formation at 5,700 feet (1,737 meters) elevation.
Flowering Plants	Hooker's buckwheat	*Eriogonum hookeri*	Grows in plateau and desert habitat often associated with pinyon-junipers.
Flowering Plants	Lewis buckwheat	*Eriogonum lewisii*	Dry, exposed, rocky, convex ridge-line knolls and crests underlain by siliceous carbonate, siliceous limestone, or dolomite on all aspects at 1970-2960m elevation. At lower elevations, occasionally found on clay hills derived from silty carbonate or calcium-rich siliceous rock. Co-dominating with Artemisia arbuscula, Chrysothamnus viscidiflorus, Elymus elymoides, and Achnatherum hymenoides.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Lobb's buckwheat	*Eriogonum lobbii*	Habitat is gravelly to rocky or talus slopes, mixed grassland, buckbrush, manzanita, and sagebrush communities, and montane, subalpine, or alpine conifer woodlands. In the high mountains of northwestern California and southwestern Oregon and the southern portion of the North Coast Range of California, plants are frequently associated with serpentine soils. In the Sierra Nevada of eastern California and west-central Nevada, the species is found almost exclusively on granitic soils and infrequently on volcanic ones.
Flowering Plants	Schoolcraft buckwheat	*Eriogonum microthecum var. schoolcraftii*	Sandy to rocky soil, sagebrush communities, pinyon-juniper woodlands; 1400-2200 meters.
Flowering Plants	False naked buckwheat	*Eriogonum novonudum*	Grows in light-colored volcanic ash-clay slopes, sandy clay slopes, and washes in saltbush and sagebrush communities and juniper woodlands.
Flowering Plants	Deeth buckwheat	*Eriogonum nutans var. glabratum*	This taxon occurs in sand on flats and slopes within saltbush and sagebrush communities at elevations 1,500 to 1,900 meters.
Flowering Plants	Calcereous buckwheat	*Eriogonum ochrocephalum var. calcareum*	Barren white volcanic ash-clay; associates include Artemisia arbuscula, Chrysothammus nauseosus, Sitanion.
Flowering Plants	Craters-of-the-Moon wild buckwheat	*Eriogonum ovalifolium var. focarium*	Occurs on black volcanic gravel on gentle slopes and flats in sagebrush communities, conifer woodlands; 1600-1900 meters.
Flowering Plants	Steamboat buckwheat	*Eriogonum ovalifolium var. williamsiae*	This species is endemic to Steamboat Hot Springs in southern Washoe County Nevada. It prefers young, shallow, poorly developed, dry soils derived from siliceous opaline sinter precipitated by past thermal spring flows, but not currently near surface water.
Flowering Plants	Palmer's buckwheat	*Eriogonum palmerianum*	Grows in many types of desert and sagebrush plateau habitat.
Flowering Plants	Prostrate buckwheat	*Eriogonum procidium*	Grows in sagebrush scrub, red fir forest, lodgepole forest, and northern juniper woodland communities.
Flowering Plants	Altered andesite buckwheat	*Eriogonum robustum*	Known only from the Virginia and Carson Ranges and on Peavine Mountain in a small area of southern Washoe and western Storey Counties. Occurs in strongly acidic (pH 3.5–4.5), hydrothermally altered andesite soils forming barren slopes with scattered yellow pines.
Flowering Plants	Playa buckwheat	*Eriogonum salicorniodes*	Grows on sparsely vegetated, open, ash deposits and clayey substrates, sometimes in disturbed areas.
Flowering Plants	Packard's buckwheat	*Eriogonum shockleyi var. packardiae*	Oolitic limestone outcrops, sandy loess over basalt, and cobbly desert pavement over deep sandy-loam; in shadscale, mixed desert shrub and sagebrush communities; elevations from 760-1300 m; this species is endemic to southwest Idaho along the Snake River and a few tributaries in Ada and Owyhee cos.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Shockey's or matted cowpie buckwheat	*Eriogonum shockleyi var. shockleyi*	Occurs on sparsely vegetated sandy-loams, cobbly desert pavement, and gravelly calcrete on lacustrine sediments; in shadscale, mixed desert shrub and sagebrush communities; elevations from 760-1300 meters.
Flowering Plants	Railroad Canyon buckwheat	*Eriogonum soliceps*	This species is found in sagebrush communities with gravelly soil, at elevations ranging from 2,500 to 2,600 meters.
Flowering Plants	Thyme-leaved buckwheat	*Eriogonum thymoides*	Sagebrush deserts, dry ponderosa pine forest openings, and open ridges in lower mountains.
Flowering Plants	Woodside buckwheat	*Eriogonum tumulosum*	This species occurs on gravel and/or clay flats and slopes, sagebrush and saltbush communities, as well as pinyon and/or juniper woodlands at elevations ranging from 1,500 to 2,300 meters.
Flowering Plants	Green buckwheat	*Eriogonum umbellatum var. glaberrimum*	Sandy to gravelly slopes, sagebrush communities, aspen and montane conifer woodlands; 1600-2300 meters.
Flowering Plants	Visher's buckwheat	*Eriogonum visheri*	The entire range of the species lies within the unglaciated Missouri Plateau where it occurs on barren, sedimentary rock outcrops, the alluvium from those outcrops, and small exposures of soil substrates in badlands topography. It is most often found on the unvegetated clay outwash at the base of slopes, on the unvegetated eroding edge of tables, benches, terraces and buttes, and on more level patches of soil exposed by wind or water erosion.
Flowering Plants	Carson Valley monkeyflower	*Erythranthe carsonensis*	This species occurs in open areas of Great Basin sagebrush/bitterbrush scrub in coarse granite soils on gentle to moderate slopes (0-15 percent), usually on north aspects but also occasionally on south to southwest aspects. Elevation 1400-1580 m (4600-5200 ft).
Flowering Plants	Membrane-leaved monkeyflower	*Erythranthe hymenophylla*	Grows on wet spots in cracks in basalt and limestone cliffs alongside ferns and bryophytes usually above flowing water in streams and rivers.
Flowering Plants	Ehemeral monkeyflower	*Erythranthe inflatula*	Observed in rocky sagebrush habitat, especially in areas still moist from early spring soaking.
Flowering Plants	Broad-toothed monkeyflower	*Erythranthe latidens*	Found in moist gravelly, rocky areas, and low, wet fields, in sagebrush-juniper zones.
Flowering Plants	Gorman's aster	*Eucephalus gormanii*	Endemic to the Cascade Mountains of Oregon on open, dry rocky slopes and cliffs.
Flowering Plants	Arctic aster	*Eurybia merita*	Open rocky places, rock crevices, alpine lithosols, and unstable talus slopes, mostly at high elevations in the mountains, from 700 to 2300 m (2400-7400 ft).
Flowering Plants	Ackerman's green gentian	*Frasera ackermaniae*	Locally endemic to foothills of the Uintas, in the Uinta Basin. It occurs on yellowish clay soil with paleosol inclusions and selenite gypsum fragments. It occurs mixed with Utah juniper, mountain brush and desert scrub.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Modoc bedstraw	*Galium glabrescens ssp. modocense*	Occurs on gravelly slopes and under edges of rocks, at elevations of 5500-8500 feet in Oregon and California.
Flowering Plants	Warner Mountains bedstraw	*Galium serpenticum ssp. warnerense*	Grows on steep slopes in rocky areas, meadows, and juniper woodlands. Found on north-facing slopes above dry creeks and in black dirt between lava rocks.
Flowering Plants	Moss gentian	*Gentiana prostrata*	Occurs in moist meadows and bogs in subalpine and alpine areas.
Flowering Plants	Cathedral Bluff dward gentian	*Gentianella tortuosa*	Found in sagebrush through spruce-fir forests on shale outcrops of the Green River Formation at 8,500 to 10,800 feet (2,591 to 3,292 meters) elevation.
Flowering Plants	White-margined wax plant	*Glyptopleura marginata*	Grows in arid grasslands, rocky or sandy deserts, alkali flats, and at elevations of 1,000 to 2,000 meters.
Flowering Plants	Boggs Lake hedge-hyssop	*Gratiola heterosepala*	Restricted to clay soils in or near shallow water such as at the margins of lakes and vernal pools.
Flowering Plants	Cronquist's forget-me-not	*Hackelia cronquistii*	North-facing gentle to moderate slopes, with the majority of plants occurring on mid or lower slope areas. Soils are sandy. Usually found with a plant association that includes big sagebrush and indian ricegrass.
Flowering Plants	Owhyee forget-me-not	*Hackelia ophiobia*	Most mesic talus and rock crevices along the Owyhee River and its tributaries near waterline and *Artemista packardiae*.
Flowering Plants	Dune sunflower	*Helianthus deserticola*	Occurs in dry, open, deep, loose, sandy soils of aeolian deposits, vegetated dunes, and dune skirt areas. Grows on flats and gentle slopes of all aspects, generally in alkaline areas; often thriving on road berms and other stabilized disturbances within such soils.
Flowering Plants	Salt heliotrope	*Heliotropium curassavicum*	Saline places at low evelevations, often in the beds of dried ponds.
Flowering Plants	Unbellate hawkweed	*Hieracium umbellatum*	Grows in moist places in thickets and open woods.
Flowering Plants	Vanilla grass	*Hierochloe odorata*	Occupies a wide range of habitats including riparian and scrub-shrub wetlands, bare rock, talus and scree, shrubland and chaparral, mesic talus and rock crevices.
Flowering Plants	Cooper's rubber-plant	*Hymenoxys cooperi var. canescens*	This variety is found in open areas, edges of juniper/pine forest, and on roadsides at elevations ranging
Flowering Plants	Cooper's rubber-plant	*Hymenoxys cooperi var. canescens*	Found in open areas, forest edges, and roadsides.
Flowering Plants	Rock hymenoxys	*Hymenoxys lapidicola*	Known from rock crevices in pinyon-juniper and ponderosa pine-manzanita communities from 1830 to 2476m elevation.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Large Canadian St. John's wort	*Hypericum majus*	Found along ponds, lakes ides, riparian habitats, or other low, wet places, from 15-710 m (50-2340 ft).
Flowering Plants	Compact gilia	*Ipomopsis congesta ssp. crebrifolia*	Occurs on limestone, sand over lava flows, on clay, or sandy soils in sagebrush steppe and pinyon-juniper woodlands.
Flowering Plants	Spreading gilia	*Ipomopsis polycladon*	This species is found in gravelly or sandy soils in pinyon-juniper woodlands, plains, washes, mesas, and desert shrublands.
Flowering Plants	Rydberg's gilia	*Ipomopsis tenuituba*	Found on gravelly to rocky slopes and dry ground in forests, meadows and disturbed areas.
Flowering Plants	Columbia quillwort	*Isoetes minima*	Seasonally moist swales and vernal pools at middle elevations among open conifer forest or sagebrush-steppe.
Flowering Plants	Sierra Valley mousetails	*Ivesia aperta var. aperta*	Occurs on shallow, vernally saturated, slowly draining, sandy to rocky clay soils derived from mostly andesitic volcanic rock or alluvium.
Flowering Plants	Rock purpusia	*Ivesia arizonica var. saxosa*	Rock Purpusia occurs in crevices of cliffs and on boulders on volcanic (granitic or ash-flow tuff) and possibly carbonate rocks in the upper mixed-shrub, sagebrush, and pinyon-juniper zones, at elevations of 1500 - 2100 meters.
Flowering Plants	Ash Creek ivesia	*Ivesia paniculata*	Shallow, rocky soils on open volcanic ridges, gravelly flats, and openings within Sagebrush Scrub, Northern Juniper Woodland, Yellow Pine Forest, Lodgepole Forest, and Red Fir Forest communities.
Flowering Plants	Pine Nut Mountains mousetails	*Ivesia pityocharis*	This species occurs in seasonally saturated soils of sagebrush flats at 2100 to 2700 meters elevation.
Flowering Plants	Grimy ivesia	*Ivesia rhypara var. rhypara*	Populations of Grimy Ivesia are found on either light-colored ash-tuff or on outcrops of volcanic ash deposited with riverbed gravels. Habitat is low sagebrush or barren without canopy cover and is very dry.
Flowering Plants	Shelly's ivesia	*Ivesia rhypara var. shellyi*	Grows in rock crevices and depressions on large boulders made of pumice and volcanic tuff.
Flowering Plants	Plumas ivesia	*Ivesia sericoleuca*	Meadows and alkaline flats/gentle slopes, usually on volcanic substrates, sometimes on mixed-alluvium Eocene lake deposits. Habitat is generally vernally moist, drying later in the season; species sometimes also found around vernal pools or seeps. These open habitats are found within Sagebrush Scrub and Yellow Pine Forest communities. 1300 - 2200 meters.
Flowering Plants	Shockley's ivesia	*Ivesia shockleyi*	Grows on open, exposed rocky ridges and outcrops at elevations ranging from 8100-13200 feet
Flowering Plants	Tweedy's ivesia	*Ivesia tweedyi*	Dry, gravelly to rocky flats, slopes, alpine ridges, often on serpentine, in subalpine conifer woodlands.
Flowering Plants	Webber's ivesia	*Ivesia webberi*	Occurs on shallow shrink-swell clay soils with a gravelly surface layer over volcanic, generally andesitic bedrock, on mid-elevation benches and flats.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Moss rush	*Juncus bryoides*	An annual that grows in many types of wet, sandy habitat.
Flowering Plants	Least rush	*Juncus hemiendytus var. abjectus*	This variety occurs in damp open habitats such as vernal depressions, swales in sagebrush flats, streambeds, forest clearing and alpine meadows at elevations ranging from 1,400 to 3,400 meters.
Flowering Plants	Kellogg's rush	*Juncus kelloggii*	Found in damp soils of sand and clay, near vernal pools, as well as low spots in fields and meadows, and seepage areas.
Flowering Plants	Santa Lucia dwarf rush	*Juncus luciensis*	Occurs in vernal pools, depressions in meadows, wet sandy soil of seepage areas on sandstone, and stream banks
Flowering Plants	Tiehm's rush	*Juncus tiehmii*	Found along stream banks and in floodplains, moist depressions, springs, washes, moist or drying meadows, and ditches.
Flowering Plants	Three-flowered rush	*Juncus triglumis var. albescens*	Found in wet meadows, seeps, gravel shores, peatlands, wet pastures, and ditches.
Flowering Plants	Inch-high rush	*Juncus unicialis*	Found on vernal pool margins and other drying places from the southern coastal ranges of California north to Washington and west to Nevada.
Flowering Plants	Bellard's kobresia	*Kobresia myosuroides*	Found in alpine grasslands on dry to wet ground at elevations of 2400–2900 m as well as talus, dry or somewhat moist fellfields, subalpine to alpine, barrens, and tundra.
Flowering Plants	Simple bog sedge	*Kobresia simpliciuscula*	Found in the Wallowa Mountains of Oregon in fens and marshes, mesic to wet tundra, gravels and rocky slopes.
Flowering Plants	Great Plains stickseed	*Lappula cenchrusoides*	Grows in dry soils in open areas
Flowering Plants	Grime's vetchling	*Lathyrus grimesii*	Endemic to Nevada, known only from a small portion of the northern Independence Range and southern Bull Run Mountains of north-central Elko County, Nevada. Grows in gravel scree derived from siliceous members of the Schoonover Formation.
Flowering Plants	Huber's pepperplant	*Lepidium huberi*	In sand or silty sands derived from the Navajo formation, Shinarump member of the Chinle and Moenkopi formations, and Park City and Weber sandstone formations. Found within a variety of shrub-dominated and coniferous forest/woodland communities, including ponderosa pine, lodgepole pine, Douglas fir, spruce-fir, sagebrush, black sagebrush, snowberry, and mountain mahogany communities at 2225 - 2960 meters.
Flowering Plants	Entire-leaved peppergrass	*Lepidium integrifolium var. integrifolium*	Endemic to northeastern Utah and southwestern Wyoming. Occurs in sparsely vegetation, seasonally saturated flats of silts and silt loams.
Flowering Plants	Davis' peppergrass	*Lepidium montanum ssp. davisii*	Inhabits the drying clay hardpan soils of its playa habitat.
Flowering Plants	Pueblo Valley peppercress	*Lepidium montanum var. nevadense*	Known only from the Pueblo Valley that straddles the Nevada/Oregon state line. Found in interdune areas on the valley floor.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Slickspot peppergrass	*Lepidium montanum var. papilliferum*	Grows in microsites called slick spots, which are soil inclusions high in clay and sodium. Found in the Great Basin sagebrush steppe habitats of the Snake River Plain and Foothills geographic areas.
Flowering Plants	Bruneau River prickly phlox	*Leptodactylon glabrum*	Known only from a few river canyons in southwestern Idaho and northern Nevada and restricted to rhyolitic cliffs.
Flowering Plants	Fremont's bladderpod	*Lesquerella fremontii*	Rocky limestone slopes and ridges in cushion plant-bunchgrass (Festuca idahoensis) communities and in montane meadows with scattered limber pine (Pinus flexilis). Often associated with three-tip sagebrush (Artemisia tripartita).
Flowering Plants	Large-fruited bladderpod	*Lesquerella macrocarpa*	Wyoming endemic found in the Great Divide and Green River Basins. Occupies upland slopes withing sparsely vegetation habitat of saltbush communities.
Flowering Plants	Mountain bladderpod	*Lesquerella montana*	This species is found on banks, rock outcrops, from plains into benchland into stony slopes and mountains, in sagebrush, open scrub oak, ponderosa pine, pinyon-juniper woodlands, and Douglas fir on granitic, often gravelly, non-calcareous soils.
Flowering Plants	Payson's bladderpod	*Lesquerella paysonii*	Endemic to the carbonate mountain ranges of west-central Wyoming. Grows on rocky summits, talus, steep slopes, rocky ridges, fine soils, red sandstone, and gravelly and gypseous substrates.
Flowering Plants	Prostrate bladderpod	*Lesquerella prostrata*	Rangewide habitats include plains, hills, and slopes in sagebrush, grass, and juniper communities, mainly on calcareous substrates, but it can also occur on igneous substrates, it occurs at 1800-2500 m (5900-8200 feet) elevation.
Flowering Plants	Common starlily	*Leucocrinum montanum*	This species is found in sandy to rocky places, short-grass prairie, scrub flats, sagebrush deserts to open montane forests, at elevations ranging from 800 to 2,400 meters.
Flowering Plants	Lee's Lewisia	*Lewisia leeana*	Found on open, north- or northwest-facing slopes and cliffs made of granite or serpentine and in conifer forests. Native to California and Oregon.
Flowering Plants	Flowering quillwort	*Lilaea scilloides*	Found in shallow water and mud flats, and in wetland and riparian systems.
Flowering Plants	Bellinger's meadowfoam	*Limnanthes floccose ssp. bellingeriana*	Found in shallow, rocky soil of meadows near vernal pools.
Flowering Plants	Granite prickly phlox	*Linanthus pungens*	This species is found in open, dry, rocky, or sandy areas, from plains to sagebrush desert, to moderate elevations in the drier mountains.
Flowering Plants	Aristulate lipocarpha	*Lipocarpha aristulata*	Wet soil and mud, often comprised of fine sand and silt, in bottomlands, sandbars, beaches, shorelines, stream banks, ponds, and ditches.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Northern twayblade	*Listera borealis*	Found in a variety of habitats including along cold streams, coniferous and mixed hardwood forests, tundra slopes, floodplains, high acidic soils, moist, rich humus of mossy coniferous or mixed seepy, marshy places along cold-air drainages.
Flowering Plants	Sagebrush pygmyleaf	*Loeflingia squarrosa ssp. artemisiarum*	Occurs in dry soils and loose sands of washes, areas bordering clay slicks, and stabilized, low sand dunes. Found in Great Basin scrub and Sonoran Desert scrub most often under Gilia and Linanthus.
Flowering Plants	Taper-tip desert-parsley	*Lomatium attenuatum*	Volcanic or limestone-derived scree and thin soil in sagebrush-grassland, grassland, open Douglas-fir (*Pseudotsuga menziesii*), and creek bottom communities.
Flowering Plants	Bentonite biscuitroot	*Lomatium bentonitum*	This species occurs in pinon-juniper woodlands and clay badlands.
Flowering Plants	Red-fruited lomatium	*Lomatium erythrocarpum*	Occurs on dry, gravely or talus-covered south-facing slopes at elevations of 2300 m (7600 ft) and above.
Flowering Plants	Basalt desert parsley	*Lomatium filicinum*	Known from open, gravelly, dry meadows and gently sloping, rocky, xeric sites in ponderosa pine and mixed conifer forest openings.
Flowering Plants	Fringed desert-parsley	*Lomatium foeniculaceum ssp. fimbriatum*	This subspecies occurs in pine woodlands and sagebrush scrub.
Flowering Plants	Greeman's desert-parsley	*Lomatium greenmanii*	Found on moist subalpine ridges and rock summits at elevations of 2370-2700 m (7760-8870 ft) in the Wallowa Mountains, Oregon.
Flowering Plants	Nuttall desert-parsley	*Lomatium nuttallii*	Nuttall's desert-parsley grows on open, rocky mid- and lower-slopes on sandstone, siltstone or clayey shale, in open pine woodlands from about 3400 to 7200 feet elevation. The vegetation is generally sparse, and commonly includes ponderosa pine, Rocky Mountain juniper, bluebunch wheatgrass, western wheatgrass, big sagebrush, and rubber-rabbitbrush.
Flowering Plants	Ochoco lomatium	*Lomatium ochocense*	Open, barren scabland with *Artemisia rigida/Poa secunda* plant association.
Flowering Plants	Packard's desert parsley	*Lomatium packardiae*	This species is found within sagebrush communities, on dry, open, rocky clay soils derived from rhyolite or volcanic ash, at elevations of 730 - 2300 meters.
Flowering Plants	Meadow lomatium	*Lomatium pastorale*	Found in scrublands, scablands, woodlands, and conifer forests.
Flowering Plants	Paiute lomatium	*Lomatium ravenii var. paiutense*	Grows on flats, slopes, ridges, generally alkaline soils, sagebrush, and pinyon/juniper woodlands.
Flowering Plants	Raven's lomatium	*Lomatium ravenii var. ravenii*	This taxon typically grows on alkaline soils of flats in sagebrush of Great Basin Scrub at elevations of 1,615 to 1,775 meters.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Adobe lomatium	*Lomatium roseanum*	Open, dry, basalt talus and scree overlying clay soils on gentle slopes; also occurs directly on black adobe soil. Usually found within low sagebrush vegetation.
Flowering Plants	Salmon River biscuitroot	*Lomatium salmoniflorum*	Grows on dry, open, rocky slopes.
Flowering Plants	Spider biscuitroot	*Lomatium tarantuloides*	Grows on wet or moist scablands, flat or gentle slopes, and serpentine-derived gravel.
Flowering Plants	Marsh felwort	*Lomatogonium rotatum*	Grows in marshes, wet meadows, tundra, and shorelines and gaps in meadow and shallow marsh vegetation in alpine areas.
Flowering Plants	Colonial luina	*Luina serpentina*	Open, rocky sites with poor soil development, such as barrens, talus, scree, forest, woodland, and grassland.
Flowering Plants	Culter's spurred lupine	*Lupinus caudatus var. cutleri*	Occurs sagebrush plains and in pinyon-juniper woodlands, at elevations of 1800 - 2560 meters.
Flowering Plants	Cusick's lupine	*Lupinus lepidus var. cusickii*	Occurs on eroding hillsides of volcanic ash on moderate to extreme slopes at elevations ranging from 1170-1280 m (2850-4200 ft).
Flowering Plants	Soft lupine	*Lupinus malacophyllus*	Grows on rocky slopes in the foothills and sandy or gravelly flats, from 4,600 to 5,660 feet elevation.
Flowering Plants	Nevada lupine	*Lupinus nevadensis*	Hillsides and valley floors, on dry, sandy, and stony soil with pinyon-juniper and sagebrush; 4400-7000 feet.
Flowering Plants	Inchhigh lupine	*Lupinus uncialis*	This species is found on limestone, rhyolite, volcanic gravels in open areas, barrens, and talus in sagebrush and pinyon/juniper woodland, at elevations ranging from 1,300 to 1,600 meters.
Flowering Plants	Sierra woodrush	*Luzula orestera*	Grows in fellfields, talus, and other habitat in regions of subalpine and alpine climates.
Flowering Plants	Dolores River skeletonplant	*Lyodesmia grandiflora var. doloresensis*	Occurs in dry open places on sandy soils, reddish purple, sandy alluvium and colluvium of the Cutler Formation between the canyon walls and the river in juniper, shadscale, and sagebrush communities, at 1364 - 2032 meters elevation. Some occurrences are along roads, and there are fewer plants away from disturbed roadsides.
Flowering Plants	Lyrate malacothrix	*Malacothrix sonchoides*	Native to much of the western United States, where it grows in sandy substrates in habitat such as Joshua tree woodland, grassland, creosote bush scrub, and ephedra-blackbrush communities.
Flowering Plants	Smith's melicgrass	*Melica smithii*	Moist woods from the lowlands to middle elevations in the mountains.
Flowering Plants	Rock melic	*Melica stricta*	Grows in mountain and plateau habitats, including areas with an alpine climate.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Pioche blazingstar	*Mentzelia argillicola*	Endemic to Lincoln County Nevada. it occurs on sparsely vegetated sites of cliffs, slopes, and knolls with xeric, soft, gypsum-rich, silty, clay soils.
Flowering Plants	Arapien blazingstar	*Mentzelia argillosa*	Long lived perennial found on the gypserious Juarassic Arapien Shale formation. Locally endemic to the Utah Great Basin, grows in the salt desert shrub and pinyon-juniper communities.
Flowering Plants	Candelaria blazingstar	*Mentzelia candelariae*	Grows in barren, often calcareous, low-competition gravelly or clay soils on weathered volcanic ash deposits, scree slopes, hot spring mounds, washes, road banks, or other recovering disturbances in the shadscale, mixed-shrub, and sagebrush zones.
Flowering Plants	Ventana stickleaf blazingstar	*Mentzelia congesta*	This species occurs in sagebrush scrub, disturbed slopes, pine forests, and pinyon/juniper woodlands, at elevations ranging from 1,200 to 2,700 meters.
Flowering Plants	Inyo blazingstar	*Mentzelia inyoensis*	Documented on a variety of substrates including carbonate rocks/gravel, calcareous pumice sand, whitish ash deposits, and clay soils of hillsides, occurs in habitats that include sagebrush scrub, shadscale scrub, and pinyon-juniper woodlands.
Flowering Plants	Smooth stickleaf	*Mentzelia mollis*	Grows in dry, open, and nearly barren habitats that are made up of clay and volcanic ash deposits.
Flowering Plants	Horse Canyon stickleaf	*Mentzelia multicaulis var. librina*	Occurs on barren gray clay soils, on steep shale slopes at elevations 1700 - 2100 meters, in sagebrush, rabbitbrush and pinyon-juniper communities on Manicos Shale and Price River formations.
Flowering Plants	Packard's mentzelia	*Mentzelia packardiae*	Occurs at the base of talus slopes along canyon walls in rocky, volcanic ash substrates.
Flowering Plants	Roan Cliffs blazingstar	*Mentzelia rhizomata*	This species is known only from steep, shaley talus slopes derived from the Parachute Creek Member of the Green River Formation. The plants are commonly associated with Gambel oak, western chokecherry, mountain mahogany and Utah juniper
Flowering Plants	Streamside bluebells	*Mertensia ciliata*	Found in wet meadows, thickets, moist open forest, talus, often along streams in montane, lower alpine areas.
Flowering Plants	Nodding silver-puffs	*Microseris nutans*	This species is found in various soils in brushlands, grasslands, woodlands, and coniferous forests at elevations ranging from 100 to 3,000 meters.
Flowering Plants	Hill monkeyflower	*Mimulus clivicola*	Typically found in pockets of moist, exposed mineral soil or fine gravel in moist to moderately dry slopes and rocky, talus outcrops in the foothills and valleys.
Flowering Plants	Disappearing monkeyflower	*Mimulus evanescens*	Grows in sagebrush-juniper plant associations, among rocky rubble and boulders in vernally moist, heavy gravel. It is generally restricted to a narrow ecotone on fluctuating banks of intermittent streams or pools, between sagebrush on the upper bank and emergent, wetland species on the lower bank.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Narrow-leaved mondardella	*Monardella angustifolia*	Rhyolitic ash tuff outcrops between 850- and 1400-meters elevation. These relatively barren areas consist of azonal soils. Surrounding vegetation includes sagebrush steppe and big sagebrush shrubland.
Flowering Plants	Annual dropseed	*Muhlenbergia minutissima*	This species is found on rocky slopes and flats, in sandy, gravelly drainages, road cuts, and open sites, as well as pinyon-juniper woodlands, yellow pine and oak-pine forests, pinyon-juniper woodlands, thorn-scrub forests, and oak-gramma savannahs, at elevations ranging from 1,200 to 3,000 meters.
Flowering Plants	Green needlegrass	*Nassella viridula*	Most commonly found in open woods and grasslands, especially on sandy soils.
Flowering Plants	Rigid threadbush	*Nemacladus rigidus*	Desert scrub, juniper or pinyon-juniper woodland, sandy and gravelly wash bottoms, volcanic ash, mostly below 2200 meters.
Flowering Plants	Holmgren smewlowskia	*Nevada holmgrenii*	This species occurs in cracks, cervices, ledges, rubble, talus, or small soil pockets on rock outcrops and cliffs, from high-elevation ridges to north facing walls at lower elevations, on various rock types (e.g. calcareous rock, schist, metamorphic rock, igneous rock). Sites are found in the lower alpine, subalpine conifer, mountain sagebrush, and upper pinyon-juniper zones.
Flowering Plants	Flaming Gorge evening primrose	*Oenothera acutissima*	Plants are restricted to sandy, gravelly, and rocky soils in seasonally wet areas and along the margin of arroyos, in meadows, shallow "rock reefs", and mixed conifer forest and sagebrush scrub from 5,300 to over 9,000 ft.
Flowering Plants	Yellow evening primrose	*Oenothera flava*	Found in moist meadows, gravelly soil of roadsides.
Flowering Plants	Saint Anthony's evening primrose	*Oenothera psammophila*	Barren areas of drifting sand, sand dunes, lake margins, edges of scrub, and areas where sand dunes meet lava outcrops.
Flowering Plants	Adder's tongue	*Ophioglossum pusillum*	Seasonally wet areas in pastures, old fields, roadside ditches, bogs, fens, wet meadows, flood plains, moist woods, grassy swales, dry or damp sand, dry hillsides, and in seasonally wet, acidic soil.
Flowering Plants	Sagebrush cholla	*Opuntia pulchella*	Occurs on the sand of dunes, dry-lake borders, river bottoms, washes, valleys, and plains in the desert.
Flowering Plants	Slender orcutt grass	*Orcuttia tenuis*	Restricted to vernal pool habitats.
Flowering Plants	Tufted cryptanth	*Oreocarya caespitosa*	Populations are usually restricted to rocky or chalky ridgetops in cushion plant communities. Forb-grass, pinyon-juniper, mountain brush, limber pine, and spruce-fir forests at 1950 to 3120 meters.
Flowering Plants	Rollins' crypthantha	*Oreocarya rollinsii*	Known from white shale slopes of the Green River Formation; in pinyon-juniper woodlands and cold desert shrubland communities at 5,300 to 5,800 feet (1,615 to 1,768 meters) elevation.
Flowering Plants	Schoolcraft's cryptantha	*Oreocarya schoolcraftii*	Generally grows in xerophytic habitats at middle elevations, but some can tolerate shade, sandy deserts, and alpine slopes.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Tall alpine aster	*Oreostemma elatum*	Grows in peatlands, marshy areas, wet meadows, montane forest.
Flowering Plants	Trotter's oreoxis	*Oreoxis trotteri*	This species grows in crevices or in sandy pockets on the Moab Tongue and (occasionally) the Slick Rock members of the Entrada Sandstone. It is found in the open, although usually on sites with a northern aspect, and, less frequently, in alcoves and along shaded cliff bases. It grows in mixed juniper and warm desert shrub community at 1,359 to 1,573 m elevation.
Flowering Plants	Shasta orthocarpus	*Orthocarpus pachystachyus*	Ultramafic alluvium with sagebrush and native bunchgrasses. 775 - 975 meters.
Flowering Plants	Spjut bristlemoss	*Orthotrichum spjutii*	Occurs on granitic rock in lower montane coniferous forest, pinyon-juniper woodland, subalpine coniferous forest, and upper montane coniferous forest.
Flowering Plants	Nevada oryctes	*Oryctes nevadensis*	Occurs on deep, loose sand of stabilized dunes, washes, and valley flats on various slopes and aspects.
Flowering Plants	Watson's spinecup	*Oxytheca watsonii*	Occurs on dry, open, loose, and/or lightly disturbed, often calcareous, sandy soils of washes, roadsides, alluvial fans, and valley bottoms in salt desert shrub communities
Flowering Plants	Bessey locoweed	*Oxytropis besseyi var. obnapiformis*	This taxon grows on barrens, sand dunes, bluffs, hilltops, or knolls in fine-textured or sandy soils or shaley talus in pinyon-juniper and sagebrush communities.
Flowering Plants	Challis crazyweed	*Oxytropis besseyi var. salmonensis*	Occurs within the shrub-steppe in sandy wash or open lower slopes on fine talus and ash.
Flowering Plants	Creeping nailwort	*Paronychia sessiliflora*	Sparsely vegetated areas, often stony soil of exposed slopes, ridge crests; plains, valleys to montane.
Flowering Plants	Colorado feverfew	*Parthenium ligulatum*	Barren or semibarren calciferous or gypsiferous outcrops of the Green River, Uinta, Ferron, Summerville, and Carmel formations in salt desert shrub, serviceberry, rabbitbrush, Indian rice-grass, greasebush, galleta, black sagebrush, pygmy sagebrush, and pinyon-juniper communities at 1705-2135 meters.
Flowering Plants	Dwarf lousewort	*Pedicularis centranthera*	Sagebrush scrub, alluvial fans; 1300 - 1500 meters.
Flowering Plants	Meadow lousewort	*Pedicularis crenulata*	This species occurs in moist grassy, alpine meadows, and sagebrush basins at elevations ranging from 1,500 to 3,200 meters.
Flowering Plants	Snowball cactus	*Pediocactus nigrispinus*	Sagebrush, grasslands, and coniferous forests; usually below 1500 meters elevation.
Flowering Plants	Simpson's hedgehog cactus	*Pediocactus simpsonii*	Pinyon-juniper woodlands, sagebrush, montane and prairie grasslands, and coniferous forests; usually above 1500 meters elevation.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Absaroka beardtongue	*Penstemon absarokensis*	Endemic to the Absaroka Range in northwest Wyoming. Occurs on sparsely vegetation steep slopes, rocky ridges and creek bottoms in montane and subalpine zones.
Flowering Plants	Stemless beardtongue	*Penstemon acaulis*	This species occurs on semi-barren substrates in pinyon-juniper and sagebrush-grass communities elevations of 1,676 to 2,504 meters.
Flowering Plants	Stemless penstemon	*Penstemon acaulis var. acaulis*	This species occurs on semi-barren substrates in pinyon-juniper and sagebrush-grass communities elevations of 1,676 to 2,504 meters.
Flowering Plants	Yampa beardtongue	*Penstemon acaulis var. yampaensis*	This species grows in sandy or gravelly or rocky soils of barren or semi-barren shale ridges or slopes, dry, sparsely vegetated limestone outcrops, gypsum hills, and shale ridges, or deposition fans from eroded slopes and alluvial fans in sparsely vegetated areas of pinyon-juniper and sagebrush-grass communities at elevations of 1,780 to 2,200 meters.
Flowering Plants	Nevada Dune beardtongue	*Penstemon arenarius*	This species is endemic to the Great Basin in central Nevada. It occurs on deep, volcanic, sandy soils at elevations of 3,940 to 4,430 feet.
Flowering Plants	Cary penstemon	*Penstemon caryi*	Regional endemic in MT and WY, Stony, calcareous soils in Douglas-fir forests, juniper woodlands, sagebrush steppe from the montane to lower subalpine zone
Flowering Plants	Bear River Range beardtongue	*Penstemon compactus*	Open, rocky, calcareous (limestone or dolomite) slopes and outcrops in the subalpine zone.
Flowering Plants	Tunnel Springs beardtongue	*Penstemon concinnus*	Endemic to the Great Basin occurring in pinyon-juniper, blue grama, mountain mahogany, cliff rose, and sagebrush communities. Found on calcareous or igneous gravels, usually on pale, limestone-derived substrates.
Flowering Plants	Variable hot-rock penstemon	*Penstemon deustus var. variabilis*	Dry foothills and lowlands, on open, dry, thin soils over basalt.
Flowering Plants	Franklin's penstemon	*Penstemon franklinii*	Occurs in grass-forb-sagebrush and in three-awn, needlegrass, matchweed, and black sagebrush communities on sandy-gravelly and sandy soils across a gently sloping landscape.at 1,650 to 1,800 meters elevation.
Flowering Plants	Gibben's beardtongue	*Penstemon gibbensii*	Endemic to the Washakie Basin and upper North Platte River valley in Wyoming and Brown's Park area near the Colorado-Utah border. Occurs on steep, bare slopes with poor soil development.
Flowering Plants	Blue-leaved penstemon	*Penstemon glaucinus*	At mid-elevations in open understory of pine forests, usually lodgepole or white-bark, occasionally ponderosa. Also, in open areas dominated by shrub-grasses on exposed slopes, rims and ridges at higher elevations.
Flowering Plants	Goodrich's penstemon	*Penstemon goodrichii*	Grows on the Badlands of the Uinta Basin and has been found on the blue-gray to red clay soils of the Duchesne River Formation. Is often associated with shadscale and juniper-mountain mahogany plant communities.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Graham's beardtongue	*Penstemon grahamii*	Graham's beardtongue is an oil shale obligate endemic to the Uinta Basin in Colorado and Utah. Plants occur in low densities on exposed and sparsely vegetated slopes of Green River oil shale among pinyon-juniper.
Flowering Plants	Harrington's beardtongue	*Penstemon harringtonii*	Open sagebrush or, less commonly, pinyon-juniper habitats, on gentle slopes. Soils are typically rocky loams and rocky clay loams derived from coarse calcareous parent materials.
Flowering Plants	Idaho penstemon	*Penstemon idahoensis*	Grows on the silica-rich tuffaceous outcrops of the Salt Lake formation, usually among sagebrush and juniper between 5,000 and 5,200 feet elevation.
Flowering Plants	Janish's beardtongue	*Penstemon janishiae*	Hillsides and slopes on clay soil derived volcanic rock with Artemisia to pinyon-juniper.
Flowering Plants	Loose beardtongue	*Penstemon laxus*	Endemic to south-central Idaho, grows in dry meadows and sagebrush shrublands.
Flowering Plants	Lemhi beardtongue	*Penstemon lemhiensis*	A regional endemic that occurs only in southwest Montana and adjacent Idaho. Occurs on moderate to steep, east- to southwest-facing slopes, often on open soils. It generally grows below or near the lower extent of Douglas-fir and/or lodgepole pine forest, in habitat dominated by big sagebrush and bunchgrasses, including western wheatgrass and Idaho fescue.
Flowering Plants	Bright penstemon	*Penstemon luculentus*	This plant is found on partly barren, arid benches and slopes in sandy clay loams of the Uinta Formation and Green River shale in sagebrush communities with Amelanchier, Chrysothamnus, and Holodiscus.
Flowering Plants	Golden-tongue penstemon	*Penstemon miser*	Grows in clayey soils, sagebrush shrublands, pine-juniper woodlands, and sandy or gravelly slopes.
Flowering Plants	Shining penstemon	*Penstemon nitidus*	Found in plains, hills and slopes.
Flowering Plants	Lahontan beardtongue	*Penstemon palmeri var. macranthus*	Found in blackbrush, sagebrush, Joshua tree, pinyon-juniper and ponderosa pine communities where subsurface moisture is available for most of the growing season.
Flowering Plants	Dad's penstemon	*Penstemon patricus*	Endemic to the Nevada Great Basin and can be found in Utah and Nevada in granite and limestone rocky outcrops with a variety of shrub, grassland, and conifer communities between 2100 and 2700 meters (6900-8860 ft) elevations.
Flowering Plants	Beautiful penstemon	*Penstemon perpulcher*	Sandy or loamy soils on the lower and middle Snake River Plains and surrounding, rolling, sagebrush-dominated foothills. 630-2000 meters elevation.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Closed-throated beardtongue	*Penstemon personatus*	Conifer forests, often moist and with a substantial Shasta red fir component. In semi-shade or open places, such as dry hillsides, forest openings and edges, and disturbed places such as clearcuts and roadsides; sometimes within Montane Chaparral areas. Often on metavolcanic substrates. 1065 - 2120 meters.
Flowering Plants	Pinyon penstemon	*Penstemon pinorum*	Pinyon-juniper, mountain-mahogany, ephedra, oak, sagebrush, and less commonly greasewood communities on Tertiary Claron Formation, i.e., quartzite cobble conglomerate and sandstone to calcareous sandstone and sandy limestone (soils are reddish and gravelly to cobble-like), across slopes of varying degree and aspect (predominately northerly) between 1713 meters and 2072 meters.
Flowering Plants	Wassuk beardtongue	*Penstemon rubicundus*	Occurs in desert scrub, sagebrush, pinyon-juniper ecosystems on rocky to gravelly soils on perched tufa shores, steep decomposed granite slopes, rocky slopes, rocky drainage bottoms, disturbed but recovering areas with enhanced runoff, including slopes that were recently burned, where it can be abundant.
Flowering Plants	Salmon River Mountains penstemon	*Penstemon salmonensis*	New species of penstemon, is native to the Salmon River Mountains in central Idaho on rocky places, such as cliff crevices and on rocky slopes and talus.
Flowering Plants	White River beardtongue	*Penstemon scariosus var. albifluvis*	Habitat is desert shrub communities or pinyon-juniper woodlands on substrates composed of fine textured soils and shale fragments, weathered from the Green River Formation.
Flowering Plants	Neese's Blue Mountain beardtongue	*Penstemon scariosus var. cyanomontanus*	Occurs in pinyon-juniper or sagebrush-grassland communities, on sandy soil or in sandstone crevices.
Flowering Plants	Short-lobed penstemon	*Penstemon seorsus*	This species is found in juniper woodlands and sagebrush shrublands at elevations ranging from 1,000 to 2,100 meters.
Flowering Plants	Susanville beardtongue	*Penstemon sudans*	This species grows in open, sagebrush or woodland dominated, rocky slopes on volcanic or other igneous substrates at elevations of 1,200 to 1,700 meters elevation.
Flowering Plants	Ward's penstemon	*Penstemon wardii*	This species grows on semi-barren, light-colored clays (often calcareous or gypsiferous) in desert shrub and pinyon-juniper communities at 1,645 to 2,075 meters elevation.
Flowering Plants	Yampa penstemon	*Penstemon yampaensis*	This species grows in sandy or gravelly or rocky soils of barren or semi-barren shale ridges or slopes, dry, sparsely vegetated limestone outcrops, gypsum hills, and shale ridges, or deposition fans from eroded slopes and alluvial fans in sparsely vegetated areas of pinyon-juniper and sagebrush-grass communities at elevations of 1,780 to 2,200 meters.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Wild crabapple	*Peraphyllum ramosissimum*	Oak-sagebrush, pinyon-juniper, mountain brush, and ponderosa pine communities at 1500 to 2500 meters.
Flowering Plants	Spine-noded milkvetch	*Peteria nevadensis*	Grows in salt desert shrublands and alluvial fans, in soils made from volcanic ash.
Flowering Plants	Argyle Canyon phacelia	*Phacelia argylensis*	Endemic to Argyle Canyon in Duchesne County, Utah. Grows in sandy-silty soil of washes in Green River Shale formation among pinyon-juniper, serviceberry, and Douglas Fir community at 7,595 feet elevation.
Flowering Plants	Cooke's phacelia	*Phacelia cookei*	Open areas, including disturbed roadsides, seedling conifer plantations, and recently burned sites, on loose volcanic sand. Found within Great Basin (Sagebrush) Scrub and Yellow Pine Forest communities, often with a scattered ponderosa pine-juniper overstory.
Flowering Plants	North Park phacelia	*Phacelia formosula*	Endemic to Colorado with the majority of occurrences found on gravelly, sparsely vegetated exposures of Coalmont Formation in North Park
Flowering Plants	Gina's phacelia	*Phacelia gina-glenneae*	Plants tend to occur in small patches on relatively steep, sparsely vegetated exposures of Troublesome Creek Formation shales. The entire known distribution of this species occurs in the Troublesome Creek ACEC in Colorado.
Flowering Plants	Reese River phacelia	*Phacelia glaberrima*	Endemic to northwestern and north-central Nevada. It occurs on open, dry to moist, alkaline, nearly barren, sometimes scree-covered, whitish to brownish shrink-swell clay soils derived from fluviolacustrine volcanic ash and tuff deposits. It is generally on the steeper slopes of low hills, bluffs, and badlands in the shadscale-greasewood, sagebrush, and lower pinyon-juniper zones.
Flowering Plants	Idaho phacelia	*Phacelia idahoensis*	Endemic to Idaho. Found in moist meadows and stream bottoms.
Flowering Plants	Obscure phacelia	*Phacelia inconspicua*	Grows in small gaps in vegetation dominated by deciduous mountain shrubs or mountain big sagebrush and on disturbed soils associated with trails and gopher diggings.
Flowering Plants	Playa phacelia	*Phacelia inundata*	Grows in the alkaline soils of playas and dry lakebeds in areas seasonally inundated.
Flowering Plants	Yellow scorpionweed	*Phacelia lutea var. calva*	Grows on barren volcanic ash clays, alkaline soils, deserts, and foothills.
Flowering Plants	Least phacelia	*Phacelia minutissima*	Occurs at moderate elevations in mountains; on damp ground, such as in meadows and along stream banks; on loam, sand, gravel, and rocky areas; and under shrubs and trees from about 4,600 to 8,200 feet in elevation.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Mono County phacelia	*Phacelia monoensis*	Grows in alkaline, barren or sparsely vegetated, grayish, brownish, or reddish shrink-swell clays of mostly andesitic origin. It grows mostly on stabilized or low-intensity artificial or natural disturbances; it is most abundant on road berms that cross such soils in the pinyon-juniper and mountain sagebrush zones.
Flowering Plants	Atwood's pretty phacelia	*Phacelia pulchella var. atwoodii*	Occurs on thin gypsiferous strata or alluvium contaminated by gypsum in pinyon-juniper, oak, sagebrush, single-leaf ash, and serviceberry communities at 1550 to 1680 meters elevation.
Flowering Plants	Dwarf phacelia	*Phacelia tetramera*	This species is found in sagebrush steppe communities, meadows, vernal pools, alkaline flats, and washes.
Flowering Plants	Hot springs phacelia	*Phacelia thermalis*	Open clay flats, slopes, and open woodlands in the western United States.
Flowering Plants	Utah phacelia	*Phacelia utahensis*	Biennial herb grows in salt desert shrub communities on the Arapien Shale Formation at 5,500 to 6,200 feet.
Flowering Plants	Sunbright	*Phemeranthus parviflorus*	This species occurs in a wide variety of habits including woodlands, grasslands, chaparral, scrub, canyon washes, mountain slopes and ledges, on sandy, rocky soils, or on outcrops. It can grow at elevations of 0 to 2,700 meters above sea level.
Flowering Plants	Spinescent fameflower	*Phemeranthus spinescens*	Basaltic outcrops and scablands in sagebrush deserts.
Flowering Plants	Thompson's talinum	*Phemeranthus thompsonii*	Occurs in shallow, gravelly soils comprised mainly of rounded, silicious pebbles of the Buckhorn Conglomerate of the Cedar Mountain Formation in pinyon-juniper, sagebrush, and ponderosa pine communities.
Flowering Plants	Many-flowered phlox	*Phlox multiflora*	Found in open meadows, including sagebrush meadows, rocky hillsides, along streambanks and in open conifer woodlands.
Flowering Plants	Beaver Rim phlox	*Phlox pungens*	Endemic to the Wind River and Green River Basins in Wyoming. Found on sparsely-vegetated cushion plant/bunchgrasses communities and openings in sagebrush grasslands.
Flowering Plants	Payson's bladderpod	*Physaria carinata*	Restricted to areas of calcareous limestone substrates on low elevation, south-facing grasslands.
Flowering Plants	Chambers' twinpod	*Physaria chambersii*	This species is found in reddish clay, limestone gravel, on dolomite ridges and roadsides, as well as in sagebrush and pinyon-juniper habitats at elevations ranging from 1,500 to 3,200 meters.
Flowering Plants	Tufted twinpod	*Physaria condensate*	Endemic to southwest Wyoming. Occurs in sparsely vegetated cushion plan bunchgrass communities.
Flowering Plants	Idaho twinpod	*Physaria didymocarpa var. lyrata*	occurs on rocky, sparsely vegetated, southerly slopes near the Salmon River and tributaries.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Dorn's twinpod	*Physaria dornii*	Dry, sparsely vegetated, calcareous-shaley slopes and ridges dominated by mountain mahogany and rabbitbrush at 1980-2200 meters elevation.
Flowering Plants	Cobre bladderpod	*Physaria kingii ssp. cobrensis*	This variety occurs in limestone gravel, silt, rocky places with low sagebrush at elevations ranging from 500 to 1,000 meters.
Flowering Plants	Pryor Mountain bladderpod	*Physaria lesicii*	Occurs only in Montana, where it is restricted to a few areas of limestone outcrops in the eastern Pryor Mountains in two distinct vegetation types - woodlands with a sparse overstory of Rocky Mountain juniper and/or mountain mahogany, and widely scattered Douglas-fir. The shrub layer may have scattered *Symphoricarpos oreophilus*, *Artemisia nova* or *A. tridentata*.
Flowering Plants	Middle Butte bladderpod	*Physaria obdeltata*	This species grows on clay, silt, or gravel over basal lava flows on barren areas, playas, or in sagebrush at elevations of 1,300 to 1,700 meters.
Flowering Plants	Thick-leaf bladderpod	*Physaria pachyphylla*	A regional endemic species, occurring only in the Pryor Mountain Desert of south-central Montana and in the Big Horn Basin of north-central Wyoming. Grows in dry, barren, and stony, yet edaphically diverse soils in the Pryor Mountain Desert which occur on exposed slopes, ridges, and valleys.
Flowering Plants	Piceance bladderpod	*Physaria parviflora*	This species is endemic to outcrops of the Green River Shale Formation in the Piceance Basin. It grows on ledges and slopes of canyons in open areas of pinon juniper communities.
Flowering Plants	Beautiful bladderpod	*Physaria pulchella*	Found on gravelly, calcareous soils of sparsely vegetated foothill slopes at elevations ranging from 6200 to 7600 feet as well as poorly developed, stony soils of subalpine slopes and ridges. At lower elevations it inhabits openings in mountain mahogany or limber pine woodlands. It also is found in sparse grassland or cushion plant communities at all elevations.
Flowering Plants	Rocky Mountain twinpod	*Physaria saximontana var. saximontana*	Endemic to Wyoming's southern Bighorn and Wind River Basins, and foothills of the Wind River and Absaroka Ranges occurs in sparsely vegetated slopes on sandy, gravelly soils.
Flowering Plants	Small-flowered ricegrass	*Piptatherum micrathum*	Grows in a variety of habitats including rocky slopes, gravel benches, creek banks, open woodlands, and moist meadows.
Flowering Plants	Altered Andesite popcornflower	*Plagiobothrys glomeratus*	Dry, shallow, mostly acidic gravelly clay soils, ridges, knolls and steep slopes in sagebrush and montane conifer zones.
Flowering Plants	Saline plantain	*Plantago eriopoda*	Found in a variety of moist and wet habitats including moist meadows and prairies, wetlands, marshes, fens, ditches, and stream banks and openings in foothills and montane areas.
Flowering Plants	Spiny skeletonweed	*Pleiacanthus spinosus*	Occupies arid grasslands on stony loam at lower elevations (5000-6400 feet).
Flowering Plants	Long tongue muttongrass	*Poa fendleriana ssp. longiligula*	Found in sagebrush-scrub, interior chaparral, and southern high plains grasslands.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Timberline bluegrass	*Poa glauca ssp. rupicola*	Dry alpine areas of western North America.
Flowering Plants	Elusive Jacob's-ladder	*Polemonium elusum*	Occurs where vegetation transitions from sagebrush and mountain mahogany to Douglas-fir woodland.
Flowering Plants	Williams combleaf	*Polyctenium williamsiae*	Occurs on relatively barren, sandy to sandy-clay or mud margins and bottoms of nonalkaline seasonal lakes perched over volcanic bedrock in the sagebrush, pinyon-juniper, and mountain sagebrush zones.
Flowering Plants	Modoc County knotweed	*Polygonium polygaloides ssp. esotericum*	Pinyon and juniper woodlands, desert scrub, vernal pools, and seasonally wet places
Flowering Plants	Fremont's combleaf	*Polyctenium fremontii*	This species is found in shallow soil on basalt, sagebrush areas, dry meadows, edge of vernal pools, gravel bars, rocky wash, mud flats, dry streambeds and swales, at elevations ranging from 1,000 to 2,700 meters.
Flowering Plants	Waterthread pondweed	*Potamogeton diversifolius*	Found in shallow, still or slow-moving water, in shallow water of small lakes and large ponds.
Flowering Plants	Black Rock potentilla	*Potentilla basaltica*	Occurs in or near alkali meadows, seeps, and marsh habitats bordering perennial thermal springs, outflows, and meadow depressions.
Flowering Plants	Tansy cinquefoil	*Potentilla bipinnatifida*	Open shortgrass prairie, alkaline bottoms, streamsides in sagebrush, and disturbed sites.
Flowering Plants	Cottam's cinquefoil	*Potentilla cottamii*	Mat forming plant that grows in cracks and crevices on quartzite cliffs at elevations 7,500 to 10,400 feet.
Flowering Plants	Bushy cinquefoil	*Potentilla paradoxa*	Moist or wet sandy soils such as in prairies, river banks, sand bars, and lake shores, sandy dunes and areas subject to seasonal water fluctuations.
Flowering Plants	Alkali primrose	*Primula alcalina*	A regional endemic, occuring only in east-central Idaho and adjacent Montana. Found in moist to wet alkaline meadows near headwaters streams at 6,300 to 7,200 feet elevation. The soil surface often displays hummock-hollow topography.
Flowering Plants	Desert prenanthella	*Prenanthella exigua*	This species occurs in gravelly, sandy, or clay soils, in desert washes and open slopes to steppes of sagebrush-juniper, at elevations ranging from 20 to 1,900 meters.
Flowering Plants	Jone's primrose	*Primula incana*	Found in river flood plains, open meadows, montane meadows, riparian areas, cold quaking bogs, saline meadows, wetlands and salt marshes.
Flowering Plants	Annual brittlebrush	*Psathyrotes annua*	Grows in desert and scrub habitat, often in areas with alkali soils among plants such as shadscale.
Flowering Plants	Slender woollyheads	*Psilocarphus tenellus*	Grows in seasonally wet habitat, such as vernal pools, as well as coastline and disturbed areas.
Flowering Plants	Lahontan indigobush	*Psorothamnus kingi*	Found occurring on streambanks and in hollows of sandy, hammocked dunes with *Artemisia*.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Beartooth large-flowered goldenweed	*Pyrrocoma carthamoides var. subsquarrosa*	Grassland or sagebrush grassland, often on calcareous soils.
Flowering Plants	Sticky golden weed	*Pyrrocoma hirta var. sonchifolia*	Meadows, rocky vernally wet places, and open or sparsely wooded slopes in foothills at moderate elevations.
Flowering Plants	Bugleg goldenweed	*Pyrrocoma insecticruris*	Mountain meadows, sagebrush/grass; 5000-6000 feet elevation.
Flowering Plants	Entireleaf goldenweed	*Pyrrocoma integrifolia*	Moist, often calcareous soil of meadows, grasslands, valleys and montane areas.
Flowering Plants	Thin-leaf goldenweed	*Pyrrocoma linearis*	Found in marshy grassy areas, swales, meadows, and vernal stream banks.
Flowering Plants	Sticky pyrrocoma	*Pyrrocoma lucida*	Grows in mountain forests and clay flats with alkali soils.
Flowering Plants	Panicled gondenweed	*Pyrrocoma racemose var. paniculata*	Found in open fields, meadows with alkaline soil, and areas near boggy places and hot springs.
Flowering Plants	Snake River goldenweed	*Pyrrocoma radiata*	A grazing-modified sagebrush/grassland community. Usually, a specific soil type that is slightly to very calcareous and often overlays a shale formation.
Flowering Plants	Rough pyrrocoma	*Pyrrocoma scaberula*	Occurs in grasslands of the Snake River Canyons/Camas Prairie region.
Flowering Plants	California chicory	*Rafinesquia californica*	This species is found in open areas in chaparral, coastal sage scrub, and oak woodlands at elevations ranging from 100 to 1,500 meters.
Flowering Plants	Alpine sedum	*Rhodiola integrifolia ssp. integifolia*	Found in in alpine and subalpine meadows, cliffs, and talus in western North America.
Flowering Plants	Wolf's currant	*Ribes wolfii*	Grows in moist forests and meadows in montane and subalpine regions.
Flowering Plants	Persistent sepal yellowcress	*Rorippa calycina*	Occurs along moist sandy to muddy banks of streams, stock ponds and man-made reservoirs
Flowering Plants	Columbia yellow cress	*Rorippa columbiae*	Associated with moist habitats that experience periodic inundation, including shorelines of lakes and playas, banks of rivers, gravel bars, streams, creeks, marshes, mudflats and swales.
Flowering Plants	Lowland toothcup	*Rotala ramosior*	Grows on exposed shorelines, stream margins, streambed outcrops, and other damp, open places.
Flowering Plants	Bartonberry	*Rubus bartonianus*	At least partially shaded in shrub communities on higher riparian terraces along streams and in shrub-dominated ephemeral stream beds, so water is available in abundance at least seasonally. Also, occasionally on lower slopes in mixed shrub communities, but never far from the riparian zone. Soils derived from basalt parent materials.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	King's snapdragon	*Sairocarpus kingii*	Found in washes, as well as on rocky slopes and scree at elevations ranging from 500 to 2,300 meters.
Flowering Plants	Red glasswort	*Salicornia rubra*	Occurs in salt flats, alkaline depressions, exposed shores of alkaline lakes, and saline swales in prairies.
Flowering Plants	Hoary willow	*Salix candida*	Cold, open fens, swamps & bogs of high pH.
Flowering Plants	Farr's willow	*Salix farriae*	Wet meadows, often near small streams, lakes; subalpine.
Flowering Plants	Snow willow	*Salix nivalis*	Subalpine and alpine (10500 to 13500 ft.); tundra, cirques, lake basins, rocky slopes.
Flowering Plants	False mountain willow	*Salix pseudomonticola*	Found in treed bogs, moist fens in white spruce forests, balsam poplar forests, and floodplains at elevations ranging from 0 to 2,500 meters.
Flowering Plants	Wolf's willow	*Salix wolfii*	Found along subalpine streambanks, wet meadows, and around ponds.
Flowering Plants	Wedge-leaf saxifrage	*Saxifraga adscendens ssp. oregonensis*	Grows in glacial moraines and alpine gravelly meadows.
Flowering Plants	Swaying bulrush	*Schoenoplectus subterminalis*	Grows in wet, moist, and shallow water habitats including lakes, ponds, rivers, streams, and bog pools.
Flowering Plants	Blaine pincushion	*Sclerocactus blainei*	Greasewood, galleta grass, shadscale, and sagebrush communities on limestone and igneous gravels with a clay matrix. 1460-1830 meters elevation.
Flowering Plants	Dawson's hookless cactus	*Sclerocactus dawsonii*	Populations occur primarily on alluvial benches along the Colorado and Gunnison Rivers and their tributaries.
Flowering Plants	Colorado hookless cactus	*Sclerocactus glaucus*	Populations occur primarily on alluvial benches along the Colorado and Gunnison Rivers and their tributaries.
Flowering Plants	Great Basin fishhook cactus	*Sclerocactus pubispinus*	Rocky hillsides of woodland and upper desert mountains. Shadscale, sagebrush, winterfat, rabbitbrush, and pinyon-juniper communities on calcareous and dolomitic gravels and outcrops at 1800 to 1955 meters.
Flowering Plants	Salmon River sedum	*Sedum valens*	Found on the steep granite canyon walls of central Idaho.
Flowering Plants	Ertter's senecio	*Senecio ertterae*	Dry clay ash deposits, sand, gravel, and talus.
Flowering Plants	Bog groundsel	*Senecio triangularis var. angustifolius*	Moist places and streambanks from the lowlands to the subalpine on sandy or gravelly soils.
Flowering Plants	Verruose sea-purslane	*Sesuvium verrucosum*	Found in alkali flats, desert playa lakes, and drying desert washes.
Flowering Plants	Shoshonea	*Shoshonea pulvinata*	Occurs on open, exposed limestone outcrops, ridgetops, and canyon rims, in thin rocky soils.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Bristly-stemmed sidalcea	*Sidalcea hirtipes*	Moist remnant prairies, fencerows, open meadows, and roadside ditches; sometimes associated with creeks and streams.
Flowering Plants	Bolander's catchfly	*Silene hookeri ssp. bolanderi*	Usually occurs in grassy openings, sometimes dry rocky slopes, canyons, or roadsides on serpentine and non-serpentine soils.
Flowering Plants	Nachlinger's catchfly	*Silene nachlingerae*	Grows on carbonate (rarely quartzite) crevices in ridgeline outcrops, talus, or very rocky soils on or at the bases of steep slopes or cliffs, mainly in the subalpine conifer zone from 7,160 to 11,250 feet.
Flowering Plants	Lost River silene	*Silene scaposa var. lobata*	Subalpine grassy, gravelly, or rocky slopes, ponderosa pine forests, juniper scrub, sagebrush.
Flowering Plants	Spalding's catchfly	*Silene spaldingii*	Deep loamy soils from wind deposits, volcanic ash, and glacial deposits. Found in bunchgrass or sagebrush communities, with Idaho fescue, Idaho fescue with rough fescue, or Idaho fescue and bluebunch wheatgrass.
Flowering Plants	Pale blue-eyed grass	*Sisyrinchium pallidum*	A regional endemic of southeastern Wyoming and northcentral Colorado. It is found in moist meadows, fens, and along streams in plant communities dominated by graminoids and forbs.
Flowering Plants	Basin goldenrod	*Solidago spectabilis*	Grows in moist habitat, including bogs, meadows, seeps, streambanks, hot springs, and wet areas on alkali flats.
Flowering Plants	Psorlea globemallow	*Sphaeralcea psoraloides*	Salt and mixed desert shrub communities and pinyon-juniper communities; can occur in areas where vegetation is sparse. Occurs on clayey, silty, sandy, and gravelly semibarrens, often under alkaline conditions.
Flowering Plants	Laramie false sagebrush	*Sphaeromeria simplex*	Endemic to the Laramie Range, Shirley Basin and Shirley Mountains in Wyoming. Occurs in cushion plant communities on rocky limestone ridges and gentle slopes.
Flowering Plants	Ute ladie's-tresses	*Spiranthes diluvialis*	Grows in moist wetland habitat, including bogs and riparian areas such as riverbanks, floodplains, lakeshores, riverside woodlands and forest, desert springs, and meadows.
Flowering Plants	Tall dropseed	*Sporobolus compositus var. compositus*	This variety occurs in meadows, prairie, plains, and pastures, as well as open woodlands and savannas.
Flowering Plants	Malheur princes-plume	*Stanleya confertiflora*	Alkaline meadows, heavy clay flats, barren clay slopes in sagebrush communities, dry sandy grounds
Flowering Plants	Hairy prince's-plume	*Stanleya tomentosa var. runcinata*	This variety is found in sagebrush communities, knolls, as well as on rocky limestone hillsides, steep grassy banks, and stony clay slopes at elevations ranging from 1,300 to 2,300 meters.
Flowering Plants	Woolly stenotus	*Stenotus lanuginosus var. lanuginosus*	This variety occurs on basaltic or granitic soils, in open pine forests, alpine meadows, and on sagebrush steppe, at elevations ranging from 300 to 2,900 meters.
Flowering Plants	Disguised wirelettuce	*Stephanomeria occultata*	Disguised wirelettuce can be found in gravel or talus slopes at 590-1650 meters (1935 - 5413 ft) elevations in mountain brush and forb communities.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Howell's streptanthus	*Streptanthus howellii*	Occurs on dry, serpentine slopes, mixed evergreen forests, open pine woods or brushy areas.
Flowering Plants	Kruhsea	*Streptopus streptopoides*	Occurs on damp, dense coniferous forests at elevations ranging from 0 to 1,600 meters.
Flowering Plants	Little ricegrass	*Stipa exigua*	Occurs in Great Basin scrub habitats.
Flowering Plants	Talapoosa Peak pearpod	*Stroganowia tiehmii*	Occupies dry, open, very rocky, clay soils or soil pockets in or near scree, talus, or boulder fields derived from basalt, other volcanic rocks, and/or fluviolacustrine sediments.
Flowering Plants	Northern slender-leaved pondweed	*Stuckenia filiformis ssp. alpina*	Occurs in freshwater and marsh wetlands and wetlands associated with riparian areas.
Flowering Plants	Nevada pondweed	*Stuckenia striata*	An aquatic plant that grows in shallow waterways, such as rivers, canals, and ponds.
Flowering Plants	Violet suksdorfia	*Suksdorfia violacea*	Grows in moist, sandy, shaded areas, mossy banks, cliffs, and rock crevices.
Flowering Plants	Swertia	*Swertia perennis*	Native to wetlands, particularly calcareous fens, in meadows and moist places at high mountain elevations.
Flowering Plants	Long-flowered snowberry	*Symphoricarpos longiflorus*	This species is found in sagebrush, pinyon-juniper communities, and rocky mountain slopes.
Flowering Plants	Rush aster	*Symphyotrichum boreale*	Lakesides, marshes, bogs, and fens, including calcareous bogs and fens, open peatland, and sedge-dominated open sphagnum bogs.
Flowering Plants	Slender-flowered evening-primrose	*Tetrapteron graciliflorum*	This species occurs in clay soil, grasslands, brushy or open slopes, as well as Yucca, juniper and oak shrublands at elevations ranging from 0 to 800 meters.
Flowering Plants	American woodsage	*Teucrium canadense var. occidentale*	Found along streambanks, lake shores and moist bottomlands.
Flowering Plants	Alpine meadowrue	*Thalictrum alpinum*	Occurs in cold, wet, boggy habitats in high mountains.
Flowering Plants	Sun-loving meadow rue	*Thalictrum heliophilum*	Endemic to northwestern Colorado found growing in open sunny sites on sparsely vegetated, barren, dry shale talus slopes, usually on the Parachute Creek Member of the Green River Shale Formation.
Flowering Plants	Green River greenthread	*Thelesperma caespitosum*	Endemic to Sweetwater County in Wyoming and Duchesne County, Utah. Found in sparsely vegetated cushion plant communities.
Flowering Plants	Uinta greenthread	*Thelesperma pubescens*	Endemic to Utah and southwest Wyoming. Found on mesa-like mountains in sparsely vegetation cushion plant communities and sagebrush grasslands.
Flowering Plants	Alpine greenthread	*Thelesperma subnudum var. alpinum*	Pinyon-juniper, mountain brush, and western bristlecone pine communities at 2100 to 2745 meters (6890 to 9006 ft).

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Arrow-leaf thelypody	*Thelypodium eucosmum*	Under or around western juniper in canyons, seasonal creek drainages, and springs.
Flowering Plants	Perennial thelypody	*Thelypodium flexuosum*	Scrubby habitat within sagebrush.
Flowering Plants	Howell's thelypodium	*Thelypodium howellii var. howellii*	This species is known from desert shrub communities, alkaline ground.
Flowering Plants	Purple thick-leaved thelypody	*Thelypodium laciniatum var. streptanthoides*	Found in sagebrush scrub communities.
Flowering Plants	Wavy-leaf thelypody	*Thelypodium repandum*	Endemic to east-central Idaho. can be found on moderate to steep, unstable slopes that face generally south. on rocky, usually on gravelly, or cindery substrates and decomposing shale banks.
Flowering Plants	California screw-moss	*Tortula californica*	Found in arid soils and on rocks at low elevations.
Flowering Plants	Hooker's townsend-daisy	*Townsendia hookeri*	This species is found in grasslands, sagebrush steppe, coniferous woodlands; plains, valleys, and montane habitats.
Flowering Plants	Sevier townsendia	*Townsendia jonesii var. lutea*	Found in salt desert and mixed desert shrub and juniper-sagebrush communities.
Flowering Plants	Cedar Mountain Easter daisy	*Townsendia microcephala*	Endemic to southwestern Wyoming. Occurs on exposed, west-facing upper slopes and ridges at high elevations.
Flowering Plants	Mountain townsendia	*Townsendia montana*	Grows on sandy calcareous soil of grasslands, sagebrush steppe, and woodlands at lower elevations.
Flowering Plants	Parry's townsendia	*Townsendia parryi*	Occurs on sparsely vegetated soil of grasslands, sagebrush steppe, dry forest, woodlands; valleys to rarely alpine.
Flowering Plants	Scapose daisy	*Townsendia scapigera*	This species is found in openings in sagebrush at elevations ranging from 1,400 to 3,400 meters.
Flowering Plants	Hairy townsend daisy	*Townsendia strigosa*	This species occurs in junipers, pinyons, desert scrub, and open places, with shales, sands, and clays at elevations ranging from 1,500 to 2,000 meters.
Flowering Plants	Barneby's clover	*Trifolium barnebyi*	Endemic to the foothills of the Wind River Range and southern Beaver Rim in Wyoming. Found in ledges, crevices, and seams at 5500-6780 feet.
Flowering Plants	Douglas clover	*Trifolium douglasii*	Open meadows, forested wetlands, stream banks, creek bottoms, and openings in pine forests.
Flowering Plants	Woolly clover	*Trifolium eriochphalum var. villiferum*	Known from a small distribution in eastern Nevada, in White Pine County, and into neighboring west-central Utah. It grows in marshes and alkaline meadows.
Flowering Plants	Leiberg's clover	*Trifolium leibergii*	Grows in soils of decomposing tuff, a volcanic ash substrate.

Taxa	Common Name	Scientific Name	Habitat Associations
Flowering Plants	Owyhee clover	*Trifolium owyheense*	Owyhee Clover occurs on barren slopes, ridges and mounds composed of talus and loose, coarse-grained, crumbly soils derived from rhyolitic ash or diatomaceous tuff at 830- 1650 m elevation within sagebrush-steppe or desert shrub vegetation.
Flowering Plants	Slender bog arrowgrass	*Triglochin palustrus*	Found in damp grassland usually on calcareous soils, fens and meadows.
Flowering Plants	Sand puffs	*Tripterocalyx micranthus*	Creosote bush, blackbrush, sandy desert shrub, and mixed desert shrub, usually in sand.
Flowering Plants	American globeflower	*Trollius albiflorus*	Found at high elevations in moist meadows and open forests.
Flowering Plants	Dotted water-meal	*Wolffia borealis*	Found in quiet, calm bodies of water, such as ponds, lakes, rivers, and streams.
Flowering Plants	Spanish bayonet	*Yucca sterilis*	Found in sandy and loamy soils within mixed dessert shrub communities with salt dessert shrub, junipers, and sagebrush between 1460 and 1770 meters (4800 - 5800 ft) elevations.
Invertebrates	Idaho point-headed grasshopper	*Acrolophitus pulchellus*	This grasshopper has limited range, mostly in Clark and Custer Counties in Idaho. It lives in dry, sparsely vegetated shrubland habitat on foothills and in floodplains. An important host plant for the insect is stemless mock goldenweed (*Stenotus acaulis*).
Invertebrates	Crescent Dunes Aegialian scarab	*Aegialia crescenta*	Found in the Crescent Dunes complex near Tonapah, NV.
Invertebrates	Hardy's Aegialian scarab	*Aegialian hardyi*	Occurs in sand dunes in Churchill County, Nevada
Invertebrates	Zigzag darner	*Aeshna sitchensis*	Prefers sedge and moss dominated northern poor fens and small cold northern open bogs in acidic peatland systems.
Invertebrates	Subarctic darner	*Aeshna subarctica*	Sphagnum bogs and deep fens with wet sphagnum.
Invertebrates	California floater	*Anodonta californiensis*	Most often found in the sand and mud of lakes and reservoirs or in stable areas of low-gradient stream reaches.
Invertebrates	Apache silverspot butterfly	*Argynnis nokomis apacheana*	Generally confined to wetlands, permanent water, and small habitat patches that support a mix of willows, grasses, sedges, and the butterflies' host plant. These include areas of insular seeps, springs, and riparian areas across the central and western Great Basin, the eastern Sierra foothills, and a few mountain valleys.
Invertebrates	Carson Valley silverspot	*Argynnis nokomis carsonensis*	wetland habitats where host plant *Viola nephrophylla* occurs; extremely wet meadow situations, with one or more native or non- native plants that produce nectar; may occur along riparian corridors, we lowland meadows including agricultural fields and perennial montane streams

Taxa	Common Name	Scientific Name	Habitat Associations
Invertebrates	Silverspot butterfly	*Argynnis nokomis nokomis*	The species requires moist, open meadows with a diversity of vegetation for shelter. Individuals require bog violet (*Viola* spp.) when in their larval stage, which they feed on exclusively.
Invertebrates	Silver-bordered fritillary	*Boloria selene*	Dependent on fen and Sphagnum bog sites located in the xeric steppe and open forests of the Columbia River Basin.
Invertebrates	Morrison bumblebee	*Bombus morrisonii*	Typically found in open dry scrub.
Invertebrates	Western bumblebee	*Bombus occidentalis*	Found in open grassy areas, prairie, urban parks and gardens, sagebrush steppe, mountain meadows to alpine tundra.
Invertebrates	Suckley's cuckoo bumblebee	*Bombus suckleyi*	The habitats of its known host species, Bombus occidentalis open grassy areas, urban parks and gardens, chaparral and shrub areas, and mountain meadows.
Invertebrates	Barry's hairstreak	*Callophrys gryneus chalcosiva*	Found in cedar or juniper areas which serve as a primary food source.
Invertebrates	Big Smoky wood nymph	*Cercyonis oetus alkalorum*	Grassy, alkaline flats; known only from the Big Smoky Valey between the Toiyabe and Toquima ranges in central Nevada
Invertebrates	Pallid wood nymph	*Cercyonis oetus pallescens*	Known only from a small alkaline area in the Reese River valley, Nevada.
Invertebrates	Carson Valley wood nymph	*Cercyonis pegala carsonensis*	Douglas, Carson City, and Washoe counties and in the Carson River drainage in Alpine Co., California.
Invertebrates	Plain-marked wood nymph	*Cercyonis pegala paucilineatus*	Endemic to north-central Nevada. Found in a variety of open habitats, such as open woodlands, woodland edges, fields, pastures, wet meadows, prairies, salt marshes, and savannas.
Invertebrates	White River wood nymph	*Cercyonis pegala pluvialis*	occurs in bottomland habitats along the White River near the White Pine and Nye county line and in the Steptoe Valley southeast of Ely
Invertebrates	Saint Anthony sand dunes tiger beetle	*Cicindela arenicola*	Patchily distributed in dune fields, largely along the Snake River Plain in ten counties of southeastern and south-central Idaho. Recently separated from the Bruneau Dunes tiger beetle.
Invertebrates	Bruneau Dunes tiger beetle	*Cicindela waynei*	Terrestrial beetle whose habitat consists of an isolated dune field in southern Idaho.
Invertebrates	Crescent Dunes adhodius scarab	*Cinacanthus crescentus*	Occurs in Crescent Dunes complex in Nye County, near Tonopah NV.
Invertebrates	Sand Mountain pygmy scarab	*Coenonycha pygmaea*	Occurs on Sand Mountain and Blow Sand Mountain, Nevada.
Invertebrates	Sullivan's sulphur	*Colias occidentalis sullivani*	Associated with a desert bush pea, Lathyrus rigidus, and occurs at the north end of the Steens Mountains in Harney County, Oregon in the lowland sagebrush/bunchgrass steppes.
Invertebrates	Dipluran	*Condeicampa langei*	Cave species found in Whipple Cave, Nevada
Invertebrates	Monarch butterfly	*Danaus plexippus*	The species is a milkweed obligate requiring these plants for larval development. Found throughout North America mainly in prairies, meadows, grasslands and along roadsides.

Taxa	Common Name	Scientific Name	Habitat Associations
Invertebrates	Humboldt aphodius beetle	*Dellacasiellus humboldti*	The genus Dellacasiellus is widely distributed through North America. All species appear to use pocket gophers as primary hosts. Members of a few species have been collected in prairie dog or other rodent burrows
Invertebrates	Darkling Beetle	*Eleodes inornata*	The genus Elodes is widely distributed through western North America.
Invertebrates	Fused Battoides blue	*Euphilotes battoides fusimaculata*	Known from two disjunct locations: the southern portion of the Toiyabe Range in Nye County Nevada and a single observation in the Robert Mountains in Eureka County Nevada.
Invertebrates	Inyo Mountains blue	*Euphilotes bernardina inyomontana*	This species' range is eastern Kern and Inyo Counties in California and adjacent Nevada counties.
Invertebrates	Peavine blue	*Euphilotes enoptes aridorum*	Known from three occurrences in southern Washoe County and Storey County, Nevada, and Pumas County, California, in sagebrush scrub and conifer woodlands.
Invertebrates	Early blue	*Euphilotes enoptes primavera*	Records of this subspecies only exist from Mineral County in the Wassuk Range. Trend unknown considered critically imperiled in Nevada
Invertebrates	Sand Mountain blue	*Euphilotes pallenscens arenamontana*	Exists only at Sand Mountain in Churchill County east of Fallon, Nevada; closely associated with its host plant, the Kearney buckwheat (*Eriogonum nummulare*).
Invertebrates	Honey Lake blue	*Euphilototes pallescens calneva*	Occurs in arid desert flats and sand dune edges.
Invertebrates	Rice's blue	*Euphilotes pallescens ricei*	Occurs in the Silver State Sand Dunes, north of Winnemucca, Nevada, USA, often in grassy or brushy habitat.
Invertebrates	Mattoni's blue	*Euphilotes pallescens mattonii*	Found primarily in the upper and lower Sonaran Zones, prairies, and sand dunes; found in pinyon-juniper woodlands and rolling prairie grasslands; host plant for the larvae is the buckwheat (*Eriogonum microthecum* nutt. Var. laxiflorum).
Invertebrates	Mono checkerspot	*Euphyryas editha monoensis*	Occurs along the eastern front of the Sierra Nevada Mountains.
Invertebrates	Gillette's checkerspot	*Euphydryas gillettii*	Occurs mostly as very widely scattered, localized, and usually small populations, apparently with little or no gene flow in most cases. Requires patches of four-line honeysuckle (*Lonicera involucrata*) exposed to morning sunlight.
Invertebrates	Railroad Valley skipper	*Hesperia uncas fulvapalla*	Found in alkali meadows on the floor of Railroad Valley in Nye County, Nevada
Invertebrates	White River Valley skipper	*Hesperia uncas grandiosa*	Alkaline meadows and saltgrass flats in early summer in the White River Valley Nevada
Invertebrates	Reese River Railroad Valley skipper	*Hesperia uncas reeseorum*	Found along the Reese River in Lander county and Mason Valley in Lyon county Nevada

Taxa	Common Name	Scientific Name	Habitat Associations
Invertebrates	Nevada viceroy	*Limenitis archippus lahontani*	This species is apparently restricted to Nevada; it is known from along the Humboldt River and lower tributaries.
Invertebrates	Western pearlshell	*Margaritifera falcata*	The species is found in cool and cold running streams that generally have a low to moderate gradient and are wider than 2 m; preferred habitat is stable sand or gravel substrates.
Invertebrates	Umatilla megomphix	*Megomphix lutarius*	This species relies on moist, shady, stable microclimates.
Invertebrates	Dune honey ant	*Myrmeocystus arenarius*	Occurs in fine dune sands. It has been documented from Sand Mountain and the Blow Sand Mountains in Churchill County, Nevada.
Invertebrates	Nye County army ant	*Neivamyrmex nyensis*	Known only from the type colony, located southeast of Beatty in Nye County, Nevada.
Invertebrates	Great Basin Yuma skipper	*Ochlodes yuma lutea*	This subspecies occurs in the Great Basin, from southern Nevada north of Las Vegas to southeastern Oregon. This subspecies only utilizes the American common reed (*Phragmites australis* ssp. *americanus*) as a larval host in rare alkaline wetland habitats.
Invertebrates	Great Basin blue	*Philotiella speciosa septentrionalis*	Distribution is unknown, but the type locality is from Fort Churchill Road in Lyon County. Larval host plants include yellowturbans (*Eriogonum pusillum*) and roundleaf oxytheca (*Oxytheca perfoliata*).
Invertebrates	Steptoe Valley crescentspot	*Phyciodes cocyta arenacolor*	Found in wetlands at Monte Neva Hot Springs, Nevada.
Invertebrates	Carson Valley sandhill skipper	*Polites sabuleti genoa*	Documented in the Carson River valley in Douglas County Nevada.
Invertebrates	Dark sandhill skipper	*Polites sabuleti negrescens*	Occurs in valley bottoms and spring habitats. Known only from the eastern part of Nevada- westward into western Eureka County from extreme east-central Elko County (Thousand Springs Creek) to north Lincoln County (Lake Valley) and northeastern Nye County.
Invertebrates	Bleached sandhill skipper	*Polites sabuleti sinemaculata*	Known only from one location, at Baltazor Hot Spring near Denio Junction in Humboldt County, Nevada.
Invertebrates	Nevada Alkali skipperling	*Pseudocopaeodes eunus flavus*	Found in desert salt grass spots on alkali flats.
Invertebrates	Carson wandering skipper	*Pseudocopaeodes eunus obscurus*	Salt grass (obligate host plant for larvae) and nearby nectarproducing flowers; salt grass typically is present where its root are inundated with water for short periods
Invertebrates	A mayfly	*Raptoheptagenia cruentata*	This species is associated with larger, perennially flowing prairie streams and rivers with sand-gravel dominated bottoms with cobble riffles.
Invertebrates	Pallid sylvinus hairstreak	*Satyrium sylvinus megapallidum*	Occurs in riparian areas. It has been documented from the Walker, Humbolt, lower Truckee, and Carson River drainages in Nevada.
Invertebrates	Crescent Dunes serican scarab	*Serica psammobunus*	Occurs at Crescent Dunes complex in Nye County, near Tonopah NV. The beetle's habitat is restricted to a small geographic area and includes the interface between wet and dry sand dunes.

Taxa	Common Name	Scientific Name	Habitat Associations
Invertebrates	Washoe stonefly	*Sierracapnia washoe*	This species is found in the Granite, Selenite, and Virginia Ranges of western Nevada
Invertebrates	Coronis fritillary	*Speyeria coronis coronis*	Various: chaparral, sage lands, open pine forest, canyons, meadows. Hosts are in genus Viola, and oak woodlands.
Invertebrates	Regal fritillary	*Speyeria idalia*	Found in wet meadows, undisturbed prairie near marshes, dry to mesic tallgrass prairie, shortgrass prairie, and restored prairie. These butterflies generally avoid areas with bare ground, instead preferring land with more litter and lower grazing intensities.
Invertebrates	Sand Mountain aphodius scarab	*Stenotothorax comosus*	Found at Sand Mountain and Blow Sand Mountain, Nevada.
Invertebrates	Lahontan aphodius scarab	*Stenotothorax lahontanensis*	Occurs under plants on dune substrates around the Pleistocene Lake Lahontan, Nevada.
Lichens	Aspicilia rogeri	*Aspicillia rogeri*	Grows on calcareous, gravelly soil in shrub-steppe habitats.
Lichens	Bryoria bicolor	*Bryoria bicolor*	This species occurs on trunks, branches, cork, and plant surfaces, as well as on siliceous rock
Lichens	White grouse pellet lichen	*Rhizoplaca idahoensis*	Grows over deep gravel calcareous alluvium soils and remains unattached to any substrates.
Lichens	Woven-spore lichen	*Texosporium sancti-jacobi*	Crustose lichen that grows on organic matter and soil. Endemic to arid regions of the western United States of America.
Lichens	Maculate tumbleweed shield lichen	*Xanthoparmelia camtschadalis*	Found in high elevation regions
Lichens	Idaho Range lichen	*Xanthoparmelia idahoensis*	Calcareous badlands, barren to sparsely covered with vascular vegetation. Slopes are approximately 45% or less. Surrounding vascular vegetation is shrub steppe, dominated by Artemisia or Atriplex.
Mammals	Pallid bat	*Antrozous pallidus*	Pallid Bats have been found in arid deserts, juniper woodlands, sagebrush shrub-steppe, and grasslands, often with rocky outcrops and water nearby. They are less abundant in evergreen and mixed conifer woodlands, but in British Columbia are found in ponderosa pine forest near cliffs. They typically roost in rock crevices or buildings, less often in caves, tree hollows, under bridges, and in abandoned mines.
Mammals	Pygmy rabbit	*Brachylagus idahoensis (Sylivalagus idahoensis)*	This rabbit generally occurs in dense stands of big sagebrush growing in deep loose soils. It is highly dependent on sagebrush for food and shelter throughout the year. Unlike most other rabbits, it digs burrows, which are around 3 inches in diameter; a burrow may have multiple entrances. Pygmy rabbits occasionally use of burrows abandoned by other species and may occur in areas of shallower or more compact soils if these sites support sufficient shrub cover

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Gray wolf	*Canis lupus*	No particular habitat preference. Minimum of 10,000-13,000 sq km (with low road density) might be necessary to support a viable population. Young are born in an underground burrow that has been abandoned by another mammal or dug by wolf. In Northwest Territories, dens were most commonly located within 50 km of northern tree line, which resulted in maximal availability of caribou during the denning and pup rearing period; within the tundra zone, dens were not preferentially located near caribou calving grounds.
Mammals	Townsend's big-eared bat	*Corynorhinus townsendii pallescens*	Townsend's big-eared bat is a colonial nester, with relatively complex and restrictive hibernation roost requirements that feature a high degree of site fidelity. The species roosts in caves or mines. Individuals are thought to not migrate great distances and have been documented making movements of less than 30 miles between summer and winter roosts.
Mammals	White-tailed prairie dog	*Cynomys leucurus*	This loosely colonial species inhabits open shrublands, semidesert grasslands, and open valleys. It lives at higher elevations and in meadows with more diverse grass and herb cover than do black-tailed prairie dogs. Young are born in underground burrows.
Mammals	Black-tailed prairie dog	*Cynomys ludovicianus*	Habitat consists of dry, flat or gently sloping, open grasslands with low, relatively sparse vegetation, including areas overgrazed by cattle. The species occurs in open vacant lots at town edges in some areas. Young are born in underground burrows.
Mammals	Utah prairie dog	*Cynomys parvidens*	Utah prairie dogs are only found in southwestern and central Utah in open habitats. Habitat consists of swale-type formations where herbaceous vegetation is available. The species requires well, drained deep soil for burrowing.
Mammals	Desert kangaroo rat	*Dipodomys deserti*	Found in low deserts, in sandy soil with sparse vegetation, or in alkali sinks. It is found in shadscale scrub and creosote bush scrub, in the lower and upper Sonoran life zones. It is mostly restricted to deposits of deep, wind-blown sand.
Mammals	Panamint kangaroo rat	*Dipodomys panamintinus*	Occupies desert flats among Joshua trees, creosote bush scrub, and pinyon-juniper woodland. It also occupies big sagebrush in west-central Nevada.
Mammals	Big brown bat	*Eptesicus fuscus*	Habitats range from high mountains to low deserts, including cities. Summer roosts generally are in buildings, bridges, hollow trees, spaces behind exfoliating bark, rock crevices, tunnels, or cliff swallow nests, in sites that do not get too hot. Maternity colonies may form in attics, barns, rock crevices, or tree cavities. Most adult females return to the same maternity roost site in successive years. Caves, mines, and especially buildings and human-made structures are used for hibernation.

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Spotted bat	*Euderma maculatum*	This species occurs in various habitats from desert to montane coniferous stands, including open ponderosa pine, pinyon-juniper woodland, canyon bottoms, riparian and river corridors, meadows, open pasture, and hayfields. Active foraging may be mostly in open terrain, including forest clearings, meadows, and open wetlands, sometimes in open areas near buildings.
Mammals	Wolverine	*Gulo gulo luscus, Gulo gulo luteus*	Alpine and arctic tundra, boreal and mountain forests (primarily coniferous). Limited to mountains in the south, especially large wilderness areas. Usually in areas with snow on the ground in winter. Riparian areas may be important winter habitat. May disperse through atypical habitat. When inactive, occupies den in cave, rock crevice, under fallen tree, in thicket, or similar site. Terrestrial and may climb trees. Young are born in a den among rocks or tree roots, in hollow log, under fallen tree, or in dense vegetation, including sites under snow.
Mammals	Western red bat	*Lasiurus blossevillii*	In California, roosting habitat includes forests and woodlands from lowlands up through mixed conifer forests of mountains; foraging habitat includes grasslands, shrublands, open woodlands and forests, and croplands, but not deserts. Red bats in California appear to be strongly associated with riparian habitats, particularly mature stands of cottonwood/sycamore in the Central Valley and lower reaches of the large rivers that drain the Sierra Nevada (Pierson et al. 2006). They sometimes use orchards, tamarisk, or other non-native trees; the degree to which sprayed orchard trees serve as viable habitats (versus population sinks) is unknown. In spring and summer, females occur primarily in lowland riparian habitat, whereas males more often are found at higher elevations.
Mammals	Eastern red bat	*Lasiurus borealis*	Inhabitats wooded and riparian areas and is reported to prefer elm, box elder, wild plum, willow, hawthorn, sumac, and a variety of other woody plants for roosting. It hibernates in woodpecker holes, tree foliage, and under loose bark.
Mammals	Hoary bat	*Lasiurus cinereus*	Hoary bats are solitary, tree roosting species and can be expected to live in any forested habitat. They are insectivores, primarily feed on moths. Impacts from wind energy have been documented at the population level, especially during migrations resulting in range wide declines of the species. Other threats to the species include increase in recreation in suitable habitats, mining activities or modifications, the spread of white-nose syndrome, and woodland management such as vegetation treatments, prescribed fire or fuels reduction projects. Much of their preferred habitat in CO is located on BLM-administered lands. Hoary bats are found in suitable habitat in every field office in Colorado...

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Black-tailed jackrabbit	*Lepus californicus*	Inhabits open plains, fields and deserts, open country with scattered thickets or patches of shrubs. Rests by day in shallow depression (form).
Mammals	White-tailed jackrabbit	*Lepus townsendii*	Open grasslands and sagebrush plains. At higher elevations found in open areas adjacent to pine forests and in alpine tundra. Rests by day usually in shallow depressions (forms) at base of bush or beside or in cavity in snow. Young are born in a well concealed depression in the ground or in burrows abandoned by other animals.
Mammals	North American river otter	*Lontra canadensis*	Riverine species widespread across most major riverine systems in the Rocky Mountains.
Mammals	Canada lynx	*Lynx canadensis*	Occurs in boreal forests, subalpine forests, and areas with dense horizontal forest cover that have deep snow and a high density of snowshoe hares.
Mammals	Dark kangaroo mouse	*Microdipodops megacephalus*	In loose sands and gravel. Found in Shadscale Scrub, Sagebrush Scrub, and Alkali Sink plant communities in the Upper Sonoran life zone. May occur in sand dunes near margins of range. Underground when inactive.
Mammals	Fletcher dark kangaroo mouse	*Microdipodops megacephalus nasutus*	Prefer loose sands and gravel and are found in shadscale scrub, sagebrush scrub, and alkali sink plant communities in the Upper Sonoran life zone. They may occur in sand dunes near the margins of their range. Found among bushes growing in soils covered with gravel or on sand dunes.
Mammals	Pale kangaroo mouse	*Microdipodops pallidus*	Habitat is nearly restricted to fine sands in alkali sink and desert scrub dominated by Atriplex confertifolia (shadscale) or Artemisia tridentata (big sagebrush). This mouse often burrows in areas of soft, windblown sand piled at the bases of shrubs.
Mammals	California myotis	*Myotis californicus*	These bats occur in various habitats, including seacoasts, desert scrub, oak-juniper woodlands, montane and humid coastal forests, mountain meadows, canyons, riparian woodlands, grasslands, rural residential areas, and towns. Night roosts are in a wide range of sheltered sites, including trees, shrubs, mines, caves, bridges, and buildings. They roost by day in crevices of various kinds, including rock fissures, tree cavities, spaces behind loose tree bark, and nooks in bridges and buildings; occasionally they roost on small desert shrubs or on the ground. Hibernation sites include caves (including lava tubes), mines, tunnels, or buildings; often in buildings in the Pacific Northwest. Maternity colonies are in rock crevices, tree cavities, under bark, or in crevices of bridges or buildings. Reproductive females often change roost sites among different trees. Foraging occurs in a wide range of habitats: over meadows/grassland, shrubland, and wooded areas; over water; and around streetlights.

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Western small-footed myotis	*Myotis ciliolabrum*	These bats generally inhabit desert, badland, and semiarid habitats; more mesic habitats in the southern part of the range); also, woodlands and dry open forests, riparian zones, and areas near cliffs and outcrop. In Utah, they occur in lowland riparian, desert shrub, juniper-sagebrush, juniper, piñon-juniper, sagebrush-rabbitbrush, sagebrush-greasewood (near piñon-juniper), highland riparian in lodgepole pine forest, montane forest and woodland (Douglas-fir-aspen), and montane grassland (grass-aspen).
Mammals	Long-eared myotis	*Myotis evotis*	These bats occupy a diverse array of habitats, including lowland, montane, and subalpine woodlands, forests, shrublands, and meadows, wooded stream courses, and areas over water bodies. Within a particular region, the range of occupied habitats may be more restricted. Daytime roosts are in buildings, railroad trestles, snags and hollow trees, spaces behind loose bark of trees or stumps, mines, caves, rock crevices (including those on the ground), erosional cavities and channels in the ground, and similar sites.
Mammals	Little brown myotis	*Myotis lucifigus*	The little brown and long-eared Myotis are found in forested areas and are thought to use rock crevices and abandoned mines for roosting and hibernacula. Management actions that may cause disturbance (OHV use, mineral extraction, vegetation treatments, etc.) can potentially impact this species. The little brown Myotis has exhibited extreme declines in local populations (over 90%) due to white-nose syndrome where the fungal pathogen occurs.
Mammals	Fringed myotis	*Myotis thysanodes*	These bats occur primarily at middle elevations in desert, riparian, grassland, and woodland habitats, but they have been recorded at 2,850 meters in spruce-fir habitat in New Mexico, and at low elevations along the Pacific Coast.
Mammals	Long-legged myotis	*Myotis volans*	These bats occur primarily in mountainous areas wooded with coniferous trees, but also may be found in riparian and desert (Baja California) habitats. They may change habitats seasonally. Hibernacula are in caves and mines, but winter habits are poorly known. Warm-season daytime roosts are in tree hollows or under loose bark, in crevices among rocks or in cliffs, or in buildings, but apparently not in caves or mines (these may be used at night).
Mammals	Yuma myotis	*Myotis yumanensis*	This species is more closely associated with water than most other North American bats. It is found in a wide variety of upland and lowland habitats, including riparian, desert scrub, moist woodlands, and forests, usually near open water. Foraging occurs over water or in open spaces over land. Warm-season roosts are in caves, cliff crevices, bridges, buildings, and tunnels, as well as abandoned cliff swallow nests and cavities and nooks in large live trees near water.

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Allen's chipmunk	*Neotamias senex*	Coniferous forests and chaparral slopes; Transition and Canadian life zones. Does not readily climb trees.
Mammals	Monterey dusky-footed woodrat	*Neotoma macrotis luciana*	Habitat includes riparian, shrubland, chapparal, and forested woodlands.
Mammals	Big free-tailed bat	*Nyctinomops macrotis*	Habitat in the southwestern United States and Mexico includes rocky areas in rugged or hilly country in both lowland and highland areas, including evergreen forest, woodlands, desert scrub, river floodplain-arroyo associations, and stream courses in areas of mixed tropical deciduous forest and thorn forest. These bats apparently roost primarily in vertical or horizontal crevices near the tops of cliffs, but sometimes they are found in buildings, caves, or occasionally tree cavities.
Mammals	American pika	*Ochotona princeps*	Restricted to rocky talus slopes or rimrocks with deep fissures and crevices, primarily the talus-meadow interface. It also occupies areas above the tree line up to the limit of vegetation and lower elevations in rocky areas within forests or near lakes.
Mammals	Mountain goat	*Oreamnos americanus*	Alpine and subalpine habitat; steep grassy talus slopes, grassy ledges of cliffs, or alpine meadows. Usually at timberline or above. May seek shelter and food in stands of spruce or hemlock in winter. Young are born on rock ledges or steep cliffs.
Mammals	Rocky Mountain bighorn sheep	*Ovis canadensis canadensis*	Rocky Mountain Bighorn Sheep inhabit grassy mountain slopes, alpine meadows, and foothills near rugged, rocky cliffs and bluffs.
Mammals	Canyon bat	*Parastrellus hesperus*	Habitat includes desert mountain ranges, desert scrub flats, shrub-steppe, rocky canyons, and associated riparian zones, particularly in areas with cliffs and most often (but not always) close to water. In some areas, these bats range into coniferous forest/woodland at higher elevations. Roosts include crevices in cliffs, rock outcrops, caves, mines, and buildings, and possibly sometimes rodent burrows and spaces under rocks. Night roosts may include sagebrush shrubs. The bats hibernate in caves, mine tunnel, or rock crevices. Typically, they visit water and drink immediately after emergence each evening. Young are born in rock crevices or in buildings.
Mammals	Fisher	*Pekania pennanti*	This carnivore lives in thick coniferous or mixed coniferous and hardwood forests. It prefers habitats with lots of tree cover and lots of hollow trees for dens.
Mammals	Silky pocket mouse	*Perognathus flavus*	Sandy, sometimes rocky, soils in arid grasslands, shrublands, and pinyon-juniper woodland, in valley bottoms, hillsides, and mesas, sometimes in rather barren areas.
Mammals	Pygmy shrew	*Sorex hoyi*	Found in a variety of habitats. Appears to prefer grassy openings of boreal forest. Moist habitats are preferred over dry areas.

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Merriam's shrew	*Sorex merriami*	Habitats include various grasslands, including grasses in sagebrush scrub and pinyon-juniper woodland, as well as mountain mahogany shrublands and mixed woodlands.
Mammals	Preble's shrew	*Sorex preblei*	Recorded habitats include arid and semiarid shrub-grass associations, openings in montane coniferous forests dominated by sagebrush (Washington), willow-fringed creeks, marshes (Oregon), bunchgrass associations, sagebrush-aspen associations (California), sagebrush-grass associations (Nevada), alkaline shrubland (Utah).
Mammals	Inyo shrew	*Sorex tenellus*	Habitats include riparian zones and canyon bottoms; rocky mountain habitat in areas with logs, boulders, or sagebrush scrub); and red fir communities. This species may be more tolerant of dry habitat than are closely related shrews. In Great Basin National Park, this shrew was found at 3,000 m elevation in habitat dominated by Engelmann spruce.
Mammals	Brazilian free-tailed bat	*Tadarida brasiliensis*	Habitat ranges from lowland deserts, shrublands, woodlands, and forests to high mountains. Major roosts are primarily in caves in the southwestern United States; generally, buildings (generally old ones) in the southeastern United States (sometimes in hollow trees), along the U.S. West Coast, and in Jamaica; in both buildings and caves in Puerto Rico. Individuals may roost in cliff faces and other rock crevices, under bridges, on signs, or in cliff swallow nests during migration. Generally, these bats roost high (at least 3 meters) above the ground to allow the amount of free fall required to attain flight. Large maternity colonies inhabit buildings and caves; culverts and bridges may also serve as maternity sites. Individuals tend to return to their natal cave to breed. Foraging bats make use of agricultural landscapes and natural habitats; in Texas, the latter were most important in late summer.
Mammals	Fish Spring pocket gopher	*Thomomys bottae abstrusus*	This species occurs in the lowlands of central, southern, and western Nevada, USA, including the Fish Springs Valley in Nye County. The lowlands consist of primarily of sagebrush, and grasses.
Mammals	Smoke Creek Desert pocket gopher	*Thomomys bottae canus*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.
Mammals	Walker River pocket gopher	*Thomomys bottae cinereus*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	San Antonio pocket gopher	*Thomomys bottae curatus*	Associated with a wide range of vegetation and soil types. Residents of open habitats and meadows, where soils are deep enough to maintain permanent burrow systems. Two subspecies of priority interest are isolated to two valleys, T. b. abstrusus in Fish Spring valley (also known as Litle Fish Lake Valley) in Nye County, and T. b. curtatus in Big Smoky Valley. A third isolate occurs near Eastgate. Presumed extinct.
Mammals	Dixie Valley pocket gopher	*Thomomys bottae depressus*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.
Mammals	Moore's Creek pocket gopher	*Thomomys bottae fumosus*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.
Mammals	Fish Lake Valley pocket gopher	*Thomomys bottae lacrymalis*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.
Mammals	Cherry Creek pocket gopher	*Thomomys bottae latus*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.
Mammals	Eastgate pocket gopher	*Thomomys bottae lucrificus*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.
Mammals	Stewart Valley pocket gopher	*Thomomys bottae solitarius*	*Thomomys bottae* comprises many reproductively isolated populations and distinct populations with little interbreeding. Patches of soil deep enough and suitable for burrowing are necessary for persistence.
Mammals	Wyoming pocket gopher	*Thomomys clusius*	This is a fossorial species. Distribution modeling indicates that T. clusius is limited to areas with Gardner's saltbush, particularly in association with other moderately halophytic species such as winterfat. This suggests an association between T. clusius and salt desert scrub communities typically found in relatively flat areas of fine-textured saline substrates in and near the Great Divide Basin. Within south-central Wyoming, any area containing measurable cover of Gardner's saltbush, particularly on shallow slopes and in combination with winterfat, could be potential habitat for T. clusius. Although habitats characterized by Gardner's saltbush are more common within the range of T. clusius than adjacent areas of Wyoming, they represent a very limited area of potential habitat within a landscape largely dominated by big sagebrush.
Mammals	Idaho pocket gopher	*Thomomys idahoensis*	Occurs in open sagebrush, grassland plains, and subalpine mountain meadows in shallow, stony soils. Fossorial.

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Merriam's ground squirrel	*Urocitellus canus*	Mainly in high desert (sagebrush, shadscale, greasewood, western juniper), grasslands, pastures; also, in river valley bottomland. Generally, in well-drained soils, especially embankments. Often around desert springs and irrigated fields. Makes extensive burrow systems. Young are born in a nest chamber in an underground burrow.
Mammals	Southern Idaho ground squirrel	*Urocitellus endemicus*	Southern Idaho Ground Squirrel populations occur in a mosaic of shrubland and grassland habitats common to foothills rangelands and pastures. They are also frequently associated with mowed fields, primarily alfalfa, found in drainage and valley bottoms.
Mammals	Piute ground squirrel	*Urocitellus mollis*	Mainly in high desert (sagebrush, shadscale, greasewood). In southwestern Idaho, highest densities were in winterfat-Sandberg's bluegrass communities, with intermediate densities in big sagebrush-dominated communities and lowest densities in shadscale communities; scarce in communities dominated by exotic annuals.
Mammals	Townsend's ground squirrel	*Urocitellus townsendii*	Townsend's ground squirrel historically occurred primarily in native shrub steppe, grasslands, and large patches of sagebrush at the lower edges of forest. A variety of human-modified habitats are now also occupied, including pastures, abandoned fields, orchards, vineyards, hop fields, canal banks, and sites adjacent to irrigated fields and springs. Occupied sites must have ample soil depths to provide space for burrow construction.
Mammals	Washington ground squirrel	*Urocitellus washingtoni*	Shrubsteppe and native grassland habitats are preferred, especially those occurring on deep silty loam soils, which provide ample digging space for burrows.
Mammals	Grizzly bear	*Ursus arctos horribilis*	Grizzly bears prefer forests with meadows and grasslands mixed in. They can also be found in dense forests, mixed-conifer forests, and riparian areas along rivers and streams
Mammals	Kit fox	*Vulpes macrotis*	Primarily open desert, shrubby or shrub-grass habitat. In central California, found in alkali sink, valley grassland, foothill woodland. In Mohave Desert, occurs in creosote bush; in Great Basin, in shadscale, greasewood and sagebrush. Young are born in an underground den. Den usually has multiple entrances (3 or more) and may be 3-6 m long, reaching 127 cm in depth. In Utah, most dens were on flat, well-drained uplands. Several dens may be used, especially in summer.

Taxa	Common Name	Scientific Name	Habitat Associations
Mammals	Swift fox	*Vulpes velox*	Habitat includes open prairie and arid plains, including areas intermixed with winter wheat fields. Viable populations exist in shortgrass prairie-sagebrush steppe transition habitat in southeastern Wyoming. Dens are in burrows. A fox may dig a burrow or use a burrow made by another mammal (e.g., marmot, prairie dog, badger), usually in sandy soil on high ground in open prairies, along fencerows, occasionally in plowed field. An individual may use several different dens throughout the year.
Mammals	Western jumping mouse	*Zapes princeps*	Found in mountain meadows and marshes and along banks of streams and ponds, in dense cover of tall grasses and herbs. It nests in burrows in well-drained mound or elevated banks or on the surface among vegetation.
Reptiles	Spiny softshell	*Apalone spinifera*	Primarily an animal of riverine systems, but also inhabits marshy creeks, bayous, oxbows, lakes, irrigation canals, and impoundments. A soft bottom in permanent bodies of water with some aquatic vegetation appears to be essential, and sandbars and/or mudflats, as well as partially submerged debris (trees, fallen logs, brush), are usually present.
Reptiles	Northern rubber boa	*Charina bottae*	Habitat includes woodlands, forest clearings, patchy chaparral, meadows, and grassy savannas, generally not far from water, also riparian zones in arid canyons and sagebrush in some areas. Generally, this snake is found in or under rotting logs or stumps, under rocks or in crevices, or under the bark of dead fallen trees.
Reptiles	Snapping turtle	*Chelydra serpentina*	Freshwater habitats with a soft mud bottom and cover such as abundant aquatic vegetation or submerged brush and logs, and brackish water in some areas.
Reptiles	Painted turtle	*Chrysemys picta*	Aquatic habitats include lakes, ponds, wetlands, and slow flowing areas of rivers and creeks. They prefer habitats that have muddy sediments and lots of aquatic vegetation.
Reptiles	Midget faded rattle snake	*Crotalus viridis concolor*	This species occurs in sagebrush communities, and needs rocky outcrops for cover, variable thermal conditions, and hibernation.
Reptiles	Great Basin collared lizard	*Crotaphytus bicinctores*	Found mainly in desert, sparsely vegetated, rocky areas on hillsides, rocky plains, and in canyons.
Reptiles	Ring-necked snake	*Diadophis punctatus*	This snake occurs in forests, woodlands, grassland, chaparral, and riparian corridors in arid regions. Habitats are moist, at least seasonally. One or multiple individuals often are found near abandoned buildings and in junk piles in wooded areas. During daylight hours, this snake generally hides underground, in or under logs, or under rocks, stumps or other surface cover. Eggs are laid (often communally) underground or under logs or rocks.
Reptiles	Western pond turtle	*Emys marmorata*	This aquatic turtle lives in streams, ponds, lakes, and permanent and ephemeral wetlands.

Taxa	Common Name	Scientific Name	Habitat Associations
Reptiles	Long-nosed leopard lizard	*Gambelia wislizenii*	Found in sandy and gravelly desert and semidesert areas with scattered shrubs or other low plants (for example, bunch grass, alkali bush, sagebrush, and creosote bush), especially areas with abundant rodent burrows. Occurs from sea level to approximately 6,000 feet (BLM 2017).
Reptiles	Plains hog-nosed snake	*Heterodon nasicus*	The Western Hog-nosed Snake prefers plains and savannahs with well drained sandy or gravelly soil where it can easily burrow or dig out prey. Where soils are appropriate can also be found in semi-agricultural areas. They have been reported in areas of sagebrush-grassland habitat underlain by sandy soils.
Reptiles	Mesa Verde nightsnake	*Hypsiglena chlorophaea loreala*	Found in a variety of habitats, often arid areas, from chaparral, Sagebrush flats, deserts, suburban lots and gardens, mountain meadows, grassland. Most commonly found in areas with abundant surface cover.
Reptiles	California kingsnake	*Lampropeltis californiae*	This primarily terrestrial snake occurs in a wide range of habitats, including forest, woodland, shrubland, swamps, marshes, river bottoms, grassland, semidesert, desert, and farmland. Periods of inactivity are spent in crevices or burrow, or under rocks, logs, stumps, vegetation, or other cover.
Reptiles	Western milksnake	*Lampropeltis gentilis*	Western milksnakes occur in most habitats within its elevation range, including shortgrass prairie, sandhills, shrubby hillsides, canyons, open stands of ponderosa pine, pinyon-juniper woodlands and arid river valleys.
Reptiles	Sonoran Mountain kingsnake	*Lampropeltis pyromelana*	Habitats are primarily rocky, montane, and often near streams or springs, but also include lower elevations in mesic canyons. Vegetation may include pinyon-juniper woodland, oak-juniper woodland, pine-oak woodland, pine-Douglas-fir woodland, or chaparral. During daylight hours, this snake may be found among rocks, logs, or dense clumps of vegetation, under objects, or exposed.
Reptiles	California Mountain kingsnake	*Lampropeltis zonata*	Typical habitat of this species consists of moist open coniferous forests, oak woodlands, riparian woodland, chaparral, coastal sage scrub, and openly wooded areas where there are rocks or rotting logs. During periods of inactivity, individuals seek shelter under rocks, logs, bark, or underground.
Reptiles	Smooth greensnake	*Opheodrys vernalis*	Habitats include meadows, grassy marshes, moist grassy fields at forest edges, mountain shrublands, stream borders, bogs, open moist woodland, abandoned farmland, and vacant lots. This snake has been found hibernating in abandoned ant mounds. Eggs are laid under rotting wood, underground, or under rocks.

Taxa	Common Name	Scientific Name	Habitat Associations
Reptiles	Pygmy short-horned lizard	*Phrynosoma douglassii*	Semiarid plains of sagebrush and bunch grass, to pinyon-juniper woodlands, to pine forests in high mountains. It is usually found in open, shrubby, or openly wooded areas with sparse vegetation at ground level. The soil may vary from rocky to sandy to hardpan, but pockets of fine loose soil or sand are typically present for burrowing. Occurs from 1,000 to 7,200 feet.
Reptiles	Greater short-horned lizard	*Phrynosoma hernandesi*	Ranges from semiarid plains to high mountains (2,000 to 10,500 feet); occupies a variety of habitats, including sagebrush, open pinyon-juniper woodland, and pine-spruce and spruce-fir forests. Substrate may be stony, sandy, or firm, but some fine, loose soil is usually present.
Reptiles	Southern Desert horned lizard	*Phrynosoma platyrhinos calidiarum*	Found on sandy flats, alluvial fans, along washes, and at the edges of dunes. Sometimes found on hardpan or among rocks, but patches of sand are generally present. Associated with sagebrush, saltbush, and greasewood in the Great Basin. Elevational range extends from below sea level in desert sinks to about 6,500 feet.
Reptiles	Northern Desert horned lizard	*Phrynosoma platyrhinos platyrhinos*	Found on sandy flats, alluvial fans, along washes, and at the edges of dunes. Sometimes found on hardpan or among rocks, but patches of sand are generally present. Associated with sagebrush, saltbush, and greasewood in the Great Basin. Elevational range extends from below sea level in desert sinks to about 6,500 feet.
Reptiles	Longnose snake	*Rhinocheilus lecontei*	Typical habitats include deserts, dry prairies, arid river valleys, thornbush, and shrubland; sometimes oak-hackberry woodland. This snake retreats underground or under rocks by day. Eggs are laid underground or under rocks.
Reptiles	Northern sagebrush lizard	*Sceloporus graciosus graciosus*	This species occurs in areas of sagebrush and other types of shrublands, mainly in the mountains, preferring open, sunny areas with scattered low bushes.
Reptiles	Western groundsnake	*Sonora semiannulata*	Found in arid habitats usually having loose or sandy soil ranging from rocky areas (talus slopes, canyon rims and outcroppings) to low desert shrub areas.
Snails	Harney Basin duskysnail	*Colligyrus depressus*	This species occurs in shallow, cold springs, and spring runs with rocky substrates and moderate to steep slopes, in sage scrub desert.
Snails	Rocky Mountain dusky snail	*Colligyrus greggii*	Presumed extirpated in Oregon.
Snails	Poplar Oregonian	*Cryptomastix populi*	This species is found primarily on moderately xeric basalt talus in canyons, typically in open situations rockslides and bushy draws, and less often on steep, cool lower slopes of major river basins. The surrounding vegetation is generally sage scrub or cottonwood.
Snails	Steptoe hydrobe	*Eremopyrgus eganensis*	Endemic to one set of springs in the Steptoe Valley, north of Ely, White Pine Co., Nevada.

Taxa	Common Name	Scientific Name	Habitat Associations
Snails	Shortface lanx	*Fisherola nuttalli*	Unpolluted, cold, well-oxygenated perennial streams and rivers, generally 100 to 325 feet wide, with a cobble-boulder substrate.
Snails	Pyramid Lake pebblesnail	*Fluminicola dalli*	Only known from the type locality and a small surrounding area in the northern area in Pyramid Lake
Snails	Ashy pebblesnail	*Fluminicola fuscus*	Inhabits clear, cold streams, under rocks and vegetation in the slow to rapid currents of streams but is sparse or absent in major rapids. Restricted to habitat with sufficient flow, oxygenation, and stable substrate.
Snails	Modoc pebblesnail	*Fluminicola modoci*	Occurs only in a small number of springs with cool clear water and rocky bottoms in southern Oregon and northern California
Snails	Turban pebblesnail	*Fluminicola turbiniformis*	This species occurs in cold, nutrient-poor springs.
Snails	Virginia Mountains pebblesnail	*Fluminicola virginius*	Found in a single spring in the Pyramid Lake basin in Washoe County
Snails	Western ridged mussel	*Gonidea angulata*	Inhabits bottom of cold creeks, rivers, and lakes from low to mid-elevations with substrates that vary from gravel to firm mud, and include at least some sand, silt or clay. Generally associated with constant-flow, shallow water (less than 10 feet in depth) and well oxygenated substrates.
Snails	Banbury Springs limpet	*Idaholanx fresti*	Requires cold, clear and well-oxygenated water with swift currents. Found on smooth basalt, boulders, or cobble-sized grounds ranging from 2 to 20 inches deep but avoid areas with green algae. Only exists at four cold-spring locations in Idaho that are isolated from each other.
Snails	Scalloped Juga	*Juga acutifilosa*	This species is found in springs, spring runs, and spring-fed creeks.
Snails	Eureka mountainsnail	*Oreohelix eurekensis*	An important habitat factor is the presence of limestone talus, outcrops, or high calcium soils. The species also requires shade from vegetation and a well-developed litter layer. This can be found under shrub or tree cover.
Snails	Costate mountainsnail	*Oreohelix idahoensis idahoensis*	This subspecies is found on steep slopes, generally talus or rock outcrops, like limestone or slate.
Snails	Whitepine mountainsnail	*Oreohelix hemphilli*	This species has a disjunct range on high elevation rocky areas mountains from a somewhat broad area
Snails	Goshute mountainsnail	*Oreohelix loisae*	Only known from two sites in the Goshute Mountains, Elko Co., Nevada.
Snails	Schell Creek mountainsnail	*Oreohelix nevadensis*	Known from a few sites and has limited distribution, in high elevation areas predominantly consisting of limestone.
Snails	Great Basin mountainsnail	*Oreohelix strigose depressa*	Found in the mountains of eastern Nevada,
Snails	Striate mountainsnail	*Orehelix strigosa goniogyra*	Composition of plant community is less important than substrate with the presence of exposed limestone being almost critical for occurrence although there are documented occurrences on sandstone.
Snails	Dalles mountainsnail	*Oreohelix variabilis ssp.*	This species occurs in areas of talus and basalt with limited vegetation cover.

Taxa	Common Name	Scientific Name	Habitat Associations
Snails	Whorled mountainsnail	*Oreohelix vortex*	This species is restricted mostly to large-scale, xeric basalt taluses and boulder fields. Sites are typically dry and open; the most common vegetation is grasses. The species prefers low to medium elevations in large stream valleys; dry open to brushy areas; vicinity of springs; basalt talus. Grasses are common at preferred sites, with some forbs and shrubs. This species occurs in association with basalt boulder fields and talus in xeric habitat. Grasses and occasionally shrubs or forbs are the most common plant associates.
Snails	Lava rock mountainsnail	*Oreohelix waltoni*	It is associated with basalt (particularly type locality) but also mixed schist/alluvium in rather dry, open areas of sage scrub vegetation. Common plants found at sites are grasses and shrubs including Artemisia, and Celrus; Sorbus, Prunus, and Physocarpus occur locally. It is associated with xeric habitat in basalt talus and mixed schist/alluvium. Dominant plants in the areas include sagebrush, netleaf hackberry, and grasses. This habitat occurs primarily along the Salmon River corridor and in the southwestern portion of the section. Much of this habitat occurs in wilderness.
Snails	Snake River physa	*Physella natricina*	Freshwater mollusk inhabiting areas of swift current on sand to boulder-sized substrate.
Snails	Black-footed tightcoil	*Pristiloma chersinella*	Little information on distribution or habitat is available. The species occurs in high-elevation places in British Columbia and the Pacific Northwest of the US
Snails	Archimedes springsnail	*Pyrgulopsis archimedis*	Found in spring-influenced areas of large lakes.
Snails	Dixie Valley pyrg	*Pyrgulopsis dixensis*	Found in Dixie Valley Nevada
Snails	Owyhee hot springsnail	*Pyrgulopsis fresti*	Requires clean, moderately swift, well-oxygenated waters, typically with gravel-boulder substrates. It inhabits thermal springs with temperatures of 24 to 33°C. The only area with known habitat for this species is in a major Owyhee river canyon with exposed basalt and other volcanic lithologies, in open and dry sage scrub
Snails	Surprise Valley pyrg	*Pyrgulopsis gibba*	Occurs in northwestern Great Basin (California, Nevada, and Oregon)
Snails	Emigrant pyrg	*Pyrgulopsis gracilis*	Occurs in the Emigrant Springs complex in the White River valley in Nye County, Nevada
Snails	Hamlin Valley pyrg	*Pyrgulopsis hamlinensis*	Recorded in two high-elevation, rocky springs in Beaver County in extreme western Utah
Snails	Upper Thousand Spring pyrg	*Pyrgulopsis hovinghi*	Freshwater snails have adapted to most North American habitats including permanent standing, intermittent, and flowing waters.
Snails	Hubbs pyrg	*Prygulopsis hubbsi*	Occurs in Hiko Spring and Crystal Springs in Lincoln County, NV.
Snails	Humboldt pyrg	*Prygulopsis humboldtensis*	Restricted to the Lahontan Basin
Snails	Kings River pyrg	*Pyrgulopsis imperialis*	Found in 13 isolated springs near Thacker Pass and the Montana Mountains, NV.

Taxa	Common Name	Scientific Name	Habitat Associations
Snails	Crooked Creek springsnail	*Pyrgulopsis intermedia*	Documented in Simpson Springs in Eureka County, Nevada.
Snails	Landyes pyrg	*Pyrgulopsis landyei*	Occurs in 2 springs along eastern edge of Egan Range in Steptoe Valley, Nevada.
Snails	Butterfield pyrg	*Pyrgulopsis lata*	Found in Butterfield Springs in White River Valley in Nye County, Nevada.
Snails	Crittenden pyrg	*Pyrgulopsis lentiglans*	Found in the Thousand Springs Creek drainage, Elko County, Nevada.
Snails	Lockes pyrg	*Pyrgulopsis lockensis*	Occurs in five thermal springs in Nye County, Nevada.
Snails	Western Lahontan pyrg	*Pyrgulopsis longiglans*	Occurs in springs and seeps in Humboldt, Washoe and Douglas Counties, Nevada.
Snails	Hardy springsnail	*Pyrgulopsis marcida*	Located in several springs in Nye, Lincoln and White Pine Counties, Nevada.
Snails	Northern Soldier Meadow pyrg	*Pyrgulopsis militaris*	Occurs in thermal spirngs in the Soldier Meadow area of Nevada
Snails	Camp Valley pyrg	*Pyrgulopsis montana*	Occurs in the Meadow Valley (Camp Valley) Wash in Nevada.
Snails	Neritiform Steptoe Ranch pyrg	*Pyrgulopsis neritella*	Occurs in Steptoe Valley Nevada.
Snails	Elongate Mud Meadows springsnail	*Pyrgulopsis notidicola*	Endemic to Soldier Meadow, Nevada, occur in small, usually fishless spring-fed water bodies.
Snails	Sub-globose Steptoe Ranch pyrg	*Pyrgulopsis orgiculata*	Restricted to two springs on private lands in White Pine County, Nevada.
Snails	A springsnail	*Pyrgulopsis owyheensis*	Lives in spring sources and stream outflows, some of which are thermal, and is found on a variety of hard substrates. Disjunctly distributed among five small areas (Owyhee River near Three Forks, Rattlesnake Creek drainage, Owyhee Spring area, lower Owyhee River, Malheur River drainage) in southeastern Oregon in Malheur County.
Snails	Big Warm Spring pyrg	*Pyrgulopsis papillata*	Found near the Duckwater tribal lands, Nevada
Snails	Bifid Duct pyrg	*Pyrgulopsis peculiaris*	Occurs in Snake and Spring Valleys in White Pine County, Nevada.
Snails	Ovate Cain Spring pyrg	*Pyrgulopsis pictilis*	Occurs in spring pools within the Reese River valley
Snails	Median-gland springsnail	*Pyrgulopsis pisteri*	Found in Marsh Spring, North Scruggs Springs, and below School Springs, Nevada all within 1.2 miles of each other
Snails	Flat-topped Steptoe pyrg	*Pyrgulopsis planulata*	Occurs in one spring near Clark Spring, Steptoe Valley, White Pine County, Nevada.
Snails	Jackson Lake springsnail	*Pyrgulopsis robusta*	Currently found in the Harney Lake-Malheur Lake area of Harney County, Oregon and one or two spring sites in the Lake Abert area of Lake County, Oregon.
Snails	Sada's pyrg	*Pyrgulopsis sadai*	Occurs in 15 sites across its range in Utah and Nevada.
Snails	White River Valley pyrg	*Pyrgulopsis sathos*	Reported from the White River Valley in Nye, Lincoln and White Pine Counties, Nevada.
Snails	Northern Steptoe pyrg	*Pyrgulopsis serrata*	Occurs in the northern Steptoe Valley, Nevada.
Snails	Sterile Basin pyrg	*Pyrgulopsis sterilis*	Known from three springs in Nye County, Nevada.

Taxa	Common Name	Scientific Name	Habitat Associations
Snails	Northwest Bonneville pyrg	*Pyrgulopsis variegata*	Found in springs in Utah's Box Elder and Tooele counties. The most common habitat for the Pyrgulopsis genus of freshwater snails is a rheocrene, which is a spring that flows freely from the ground.
Snails	Varner's pyrg	*Pyrgulopsis varneri*	Found in 3 spring complexes in Soldier Meadow Nevada.
Snails	Duckwater Warm Springs pyrg	*Pyrgulopsis villacampae*	Occurs in the Big Warm Springs complex in Nye County, Nevada.
Snails	Vinyard's pyrg	*Pyrgulopsis vinyardi*	Endemic to Nevada; This species found in rheocrene springs at elevations ranging from 1,689 to 1,698 m (5,541 to 5,571 ft).
Snails	Wong's pyrg	*Pyrgulopsis wongi*	Occurs in springs in far western Nevada and adjacent eastern California.
Snails	Unexpected snail	*Taylorconcha insperata*	Newly described species in the Malheur and Owyhee Rivers in Oregon. Occurs on stable substrates on the undersides of loose, large cobbles or boulders in back eddies below rapids in shallow rivers and tributary deltas (0 to 1m deep), and at elevations around 1200m.
Snails	Grated tryonia	*Tryonia clathrate*	Observed in Nye County, Nevada.
Snails	Monitor tryonia	*Tryonia monitorae*	Restricted to HotSprings, Potts Ranch and Monitor Valley, Nevada.
Snails	Lined ramshorn	*Vorticifex effusa diagonalis*	This species is found in freshwater habitats with a preference for still or slow-moving water with live aquatic vegetation

Appendix 12. Reasonably Foreseeable Development Scenario

This document was developed to support the Greater Sage Grouse planning effort. It is intended to provide a reasonable projection of future activity associated with mineral exploration and development in the planning area under each of the proposed alternatives, in order to assist in the analysis of impacts resulting from proposed actions. It is intended to provide an update to information in previous Greater Sage Grouse planning efforts. Information from these previous efforts was gathered, examined against development trends, advances in technologies, and economic conditions since the time of publication. This was examined in consultation with various Bureau of Land Management (BLM) resource specialists to determine the need for changes or updates to the assumptions and information used to develop expectations regarding mineral exploration and development in the planning area. Once any revisions were completed the information was used to analyze the impact of the proposed alternatives during the 20-year planning period.

12.1 Fluid Minerals – Colorado

12.1.1 Methodology

BLM mineral resource experts examined the reasonably foreseeable development (RFD) document produced for the 2015 Northwest Colorado Greater Sage Grouse (GRSG) Land Use Plan Amendment (LUPA) and Environmental Impact Statement (EIS) as well as development trends and data from development since that time and determined that the methodology and trends that were used to produce the projections did not need modifications given the lack of significant changes in trends surrounding fluid mineral development. Assumptions and methodology used to develop the updated projections below are the same assumptions and methodology described in Appendix N of the 2015 Northwest Colorado Greater Sage-Grouse Proposed LUPA/Final EIS (2015 CO Plan). These were used along with new information to revise the projections provided to the current date and to analyze the proposed Alternatives. Limited data on how the 2015 projections were created is available, but because the trend of the projections is consistent with conditions since that time, they were able to be extended into the future. The projections by alternative taken from Table N.17 were compared to the current Alternatives, to determine the closest matches of alternatives from the two plans using management direction. Alternative 1 would continue management from the 2015 CO Plan. Alternative 2 would continue management from the 2018 Northwest Colorado GRSG Proposed Resource Management Plan Amendment/Final Environmental Impact Statement which would open to leasing approximately 224,200 acres closed under Alternative 1 and add an allowance for exceptions to NSO stipulations; the 2018 Plan did not provide projections of future development, but this management is very similar to what was proposed under Alternative D in the 2015 Plan. Alternative 3 would close all GRSG habitat to leasing, which is similar management to Alternative C in the 2015 CO Plan which proposed closing occupied habitat areas to fluid mineral leasing and applied NSO to the majority of the remaining area; so Alternative C projections were used for Alternative 3. Alternatives 4, 5, 6 and the Proposed RMP Amendment would make approximately 751,000 acres of PHMA open to leasing with NSO stipulations and apply NSO buffers around Leks in the 786,000 acres of GHMA, NSO stipulations would allow for waivers, exemptions, and modifications (WEMs) under this Alternative. The Proposed RMP Amendment would also manage approximately 5,000 acres of the total PHMA as Limited Exception. When comparing against the 2015 CO Plan Alternatives, this proposed management falls between Alternative D which proposed NSO stipulations on 1,347,400 acres, and Alternative A which proposed NSO stipulations on 350,300 acres (2015

CO Plan Table 2.6). The average of the projections for Alternatives A and D was calculated for use as the projections for Alternative 4, 5, and the Proposed RMP Amendment. Alternative 6 would apply the same management as Alternative 5 except that it would consider the designation of certain areas as areas of critical environmental concern (ACECs), however much of the designated ACEC acreage is already closed to leasing from management of other resources so the ACEC designations were determined to be unlikely to cause major changes to projections.

Projections created for the 2015 CO Plan included wells and production from Federal Minerals under Forest Service surface, however Federal Minerals under Forest Service surface are not part of the decision area in the current planning effort, so these areas were removed from the projections by calculating the proportion of the 2015 decision area that was Federal Minerals under Forest Service surface and then reducing the projections by that proportion.

The 2015 projections of production of oil and gas by Alternative in Table N.18 in the 2015 CO Plan were used for current plan projections using the same match-up between the 2015 and current Alternatives as described for the well projections above. These production amounts were also reduced by the proportion of Federal Minerals under Forest Service surface in the GRSG habitat areas, the Forest Service was not involved in the current planning effort so federal mineral estate located under Forest Service surface estate, which require consent of the Forest Service before BLM can lease, were not included in the decision area and their impact was removed from the projection results.

It was noted that the projected 20-year oil production projections in the 2015 CO Plan were significantly higher than the peak production from the entire state of Colorado despite the analysis area not containing the highest producing fields in the state. According to Energy Information Administration[1] Colorado had a peak production of 192,238 thousand barrels in 2019 (192,238,000 * 20 years = 3,844,760,000 barrels), under the Proposed RMP Amendment in Table N.18 the 20-year production from Federal, State, and Fee Minerals, All Surface is listed as 44,879 million (44,879,000,000) barrels under the low case scenario and 72,617 million (72,879,000,000) barrels under the high case scenario. Because of this and based on production history from the counties containing the GRSG habitat, it was determined that the projections had been incorrectly converted and were off by a factor of 100, so projected barrels of production were converted by this amount (i.e., 35,903,966,373 barrels became 359,039,664 barrels).

Surface disturbance was calculated by the number of new wells under the high development scenario for each Alternative. Short-term disturbance calculations used the number of wells drilled, and long-term disturbance calculations used the number of wells completed for each Alternative. The disturbance acreage per well was derived from Tables 1 and 2 in the Reasonably Foreseeable Development (RFD) Scenario for Oil and Gas for Grand Junction Field Office,[2] which was chosen because it was the most recent RFD completed in the Planning area. Short term disturbance per well, which is the disturbance that occurs during drilling, was multiplied by the number of wells drilled for each Alternative. The long-term disturbance per well, which is the remaining disturbance necessary for the production of oil and gas after areas of disturbance only needed for drilling and completion of well have been reclaimed, was multiplied by the number of

[1] Energy Information Administration. 2023. Petroleum & Other Liquids- Colorado Field Production of Crude Oil. https://www.eia.gov/dnav/pet/hist/LeafHandler.ashx?n=pet&s=mcrfpco1&f=a

[2] Reasonably Foreseeable Development Scenario for Oil and Gas, Grand Junction Field Office, Colorado. United States Department of the Interior, Bureau of Land Management. June 18, 2012.

completed wells under each Alternative. Wells that are drilled but not completed would be plugged and abandoned, and the disturbance would be fully reclaimed.

Both a high and a low scenario are presented. The high scenario is based on RFDs from each field office in the decision area and is designed as a high case scenario, by assuming that both the number of wells drilled and production per well would be on the high side of what is likely to occur, in order to analyze the impacts of an increase in the rate of drilling and production. The low scenario adjusts projections based on actual spud information from the Automated Fluid Minerals Support System and production levels and is considered a more realistic scenario.

12.1.2 Oil and Gas

The oil and gas potential rankings created in response to the Energy Policy and Conservation Act (EPCA) were overlaid with GRSG habitat management areas (HMAs) using a geographic information system (GIS) to analyze the likelihood of development in priority habitat management area (PHMA) and general habitat management area (GHMA). While more recent assessments of oil and gas development potential are available for many states, the EPCA potential rankings were chosen for use because they are the most recent assessment that covers the entire GRSG planning area, this is desirable because it allows for comparison of development potential across different states. High potential areas are most likely to be developed, medium potential areas are the second most likely to be developed, and low potential areas are the least likely to be developed. The boundaries of HMAs vary slightly by alternative so the Alternative 4 boundaries were used for the purposes of calculation but the distribution of potential by HMA area does not vary significantly across the proposed Alternatives.

Table 1: EPCA Potential for Oil within Colorado GRSG HMAs

Existing Oil and Gas Leasing Activity

Existing leases, which could still be developed under the management associated with the resource management plan (RMP) which the lease was issued under, even in areas which would be closed or have more restrictive stipulations applied under the Proposed RMP Amendment, were overlaid with potential and HMA type in GIS to show how much of the oil and gas in the planning area might not be impacted by the proposed new management.

Projected Drilling Activity by Alternative

Projections of future oil and gas development contained in Appendix N of the 2015 Colorado GRSG Final EIS were used with details about the new proposed alternatives to create the following updated projections for the development of oil and gas in the planning area under the new proposed alternatives.

Table 4: Number of Oil and Gas Well Projected to be Drilled and Completed on BLM-managed Federal Minerals in the Planning Area During the 20-year Forecast Period

Alternative	Low Scenario	High Scenario
Alternative 1-wells drilled	8,635	16,963
Alternative 1-wells completed	8,204	15,910
Alternative 2- wells drilled	8,760	17,088
Alternative 2-wells completed	8,322	16,026
Alternative 3- wells drilled	8,687	12,716
Alternative 3-wells completed	8,253	11,997
Alternative 4- wells drilled	9,018	17,533
Alternative 4-wells completed	8,567	16,422
Alternative 5- wells drilled	9,018	17,533
Alternative 5-wells completed	8,567	16,422
Alternative 6-wells drilled	9,018	17,533
Alternative 6-wells completed	8,567	16,422
Proposed RMP Amendment-wells drilled	9,018	17,533
Proposed RMP Amendment-wells completed	8,567	16,422

Projected Surface Disturbance Due to Oil and Gas Activity by Alternative

Table 5: High Scenario Projected 20-year Surface Disturbance from Well Pads, Roads, and Pipelines

Alternative	Short term disturbance* (acres)	Long term disturbance* (acres)
Alternative 1-wells drilled	61,729	-
Alternative 1-wells completed	-	19,895
Alternative 2- wells drilled	62,181	-
Alternative 2-wells completed	-	20,040
Alternative 3- wells drilled	46,272	-
Alternative 3-wells completed	-	15,001
Alternative 4- wells drilled	63,804	-
Alternative 4-wells completed	-	20,535
Alternative 5- wells drilled	63,804	-
Alternative 5-wells completed	-	20,535
Alternative 6-wells drilled	63,804	-
Alternative 6-wells completed	-	20,535
Proposed RMP Amendment --wells drilled	63,804	-
Proposed RMP Amendment --wells completed	-	20,535

Source: Derived using data from Table 1 and Table 2 in the Grand Junction Field Office RFD (2012) and high scenario oil and gas well projections above.

*Short term disturbance is generated by pads for all wells drilled, and construction of roads and pipelines. Long term disturbance is generated by pads for completed wells, and road and pipeline disturbance remaining after reclamation of areas disturbed by construction, well pads for wells that are not completed are reclaimed.

Projected Production by Alternative

Table 6: Projected 20-Year Oil and Gas Production by Alternative

Alternative 1		Alternative 2		Alternative 3		Alternative 4, 5, 6, and Proposed RMP Amendment	
Gas (BCF)	Oil (MMBO)	Gas (BCF)	Oil (MMBO)	Gas (BCF)	Oil (MMBO)	Gas (BCF)	Oil (MMBO)
Low Scenario							
Federal Minerals Below All Surface except Forest Service							
13,100	183.79	13,288	186.44	12,962	138.61	13,715	203.50
High Scenario							
Federal Minerals Below All Surface except Forest Service							
25,406	356.44	25,591	359.04	18,842	201.49	26,288	389.95

Sources: Derived from the 2015 Colorado GRSG Final EIS table N.18.
BCF = billion cubic feet; MMBO = million barrels of oil

12.1.3 Geothermal

Although the potential for geothermal development is high in some areas, there currently is no ongoing geothermal power generation on BLM lands in Colorado. Recent increased interest and technological advancements increase the likelihood of its development in the future.

The 2015 and 2018 Sage Grouse Plans did not project the occurrence of geothermal development. Because there is no existing development and no previous estimates to use, the following assumptions are made to analyze the impacts of geothermal development and associated surface disturbance. For the purposes of analysis, it is assumed that under all Alternatives except Alternative 3 up to one 20 megawatt (MW) geothermal power generation facility would be developed on BLM-managed lands in GRSG habitat over the next 20 years. This facility would disturb up to 6 acres for the drilling of up to 6 thermal gradient wells and would disturb up to 24 acres for the drilling of up to 8 production and injection wells. Construction of pipelines would disturb up to 14 acres, and an additional 10 acres could be disturbed for the construction of the generating plant. An assumed 10 miles of road would disturb approximately 50 acres, and 8 miles of power line would disturb approximately 40 acres. Under Alternative 3, it is assumed that no geothermal power development would occur on BLM-managed lands in GRSG habitat because under this alternative all GRSG habitat would be closed to fluid mineral leasing.

12.2 Fluid Minerals – Idaho

12.2.1 Methodology

Assumptions and methodology used to develop the updated projections below are the same assumptions and methodology described in Appendix O of the 2015 Idaho and Southwestern Montana Greater Sage-Grouse Proposed LUPA/Final EIS.[3] These were used along with new information to revise the projections provided to the current date and to analyze the proposed Alternatives.

Tables O-1 and O-2 from Appendix O of the 2015 Idaho and Southwestern Montana Greater Sage-Grouse Proposed LUPA/Final EIS (2015 ID Plan) were used as the basis for updating projections. Dillion Field Office is located in Montana and was removed from the data for Idaho and moved to the Montana projections for the current planning effort. The proposed management in the current Alternatives was compared to the management in the proposed 2015 ID Plan Alternatives. Alternative 1 would continue the Proposed RMP Amendment management from the 2015 ID Plan. Based on the information in the 2015 ID Plan, it is

[3] https://eplanning.blm.gov/eplanning-ui/project/103344/510

reasonably foreseeable that under this Alternative that 15 new oil and gas exploratory wells would be developed on federal fluid mineral estate in the decision area in the next 20 years. Under Alternative 2, areas within PHMA and important habitat management area (IHMA) will be open to mineral leasing, development, and geophysical exploration, subject to NSO stipulations with limited exception, GHMA will be open to mineral leasing and development and geophysical exploration subject to controlled surface use stipulations. Compared to Alternative 1, Alternative 2 would allow for exceptions to NSO stipulations in certain situations if approved by the BLM Authorized Officer but would otherwise apply the same management. It is reasonably foreseeable for planning purposes that 20 new oil and gas exploratory wells would be developed on federal fluid mineral estate in the decision area within the next 20 years under Alternative 2. Alternative 3 is similar to the 2015 Plan Alternative C and would close GRSG to habitat to fluid mineral leasing. Under this Alternative, 13 new oil and gas exploratory wells are projected to be developed on federal fluid mineral estate in the decision area within the next 20 years. Alternative 4 would apply NSO in PHMA and IHMA with WEMs available, and an NSO buffer around Leks in GHMA with WEMs available. Compared to Alternative A from the 2015 Plan this would have fewer acres closed to leasing, but more acres managed with NSO stipulations and would allow waivers, exceptions, and modifications (WEMs) to NSO stipulations if approved by the BLM Authorized Officer. It is reasonably foreseeable for planning purposes that 25 new oil and gas exploratory wells would be developed on federal fluid mineral estate in the decision area within the next 20 years. Compared to Alternative 4, Alternative 5 would decrease the number of acres open with standard stipulations by approximately 1.65 million acres and increase the number of acres open with moderate stipulations by approximately 1.28 million. Acres managed as closed to leasing would have a small decrease and acres managed as open with major stipulations would increase slightly. Moderate stipulations typically have a minimal impact, especially in exploratory drilling, where minor changes in drill location have little consequence (versus established fields where drill locations established in layouts located to maximize resource recovery). It is reasonably foreseeable for planning purposes that 24 new oil and gas exploratory wells would be developed on federal fluid mineral estate in the decision area within the next 20 years under Alternative 5. Alternative 6 would apply Alternative 5 management and in addition designate certain areas as ACECs, which would be closed to leasing. However, most of the area that would be designated as ACECs are already closed or under NSO stipulations under the Alternative 5 management, so changes in development due to the ACEC designation would be minimal. Disturbance estimates were based on the projected number of wells under each alternative using the estimated disturbance associated with each well provided in Table O-2 in Appendix O of the 2015 ID Plan. The Proposed RMP Amendment would manage implement approximately the same management as under Alternative 5.

Geothermal projections were based on information provided in Appendix O of the 2015 ID Plan and on Table O-3 in the plan, as well as information about geothermal development provided in the more recent Four Rivers Resource Management Plan (2020). It was assumed that up to 70MW of geothermal generations could be developed during the 20-year planning period in the FRFO RMP and 40MW in Appendix O of the 2015 ID Plan, surface disturbance associated with that level of development was calculated based on information provided in Table O-3 of the 2015 ID Plan and information from the Four Rivers Resource Management Plan (2020).

12.2.2 Oil and Gas

Over 180 oil and gas wells have been drilled in Idaho of which 19 were drilled between 2015 and 2022. Currently there is only one region with active Federal oil and gas leases in the state, the Southwest Idaho oil and gas play near Payette, Idaho. Until 2008, no commercially viable oil or gas resources had been found in Idaho, despite the drilling of around 150 wells throughout the state by that time. In 2008, a natural gas field

named Willow Field was discovered in the Southwest Idaho oil and gas play and then in 2015, commercial production began from six wells on private lands. The resource is a relatively small, conventional deposit. The reservoir includes porous sand, is accessed via vertical and directional drilling, and does not require hydraulic fracturing (also referred to as fracking). The field was discovered largely due to recent advances in three-dimensional seismic technology.[4]

There are no existing or pending leases anywhere within the Sage Grouse HMA boundaries proposed under Alternatives 4, 5, 6 and the Proposed RMP Amendment.

Projected Drilling Activity by Alternative

The total estimated future surface disturbance for wells, roads, and well pads by Alternative is shown in the table below. These estimates were derived based on information from Table O-1 in Appendix O of the 2015 Idaho and Southwestern Montana Greater Sage-Grouse Proposed LUPA/Final EIS. The proposed alternatives were compared to the proposed management in that document. Alternative 1 proposed approximately the same management as the Proposed RMP Amendment from the 2015 document. Alternative 2 was based on the Proposed RMP Amendment from the changes made to GRSG management in Idaho in 2019 and 2020, the management allows for more mineral leasing and development, and geophysical exploration than Alternative 1. Alternative 3 is substantially similar to Alternative C from the 2015 Idaho and Southwestern Montana Greater Sage-Grouse Proposed LUPA/Final EIS. Alternative 4 would have fewer closed acres than Alternative 1, would manage PHMA and IHMA as open to leasing with No Surface Occupancy (NSO) stipulations that allow exceptions, and apply a NSO lek buffer around leks in GHMA. Alternatives 5, 6, and the Proposed RMP Amendment would apply similar management as Alternative 4 but would decrease the number of acres open with standard stipulations and increase the number of acres open with moderate stipulations. The application of moderate stipulations (CSU and/or timing limitations) typically have a minimal impact, especially in exploratory drilling where minor changes in drill location have little consequence (versus established fields where drill patterns are often carefully designed to maximize resource recovery). Alternative 6 will also designate some areas as ACECs which would be managed as closed to leasing.

Table 7: Reasonably Foreseeable Development Scenario for the Idaho in the next 20 years.

Alternative	Total Wells	Acres of Drill Pads[1]	Miles of Road[2]	Acres of Roads[3]
Alternative 1	15	45	30	150
Alternative 2	20	60	40	200
Alternative 3	13	39	26	130
Alternative 4	25	75	50	250
Alternative 5	24	72	48	240
Alternative 6	24	72	48	240
Proposed RMP Amendment	24	72	48	240

Source: updates to data from Table O-1 in Appendix O of the 2015 Idaho and Southwestern Montana Greater Sage-Grouse Proposed LUPA/Final EIS based on changes to management under the proposed Alternatives.
[1] Assumes 3 acres each.
[2] Miles of road per exploration well varies by RFDS. Miles of road for step-out wells equals one mile per well (in accordance with Idaho well spacing rule).
[3] Assumes 5 acres per mile.

12.2.3 Geothermal Summary

The only utility scale geothermal power development in the state of Idaho is the Raft River geothermal project located in Cassia County Idaho, at a former United States Department of Energy (DOE) geothermal site.

The project was acquired by US Geothermal in 2002 and construction began in June 2006. The plant began commercial operation in January 2008 and utilizes a binary-cycle water cooled system. The Raft River Plant was acquired by Ormat in 2018 and provides about 11MW of net capacity.[5]

The Raft River Geothermal Power plant in the Raft River Valley in Idaho expanded onto public land in GHMA between the 2015 Sage Grouse Plan and the 2018 Sage Grouse Plan Amendment.

According to the Proposed Four Rivers RMP and Final EIS[6] based on the geothermal potential for the planning area, it is reasonable to assume that a 50 MW plant might be developed in those areas determined to have high potential for indirect use. It is reasonable to assume that a 20-MW geothermal power plant might be developed anywhere along a fault zone that trends northwest from east of Mountain Home, Idaho to the Oregon Border, particularly on the southwest (valley) side of the fault zone, over the 20-year life of the plan. This northwest trending fault zone has a medium to high geothermal potential. According to the Proposed Four Rivers RMP and Final EIS, cumulative disturbance associated with development of a 50 MW plant is anticipated to be between 147 and 181 acres, while disturbance associated with developing a 20 MW plant is anticipated to be between 60 and 75 acres. This development includes the construction of drill pads to support the drilling of 20 temperature-gradient wells and 25 production and injection wells, road construction, power plant development, and pipeline and transmission line construction. Much of this disturbance would be reclaimed after each phase of development, such that once the power plant is operational, the actual disturbance would be considerably less than the cumulative total. Development is likely to occur in stages, however this is not always the case. Surface disturbances associated with direct use activities are expected to be much less than those anticipated for indirect use.

Projected Activity by Alternative

Geothermal projections and surface disturbance were developed based on the geothermal section of the RFD in the 2015 ID GRSG Plan[7] and additional information contained in the 2020 Four Rivers RMP Geothermal RFD,[8] as well as existing conditions and recent development as described in the summary above. The total of 70MW of geothermal power development predicted in the Proposed Four Rivers RMP and Final EIS was added to the total of 40MW of geothermal power development outside of the Four Rivers Field Office that was predicted in the 2015 ID GRSG Plan. Acres of disturbance associated with the total of

110MW predicted development were developed based on the information regarding facility sizes in the two documents. Alternative 3 would manage all GRSG habitat as PHMA and would close it to fluid mineral leasing, this would prevent new leasing that would be required for some geothermal development which would reduce development on federal mineral estate, resulting in reduced total geothermal development or shifting of development to non-federal mineral estate, however some development could still occur on existing leases. To reflect this, the total projected MW under Alternative 3 was reduced.

Table 8: Reasonably Foreseeable New Generating Capacity and Total Disturbance Acreage by Alternative for Geothermal Resources over the next 20-years

Alternative	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Alternatives 5, 6, and Proposed RMP Amendment
MW Predicted	110	110	35	110	110
Acres Disturbed by Thermal Gradient Drilling (1 acre per well)	31	31	10	31	31
# of Prod/ Inj. Wells Predicted	39	39	13	39	39
Acres of Drill Pads (3 acres each)	117	117	39	117	117
Total Miles of Road	30	30	9.5	30	30
Acres of Roads (5 acres Per mile)	150	150	47.5	150	150
Acres of Powerplant Construction (1/2 acre per MW)	55	55	17.5	55	55
Pipeline Construction disturbance (acres)	75	75	24	75	75
Transmission Line Construction (5 acres per mile)	25 miles = 125 acres	25 miles = 125 acres	8 miles = 40 acres	25 miles = 125 acres	25 miles = 125 acres
Total Permanent Disturbance (acres)	553	553	178	553	553

12.3 FLUID MINERALS – MONTANA

12.3.1 Methodology

BLM mineral resource experts examined the RFD projections in plans produced for the 2015 GRSG planning effort, including the Miles City, HiLine, Billings, Lewistown, and Southwest Montana Plans. They also looked at updates such as the 2021 Lewistown RMP Revision, as well as development trends and data from development since that time and determined that the methodology and trends that were used to produce projections did not need significant modifications given the minimal changes in trends surrounding fluid mineral development in the state.

Assumptions and methodology used to develop the updated projections below are the same assumptions and methodology described in the RFDs developed for the Billings, Hi-Line, Lewistown, Miles City, Dillon, and Butte Field Offices. The Upper Missouri River Breaks National Monument is also part of the planning area but is withdrawn from all forms of entry, location, selection, sale, or leasing or other disposition under

the public land laws, however it does have some legacy leases which predate the monument designation that could be developed. All of the above information was used, along with new information, to revise the projections provided to the current date and to analyze the proposed Alternatives.

To develop updated projections for Montana for the current planning effort the projections from all the field office plans that were created in 2015 were collected. These projections were then examined and updated to remove developments that did not occur and modify information on developments that have not met the level of development previously expected. This included removing all projected coalbed natural gas wells, because development of that type in the planning area has not been economically viable due to recovery rates and natural gas prices, so planned projects were abandoned, and no coalbed natural gas development has occurred recently. The Bowdoin Natural Gas Project Area in the HiLine District was also removed because specialists reported that it had been developed and was played out with no further wells expected.

The Alternatives from the current planning effort were then compared to earlier Alternatives to determine how the projections would vary by Alternative. Based on the proposed management of PHMA and GHMA including the acres of closed to leasing, open to leasing with additional NSO stipulations, open to leasing with additional minor stipulation or open with standard stipulations. It was determined that the Alternatives 1, 2, 4, 5, 6, and the Proposed RMP Amendment are substantially similar to each other, and to the selected management in the various 2015 plans (HiLine Alternative E, Billings Pompey Alternative D, Lewistown Alternative C2, Miles City Alternative E, [Dillon did not project any oil and gas production under any Alternative]). Alternative 3 from the current plan is similar to the various lowest development alternatives from the 2015 plans (Alternative B for all plans). The Billings, and Dillon RMPs did not differentiate the projected number of wells by alternatives, due to low levels of development expected, the projections from these plans were carried forward into the update without differentiation by alternative. The projections for the total number of wells, surface disturbance, and production of oil and gas projected to occur under the Alternatives in each of the field offices that were most similar in management to the current alternatives being considered were added together to get totals for each of the current Alternatives.

Because there is no geothermal development ongoing or planned within the planning area and no earlier projections of geothermal development are available, no projections were developed for this planning effort.

12.3.2 Oil and Gas

Oil and Gas Development Potential

The tables below show the development potential ranking for oil and gas resources in the planning area by proposed GRSG habitat areas under Alternative 4. The decision area is slightly different under the different Alternatives, so the Alternative 4 decision area was used for the following calculations, but the results are generally applicable across all the Alternatives. Lease status is not considered in development potential rank, both leased and unleased areas are included.

From 2013 to 2023 a total of 755 wells were completed in the state across all mineral estate types.[9]

[9] Montana Board of Oil & Gas Conservation. 2024. Well Activity. https://bogapps.dnrc.mt.gov/dataminer/Statistics/StatsHorzCompletionCount.aspx

RFD Scenario

The Montana study area for the projections below includes Billings, Butte, Dillon, Hi-Line, Lewistown, and Miles City Field Offices, and the Upper Missouri River Breaks National Monument. A number of the Field Office RFDs prior to the 2015 Greater Sage Grouse planning effort projected large amounts of development of coal-bed natural gas, however BLM specialists reported that since that time coal-bed natural gas development in the state has been much less than was projected and that coal-bed natural gas was no longer considered economically viable in the area. As a result, projections of coal-bed natural gas wells or development were not included in this analysis. The projected number of wells developed on Federal mineral estate in Montana under the proposed Alternatives, and resulting surface disturbance, and oil and gas production is shown in the tables below.

Table 11: Oil and Gas Well 20-year Projections Federal Minerals in Montana

12.3.3 Geothermal

Geothermal energy is heat energy contained in the rocks of the earth's crust. Certain geologic conditions and processes resulted in shallow geothermal resources that underlie substantial portions of many western states, including land administered by the BLM in Montana.

These shallow resources can be classified as low temperature (less than 194 degrees Fahrenheit [° F]), moderate temperature (194° F to 302° F), and high temperature (greater than 302° F). Low and moderate temperature resources are generally used for heating, rather than power generation. Binary steam plants can generate power with fluid temperatures between 225° and 360° F.

Montana's geothermal systems reflect local and regional geology. The Basin and Range, Yellowstone Hotspot, Northern Great Plains, and intrusive rocks provide favorable conditions for geothermal waters. Montana hosts approximately 150 low- to moderate-temperature springs and wells; most are in the southwestern part of the State. Co-produced water from petroleum wells in eastern Montana reaches temperatures of over 300°F. Naturally occurring hot water and steam, including hot water coproduced or produced from re-purposed petroleum wells, can be used in heat exchangers or steam turbines to generate electrical power. However, direct-use applications in the state are currently limited to local use for heating structures and for recreation and resorts.[10] There is currently a low level of interest in developing federally owned geothermal resources in Montana, so no development is expected in GRSG habitat, and no projections were deemed necessary.

12.4 Fluid Minerals – Nevada and Northeastern California

12.4.1 Methodology

This report is an update to Appendix P- Fluid Minerals Reasonably Foreseeable Development Scenario of the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final EIS with the most current publicly available information. Trends from the 2015 RFD are assumed to continue and it is assumed that the demand for renewable energy, including geothermal will continue to increase and may be influenced by such factors as advances in enhanced geothermal systems (EGS). Technological advances could increase the size and scope of the impacts. These impacts should be considered as potential developments that could lead to further increase in exploration and development of geothermal resources in Nevada in typical geothermal systems and in areas not generally recognized as having high geothermal potential.

This document is limited to publicly available information and does not include confidential drilling data. It does not attempt to quantify the potential impacts of advances in EGS or other technology that is currently being tested for viability and has not been commercially proven. If future developments exceed predictions the BLM will assess these impacts at that time.

Updated projections were developed based on consultation with BLM specialists and the data available from the Nevada Division of Minerals (NDOM). Projections are based on the assumptions and methodology used in the 2015 RFD which were examined in connection to ongoing trends and determined to still be valid.

Projections for oil and gas development were based on Table P-5 from Appendix P of the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final EIS. In this plan a large proportion of the wells projected in Table P-5 were attributed to a development being planned for the Elko-Noble area. BLM specialists confirmed that this planned development was no longer ongoing, and no further wells were expected. As a result, the Elko-Noble area projections were removed from the updated table. The current

[10] https://www.mbmg.mtech.edu/MontanaGeology/EnergyResources/geothermal.asp#

Alternatives were matched up to the Alternatives from 2015 based on the proposed management. Current Alternative 3 proposes similar fluid mineral management as was proposed under Alternative C in the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final EIS, and all other current Alternatives propose the same or very similar management as under the Proposed RMP Amendment in the same Plan.

Surface disturbance projections were derived from the same Alternative matches described in the previous paragraph. These were based on Table P-9 in the Appendix P of the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final EIS. The production of oil was based on information in Appendix P that based on production data, production wells within the planning area produce on average 14 barrels per day per well. The planning area does not produce significant quantities of natural gas so no projections for natural gas were created.

Geothermal projections from the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final EIS were identified as being potentially too low given the level of ongoing and planned development. There are 732 megawatts (MW) of geothermal power generation operational on federal lands in Nevada as of 2023.[11] Additionally, there is approximately 180MW of generation which has been authorized but not yet constructed, and there is an additional approximately 300 MW of generation in the permitting stage, for a total of 1,042MW likely to be online in the near future. Based on this trend it was assumed that up to 1150MW of generating capacity could be operational by 2035. In 2015 480MW of generating capacity was operational. A linear regression was created using these data three points (480MW in 2015, 732MW in 2023, and 1150MW in 2035) to extend the projections out to 2043, the end of the 20-year planning period. Table P-1 from Appendix P of the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final EIS was used to estimate surface disturbance but the disturbance from power plant and substation facilities was increased from 10 acres of temporary and permanent disturbance per facility to 20 acres of temporary and 15 acres of permanent disturbance per facility because BLM specialists reported that operators were trending towards larger facilities and producing more MW per facility.

12.4.2 Oil and Gas

Oil production has decreased from 281,382 barrels in 2015 to 223,493 barrels in 2021.[12] This decline is assumed to continue unless new reserves or fields are discovered. Most of the production and exploration activities since 2015 were concentrated in Railroad Valley, Nye County and Pine Valley in Eureka County. There is very little natural gas production in Nevada. The California portion of the decision area has minimal oil and gas development.

Since 2013 a total of 19 oil and gas wells were drilled in Nevada, a number of the wells did not successfully produce. The results of these wells where information is available are described as follows. In December of 2017 True Oil drilled a well in Railroad Valley in Nye County, the well was plugged and abandoned (P&A) in January of 2018. Major Oil drilled a well in Hot Creek Valley, Nye County, in May 2018, the well was P&A in May 2019. Major Oil also drilled another well in Hot Creek Valley in November 2020, the well was P&A in April of 2021. Grant Canyon Oil and Gas drilled two conventional horizontal wells in the 3 Bar Field in Pine Valley, Eureka County, since 2015. One well was drilled in May of 2019 and completed in May of 2019, the well is averaging approximately 994 barrels of oil and 807 barrels of water per month. Another well was drilled in the 3 Bar Field and had reported production of 111 barrels oil and 907 barrels water in May of 2023. Sam Oil drilled a well in White River Valley, Nye County, the well is shut in and has no reported

[11] Alex Jensen, BLM Nevada State Office Geothermal Program Lead 9/28/2023.
[12] https://data-ndom.opendata.arcgis.com/pages/oilgasandgeothermalproduction

production. Other exploration wildcat wells have been drilled in Newark Valley (all reported as shut in) in Nye County. A well was drilled by Great Basin Operating in 2022 in southwest Elko County, the well is reported as being shut in.[13] The Elko-Noble Project which was a large contributor to the projected number of wells in the 2015 Nevada RFD was less successful than anticipated and is no longer active. Wells that may be drilled in the area are no longer called out as a separate item in projections below.

Oil and Gas Well Projections

Oil and gas well projections by Alternative are shown below in the table.

Table 14: Oil and Gas Well Projections for the Nevada-California GRSG Decision Area for the 20-year Planning Period

Alternative	Oil Wells Expected to be Drilled			Oil Wells Expected to be Producing		
	On Existing Leases	On New Leases	Total	On Existing Leases	On New Leases	Total
1	14	19	33	3	4	7
2	14	19	33	3	4	7
3	10	0	10	2	0	2
4	14	19	33	3	4	7
5	14	19	33	3	4	7
6	14	19	33	3	4	7
Proposed RMP Amendment	14	19	33	3	4	7

Source: Derived from Table P-5 from the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final and Proposed Alternative information.

Based on production data within the planning area, production wells produce on average 14 barrels per day per well. Gas production in expected to be negligible. Estimated production by alternative is shown below.

Table 15: Decision Area New Well Production by Alternative

Alternative	New Annual Production (barrels)	Total 20-year Production from New Oil Wells (barrels)
1	35,770	715,400
2	35,770	715,400
3	10,220	204,400
4	35,770	715,400
5	35,770	715,400
6	35,770	715,400
Proposed RMP Amendment	35,770	715,400

[13] Nevada Division of Minerals, Well Database, 2022.

12.4.3 Geothermal

Nevada has eighteen operating geothermal power plants with federal interest, for a total generating capability of over 600 MW, and nearly 400 MW of additional geothermal projects in the permitting, exploration, development, and construction phases are expected to increase that capacity in the near future.[14]

Geothermal leases are for an initial 10-year period with 50 percent of the funds disbursed to the state, 25 percent is disbursed to the respective county, and 25 percent remaining in the Department of the Treasury.

The average kilowatt hours (Kwh) produced using geothermal energy in Nevada shows an increasing trend.[15] The trend for generation from Federal leases is also increasing as shown in the table below.

Table 16: Reported Electrical generation, Federal Geothermal leases.

There is also reported geothermal production from federal leasing in Lassen County California which is in the Nevada-California decision area. Electrical generation was reported from 2014 through 2018 and is shown in the table below. It is not clear if electrical generation stopped after 2018 or if the reporting type changed. Geothermal direct utilization, which is reported in millions of British thermal units, also was reported in Lassen County California from 2003 through 2023. This is shown in **Table 17** below. The data obtained from the Office of Natural Resources Revenue does not contain the name of the reporting facilities, but a search of federal leases in Lassen County shows only one currently active lease (CACA105468859)

Geothermal Production Projections

The table below shows the projected geothermal generation capacity on federal leases in the Nevada-California GRSG planning area over the next 20 years. Approximately 672 MW of geothermal generation capacity would be added over the next 20 years. Typical existing geothermal plants range from 20 to 40 MW of generation capacity with an average of 24 MW per plant, due to efficiencies associated with scaling up it was assumed that future plants might be slightly larger at approximately 30 MW generating capacity per plant. The addition of 672 MW may translate into 23 new power plants (672 MW ÷ 30 MW average per power plant = 23 power plants). Based on the typical existing plant which produces 24MW using 5 production and 3 injection wells, the new plants would require approximately 225 wells (672 MW ÷ 3 MW per well = 225 new wells). Geothermal plant capacity and the number of wells required to support each

[16] https://www.calbiomass.org/facilities/greenleaf-honey-lake-power/

plant can vary drastically based on the characteristics of the geothermal resource being utilized so individual projects can be expected to deviate from the above averages.

Table 18: Projected Geothermal Generation Capacity on Federal Leases in Nevada 2023-2043

Year	Geothermal Generation Capacity in Megawatts (MW)
2023	743
2024	776
2025	810
2026	843
2027	877

2043	1,415

Source: Derived from information contained in Appendix P of the 2015 Nevada and Northeastern California Greater Sage-Grouse Proposed LUPA/Final EIS and information from the BLM Nevada Geothermal webpage.[17]

As of 2022 there were approximately 160,000 acres of existing nonproducing federal geothermal leases in GRSG habitat in Nevada, and a total of approximately 476,000 acres of non-producing federal geothermal leases in all of Nevada. There are approximately 14,000 acres of producing federal geothermal leases in GRSG habitat in Nevada, and approximately 56,000 acres total of producing federal geothermal leases in Nevada. Based on the production capacity of existing producing leases, the amount of acreage under existing nonproducing leases within Greater Sage Grouse habitat is sufficient to meet the projected growth in geothermal generation capacity during the 20-year planning period several times over, so assuming development is pursued on these leases and exploration determines that most have suitable geothermal resources. Increases in the amount of geothermal generation are expected to be the same under all the proposed Alternatives. Alternative 3 would close Greater Sage Grouse habitat to new geothermal leasing,

[17] https://www.blm.gov/programs/energy-and-minerals/renewable-energy/geothermal-energy/regional-information/nevada "Nevada BLM has eighteen operating geothermal power plants with federal interest, for a total generating capability of over 600 MW and nearly 400 MW of additional geothermal projects in the permitting, exploration, development and construction phases."

which could prevent some future development in Alternative 3 PHMA, but it is likely that the development that would have occurred in these areas would relocated to other geothermal leases in Nevada.

Geothermal Activity Surface Disturbance Projections

Most geothermal development in the planning area has been of air-cooled binary systems which have the largest acreage disturbance for geothermal development, however that disturbance has been trending down, averaging less than 2 acres per MW of capacity for recent developments. Advances in drilling technology such as directional drilling have allowed for smaller surface disturbance. EGS technology has the potential to use far less groundwater to create binary geothermal production, however it has not yet been proven at the commercial scale, so estimates are based on traditional geothermal developments.

Table 19: Estimated Total New Decision Area Disturbance from Geothermal Development During the Planning Period

Disturbance Type	Temporary Disturbance per Facility (acres)	Permanent Disturbance per Facility (acres)	Number of New Facilities	Total New Temporary Disturbance (acres)	Total New Permanent Disturbance (acres)
Production & Injection Wells (Disturbance from all facility wells)	36	23	27	972	621

12.5 FLUID MINERALS – NORTH DAKOTA

12.5.1 Methodology

Since the publication of the 2015 Greater Sage Grouse plan for North Dakota an updated Reasonably Foreseeable Development Scenario for Oil and Gas Development in North Dakota[18] was published in 2022 as part of the revision of the North Dakota Resource Management Plan. Assumptions and methodology used to develop the updated projections below are the same assumptions and methodology described in the RFD for the North Dakota RMP revision. These were used along with new information where available to revise the projections provided to the current date, focus the analysis on the portions of the state with GRSG, and to analyze the proposed Alternatives. GRSG habitat management area in North Dakota is in the south-west corner of the state and limited to a small amount of the total area of the state. Much of the BLM fluid mineral decision area is already under an existing lease with approximately 15 percent unleased. To develop the below projections, the parcels of BLM-administered federal mineral estate that are within the GRSG planning area and the North Dakota boundaries were examined by township and information on the acres of BLM-administered federal mineral and amount leased vs available to lease in each township was recorded. The 20-year projections wells producing federal minerals for townships containing GRSG habitat were counted, and it was determined that under the existing rate of development a total of 222 production wells and 29 support (non-producing) wells are projected to be drilled on BLM-administered federal mineral estate over the next 20 years. To figure out projections by year the total projected federal North Dakota wells projected in a particular year were divided by the total 20-year projected federal wells and then

[18] https://eplanning.blm.gov/public_projects/1505069/200366341/20072477/250078659/NDRMP_Oil%20and%20Gas%20RFD_Oct2022_508.pdf

multiplied by the total GRSG area wells to get the proportion of the total wells that occurred in that year. A similar method was used to get the projected production in GRSG habitat, the total production from new federal wells for a specific year was divided by the total number of new federal wells to get per well production for that year which was then multiplied by the number of new GRSG area federal production wells for that year. The reduction under Alternative 3, which would manage all GRSG habitat as closed to leasing, was calculated by determining the proportion of unleased federal mineral estate in the North Dakota GRSG planning area. Approximately 15.38 percent of the area is unleased and thus would not be leasable or able to be developed under Alternative 3, so the projection totals from the other Alternatives were reduced by 15.38 percent for this Alternative.

Surface disturbance projections were based on information from the Reasonably Foreseeable Development Scenario for Oil and Gas Development in North Dakota which assumed that 1.3 acres of surface disturbance per well would occur for new wells on BLM minerals. However, the GRSG area is outside the Bakken/Three Forks Formation where locating many horizontal wells on a single pad, which results in smaller per well disturbance, is the typical method of development. As a result, it was assumed 3 acres of surface disturbance per well would occur to be more in line with the type of development seen in the GRSG area of North Dakota.

12.5.2 Oil and Gas

Since the publication of the 2015 Greater Sage Grouse plan for North Dakota an updated Foreseeable Development Scenario[19] oil and gas development in North Dakota was published in 2023 as part of the revision of the North Dakota Resource Management Plan. Assumptions and methodology used to develop the updated projections below are the same assumptions and methodology described in the RFD for the ongoing North Dakota RMP revision. These were used along with new information where available to revise the projections provided to the current date, focus the analysis on the portions of the state with GRSG, and to analyze the proposed Alternatives. GRSG habitat management area in North Dakota is in the south-west corner of the state and limited to a small amount of the total area of the state. Much of the BLM fluid mineral decision area is already under an existing lease with approximately 15 percent unleased.

Oil and Gas Development Potential

The North Dakota decision area is located on areas given a development potential rank of medium to high in the North Dakota Field Office RFD prepared for 2020-2040, updated in 2022, and released in 2023 with the Draft RMP/EIS as part of the North Dakota Resource Plan Revision and EIS.[20]

Since 2015 there have been six wells drilled on BLM administered lands in the Greater Sage Grouse decision area in North Dakota, all the drilled wells were located in PHMA,[21] however it is likely that there are other wells that are located outside of the decision area but are producing from federal minerals within the decision area by horizontal or directional drilling.

[21] IHS Enerdeq 2023

RFD Scenario

Projected Drilling Activity by Alternative

The 2020-2040 North Dakota RFD predicted that up to 222 wells would be drilled on federal minerals in the North Dakota GRSG decision area. In North Dakota, the vast majority of wells are horizontal wells.

Under the proposed Alternatives almost all of the North Dakota decision area would be PHMA so only PHMA management is presented in the following summary. Under Alternative 1 (existing management) PHMA would be managed as open to fluid mineral leasing subject to NSO stipulation, without waiver or modification, and with limited exception. Because much of the are decision area is already under existing leases which would not be impacted by the application of NSO stipulations to new leases, the potential area impacted by the proposed Alternatives is small. Also, because the vast majority of wells in North Dakota are horizontal, the impacts of NSO stipulations is not expected to have a major impact on the rate of development in most cases. Operators wanting to develop NSO area would be able to locate wellheads outside of NSO and horizontally drill into the minerals without much change to their standard development process. Alternative 2 would apply the same management as Alternative 1. Alternative 3 would manage all GRSG habitat as PHMA, under this Alternative all PHMA would be closed to leasing which would prevent any currently unleased BLM-administered federal mineral estate from being leased and developed. This would reduce the number of wells and total production compared to Alternative 1, but development and production would still occur on existing federal leases in the area, and private minerals would still be available for leasing. Under Alternatives 4, 5 and 6, PHMA would be managed as open to fluid mineral leasing subject to NSO stipulation with waivers, modifications, and exceptions available at the discretion of the authorized officer. The allowance for waivers, modifications, and exceptions might result in increased development and production compared to Alternative 1, but because waivers, modifications, and exceptions are discretionary it is impossible to quantify any potential increase.

Source: Derived from the RFD for the 2022 North Dakota RMP revision, updated for the GRSG forecast period. Federal mineral estate located under US Forest Service administered federal surface estate is not included.

Projected Surface Disturbance Due to Oil and Gas Activity by Alternative

Much of the BLM-administered federal mineral estate in the planning area is split estate (meaning the surface is not federal land). Additionally, there is US Forest Service administered federal surface overlying federal mineral estate in some areas, which is not included in the decision area for this Greater Sage Grouse planning effort. The following disturbance calculations project disturbance resulting from development of BLM-administered federal minerals but much of the surface disturbance would occur on non-federal surface, both because only there are 55,000 acres of BLM-administered federal mineral estate but only approximately 33,000 acres of BLM-administered federal surface estate in the decision area, and because operators generally prefer to locate wells on non-federal surface where possible because permitting and documentation required in order to operate on BLM-managed surface adds cost to the project.

The RFD for the 2022 North Dakota RMP/EIS assumed an average of 1.3 acres per well and associated infrastructure for new wells on BLM minerals. However, the GRSG decision area is outside the Bakken/Three Forks Formation where locating many horizontal wells on a single pad is the preferred method of development, so disturbance is likely to be greater; it was assumed that 3 acres of surface disturbance per well would occur in the GRSG area in order to be avoid the chance of underestimating surface disturbance. Using this methodology, it is assumed that approximately 666 acres of total surface disturbance from well pads, roads and tank batteries associated with oil and gas development on BLM-administered federal mineral estate could occur over the 20-year forecast period.

12.5.3 Geothermal

Currently, little geothermal development exists in North Dakota and the state has lower potential than many other western states.[22] However, the extensive deep drilling for oil and gas that has occurred in the state provides an extensive record of subsurface conditions.[23] Research into using co-produced fluids (petroleum and hot water) from deep oil wells is ongoing, and researchers at the University of North Dakota completed a test of the technology that successfully generated geothermal power from hot water that flows naturally from petroleum wells in the Williston Sedimentary Basin in western North Dakota.[24] Research

[22] https://www.osti.gov/servlets/purl/1209221

[23] https://www.ndstudies.gov/energy/level2/module-5-biofuels-geothermal-recovered/geothermal-energy-north-dakota

[24] https://www.energy.gov/eere/success-stories/articles/eere-success-story-doe-funded-project-first-permanent-facility-co

into redeveloping end of life oil wells into geothermal generation wells is also ongoing. Development of electrical generation using geothermal resources could occur anywhere in the state where existing oil wells coproduce sufficient amounts of water at high temperatures, but the scalability and commercial viability of the technology has yet to be proven.

No development of geothermal resources on BLM-administered federal mineral estate in the GRSG planning area is reasonably foreseeable during the 20-year plan life. This is due to a number of factors including the likely need to obtain a federal geothermal lease for use of existing oil wells for development, and heat at depth being higher in parts of the state outside the GRSG planning area.[25]

12.6 FLUID MINERALS – OREGON

12.6.1 Methodology

There is no ongoing development of oil and gas or geothermal resources on BLM administered surface or mineral estate within the planning area. No projections of development of these types could be developed based on available information. Given the possibility of future geothermal development an assumption was made regarding the possible size and disturbance associated with a theoretical geothermal development for the purpose of being able to analyze impacts associated with any future geothermal development that might occur.

12.6.2 Oil and Gas

Oil and Gas Development Potential

Assessment of oil and gas potential conducted as part of Section 604 of the EPCA ranks all Greater sage grouse HMAs in Oregon as having low potential for both oil and gas. None of the producing oil and gas fields in Oregon are located in GRSG habitat. There are approximately 78,652 acres of oil and gas leases on BLM-managed federal fluid mineral estate within GRSG historical range as of 3/3/2023, none of the leases are producing.

Projected Activity by Alternative

Sage Grouse habitat in the Oregon planning area is presumed to have low oil and gas development potential, however there are current leases. It is expected that minimal if any, leasing, production, or surface disturbance associated with oil and gas exploration and development would occur in the planning area in Oregon over the next 20-years. Because there is no history of development no trend is available to estimate any future production.

12.6.3 Geothermal

There is no ongoing geothermal power generation on BLM-managed fluid mineral estate in Oregon. There are approximately 22,057 acres of authorized or pending federal geothermal leases within the Oregon Sage Grouse historical range as of 3/3/2023.

The state of Oregon has some of the nation's best geothermal resources.[26] Oregon's first geothermal power plant began operating in 2010 at the Oregon Institute of Technology in Klamath Falls. The initial electricity-generating capacity was 0.28 MW. A second plant at Oregon Institute of Technology generates 1.75 MW of power. The only commercial producing geothermal power plant is the Neal Springs plant in Malheur County. It is not within the GRSG planning area. The facility has five permitted production wells and six permitted injection wells, and the plant has an average net production of 22 MW. The city of Klamath Falls uses

[25] https://www.osti.gov/servlets/purl/1209221
[26] https://www.eia.gov/state/analysis.php?sid=OR

geothermal energy to heat buildings, homes, pools, and melt snow and ice from sidewalks and roads. In the town of Lakeview, a geothermal well system is used to heat school properties and hospital buildings.[27]

AltaRock Energy developed an EGS demonstration project[28] and Newberry geothermal research project at Newberry, which lies within the Deschutes National Forest and is near but not within the GRSG planning area. Alta Rock announced that results from the site could support construction of a 35 MW binary geothermal power plant utilizing a dry cooling system[29] but no development has been proposed at the site. Funding from the US Department of Energy expired in 2015[30] so future use of the site appears to be uncertain, however the operator is applying for additional Department of Energy grants and is planning to restart stimulation and exploration. EGS technology has the potential to be developed in the planning area, but because EGS technology has not been proven to be commercially viable at this time the scope of such projects is unknown.

Projected Activity by Alternative

The 2015 and 2019 Sage Grouse Plans for Oregon did not project the occurrence of geothermal development in Oregon. Because there was no existing development and no previous estimates to use, the following assumption is made to analyze the impacts of potential geothermal development and associated surface disturbance. For the purposes of analysis, it is assumed that under all Alternatives except Alternative 3 up to one 20MW geothermal power generation facility would be developed on BLM-managed lands in GRSG habitat over the next 20 years. This facility would disturb up to 6 acres for the drilling of up to 6 thermal gradient wells and would disturb up to 24 acres for the drilling of up to 8 production and injection wells. Construction of pipelines would disturb up to 14 acres, and an additional 10 acres could be disturbed for the construction of the generating plant. An assumed 10 miles of road would disturb /approximately 50 acres, and 8 miles of power line would disturb approximately 40 acres. The total estimated disturbance acres for this scenario equals 144 acres. Under Alternative 3, all BLM-managed minerals in GRSG habitat would be closed to fluid mineral leasing so it is assumed that geothermal power development would be less under this alternative, but existing leases could still be used for development.

12.7 FLUID MINERALS – SOUTH DAKOTA

12.7.1 Methodology

BLM mineral resource experts examined the RFD projections produced for the 2015 South Dakota GRSG RMP/EIS as well as development trends and development data available since that time and determined that the methodology and trends that were used to produce the projections for that document did not need modifications given the lack of significant changes in trends surrounding fluid mineral development in the state.

Assumptions and methodology used to develop the updated projections below are the same assumptions and methodology described in the RFD for the of the 2015 South Dakota Proposed LUPA/Final EIS (2015 South Dakota Plan). These were used, along with development data since 2015, to revise the projections in that document to fit the current planning timeline, and to analyze the new proposed Alternatives.

The original RFD for South Dakota was produced in 2009, however as part of the 2015 GRSG planning effort the BLM produced an updated analysis for the planning area titled "Oil and Gas Reasonably Foreseeable Development by Alternative for the South Dakota RMP April 2014", this document contains a summary table for the RFD projections adjusted for the management of the 2015 proposed alternatives. This table was used to analyze the proposed alternatives from the current planning effort. Alternative 1 would continue the management in the preferred Alternative (Alternative D) analyzed in the 2015 South Dakota Plan. Alternative 2 would apply similar management to Alternative 1, as would Alternatives 4 and 5 except that they would allow for more WEMs. Alternative 6 would apply the same management as Alternative 5 except that it would designate ACECs which would be closed to leasing, however no ACEC areas would be designated in South Dakota, so impacts would not differ from Alternative 5. Alternative 3 in the current planning effort proposes approximately the same management as was proposed under Alternative C in the 2015 SD Plan. The projected number of new wells spud (drilled), producing from the Alternatives C and D were carried forward to the updated summary table below. Projections of surface disturbance were similarly taken from the Alternatives C and D projections shown in Table 4-5 in the 2015 SD Plan.

Production projections were created using Table 6 in the 2009 South Dakota Reasonably Foreseeable Development Scenario. The proportion of BLM-administered federal minerals within the GRSG planning area out of the total RFD study area was used to scale the annual production projections for oil and gas provided in the RFD to only the GRSG decision area. The projections provided in the RFD were for the years 2010 through 2029 so the regression equations for the projections of annual production of oil and of gas were calculated and used to extend the projections through 2043, the end of the 20-year planning period of the current effort. Information in the "Oil and Gas Reasonably Foreseeable Development by Alternative for the SD RMP April 2014" Table 6 presented a baseline of expected production. Based on the number of wells projected under the action alternatives compared to the baseline it was determined that Alternatives 1, 2, 4, 5, 6, and the Proposed RMP Amendment represented an approximately 8 percent reduction in production compared to the baseline and that Alternative 3 represented an approximately 9 percent reduction in production compared to the baseline. The projections of oil and gas production within the South Dakota GRSG mineral decision area were reduced by these percentages to calculate the projected production under each of the current Alternatives during the planning period.

There is no ongoing development of geothermal resources on BLM administered surface or mineral estate within the planning area. No geothermal development is expected, and no projections of geothermal development were created.

12.7.2 Oil and Gas

Oil and Gas Development Potential

The table below shows the potential ranking of the RFD scenario area, however GRSG are only found in the portion of the RFD scenario area considered in the 2015 South Dakota RMP Revision.

Table 21: South Dakota Oil and Gas Development Potential in the RFD Scenario

Development Potential	Total Acres in RFD Study Area (All Ownerships)	Acres of BLM Administered Federal Minerals	Number of Townships	Percent of RFD Study Area (All Ownerships)
High	318,000	113,473	13.81	1.24
Moderate	476,000	80,459	20.65	1.86
Low	1,082,000	284,555	46.95	4.23

Development Potential	Total Acres in RFD Study Area (All Ownerships)	Acres of BLM Administered Federal Minerals	Number of Townships	Percent of RFD Study Area (All Ownerships)
Very Low	22,068,000	1,138,091	957.82	86.33
None	1,617,000	54,162	70.20	6.33

Source: 2015 South Dakota Proposed RMP/Final EIS, Table 4-2.

Projected Drilling Activity by Alternative

The projections for the number of wells drilled on Federal minerals in the decision area are shown in the table below. It is estimated that during the 20-year forecast period approximately 355 conventional wells and up to 71 coalbed methane wells would be drilled on non-BLM administered minerals in the state.

Table 22: Oil and Gas Well Projections for Federal Minerals (except federal minerals under US Forest Service surface) Over the 20-year Forecast Period

Well Type	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Alternative 5	Alternative 6	Proposed RMP Amendment
Number of oil and gas wells drilled	59.9	59.9	55.5	59.9	59.9	59.9	59.9
Producing oil and gas wells	53.6	53.6	50	53.6	53.6	53.6	53.6
Number of CBNG gas wells drilled	2.3	2.3	1.4	2.3	2.3	2.3	2.3
Producing CBNG gas wells	2	2	1.3	2	2	2	2

Source: Derived from the RFD Summary Table in the 2015 the South Dakota RMP RFD updated and adjusted to remove Forest Service decision area from the projections.
CBNG = Coal bed natural gas

Projected Surface Disturbance Due to Oil and Gas Activity by Alternative

Because of split estate (non-federal surface over federal minerals) and use of horizontal and directional drilling in the planning area most development of federal minerals will occur using wells that are not located on BLM-managed surface. The project disturbance from development of federal minerals regardless of surface ownership, and projected disturbance on BLM-administered surface are both shown in the table below.

Table 23: Potential Surface Disturbance from Oil and Gas and Coalbed Gas Drilling on BLM Land 2023-2043

Alternative	Total Wells Projected on BLM-Managed Federal Minerals	Short-Term Surface Disturbance on Federal Minerals (5.3 acres per well)	Long-Term Surface Disturbance on Federal Minerals (3.2 acres per well)	Percent of Federal Minerals Overlain by BLM Surface	Total Wells Projected for BLM-Managed Surface	Short-Term Surface Disturbance on BLM Surface (5.3 acres per well)	Long-Term Surface Disturbance on BLM Surface (3.2 acres per well)
Potential Surface Disturbance from Oil and Gas Drilling							
Alternative 3	55.5	294	178	16	9	48	29
Alternatives 1,2,4,5,6, and Proposed RMP Amendment	60	318	192	16	10	53	32
Potential Surface Disturbance from Coalbed Gas Drilling							
Alternative 3	1.5	8	4.8	16	0.2	1	0.6
Alternatives 1,2,4,5,6, and Proposed RMP Amendment	2.5	13.2	8	16	0.4	2	1.3

Source: Derived from Table 4-5 in the 2015 South Dakota Proposed RMP/Final EIS, adjusted to reflect changes in well projections.

Projected Production by Alternative

12.7.1 Geothermal

Currently, little geothermal development exists in South Dakota and no high temperature geothermal resources (greater than 302°F). have been identified in the state. The development that does exist is comprised of hot springs developed for recreational use (located in the town of Hot Springs) and a few local heating ventures in the western part of the state, none of which are on public land. The few hot springs are connected by faults to deeply buried reservoirs that contain geothermal water that moves upward along the fault zones to discharge at the land surface. See Chapter 3 of the 2015 South Dakota Proposed RMP/Final EIS for more information.

No development of geothermal resources is reasonably foreseeable or likely to occur on federal minerals in the planning area during the 20-year plan life.

12.8 Fluid Minerals – Utah

12.8.1 Methodology

BLM mineral resource experts examined the RFD projections produced for the 2015 Utah Greater Sage-Grouse LUPA and EIS, the 2019 Utah Greater Sage-Grouse Resource Management Plan Amendment (RMPA) and EIS, and the 2020 Utah Greater Sage-Grouse Supplemental EIS.[31] They also looked at development trends and production data available since that time. It was determined that because of the lack of significant changes in trends associated with fluid mineral development in the state, the methodology and trends that were used to produce projections of well development and production in the 2015 Utah Greater Sage-Grouse LUPA and EIS did not need modifications. The assumptions and methodology described in the Oil and Gas Reasonably Foreseeable Development Scenario for Greater Sage-Grouse Occupied Habitat in Utah Sub-Region which was included as Appendix R as part of the 2015 Utah Greater Sage-Grouse Proposed LUPA/Final EIS,[32] were used to develop the updated projections below. These assumptions and methodology were used to incorporate new development data and other relevant

[31] Call 1/26/2023 with Quincy Bahr, Mary Higgins, Kevin Kelley, Laura Opal, Teresa Snyder, Duane Spencer, and David Chase (BLM), and Francis Craig and Kate Krebs (EMPSi), and a call 2/15/2023 with Quincy Bahr and Angela Wadman (BLM) and Francis Craig and Kate Krebs (EMPSi).

[32] https://eplanning.blm.gov/public_projects/lup/103346/143763/177169/AppendixR_OilGasForeseeableDevelopment.pdf

information regarding oil and gas development since 2015 to revise the projections provided to the current planning period and to analyze the current proposed Alternatives. Data incorporated included the number, trend and location of wells drilled since 2013, production from federal mineral estate in the state, and information on federal leases in the decision area.

Well projections from the 2015 Utah Proposed Land Use Plan Amendment/Final Environmental Impact Statement Appendix R[33] Table R.1. The projections of new oil and gas wells in the 2015 plan were for a 15-year planning period and included federal minerals estate under Forest Service surface estate in GRSG habitat in the decision area. Because the current planning process is considering a 20-year timeline and federal minerals under Forest Service surface are not included in the current decision area the projections required adjustment. The total number of wells was from Table R.1 was reduced using a factor of approximately 0.786, the ratio of the change in the decision area total acreage of approximately 3,151,000 acres in 2023 from the approximately 4,008,600-acre total in the 2015 plan, to calculate the number of new wells projected in the new decision area (assuming equal distribution of the wells across the landscape). The resulting total number of projected new wells was divided by 15 to calculate the annual average number of new wells and then multiplied by 20 to calculate the total for the 20-year planning period of the current effort.

The Proposed RMP Amendment and Alternative C from the 2015 RFD were brought forward for use in projections for the current planning effort. These Alternatives were selected because they applied similar management to the current alternatives being considered. Alternative 3 would designate all GRSG habitat in the decision area as PHMA and close all PHMA to fluid mineral leasing, Alternative C from 2015 closed all GRSG habitat to fluid mineral leasing and used a similar decision area, so the rate of development from this alternative was extended forward. Alternative 1 would continue management from the 2015 Proposed RMP Amendment, PHMA would be open to leasing with NSO stipulations applied subject to WEMs and GHMA would be NSO around Leks. Alternative 2 would apply essentially the same management for fluid minerals as Alternative 1, and Alternatives 4 and 5 would also apply the same management but with minor changes to PHMA boundaries and the addition of WEMs. Alternative 6 would apply the same management as Alternative 5 but with the addition of NSO stipulations applied in ACECs, however most of the acreage that would be designated as ACECs under Alternative 6 already are closed to leasing or has existing NSO stipulations applied to protect resources other than GRSG, so this alternative would be minimally different from Alternative 5 in impacts on oil and gas development. The Proposed RMP Amendment would implement management most similar to Alternative 4, but with minor adjustments to habitat boundaries For all Alternatives other than Alternative 3 the management of fluid minerals would be sufficiently similar, and differences between them due to the allowances for WEMs under some alternatives, are not quantifiable because WEM decisions are made by the BLM Authorized Officer on a case-by-case basis and cannot be predicted in advance. As a result it is assumed that impacts on fluid mineral development would be approximately the same under Alternatives 1, 2, 4, 5, 6, and the Proposed RMP Amendment; and as a result the projections of oil and gas development from the Proposed RMP Amendment management from the 2015 Plan was extended forward for use in the analysis of impacts on oil and gas development under these alternatives for the current planning effort.

Production was determined using information from the 2015 Utah Proposed Land Use Plan Amendment/Final Environmental Impact Statement Appendix W[34] which details the expected average

[33] https://eplanning.blm.gov/public_projects/lup/103346/143763/177169/AppendixR_OilGasForeseeableDevelopment.pdf
[34] https://eplanning.blm.gov/public_projects/lup/103346/143763/177174/AppendixW_EconomicImpactAnalysisMethodology.pdf

production of oil and gas from new oil and gas wells as 200 thousand barrels of oil per oil well and 1,471 million cubic feet per gas well, over a 20 year well life. These production amounts were multiplied by the number of new oil and gas wells, respectively, over the 20-year planning period that were derived using the process described above. Surface disturbance was determined based on the total number of new wells in the 20-year planning period multiplied by the average disturbance per each feature type from Tables R.3 through R.7 in the 2015 Utah GRSG RMP/EIS Appendix R.

12.8.2 Oil and Gas

In order to show the oil and gas potential of the Utah GRSG planning area and allow for comparison of the development potential across the entire GRSG planning area, the assessment of oil and gas potential conducted under part of the Section 604 of the EPCA was intersected with GRSG HMAs in the current BLM decision area. The boundaries of GRSG habitat vary slightly between some of the alternatives so the Alternative 4 and 5 boundaries were used in the calculations shown in the table below. Very little of the planning area has a high development potential for either oil or gas.

Table 25: Oil and Gas Potential Ranking in the Decision Area

Utah Oil Potential by GRSG Habitat Type	Acres
PHMA	3,388,000
Low Potential	2,193,000
Moderate Potential	2,120,000
High Potential	0
GHMA	1,195,000
Low Potential	950,000
Moderate Potential	234,000
High Potential	11,000
Utah Gas Potential by GRSG Habitat type	
PHMA	2,193,000
Low Potential	2,031,000
Moderate Potential	162,000
High Potential	0
GHMA	1,195,000
Low Potential	848,000
Moderate Potential	347,000
High Potential	0

Source: EPCA 2018, BLM GIS 2018

Historical Drilling Trends

In Utah there are 94,000 acres of federal oil and gas leases in PHMA and 276,000 acres of federal leases in GHMA. Of these 89,000 acres in PHMA and 211,000 acres in GHMA are authorized, no matter which Alternative is chosen, these leases would be available for development in the future unless they expire, are relinquished, or are surrendered due to lack of diligent development. The remaining lease acres are listed under pending or interim status.

Since 2013 there have been 4,883 new wells spud (meaning drilling of the well was started) within Utah on both federal and non-federal lands, out of these approximately 90 percent were intended to be producing wells. Approximately 42% of the wells were directional wells, 14% were horizontal wells, and 44 percent

were vertical wells.[35] The trend in the number of well spuds per year is highly variable as shown in **Table 26**, below.

Table 26: Well Spuds by Year

Year	Well Spuds
2013	685
2014	1434
2015	402
2016	246
2017	501
2018	474
2019	303
2020	69
2021	292
2022	350
2023*	127

Source: IHS Enerdeq 2023, query date 7/24/2023
*2023 data complete through approximately mid-July 2023.

A total of 60 wells have been recorded as being drilled at a surface location in GRSG PHMA or GHMA federal surface in the decision area, but more wells producing federal minerals by horizontal or directional drilling from a non-federal surface location likely exist.

Projections produced as part of RFD scenarios typically aim to estimate levels of development that would be nearer the upper bound of expected development in order to allow for an analysis of impacts associated with fluid mineral development that avoids understating possible impacts. If actual levels of development have exceeded the projections it is an indicator that an update to the projections is needed, however if actual levels of development have not reached the level projected that is acceptable.

The projections below were based on the development scenarios created in the 2015 Utah GRSG RFD which were based on criteria including past and present oil and gas exploration, development and production activity within and near Greater Sage-Grouse occupied habitat, existing oil and gas leases, expressions of interest submitted by industry, exploration and development trends, locations of seismic surveys, existing infrastructure, and commodity prices.

The Carbon, Uintah, and Rich population areas (Carbon, Duchesne, Daggett, Rich, Summit and Uintah Counties) are the areas expected to have the majority of the oil and gas development that would potentially be impacted under the proposed Alternatives. The rest of the planning area is expected to have minimal to no future oil and gas development.

Because the planning effort for which this document has been developed is being conducted on a range-wide scale, projections were extended at the state-level scale rather than the population area scale that was used in previous planning.

Projections by Proposed Alternative

Proposed Alternatives 1 and 2 continue the management from the 2015 and 2018 GRSG planning efforts, respectively, in order to form the dual No Action Alternatives. Proposed Alternative 1 is the same as the Proposed RMP Amendment from the 2015 Utah GRSG LUPA and EIS, the projections assumptions which

[35] IHS Enerdeq 2023, query date 7/24/2023.

were defined in the 2015 Utah GRSG RFD continue to be used for Alternative 1. Proposed Alternative 2 is the same management Proposed RMP Amendment from the 2018 Utah GRSG RMPA and Final EIS. The analysis of the Proposed RMP Amendment in the 2018 Utah GRSG RMPA and Final EIS concluded that the projected number of wells under the 2018 Proposed RMP Amendment would be approximately the same as the number of wells that was projected under the 2015 Proposed RMP Amendment. Thus Alternatives 1 and 2 continue to result in the same proposed levels of oil and gas development. Proposed Alternative 3 would manage all GRSG habitat as PHMA and close all PHMA to fluid mineral leasing. This same management was proposed and analyzed as Alternative C in the 2015 Utah GRSG LUPA and EIS, and the 2015 Utah GRSG RFD. The analysis and assumptions from those documents are carried forward and used in the Analysis of Alternative 3 below. Proposed Alternatives 4 and 5 would manage PHMA as open to leasing with NSO stipulations, subject to waivers, exemptions, and modifications; and manage GHMA as open to leasing with NSO applied around leks only. This would result in effectively the same management of fluid minerals as under Alternative 1. As a result, the projections of future oil and gas development are the same across Alternatives 1, 2, 4, 5, and 6. Alternative 3 would result in reduced oil and gas development and production compared to the other Alternatives, due to the decision to close all PHMA to leasing, but because preexisting lease that are in the new PHMA boundary could still be developed, some new well drilling and production would continue under Alternative 3. The results are shown in the tables below.

Table 27: Projected Wells Drilled in GRSG Habitat 2023-2043

Alternative	Total Wells	Total Gas Wells	Total Oil Wells
1	3,111	2,436	676
2	3,111	2,436	676
3	2,775	2,159	616

12.8.3 Geothermal

Utah currently has three operational utility scale geothermal energy facilities with an installed capacity of 72.5MW. The Blundell Plant operated by PacifiCorp Energy consists of a 23MW flash steam plant and 10MW secondary recovery binary plant.[36] The Cove Fort Hybrid Plant operated by Enel Green Power is a geothermal-hydro hybrid power plant with a 25MW installed capacity.[37] The Thermo Geothermal Power Plant operated by Cyrq Energy consists of a 14.5MW binary process plant.[38] Both Blundell and Cove Fort plants have federal geothermal leases, but neither are located in GRSG HMAs. The Utah BLM has conducted geothermal lease sales during three of the past 4 years; 3045.19 acres were leased in 2023, 21,685.35 acres were leased in 2022, and 26,200.62 acres were leased in 2020.[39]

The table below shows geothermal electrical generation from federal geothermal leases in Utah from 2013 to 2023. This shows the trend over time which is tied to the amount of geothermal development.

Table 31: Utah Geothermal Electrical Generation from Federal Geothermal Leases in Kilowatt Hours

Year	Kilowatt Hours (kwh)*
2013	12,986,766
2014	132,080,000
2015	130,138,400
2016	150,003,437
2017	144,419,064
2018	132,624,724
2019	143,793,551
2020	112,090,593
2021	129,606,607
2022	128,459,411
Total	**1,216,202,553**

Source Office of Natural Resources Revenue 2023
*Some geothermal electrical generation in Utah is reported by ONNR in thousands of pounds (presumed to be of steam for a flash steam plant) which are not able to be converted to kilowatt hours generated without additional information, as a result that data is not included in these totals.

The 2015 Utah Greater Sage-Grouse LUPA and EIS contained the following as an RFD scenario for Geothermal:

> *It is possible that the existing Thermo Geothermal Field (currently, Cyrq-owned wells and generation plant) could expand in the future to include an adjacent 980-acre geothermal lease (UTU-087662) that is located within the Bald Hills Populated Area. Development of this lease is expected to comprise of drilling five geothermal energy production or produced fluid injection wells. With an estimated surface disturbance of 7 acres per well, including respective access roads and pipelines, a total of 35 acres of long-term surface disturbance would result.*

[36] https://geology.utah.gov/docs/emp/geothermal/ugwg/pdf/larsen0408.pdf
[37] https://www.enelgreenpower.com/our-projects/operating/cove-fort-hybrid-plant
[38] https://cyrqenergy.com/energy-plant-locations/#minersville-ut
[39] https://www.blm.gov/programs/energy-and-minerals/renewable-energy/geothermal-energy/regional-information/utah

It also noted that geothermal resources are plentiful in the middle and northwest portions of the state, although a lack of transmission capacity may hinder electricity development in the northwest corner.

The 2019 Utah Greater Sage-Grouse RMPA and EIS did not provide an updated RFD scenario for geothermal development, but did provide the following updates to geothermal information:

> *Between 2015 and 2017, the BLM has offered for lease 24,468 acres within HMAs. Lease stipulations apply as described in the leases as analyzed in the 2015 Final EIS.*
>
> *Six geothermal development permits have been approved and drilled on existing pads on existing leases. McGinness Hills Phase 3 Environmental Assessment authorized up to 42 acres of disturbance on existing leases, which will be offset according to the mitigation hierarchy.*

Since 2019 the BLM in Utah has conducted annual geothermal lease sales which can be viewed on the Utah Geothermal Energy webpage.[40]

Geothermal RFD scenario

Over the next 20 years both exploration and development activities could occur on existing and future geothermal leases. Test and thermal gradient wells typically disturb approximately 1 acre per well and production and injection wells for power generation typically disturb up to 7 acres. For the purposes of analysis, it is assumed that one 30MW geothermal power generation facility would be developed on BLM-managed lands in GRSG habitat over the next 20 years. This facility could disturb up to 6 acres for the drilling of up to 6 thermal gradient wells and would disturb up to 56 acres for the drilling of up to 8 production and injection wells. Construction of pipelines would disturb up to 14 acres, and an additional 10 acres could be disturbed for the construction of the generating plant. An assumed 10 miles of road would disturb approximately 50 acres, and 8 miles of power line would disturb approximately 40 acres. Because the existing issued geothermal leases are likely sufficient develop a facility of this size this could occur under any of the proposed Alternatives, but it would be less likely under Alternative 3 because the closure of all GRSG PHMA to new fluid mineral leasing would not allow new geothermal leases to be issued within GRSG HMAs under Alternative 3. The potential surface disturbance from the development of a new geothermal facility by Alternative are shown in the table below.

Table 32: Surface Disturbance Associated with the Development of a Geothermal Generating Facility

12.9 FLUID MINERALS – WYOMING

12.9.1 Methodology

Production projections from the 2015 document were derived from earlier Field Office RFDs which are largely no longer reflective of conditions due to changes in fluid mineral development technology and methods allowing for more production from fewer wells. Additionally, there was limited documentation of how older projections were adapted to the 2015 plan. As a result, new projections of oil and gas development were created using available data and information. Data on the production of oil and gas from federal mineral estate in Wyoming was pulled from the US Department of Interior (DOI) Office of Natural Resource Revenue (ONNR).[41] Data on total production of oil and gas in Wyoming was sourced from the Wyoming Oil and Gas Conservation Commission[42](WOGCC). An initial attempt to was made to develop projections of new wells and oil and gas production using the rate of new wells and historic production. However, in Cooperating Agency review the WOGCC raised concerns that due to changes in methods of development occurring within the period of historic data used, and the use of a linear approximation of well production decline, this method would underestimate the impacts on production of oil and gas that would result from reduction in the number of wells that was projected under some of the Alternatives. In coordination with WOGCC, BLM revised the methodology to incorporate well decline curves based on recent wells located in areas where future development is anticipated to occur. WOGCC obtained 20-year monthly production tables from industry partners for use in the analysis. The data used was for federal and mixed mineral production wells (wells which are producing from both federal and non-federal mineral estate). The State was bisected with the High Plains District (HP) on one side and the High Desert/Wind River and Bighorn Basin Districts (HD) on the other, with typical HP development being horizontal drilling and typical HD development being directional drilling. Due to improvements in drilling technology allowing for greater reach and production from a single well, the rate of well spuds in the planning area has decreased in recent years. The number of new wells that would be drilled each year over the 20-year planning period for Alternatives 1 and 2 which would continue existing management, was determined in the HP district by averaging the number of federal and mixed mineral wells with first production dates from 2015-2023, which is 145 wells per year. In the HD, the same methodology yielded an unreasonably high estimate of 174 wells per year due to the variability of the number of wells starting production each year. In recent years only 30-

[41] https://revenuedata.doi.gov/query-data?dataType=Production
[42] https://pipeline.wyo.gov/grouptrpMenu.cfm

70 wells have begun production each year. Based on the knowledge of current and expected future development the BLM and WOGCC concluded that an average of 100 wells per year for this area was representative of future conditions. Legacy production for both oil and gas was determined by fitting a decline curve to federal and mixed mineral production from 2015-2023 using only wells with a first production date prior to 2015 for each of the two areas. Total production was derived by the sum of annual production from legacy and new wells for each year.

While Coal Bed Natural Gas (CBNG) wells were seeing considerable interest in the period leading up to the development of the 2015 Greater Sage Grouse planning, since that time the economics have been unfavorable and developments have underperformed. In Wyoming no CBNG wells have been drilled in the planning area in the past 10 years and none are likely in the future. As a result, CBNG wells were removed from all projections and not projected forward into the future.

For updating well projections, Table 4-43[43] from the 2015 Wyoming Greater Sage-Grouse Land Use Plan (LUP) Amendment (2015 WY Plan), was used as a starting point. For Alternatives 1 and 2 which would continue current management, the rate of new wells with first production dates from 2015-2023, the years for which the current plan has been in effect, were used as described above. For Alternative 3, concerns were raised with how the Alternative C projections from the 2015 plan which proposed approximately the same management as Alternative 3 in the current plan did not fully account for the impacts associated with closing lands around existing undeveloped leases, the extent of possible development in areas with NSO stipulations, and ROW exclusions preventing the construction of new off-lease roads and pipelines required for development of existing undeveloped leases. Similar concerns were raised that Alternatives 4, 5, and 6 would need to account for areas where existing undeveloped leases surrounded by NSO would be stranded due to lack of access, and areas where NSO would be too far from locations where surface facilities could be placed to develop NSO by horizontal or directional drilling. To account for these concerns a process was developed in consultation with WOGCC staff. All proposed NSO areas in alternatives 3, 4, 5, 6, and the Proposed RMP Amendment were reverse buffered using GIS software to calculate the area within the average reach of directional or horizontal drilling technology, a 0.5 mile inward buffer distance from all edges of NSO areas was used for all areas of Wyoming, except for the Power River Basin (as delineated by the Wyoming State Geologic Survey[44]) which used a 2-mile inward buffer distance because the producing formations in the Powder River Basin are horizontal and continuous making them straightforward to develop using long reach horizontally drilling. In the remaining NSO area, and all areas that would be closed to new leasing, existing leases that were not recorded as held by production (existing leases held by production are assumed to already have needed off-lease infrastructure in place) were overlaid with data of existing roads and pipelines to determine how many of these leases would be able to be accessed using existing roads and production pipelines, and how many could be cut off from being able to access the lease to develop wells and transport produced oil and gas to market. It was assumed that the existing leases not held by production that intersected roads or pipelines would be able to use these corridors to construct additional off lease road or pipeline infrastructure if needed. The results of these steps created a layer which was termed "developable NSO" (NSO within the reach of horizontal or directional drilling, on an existing lease that is held by production, or on an existing lease not held by production but with road or pipeline access), this area was considered able to be developed in comparisons of the alternatives used to adjust projection. The remaining non-accessible NSO acreage, which would not be able to be developed because it would be out

[43] https://eplanning.blm.gov/public_projects/lup/103347/143798/177223/11_Chapter-4_Environmental-Consequences_FEIS_052115.pdf

[44] https://www.wsgs.wyo.gov/pubs-maps/gis.aspx see the "Wyoming Basins" dataset under the Geology tab.

of reach of horizontal or directional drilling, or unable to be accessed by a new ROW or using existing infrastructure was treated as effectively closed to leasing when comparing against the 2015 WY Plan projections.

An additional concern raised was that existing leases in areas that would be closed to leasing would not be considered for extension, and many leases in areas with new NSO stipulations applied would be likely to have reduced leasing interest making them less likely to be renewed. Information from US Government Accountability Office Report 21-138[45] which calculated that approximately 25 percent of existing leases get developed in their first term was used to account for this impact in adjusting projections by the Alternatives. Using data of acreage of existing leases by lease status and production status, the total acreage of existing leases not held by production in NSO and closed areas was reduced by 75 percent to reflect that only 25 percent of leases in these areas are likely to be developed. The results of this were factored into projection comparisons. The output map of proposed management under each alternative with developable NSO, non-developable NSO, and existing leases, was examined for 'islands' of minerals open to leasing fully surrounded by areas with NSO stipulations or closed to leasing, that are also managed as ROW exclusion and with no existing roads/or pipeline corridors, because these areas would not be able to be accessed for development, and any such areas were added to the projection comparisons as a reduction of the acres total. The results of this process were used to adjust projections of wells for Alternatives 3, 4, 5, 6, and the Proposed RMP Amendment. The end results determined that under Alternative 3 approximately 30% as many new wells would be drilled as under Alternatives 1 and 2; under Alternative 4 approximately 63% as many wells would be drilled as under Alternatives 1 and 2; under Alternative 5 approximately 94% as many wells would be drilled as under Alternatives 1 and 2; under Alternative 6 approximately 93% as many wells would be drilled as under Alternatives 1 and 2. Under the Proposed RMP Amendment, which applies similar management as under Alternative 5 but with an area within PHMA managed as limited exception which would be expected to result in slightly reduced development compared to Alternative 5, approximately 93% as many wells would be drilled as under Alternatives 1 and 2.

There is no ongoing development of geothermal resources on BLM administered surface or mineral estate within the planning area. No projections of geothermal development could be developed based on available information. However, given that the possibility of future geothermal development exists, an assumption was made regarding the possible size and disturbance associated with a theoretical geothermal development for the purpose of being able to analyze impacts associated with future geothermal development that might occur.

12.9.2 Oil and Gas

Oil and Gas Development Potential

The 2015 GRSG plan for Wyoming did not fully anticipate the level of changes associated with technological improvements in horizontal and directional drilling. Improvements in horizontal drilling and geosteering technology have allowed for a reduction in surface impacts associated with developing of oil and gas. Multiple horizontal wells can be located on a single well pad and extend well bores horizontally for two or more miles out in the productive formations under ideal conditions. This allows a reduction in surface infrastructure as a single well pad can produce from the same area that would previously have required numerous conventional or less advanced wells in the past. This allows for a reduction in disturbance associated with development infrastructure such as roads and pipelines which now only route to a small

[45] Oil and Gas: Onshore Competitive and Noncompetitive Lease Revenues. US Government Accountability Office. GAO-21-138. Published: November 19, 2020. https://www.gao.gov/products/gao-21-138

number of multi-well pads rather than numerous pads across the landscape. Improvements in this technology also allow for greater development of resources in areas where NSO stipulations are applied. In basins where the characteristics of the productive formations are well suited to this type of development, including the Powder River Basin in the Buffalo Field Office and Casper Field Office, this has become the dominate form of development resulting in a reduction of surface impacts per unit of production.

The Wyoming Oil and Gas Conservation Commission database repots a total of 6,455 unique well spuds of oil, gas, and coalbed methane production wells in both federal and non-federal minerals in the state from 2013 through 2023.[46]

The tables below show the EPCA development potential ranking for oil and gas in the proposed GRSG management areas from Alternative 4. The decision area is slightly different under the different Alternatives, so the Alternative 4 decision area was used for the following calculations, but the results are generally applicable across all the Alternatives, except Alternative 3 which would manage all HMA as PHMA. Not all areas were given a developmental potential rank, so the totals below do not add up to the entire decision area.

Table 33: EPCA Oil Development Potential within Alternative 4 Greater Sage-grouse HMAs in Wyoming

Total Projected Long-term Surface Disturbance from new well pads, roads, and pipelines (acres)	20,825	20,825	6,173	13,184	19,549	19,294	19,294

Source: updates to data from Table 4-43 in the 2015 Wyoming Greater Sage-Grouse Land Use Plan Amendment based on changes to management under the proposed Alternatives and changes to the decision area. Wyoming Oil and Gas Conservation Commission 2024.

*Coal Bed Natural Gas (CBNG) wells were seeing considerable interest in the period leading up to the development of the 2015 Greater Sage Grouse planning, however since that time the economics have been unfavorable and developments have underperformed, in Wyoming no CBNG wells have been drilled in the planning area in the past 10 years and none are likely in the future, CBNG wells were removed from the projections.

Projected Production by Alternative in the Decision Area

Under Alternatives 1 and 2 approximately 1,463,605,462 barrels of oil and 19,862 Bcf of natural gas are projected to be produced over the 20-year planning period of 2023-2043.

Under Alternative 3, approximately 801,162,784 barrels of oil and 12,807 Bcf of natural gas are projected to be produced over the 20-year planning period of 2023-2043.

Under Alternative 4, approximately 1,119,048,213 barrels of oil and 16,147 Bcf of natural gas are projected to be produced over the 20-year planning period of 2023-2043.

Under Alternative 5 approximately 1,405,252,186 barrels of oil and 19,254 Bcf of natural gas are projected to be produced over the 20-year planning period of 2023-2043.

Under Alternative 6 approximately 1,392,469,048 barrels of oil and 19,145 Bcf of natural gas are projected to be produced over the 20-year planning period of 2023-2043.

Under the Proposed RMP Amendment approximately 1,392,469,048 barrels of oil and 19,145 Bcf of natural gas are projected to be produced over the 20-year planning period of 2023-2043.

12.9.3 Geothermal

Geothermal Summary

There is no existing use of geothermal resources in Wyoming for power generation.[47] A study conducted for the Wyoming Energy Authority found that:[48]

> *Detailed literature review and analysis suggests Wyoming's geothermal resources are moderate to low temperatures, approximately 300 °F or less… and situated in localized regions throughout the state. Most of the geothermal resources are below 200 °F, below ideal electrical generation potential temperatures. There are no indications for a widespread high temperature geothermal resource that would provide significant geothermal value to Wyoming and the costs and risks of exploration for high-temperature resources are high; however, technologies to utilize lower temperature resources are likely to have the greatest economic impact and benefit for Wyoming, given the widespread indication of potential low temperature geothermal resources.*

There has been discussion of the possibility of converting oil and gas wells with favorable temperature characteristics that are no longer productive for oil and gas into use as geothermal wells, but this has not been commercially proven at this time.

Projected Geothermal Activity by Alternative

It is unlikely that any geothermal energy development would occur in GRSG habitat during the 20-year planning period. However, for the purposes of analysis it is assumed that under all Alternatives except Alternative 3 up to one 20MW geothermal power generation facility would be developed on BLM-managed lands in GRSG habitat over the next 20 years. A facility of this size could disturb up to 6 acres for the drilling of up to 6 thermal gradient wells and disturb up to 24 acres for the drilling of up to 8 production and injection wells. Construction of pipelines would disturb up to 14 acres, and an additional 10 acres could be disturbed for the construction of the generating plant. An assumed 10 miles of road would disturb approximately 50 acres, and 8 miles of power line would disturb approximately 40 acres. Under Alternative 3 it is assumed that no geothermal power development would occur on BLM-managed lands in GRSG habitat because under this alternative all GRSG habitat would be closed to fluid mineral leasing and there are no existing geothermal leases that could be developed.

12.10 WIND AND SOLAR ENERGY

12.10.1 Wind Energy

The following criteria and assumptions were used in the development of the RFD table (**Table 37**).

General Assumptions

- Alternative 1 - See **Table 38** of this document.
- Alternative 2 - No changes from Alternative 1. Nevada exceptions do not apply to the RFD Table. Utah avoidance criteria are not incorporated due to the fact that exact lek locations are not known.
- Alternative 3 - All habitat is managed as exclusion.
- Alternative 4 - PHMA is managed as exclusion areas for utility scale wind. IHMA is managed as avoidance areas for utility scale wind. All BLM managed surface (regardless of PHMA, GHMA, IHMA or non-HMA status) within 0.5 miles of PHMA are managed as utility scale wind avoidance areas. GHMA not included in the 0.5-mile buffer is managed as avoidance areas for utility scale wind projects.
- Alternative 5 - PHMA and IHMA would be avoidance areas for utility scale wind and solar energy development. GHMA is open with minimization measures.
- Alternative 6 - PHMA and IHMA would be avoidance areas for utility scale wind and solar energy development. GHMA is open with minimization measures.
- Proposed RMP Amendment – PHMA and PHMA with Limited Exception would be exclusion. GHMA would be open with applicable state specific minimization measures, and some states would manage GHMA as avoidance.
- Existing Avoidance and Exclusions include protections for other resources, Wind Mapper exclusion and avoidance datasets combined to create this data.

Data Gaps

- Colorado - No Linkage Management Area (LMA) in calculations, No GHMA Avoidance or Exclusion ROW data available
- Nevada and California - No other habit management area (OHMA) in calculations
- Montana - No restoration habitat management area (RHMA) or connectivity habitat management area (CHMA) in calculations
- North and South Dakota - There is no existing ROW avoidance or exclusion data.
- Utah - No GHMA Acres under Alternative 2

GIS Workflow

Wind energy development constraints (ROW avoidance, RMP wind energy avoidance, low wind energy potential, etc.) are all combined together to create a total constraints layer. The wind potential layer then has this master constraints layer erased from it to identify areas where there are no constraints to wind energy development (labeled as "potential developable wind resources"); this layer is combined with the master constraints layer to create a comprehensive wind development layer indicating constraints or lack of constraints and annual wind speeds for these areas. The comprehensive wind development layer is then clipped to BLM-managed surface across the 10 states included in the RFD. This layer is then combined with the GRSG Habitat Management Area layer(s) for each alternative (these have also been clipped to BLM surface). The output of this workflow is a layer that contains wind speed data for each GRSG HMA by alternative, and information on constraints to wind energy development that might impact the ability to develop wind energy in these areas.

Proposed RMP Amendment	**Data Inputs**
Total Acres of BLM Surface within HMAs	State Total
Land Unsuitable for Wind Resources	"Low Wind Resources"
ROW Exclusion Acres	Wind ROW exclusion - PHMA
ROW Avoidance Acres	Wind ROW avoidance – GHMA except in Idaho and Wyoming
Land Open for Development	State Total-Land Unsuitable-ROW Avoidance-ROW Exclusion

12.10.2 Solar Energy

The RFD for solar development is needed to guide analyses on the effect of alternatives being considered to solar power generation. The solar development RFD for this GRSG EIS incorporates and builds on the RFD from the 2023 Solar Programmatic EIS (PEIS), under concurrent development.

In order to evaluate the adequacy of lands available for application in meeting the nation's renewable energy goals, the Solar PEIS developed a projection of the land area and electricity-generating capacity (power) requirements for future solar energy development. For the 2024 Solar PEIS (BLM 2024), the amount of land area and power projected for utility-scale solar energy development in the 11-state Solar PEIS planning area through the year 2045 is used as the RFD. The year 2045 was used because it allows for approximately 20 years of development, which is the typical time period the BLM uses for programmatic planning. The amount of land area projected for utility-scale solar energy development in the Solar PEIS 11-state planning area is shown in **Table 3-10**.

The 2023 GRSG EIS and 2023 Solar PEIS each have five different alternatives and differing planning areas, and it is not known which alternative (or combination of alternatives) either process will ultimately select. Because of this, the GRSG EIS solar RFD is a qualitative analysis that builds off the RFD from the Solar PEIS RFD. The allocations associated with solar energy ROW development in the GRSG EIS are shown in **Table 40** below, organized by each state within the GRSG planning area and by GRSG habitat management area.

[1] – IHMA in Idaho, [2] – Greater than 20 Megawatt facilities, [3] – Based on Major ROW for Utility Corridors, [4] – Based on 2012 Solar EIS, [5] – Avoidance for solar in Lake, Harney, and Malheur Counties outside of SFAs, [6] – Avoidance in IHMA, [7] – Managed as exclusion without exception in areas designated as PHMA with limited exceptions.

The acres associated with these habitat management areas are shown in **Table 2-3** in **Chapter 2** of the GRSG EIS. Additional information on ROW management and criteria that define these management actions are in **Section 4.8**, Lands and Realty, of the EIS.

The basis for the Solar PEIS' state-level projections of solar energy development by 2045 in **Table 3-10** (**Appendix 9**) was the DOE's Solar Futures study (2021) and its companion report on environmental implications (Heath et al. 2022). The Solar PEIS concluded that in general, the lands available for solar energy development in each state, usually outside of GRSG PHMA, would be adequate to meet the RFD under each of the Solar PEIS alternatives. However, due to the uncertainties in estimating RFD values by state, both the Solar PEIS and GRSG EIS recommended that the total RFDs for BLM-administered lands across the planning area be considered the most likely development level across all alternatives and that the state-level breakdown of the RFDs be recognized as forecasted estimates that may shift among states. None of the management actions in the GRSG EIS alternatives would preclude achieving the RFD projections of acres needed to achieve the nation's renewable energy goals. The nature and type of effects of the GRSG RFDs are discussed in Section 4.8 of the GRSG EIS.

12.11 Air Pollutant and Greenhouse Gas Emission Calculation

Air pollutant and GHG emissions presented in **Chapter 4** of the Greater Sage-Grouse EIS focus on projected emissions from oil and gas development in Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming. Oil and gas development represents the main source of change in emissions causing impacts in the planning area. Quantitative estimates were scaled according to development projections from the decision area in each state relative to the projected emissions from all existing and reasonably foreseeable federal and nonfederal oil and gas development anticipated for these states through 2032. This section provides a summary of methodology for estimating emissions from projected oil and gas development under each alternative in Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming. Quantitative analysis for California, Oregon, and Idaho was not conducted due to limited production in the planning area which is not anticipated to result in major differences in impacts under the alternative, and due to a lack of projected emissions for these areas.

Emissions from oil and gas development and production over the next 20 years were estimated by scaling annual emissions relative to circa 2032 modeled emissions. BLM developed a photochemical modeling platform to assess the impacts of oil and gas development and coal production and other cumulative sources on air quality and air quality related values in BLM-administered lands for circa 2032 in the seven Intermountain West states including Colorado, Montana, New Mexico, South Dakota, Utah, and Wyoming (except the Newcastle Field Office; Ramboll 2023). Modeling results are presented in the BLM Western US Photochemical Air Quality Modeling For 2032 Emissions report (Ramboll 2023). The emissions inventory that supports the modeling effort, summarized by state in Appendix A of the report (Ramboll 2023, Appendix A, Tables 4 through 10) is presented in **Table 41**.

Table 41: Modeled oil and gas activity by mineral designation for each state: circa 2032

State	Well and Spud Count	Gas Production (Thousand Cubic Feet per Year)	Oil Production (Barrels per Year)
Colorado	70,759	1,651,000,000	224,000,000
Montana	15,723	63,000,000	51,000,000
North Dakota	42,200	1,707,000,000	829,000,000
South Dakota	330	2,000,000	2,000,000
Utah	20,362	254,000,000	32,000,000
Wyoming	50,726	1,850,000,000	143,000,000

Source: Ramboll 2023, Appendix A, Table 1

State-specific scaling factors were calculated for each activity type (well development, gas production, and oil production) by dividing the projected average annual RFD scenario (**Table 42**), by the circa 2032 modeled oil and gas activity level (**Table 41**). **Table 42** includes estimated scaling factors under each alternative by activity type and state. Circa 2032 emissions from well development, oil production, and gas production are shown in **Table 43**, **Table 44**, and **Table 45**, respectively. Emissions are calculated by multiplying the scaling factors in **Table 42** by the circa 2032 emissions (**Table 43**, **Table 44**, and **Table 45**) for each activity type (Ramboll 2023). Emissions from well development, oil production, and gas production are summed to provide total emissions from oil and gas activity under the Greater Sage-grouse LUPA in each state.

Table 42: Average Annual Oil and Gas Development and Scaling Factor by State

State	Average Annual Development based on RFD Scenario			Scaling Factor

RMP	resource management plan
ROW	right-of-way
US	United States
WHB HMA	wild horse and burro herd management area

Chapter 1. Introduction

The United States (US) Department of the Interior, Bureau of Land Management (BLM) revised land use plans in 2014 and 2015 in the states of California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming (2015 Sage-Grouse Plan Amendments) to provide for greater sage-grouse (GRSG) conservation on public lands. These amendments were accompanied by environmental impact statements (EISs) that included analyses of the impacts on social and economic conditions as a result of proposed management.

Subsequently, the BLM amended several of those revised plans in 2019 in California, Colorado, Idaho, Nevada, Oregon, Utah, and Wyoming (2019 Sage-Grouse Plan Amendments). On October 16, 2019, the US District Court for the District of Idaho preliminarily enjoined the BLM from implementing the 2019 Sage-Grouse Plan Amendments (Case No. 1:16-CV-83-BLW).

Since the completion of these 2019 Sage-Grouse Plan Amendments, the BLM has found that the 2019 Sage-Grouse Plan Amendments (and for Montana, North Dakota, and South Dakota, the 2015 Sage-Grouse Plan Amendments) are potentially inconsistent with new science and rapid changes affecting the BLM's management of the public lands, including the effects of climate change (such as drought, loss of habitat, more frequent wildland fires, and less riparian areas).

This socioeconomic baseline report serves as an update to the social and economic baseline conditions discussed in the 2015 Sage-Grouse Plan Amendment EISs. The report provides a discussion on updates and changes to key social and economic factors for the relevant states and counties, including population, employment, and income data and trends. In addition, updated information is provided for BLM resources and resource uses. An overview of nonmarket values associated with BLM resources and resources uses is also included, pulling from the 2015 discussion with updates for more recent literature. In addition, screening of environmental justice populations at the county level throughout the planning area has been updated based on 2022 BLM guidance (BLM 2022a). The economic data presented in this discussion include annual averages for the most recent reporting periods. These include the widespread economic effects of the recession brought about by the 2020 global COVID-19 pandemic, which might have impacted local and regional economies through short-term reductions in employment and industry output. The effects may be ongoing and may not be evenly distributed across industries.

The planning area includes portions of California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming, regardless of jurisdiction. Due to the nature of social, economic, and environmental justice conditions, the social and economic analysis utilizes a different study area than is used for other resources. Socioeconomic analysis areas and environmental justice analysis areas have been determined for each state to include counties that contain GRSG habitat on BLM-administered lands or minerals and within which social and economic conditions might reasonably be expected to change based on alternative management actions.

In the previous analysis associated with the 2015 GRSG planning effort, some subregions included additional "secondary" analysis areas to capture counties with important economic or social linkages to counties that do not contain habitat. For the current analysis, these "secondary" counties are not included in the analysis area; this is because these counties are generally more populous, and demographic data from these counties, if included, could overemphasize certain characteristics that are not necessarily representative of the area that would be most impacted by changes in BLM management decisions related to GRSG. An overview of counties included in each state analysis area is included in **Appendix A**, **Table A-1**.

Chapter 2. Demographic and Economic Baseline Conditions

Historical and projected population growth are important socioeconomic indicators because they aid in estimating future demand for public lands and potential shifts in demand for various land uses as well as they provide context for how land use planning changes could affect the local population, further informing associated economic analyses. Population changes since 2010 and anticipated population growth within the analysis area are described below.

This chapter also provides a summary of economic data, including trends and current conditions for per capita income and unemployment. The unemployment rate is a key indicator that measures the percentage of unemployed people to the number of people in the labor force, and it is often used as an indicator of economic health and conditions. A high unemployment rate is a concern for the general economy and likely indicates that many individuals in the labor force are unable to find employment, which could lead to in economic distress due to the lack of work and associated income (Bondarenko 2024). Changes in the unemployment rate from year to year provide a good picture of the relative health of the economy over time.

In addition, this chapter identifies and describes major economic sectors in the socioeconomic study area that can be affected by public land management actions. Those economic activities that rely on or could rely on BLM-administered lands, such as livestock grazing or energy development, are the most likely affected. Differences in major sectors since the publication of the 2015 Sage-Grouse Plan Amendment EISs are highlighted below; for all other sectors, please refer to the respective 2015 Sage-Grouse Plan Amendment EIS.

2.1 CALIFORNIA

The California analysis area includes two counties, Lassen County and Modoc County, which are in the northeast corner of California (see **Figure A-1** in **Appendix A**). These two counties were included in the analysis area because they include a large percentage of BLM-administered land in GRSG habitat management areas (HMAs). About 32 percent of all acres in Lassen County and 9 percent of all acres in Modoc County are in HMAs on BLM-administered surface acres. Of the BLM surface acres in Lassen County and Modoc County, over 90 percent are in HMAs for both counties.

California's population and economic growth have slowed in recent years, which is expected to continue in the near future. From 2010 to 2021, the population in California increased by about 2.8 million—a growth rate of about 7.7 percent, which was slightly less than the population growth rate for the US (8.5 percent; US Department of Commerce 2022). Over the next 20 years, the population in California is projected to remain stagnant, with a slight increase of about 1.7 percent (see **Table 2-1**; California Department of Finance 2023).

Table 2-1. California Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–21	% Change 2021–2040 (estimated)
Lassen County, California	35,081	32,949	21,772	-6.1	-33.9
Modoc County, California	9,605	8,723	7,463	-9.2	-14.4
California	36,637,290	39,455,353	40,106,449	7.7	1.7

Sources: California Department of Finance 2023; US Department of Commerce 2022

Employment within California from 2010 to 2021 grew by almost 4.3 million jobs, which was an increase of about 22 percent. The largest magnitude of employment increases occurred in the health care and social assistance; transportation and warehousing; and professional, scientific, and technical services industries (see **Table A-2** in **Appendix A**). The historical increase in employment is consistent with the steady reduction in the unemployment rate in California from 6.3 percent in 2015 to 4.1 percent in 2019. However, the unemployment rate across California more than doubled in 2020 due to large number of layoffs that occurred during the global COVID-19 pandemic (see **Table 2-2**; BLS 2023). This increase in the unemployment rate could contribute to the projected population stagnation in California, as workers move to other locations in search of employment. On the other hand, per capita income in 2021 was higher than the US average per capita income; also, the real total earnings in California increased from 2010 to 2021 by about 42 percent (BEA 2021a, 2021b).

Table 2-2. California Analysis Area Unemployment Rate

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Lassen County	7.3	7.0	5.5	4.9	4.7	7.4	5.9
Modoc County	8.6	7.8	8.2	7.6	7.2	8.9	7.1
California	6.3	5.5	4.8	4.3	4.1	10.2	7.3

Source: BLS 2023

In contrast to the state of California, the population in the California analysis area where the HMAs largely exist decreased, with Lassen County experiencing a population loss of 6.1 percent and Modoc County a loss of 9.2 percent between 2010 and 2021 (see **Table 2-1**; US Department of Commerce 2022). Population in the California analysis area counties is anticipated to continue to decline through 2040 with a loss of 33.9 percent in Lassen County and 14.4 percent in Modoc County, compared with a 1.7 percent population gain in the state of California (see **Table 2-1**; California Department of Finance 2023).

Lassen County is the most populus county in the California analysis area, with a population of 32,949 people. Modoc County has a population of 8,723, representing the lowest populus county in the California analysis area. This suggests that Lassen County has a larger economy than Modoc County, and more residents and employment are in Lassen County. Lassen County also has more BLM-administered surface and subsurface acres in GRSG HMAs, which means the population in this county could face more impacts from BLM decisions related to GRSG.

The population reduction in the California analysis area could be due to limited or decreasing employment opportunities, which could influence residents to move to more populated areas in California or out of state. This is especially true in Lassen County. For example, in 2023, a prison closed in Lassen County, which caused many people employed at the prison to lose their jobs and search for employment elsewhere

(Castleman 2023). From 2010 to 2021, total employment in Lassen County decreased by 8 percent (a reduction in over 1,000 jobs). Total employment in Modoc County was largely stagnant, with a slight increase of about 1 percent (about 60 jobs). Government and government enterprises represented the industry with the highest employment in both Lassen and Modoc Counties, with 49.8 percent and 27.5 percent of total jobs, respectively, in 2021. However, from 2010 to 2021, employment in the government and government enterprises industry decreased by almost 800 jobs in Lassen County and 120 jobs in Modoc County. This was the largest magnitude reduction in employment across all industries (see **Table A-2** in **Appendix A;** BEA 2021a, 2021b). From 2015 to 2019, the average annual unemployment rates in Lassen County and Modoc County were greater than the average annual unemployment rate in California, which highlights the more limited employment opportunities in these counties compared with other areas of California. During the 2020 COVID-19 pandemic, the unemployment rates in Lassen County and Modoc County increased to similar, but slightly lower, rates than the state of California (see **Table 2-2**; BLS 2023).

The average labor income in Lassen and Modoc Counties could also play a role in encouraging workers to seek jobs elsewhere. In 2021, the average earnings per employee were about $71,000 in Lassen County and $57,000 in Modoc County, which were lower than per capita income across California by about $17,000 and $31,000, respectively. This is partially due to the concentration of employment in three industries in Lassen and Modoc Counties that had lower earnings per employee than the same industries in California (government and government enterprises, retail trade, and other services). From 2010 to 2021, real per capital income increased in both Lassen County and Modoc County, by over $5,000 and almost $11,000, respectively, accounting for inflation (which was a 15 percent and 24 percent increase for Lassen County and Modoc County, respectively); however, the increases in magnitude and percentage of per capita income were less than the increase in per capita income for the state of California, which increased by over $22,000 (an increase of about 41 percent over the decade; see **Table A-2** and **Table A-3** in **Appendix A**; BEA 2021a, 2021b).

In 2021, farming in California only represented 1 percent of total employment and less than 1 percent of total earnings.[1] However, in the California analysis area, farming plays a more important role in the local economies. In Modoc County, farming was the second-largest industry for employment and labor earnings (only falling below the government and government enterprises industry), with about 12.8 percent of total jobs and 19.4 percent of total earnings coming from the farming industry. In Lassen County, farming was the fourth-largest industry for employment (falling below government and government enterprises, retail trade, and other services), with 4.5 percent of total employment coming from the farming industry. The farming industry was the third-largest contributor of total labor earnings in Lassen County (only falling below government and government enterprises and retail trade industries), with about 3.9 percent of total labor earnings coming from farming (see **Table A-2** and **Table A-3** in **Appendix A**; BEA 2021a, 2021b). This suggests that the local economies in the California analysis area could be susceptible to impacts on farming, including potential changes to livestock grazing and ranching (see EIS **Section 3.1.7**, Livestock Grazing, for more details on grazing and ranching use on BLM-administered lands in the California analysis area).

Employment in the mining industry (including quarrying and oil and gas extraction) remained low from 2010 to 2021 in both Lassen and Modoc Counties, as did labor income from the mining industry, with less than 1 percent of the total jobs and labor income coming from this industry (see **Table A-2** and **Table**

[1] Farming employment includes the labor of farm proprietors, but not unpaid family labor; therefore, the statistics presented in this report do not include the total value of farming through employment.

A-3 in **Appendix A**; BEA 2021a, 2021b). This suggests that the economies in these two counties do not depend on the mining industry, and these economies would likely not be sensitive to changes in mineral development.

The retail trade industry is another important industry within the California analysis area. In Lassen County, in 2021, the retail trade industry contributed about 9.4 percent of total employment and about 5.3 of nonfarm earnings. In Modoc County, retail trade contributed 8.4 percent of total employment as well as 5.8 percent of nonfarm earnings in 2021(see **Table A-2** and **Table A-3** in **Appendix A**; BEA 2021a, 2021b).

Statistics included in the 2015 Sage-Grouse Plan Amendment EIS, which included data from 2010, showed similar trends in employment and labor income across industries. This suggests that the economic significance of major industries in the California analysis area have remained fairly consistent over the past decade.

2.2 COLORADO

The Colorado analysis area includes eight counties clustered in the northwest corner of Colorado (see **Figure A-2** in **Appendix A**). The counties with the largest amount of BLM-administered surface acres in GRSG HMAs include Moffat County, Rio Blanco County, and Jackson County, with about 1.1 million acres, 206,000 acres, and 141,000 acres of BLM-administered surface lands in GRSG HMAs, respectively. Additionally, the acres in GRSG HMAs made up over 70 percent of BLM-administered surface lands in Moffat County and Jackson County.

From 2010 to 2021, the population in Colorado increased by about 765,000 people, which is an increase of about 15.1 percent (see **Table 2-3**). This increase is projected to continue over the next 20 years, with the population increase estimated to be about 21.6 percent. One reason for the increase in population is that Colorado has shown steady economic growth and has numerous job opportunities (Grand Park Colorado 2019). From 2010 to 2021, employment in Colorado grew by about 800,000 jobs, which was an increase of about 25.5 percent. The largest magnitude of employment increases occurred in the professional, scientific, and technical services; transportation and warehousing; and construction industries (see **Table A-4 (Part 1)** and **Table A-4 (Part 2)** in **Appendix A**).

Table 2-3. Colorado Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040
Eagle County	52,057	55,701	69,698	7.0	25.1
Garfield County	56,150	62,150	86,470	10.7	39.1
Grand County	14,790	15,838	18,427	7.1	16.3
Jackson County	1,387	1,357	1,244	-2.2	-8.3
Mesa County	147,155	157,323	202,388	6.9	28.6
Moffat County	13,806	13,160	12,621	-4.7	-4.1
Rio Blanco County	6,617	6,461	5,908	-2.4	-8.6
Routt County	23,439	25,098	33,472	7.1	33.4
Colorado	5,050,332	5,814,707	7,073,418	15.1	21.6

Sources: Colorado State Demography Office 2022; US Department of Commerce 2022

The unemployment rate in Colorado was stable through 2019, with a slight decrease from 3.7 percent in 2015 to 2.6 percent in 2019. Consistent with the rest of the country, the unemployment rate across Colorado increased sharply in 2020 due to a large number of layoffs that occurred during the global COVID-

19 pandemic (see **Table 2-4**; BLS 2023). In addition to the stability and increase in the job market in Colorado, per capita income in 2021 was higher than the US average per capita income. Real total earnings in Colorado increased from 2010 to 2021 by about 38 percent, which could have factored into individuals' decisions to move to Colorado (BEA 2021a, 2021b).

Table 2-4. Colorado Analysis Area Unemployment Rate

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Eagle County	3.0	2.6	2.2	2.5	2.1	9.0	4.4
Garfield County	4.0	3.3	2.7	2.9	2.6	6.5	4.7
Grand County	3.1	2.6	2.1	2.5	2.0	8.0	4.2
Jackson County	3.6	2.6	1.7	2.5	2.2	4.0	3.3
Mesa County	5.3	5.1	3.0	3.7	3.2	7.1	5.7
Moffatt County	4.4	3.8	3.1	3.4	3.2	5.8	4.8
Rio Blanco County	5.1	4.8	3.6	3.9	3.5	5.2	5.5
Routt County	3.1	2.5	2.2	2.5	2.1	7.5	4.2
State of Colorado	**3.7**	**3.1**	**2.6**	**3.0**	**2.6**	**6.9**	**5.4**

Source: BLS 2023

Across the Colorado analysis area, the population increased by about 22,000 people from 2010 to 2021, which is an increase of about 6.9 percent; this is a slightly smaller growth rate than for the whole state of Colorado. However, the historical population growth in the Colorado analysis area varied by county. The county with the largest increase in population in the Colorado analysis area was Mesa County, with an increase of about 10,000 people (Mesa County is also the most populous county in the Colorado analysis area, with a population of 157,323 people; see **Table 2-3**). The county with the largest magnitude decrease in population from 2010 to 2021 in the Colorado analysis area was Moffat County, with a decrease of about 600 people (see **Table 2-3**; US Department of Commerce 2022). The population growth rates in the Colorado analysis area counties are anticipated to continue through 2040, with an increase in population in the counties that saw historical growth and a decrease in population in the counties that saw historical population decline (see **Table 2-3**; Colorado State Demography Office 2022).

Similar to the state of Colorado as a whole, the change in population in the Colorado analysis area counties is likely correlated with the number of job opportunities. From 2010 to 2021, Mesa County, which had the largest increase in population, had the largest increase in employment across the analysis area, with almost 10,000 additional jobs. This increase in total employment was largely driven by an increase in employment in the health care and social assistance industry, which accounts for the largest percentage of total employees in Mesa County at 13.7 percent. Moffatt County, which had the largest percentage decrease in population, had the largest decrease in employment, with a decrease of almost 600 jobs (see **Table A-4 (Part 1)** and **Table A-4 (Part 2)** in **Appendix A**). The decrease in total employment in Moffatt County was largely due to a decrease in employment in the government and government enterprises industry and the mining industry (including quarrying and oil and gas extraction); these industries represent two important industries in the county, with about 15.1 percent and 5.7 percent of total employment, respectively.

In contrast to total employment trends, which followed the population for most of the analysis area, the average annual unemployment rates followed similar trends across counties in the analysis area (see **Table 2-4**; BLS 2023). All counties in the analysis area had lower unemployment rates in 2019 than in 2015. The unemployment rates in the Colorado analysis area increased in 2020 during the COVID-19 pandemic. In all counties in the Colorado analysis area, except for Rio Blanco County, the unemployment rates decreased from 2020 to 2021 (in Rio Blanco County, the unemployment rate did not increase as much as other counties

from 2019 to 2020; therefore, the increase in the unemployment rate from 2020 to 2021 could have been due to delayed impacts from COVID-19). This difference in trends between the total employment and average annual unemployment rate is likely due to an increase in the number of individuals returning to the work force as the number of jobs increase.

In addition to the number of job opportunities attracting people to move to the Colorado analysis area, higher per capita income could also encourage population growth in the Colorado analysis area counties, and lower per capita income could lead to population decline. In 2021, Moffat County, which saw the highest decrease in population and employment from 2010 to 2021, had the lowest reported per capita income across all industries at about $49,000. Routt County and Eagle County had the highest per capita income across all counties in the analysis area, with per capita income amounts of about $98,000 and $97,000, respectively. Both counties saw growth in population, employment, and real per capita income from 2010 to 2021.

The per capita income for Routt County and Eagle County was higher than the per capita income for the state of Colorado, which had a per capita income of about $71,000 in 2021. In Routt County, the key industries with the highest average earnings per employee (which is calculated by dividing total earnings by the total number of employees; see **Table A-4 (Part 1)**, **Table A-4 (Part 2)**, **Table A-5 (Part 1)**, and **Table A-5 (Part 2)** in **Appendix A**; BEA 2021a, 2021b) were utilities, mining, and wholesale trade. In Eagle County, the industries with the highest average earnings per employee were utilities, wholesale trade, and health care and social assistance.

In 2021, the farming industry in Colorado only represented about 1 percent of total employment and less than 1 percent of total earnings.[2] However, in the Colorado analysis area, farming plays a more important role, especially in Jackson, Rio Blanco, and Moffatt Counties. In Jackson County, farming was the second-largest industry for employment (only falling below the government and government enterprises industry) and the largest industry for labor earnings, with about 15.1 percent of total jobs and 16.4 percent of total earnings coming from the farming industry. In Rio Blanco County, farming was the third-largest industry for employment, representing about 9.8 percent of total employment (behind government and government enterprises and mining); however, farming only accounted for about 2 percent of total earnings in the county. In Moffatt County, farming was the fourth-largest industry for employment, representing about 8.4 percent of total jobs (behind government and government enterprises, retail trade, and health care and social assistance); however, similar to Rio Blanco County, farming only accounted for about 2.1 percent of total earnings (see **Table A-4 (Part 1)**, **Table A-4 (Part 2)**, **Table A-5 (Part 1)**, and **Table A-5 (Part 2)** in **Appendix A**; BEA 2021a, 2021b).

These three counties have a high percentage of BLM-administered lands in GRSG HMAs. Therefore, these counties could be susceptible to impacts on farming, including potential changes to livestock grazing and ranching from BLM decisions on GRSG HMAs (see **Section 3.1.7**, Livestock Grazing, for more details on grazing and ranching use on BLM-administered lands in the Colorado analysis area). Additionally, from 2010 to 2021, there were declines in total population for all three counties as well as declines in total employment for Moffat County and Rio Blanco County. This suggests that these counties are more sensitive to changes in economic conditions than the rest of the Colorado analysis area.

[2] Farming employment includes the labor of farm proprietors, but not unpaid family labor; therefore, the statistics presented in this report do not include the total value of farming through employment.

In 2021, the mining industry (including quarrying and oil and gas extraction) accounted for less than 5 percent of total employment and less than 5 percent of labor earnings in each county in the Colorado analysis area, except for Rio Blanco and Moffatt Counties. In Rio Blanco County, mining was the second-largest industry for employment and labor earnings, representing about 12.3 percent of total jobs and 28.2 percent of total earnings (behind government and government enterprises). In Moffat County, mining was the eighth-largest industry for employment and represented about 5.7 percent of total jobs in the county. However, mining accounted for 13.4 percent total labor earnings, which was the second-largest industry in Moffat County (see **Table A-4 (Part 1)**, **Table A-4 (Part 2)**, **Table A-5 (Part 1)**, and **Table A-5 (Part 2)** in **Appendix A**; BEA 2021a, 2021b). As mentioned above, Moffat and Rio Blanco Counties had a decline in population and employment. This suggests that the economies rely on the mining industry, and they are likely sensitive to changes in mineral development that could impact economic conditions.

Other top industries within the Colorado analysis area include the government and government enterprises industry, recreation and tourism-related industries (such as the accommodation and food industry and retail trade industry), construction industry, healthcare and social assistance industry, and real estate and rental and leasing industry. The percentages of total employment from these industries across the Colorado analysis area have not changed substantially from the data included in the 2015 Sage-Grouse Plan Amendment EIS, which included data from 2010. This suggests that the economic significance of major industries in the Colorado analysis area have remained consistent over the past decade.

2.3 IDAHO

The Idaho analysis area includes 27 counties spread across most of southern and eastern Idaho (see **Figure A-3** in **Appendix A**). Owyhee County and Custer County have the largest amount of BLM-administered surface acres in GRSG HMAs, with about 3.1 million acres and 769,000 acres of BLM-administered surface lands in GRSG HMAs, respectively. Owyhee County is on Idaho's southwest border, and Custer County is in the center of Idaho.

From 2010 to 2021, the population in Idaho increased by 18.7 percent, or 284,820 people (**Table 2-5**). This population increase is largely due to Idaho's strong economy, low unemployment rate, and job growth, in addition to the lower cost of living and social considerations of living in Idaho (Callison 2023). Idaho is forecasted to grow from 2021 to 2032 by about 23.2 percent (Idaho Department of Labor 2023). From 2010 to 2021, employment in Idaho grew by about 256,000 jobs, which was an increase of about 30 percent. The largest magnitude of employment increases occurred in the construction, health care and social assistance, accommodation and food services, and construction industries (see **Table A-6** in **Appendix A**).

Table 2-5. Idaho Analysis Area Population

Geographic Area	2010	2021	2032[1]	% Change 2010–2021	% Change 2021–2032
Adams County	3,924	4,321	5,480	9.6	26.8
Bear Lake County	6,026	6,327	7,432	5.0	17.5
Bingham County	44,496	47,540	53,968	6.8	13.5
Blaine County	21,329	23,868	27,077	11.9	13.4
Bonneville County	100,213	121,771	150,622	8.5	23.7
Butte County	2,842	2,573	2,543	-9.5	-1.2
Camas County	1,216	1,044	1,179	-14.1	12.9
Caribou County	6,900	7,003	7,577	1.5	8.2
Cassia County	22,109	24,469	27,732	10.7	13.3
Clark County	857	839	729	-2.1	-13.1

Geographic Area	2010	2021	2032[1]	% Change 2010–2021	% Change 2021–2032
Custer County	4,277	4,273	4,475	-0.1	4.7
Elmore County	26,669	28,396	31,170	6.5	9.8
Fremont County	13,062	13,370	14,631	2.4	9.4
Gem County	16,778	18,692	23,538	11.4	25.9
Gooding County	15,140	15,422	15,981	1.9	3.6
Jefferson County	24,523	30,427	39,671	24.1	30.4
Jerome County	21,282	24,081	27,639	13.2	14.8
Lemhi County	7,861	7,948	8,442	1.1	6.2
Lincoln County	5,021	5,184	5,360	3.2	3.4
Madison County	36,413	50,979	75,961	40.0	49.0
Minidoka County	19,524	21,393	24,229	9.6	13.3
Oneida County	4,212	4,514	5,140	7.2	13.9
Owyhee County	11,389	11,815	13,600	3.7	15.1
Payette County	22,451	24,928	30,493	11.0	22.3
Power County	7,633	7,854	8,169	2.9	4.0
Twin Falls County	74,929	89,128	107,446	18.9	20.6
Washington County	10,105	10,425	11,904	3.2	14.2
State of Idaho	1,526,797	1,811,617	2,232,538	18.7	23.2

Sources: Idaho Department of Labor 2023; US Department of Commerce 2022
Forecasted population data were only forecasted through 2032 for Idaho.
The total for all counties in southwestern Idaho also includes data for Ada, Boise, Canyon, and Valley Counties, which are not included in the Idaho analysis area.
All counties in south-central Idaho are in the Idaho analysis area.
The total for all counties in southeastern Idaho also includes data for Bannock and Franklin Counties, which are not included in the Idaho analysis area.
The total for all counties in eastern Idaho also includes data for Teton County, which is not included in the Idaho analysis area.

The unemployment rate in Idaho was stable through 2019, with a slight decrease from 3.9 percent in 2015 to 3.0 percent in 2019. Consistent with the rest of the country, the unemployment rate across Idaho increased sharply in 2020 due to a large number of layoffs that occurred during the global COVID-19 pandemic (see **Table 2-6**; BLS 2023). Real total earnings in Idaho increased from 2010 to 2021 by about 48 percent; however, per capita income in 2021 was slightly lower than the US average per capita income, which suggests that Idaho's population increase was not largely motivated by higher incomes (BEA 2021a, 2021b).

Table 2-6. Idaho Analysis Area Unemployment Rate

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Adams County	7.1	6.7	5.7	5.5	6.9	9.6	6.6

Source: BLS 2023

Across the Idaho analysis area, the population increased by about 77,000 people from 2010 to 2021, which is an increase of about 15 percent; this is a smaller growth rate than for the whole state of Idaho. However, the historical population growth in the Idaho analysis area varied by county. The county with the largest increase in population in the Idaho analysis area was Bonneville County, with an increase of about 22,000 people (Bonneville County is also the most populous county in the Idaho analysis area, with a population of about 122,000 people; see **Table 2-5**). The population in Bonneville County is expected to continue to increase, with a projected population growth of about 23.7 percent from 2021 to 2032 (Idaho Department of Labor 2023; see **Table 2-5**). The county with the largest decrease in population from 2010 to 2021 in the Idaho analysis area was Butte County, with a decrease of about 300 people (see **Table 2-5**; US Department of Commerce 2022). The population in Butte County is expected decrease slightly through 2032, with a forecasted population decline of about 1.2 percent (Idaho Department of Labor 2023; see **Table 2-5**).

Similar to the state of Idaho as a whole, the change in population in the Idaho analysis area counties is likely correlated with the number of job opportunities. From 2010 to 2021, Bonneville County, which had the largest increase in population, had the largest increase in employment across the analysis area, with almost 21,000 additional jobs. This increase in total employment was largely driven by an increase in employment in the health care and social assistance industry, which accounts for the largest percentage of total employees in Bonneville County at 15.6 percent.

The only county in the Idaho analysis area that experienced a decrease in employment was Clark County, with a decrease of 26 jobs (5 percent; see **Table A-6** in **Appendix A**). Clark County also experienced a decrease in population over the same time period. This decrease in total employment was largely due to a decrease in employment in the government and government enterprises industry, which currently represents the largest percentage of total employment in the county at 25.3 percent. Clark County was also the only county in the analysis area to have an increase in the unemployment rate from 2015 to 2019 (see **Table 2-6**; BLS 2023); all other counties in the analysis area had lower unemployment rates in 2019 than in 2015. The unemployment rates in all counties in the Idaho analysis area increased in 2020 during the COVID-19 pandemic. In all counties in the analysis area, with the exception of Butte County, the unemployment rates decreased from 2020 to 2021.

In addition to the number of job opportunities attracting people to move to the Idaho analysis area, labor income plays a part in encouraging population growth or decline. In 2021, Blaine County reported the highest per capita income across the Idaho analysis area at almost $135,000 (over $82,000 more than the per capita income for the state of Idaho and almost $71,000 more than the per capita income for the US; BEA 2021a, 2021b). Blaine County also reported a high population growth rate of 11.9 percent from 2010 to 2019.

The county that had the lowest per capita income in the Idaho analysis area was Madison County, with per capita income of $26,000. Madison County had the largest percentage increase in population from 2010 to 2021. This suggests that there were other factors that drove people to move to Madison County besides higher income. For example, Madison County is home to Brigham Young University-Idaho, which attracts students and young professionals to the area.

In 2021, the farming industry played a key role in the economy across Idaho, especially in the analysis area counties. In Idaho, farming represented about 3.5 percent of total employment and 2.7 percent of total earnings.[3] In the Idaho analysis area, the farming industry made up over 9 percent of employment in 21 of the 27 counties in the Idaho analysis area. Farming was the largest industry for employment in Camas, Gooding, Lincoln, and Owyhee Counties, with about 22.7 percent, 22.6 percent, 24.1 percent, and 23.9 percent of total jobs coming from farming, respectively. Farm earnings made up less of a percentage of the total earnings in most of the counties in the analysis area, but they still made up over 8 percent in 11 counties in the analysis area.

Owyhee County is one of the counties with the most BLM-administered lands in GRSG HMAs; therefore, it could be more susceptible to impacts on farming, including potential changes to livestock grazing and ranching from BLM decisions on GRSG HMAs (see **Section 3.1.7**, Livestock Grazing, for more details on grazing and ranching use on BLM-administered lands in the Idaho analysis area).

In 2021, the mining industry (including quarrying and oil and gas extraction) accounted for less than 1 percent of total employment for each county in the Idaho analysis area, except for Caribou County. In Caribou County, mining was the third-largest industry for employment and second-largest industry for labor earnings, representing about 12.3 percent of total jobs and 20.9 percent of total earnings (see **Table A-7** in **Appendix A**; BEA 2021a, 2021b). Furthermore, mining employment in Caribou County increased slightly from 2010 to 2021 by about 300 jobs.

Recreation and tourism-related industries, such as the accommodation and food industry and retail trade industry, are other important industries within the Idaho analysis area, especially in Bear Lake, Bonneville, Cassia, Gem, Lemhi, Madison, Oneida, and Twin Falls Counties, where they made up 10 percent or more of the total employment in each county. The percentages of total employment and earnings from these key industries across the Idaho analysis area have not changed substantially from the data included in the 2015 Sage-Grouse Plan Amendment EIS, which included data from 2010. This suggests that the economic significance of major industries in the Idaho analysis area have remained consistent over the past decade.

2.4 MONTANA

The 26 counties included in the Montana analysis area are mostly clustered in the eastern and central portions of the state. Madison and Beaverhead Counties (which were previously included in the 2015 Sage-Grouse Plan Amendment EIS for Idaho) are in Montana's southwest corner (see **Figure A-4** in

[3] Farming employment includes the labor of farm proprietors, but not unpaid family labor; therefore, the statistics presented in this report do not include the total value of farming through employment.

Appendix A). The counties with the largest amount of BLM-administered surface acres in GRSG HMAs are Valley County and Phillips County in northern Montana and Carter County in Montana's southeast corner, with about 965,000 acres, 855,000 acres, and 486,000 acres of BLM-administered surface lands in GRSG HMAs, respectively.

From 2010 to 2021, the population in Montana increased by 10.3 percent, or 101,727 people (**Table 2-7**). The state population is projected to increase by another 12.5 percent by 2040. Statewide, government and government-based enterprises, health care and social assistance, and retail trade represent the largest employment industries, with 13.5 percent, 11.2 percent, and 10.9 percent, respectively. Both the health care and social assistance and retail trade industries increased in the number of jobs from 2010 to 2021, which could have contributed to the statewide population growth. Trends indicate an economic expansion is occurring through the state due to increased levels of available employment opportunities, higher population numbers, and a growing service-based economy.

Table 2-7. Montana Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040

* Beaverhead and Madison Counties are managed under Idaho plans but are included in the Montana analysis area population table.

Within the Montana analysis area, the counties with the largest percentage increase in population between 2010 and 2021 were Madison, Yellowstone, and Carbon Counties, with increases of 20.9 percent, 11.0 percent, and 10.3 percent, respectively. These counties are also expected to see large percentage increases

in population going forward, with increases of 46.1 percent, 8.3 percent, and 20.9 percent by 2040 for Madison, Yellowstone, and Carbon Counties, respectively. The rapid population growth in these counties may be due in part to the development of the area's recreation and tourism industries and the presence of the Billings Metropolitan Statistical Area, which is an expanding urban area that spans Yellowstone and Carbon Counties (Madison County 2015; City of Billings 2023; **Table A-8** in **Appendix A**). Additionally, unemployment rates for Madison, Yellowstone, and Carbon Counties have been consistently below or similar to the state average, and total employment increased from 2010 to 2021 in all three counties (**Table 2-8**).

Table 2-8. Montana Analysis Area Unemployment Rate

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Beaverhead County	3.5	3.4	3.2	3.1	2.9	4.0	2.8

Source: BEA 2023

Fifteen counties within the Montana analysis area decreased in population, with the most substantial decreases in Prairie and Phillips Counties, which decreased 10.4 percent and 10.3 percent, respectively (**Table 2-7**). Both counties are sparsely populated and rural. Phillips County had a consistently above-average unemployment rate, which may be contributing to this population decline and future stagnation as individuals move to other areas in search of employment (**Table 2-8**). On the other hand, unemployment rates in Prairie County have been similar to the state average, which could be a contributor to the forecasted population increase in the county of 7.8 percent by 2040 (Montana Department of Commerce 2022; see **Table 2-7** and **Table 2-8**). Across the Montana analysis area, Rosebud, Roosevelt, and Big Horn Counties are projected to see the largest percent decrease in population by 2040, with a decrease of about 26.4 percent, 18.7 percent, and 13.8 percent, respectively. Similar to Phillips County, all three counties have

experienced consistently high unemployment rates since 2015, indicating that population declines may be related to stagnant economic conditions.

Since 2010, many counties in the analysis areas have seen an increase in the number of available jobs for multiple industry sectors. Across almost all counties, industries with a relatively high concentration of employment include retail trade, accommodation and food services, and wholesale trade. This is consistent with statewide trends for these industries. Average labor earnings for retail trade and accommodation and food services are relatively low compared with the state average of $53,000, while the average labor earnings for wholesale trade are higher at $80,000. Healthcare is a significant source of employment for counties like Yellowstone County, where it represents 13.7 percent of employment. Most counties also hold high concentrations of government and construction jobs, both of which pay above-average labor wages relative to the statewide all-industry labor earnings (**Table A-9** in **Appendix A**).

Real labor income has increased since 2010 in Montana and all counties in the Montana analysis area, except Fallon and Petroleum Counties. Government and government enterprises represent a key industry for labor income, with over 8 percent of labor income coming from this sector in all counties across the Montana analysis area. The mining (including quarrying and oil and gas extraction), construction, and transportation and warehousing industries represent a large portion of incomes for certain counties, such as Fallon; however, most of the other counties in the Montana analysis area have high labor income in the retail trade and health care and social assistance industries. Manufacturing, utilities, forestry, educational services, and management of companies continue to represent the lower portion of labor incomes in the Montana analysis area. Although the total share of income from these industries is, as a whole, relatively low, professions in certain sectors, such as utilities, yield above-average labor wages while employing fewer people.

The mining industry (including quarrying and oil and gas extraction) is not a significant source of employment at the state level, constituting 1.4 percent of all employment in 2021 and 1.8 percent in 2010; however, for certain counties in the Montana analysis area, mining plays a key role. Big Horn and Fallon Counties are characterized by a particularly high proportion of jobs in mining and oil and gas extraction, and both have undergone declines over the past decade. In 2010, mining represented 10.1 percent and 16.2 percent of employment in Big Horn and Fallon Counties, respectively; however, by 2021, these numbers had fallen to 8.1 percent and 11.4 percent. In 2010, Musselshell and Rosebud Counties also held a relatively large proportion of employment in this sector, with 13.2 percent and 9.1 percent, respectively; however, 2021 numbers are not available.[4]

Statewide, the average mining labor wages ($97,000) are higher than the average across all employment sectors. This trend is also reflected in Big Horn and Fallon Counties. In Big Horn County, the average mining labor wage is $96,000 as compared with a county average wage of $54,000. In Fallon County, the average mining labor wage is $105,000, which is higher than the county average of $49,000. This suggests these counties that rely on mining could be more sensitive to BLM decisions on mining in GRSG HMAs.

At 4.1 percent, farm employment is also a relatively minor source of employment in Montana. However, numerous counties in the analysis area are largely dependent on farming, with this sector comprising greater than 20 percent of county employment in nine counties in the analysis area; these are Carter,

[4] The BEA excludes employment and labor data for industries in certain locations to avoid disclosure of confidential information, as is the case for 2021 employment data in Musselshell and Rosebud Counties in Montana.

Chouteau, Garfield, McCone, Petroleum, Powder River, Prairie, Treasure, and Yellowstone Counties. Average labor wages for farming are relatively low at both the county and state level, ranging from approximately $8,000 in Prairie County to approximately $26,000 in Chouteau County. Although the farming industry does not represent high labor earnings, the high employment in the farming industry highlights the sensitivity of these counties to changes in BLM decisions that could impact farming, livestock grazing, and ranching.

2.5 NEVADA

The Nevada analysis area includes 10 counties, encompassing almost the entire state of Nevada. The analysis area only excludes some counties on Nevada's southern border (see **Figure A-5** in **Appendix A**). Seven of the 10 counties in the Nevada analysis area contain over 1 million acres of BLM-administered lands in GRSG HMAs: Elko, Eureka, Humboldt, Lander, Nye, Washoe, and White Pine Counties. Elko, White Pine, Humboldt, and Washoe Counties have the largest amount in BLM-administered surface lands in GRSG HMAs, with about 4.9 million acres, 2.9 million acres, 2.8 million acres, and 2.3 million acres, respectively.

From 2010 to 2021, the population in Nevada increased by 16.2 percent. From 2010 to 2021, overall employment increased in Nevada while real labor wages largely remained stagnant, with a slight increase from $61,000 to $62,000. As of 2021, the largest employment industries are the accommodation and food services; forestry, fishing, and related activities; retail trade; and government and government-related enterprises, with 14.8 percent, 13.4 percent, 9.9 percent, and 9.4 percent, respectively. At the state level, sectors that pay notably higher than the state average labor wage of $62,000 across all sectors include mining (including quarrying and oil and gas extraction), utilities, management, and information. These industries might not contribute to a large number of employees; however, due to the higher incomes, they play an important role in the local economies.

With a population of 479,758 people, Washoe County is the most populous county in the Nevada analysis area. It had the highest growth rate between 2010 and 2021, with a 16.2 percent increase, which was the same as the entire state of Nevada. The growth of Washoe County is likely due in part to an influx of people to the county's urban areas in the last 10 years, with this trend continuing through 2040. Nye County closely followed, with a population increase of around 14.2 percent. The continuous rapid growth of Nye County may also be related to urban expansion of Nevada's largest cities and spillover from Clark County, the fastest-growing county in Nevada (Nevada Department of Taxation 2021).

Counties with declining or stagnant populations tend to be more rural and sparsely populated, both historically and at present. Lincoln County had the greatest population decrease between 2010 and 2021, at about 9.1 percent, followed by a 7.0 percent decrease in Eureka County (see **Table 2-9**). While the population of Lincoln County is projected to decrease further, a 19.4 percent increase is anticipated in Eureka County. This contrast in population growth trends may be related to the volatility of the county's mining and energy industries, and the consequent fluctuations in worker migration patterns (Eureka County 2018). The estimated population change by county between 2021 and 2040 indicates a range of population changes throughout the analysis area, with the largest projected increase in Nye and Washoe Counties and a continued decrease in Lincoln County (Nevada Department of Taxation 2021).

Table 2-9. Nevada Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040 (estimated)
Churchill County	24,946	25,077	28,597	0.5	14.0
Elko County	47,707	53,420	58,521	12.0	9.5
Eureka County	1,603	1,724	2,058	-7.0	19.4
Humboldt County	15,986	17,218	17,908	7.7	4.0
Lander County	5,545	5,729	5,946	3.3	3.8
Lincoln County	5,060	4,600	4,481	-9.1	-2.6
Nye County	43,878	50,096	67.656	14.2	35.1
Pershing County	6,703	6,668	6,753	-0.5	1.3
Washoe County	412,844	479,758	590,280	16.2	23.0
White Pine County	9,765	9,192	10,517	-5.9	14.4
State of Nevada	2,633,331	3,059,238	3,785,099	16.2	23.7

Sources: Nevada Department of Taxation 2021; US Department of Commerce 2022

The mining industry (including quarrying and oil and gas extraction) represents a larger percentage of employment in Humboldt, Pershing, and White Pine Counties (greater than 20 percent; **Table A-10** in **Appendix A**). The average labor income for this industry (over $110,000 in each of the three counties) is almost double the average state income across all employment sectors; it is also comparable to the state average for mining labor wages. From 2010 to 2021, total employment declined in Eureka, Humboldt, and White Pine Counties, suggesting a contraction of the workforce, which could impact available jobs in the mining industry. These trends parallel the stagnant or declining population levels in Eureka and White Pine Counties (**Table 2-9**). This suggests these counties that rely on mining could be more sensitive to BLM decisions on mining in GRSG HMAs, especially as external pressures lead to a decline in available mining jobs.

Farming employment decreased statewide and across all analysis area counties between 2010 and 2021. Lincoln and Pershing Counties hold the highest rate of farm employment, at 9.5 percent and 8.1 percent, respectively. Both counties have experienced declines in farm employment since 2010, from 10.1 percent and 10.6 percent, respectively. The average labor wage for farm employment was $65,000 in Lincoln County and $58,000 in Pershing County. These wages are similar to the state labor wage across all employment sectors, and higher than the statewide average for farming labor wages of $36,000 (see **Table A-11** in **Appendix A**). Similar to the counties that depend on the mining industry, these counties that rely on farming for economic conditions could be more sensitive to BLM decisions on livestock grazing in GRSG HMAs.

In terms of labor income, the trends and key sectors are similar to those for employment. Statewide, labor income is concentrated in mining, as well as in utilities, information, and management. The data show that since 2010, industry earnings have increased for most employment sectors in Nevada. However, mining, farming, forestry, and service-based industries have had a decline in their overall percentage of earnings. Government-based wages continue to be responsible for a large proportion of income for many counties, particularly Churchill County (37.7 percent), Pershing County (32.7 percent), and White Pine County (30.2 percent).

Income in the mining industry (including quarrying and oil and gas extraction) accounts for the largest percentage of income for Humboldt County (37.8 percent), Pershing County (55 percent), and White Pine County (41.7 percent), further indicating their reliance on mineral extraction, as discussed above. Moreover, across these mining-dependent counties, the average labor wages for the mining industry (including quarrying

and oil and gas extraction) in these counties—at over $110,000—are disproportionately high relative to the county averages for all employment sectors (approximately $70,000; **Table A-11** in **Appendix A**). However, the reliance on the mining industry for labor income in these three counties means the economies in these areas are likely susceptible to boom-and-bust cycles and would be more sensitive to changes in BLM management decisions that could affect mineral extraction (Vega 2022).

Unemployment rates across the Nevada analysis area had similar trends from 2015 to 2021. The counties had a decrease in unemployment rates in 2019 from 2015 levels. In 2020, the unemployment rates increased in all counties in the Nevada analysis due to restrictions during the 2020 COVID-19 pandemic. In 2021, unemployment rates decreased as businesses and economies opened back up (**Table 2-10**). Most counties in the Nevada analysis area had lower unemployment rates than the state of Nevada; however, from 2015 to 2019, Nye County experienced higher unemployment rates than the state of Nevada. Unemployment rates were also higher than the state rate in Churchill County in 2015, Lander County in 2016, and Pershing County in 2015 and 2016.

Table 2-10. Nevada Analysis Area Unemployment Rate

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Churchill County	7.1	5.6	4.5	3.8	3.6	5.7	3.5
Elko County	5.2	4.5	3.7	3.1	3.0	5.9	3.3
Eureka County	5.9	4.6	3.0	2.5	2.5	3.5	2.6
Humboldt County	6.1	5.6	4.2	3.3	3.0	5.0	3.4
Lander County	6.8	6.3	4.5	3.5	3.2	4.9	3.6
Lincoln County	6.1	5.4	4.8	4.3	4.0	5.1	3.4
Nye County	8.9	7.4	6.4	5.6	5.3	10.2	6.1
Pershing County	7.0	6.0	4.6	4.0	4.0	4.8	3.6
Washoe County	6.3	5.1	4.1	3.5	3.3	8.2	4.3
White Pine County	5.5	4.7	4.1	3.5	3.0	4.2	3.0
State of Nevada	6.8	5.8	5.0	4.4	4.0	13.5	7.2

Source: BLS 2023

2.6 NORTH DAKOTA

The North Dakota analysis area lies in the state's southwestern corner and consists of Bowman and Slope Counties (see **Figure A-6** in **Appendix A**). Of the BLM-administered surface acreage in Bowman County, 100 percent falls within GRSG HMAs. In Slope County, 82,000 acres of non-surface mineral estate, or approximately 11 percent of total acres in the county, falls within HMAs.

From 2010 to 2021, the population of North Dakota increased by 17.2 percent, or 113,486 people (**Table 2-11**). The statewide population growth between 2010 and 2021 was likely fueled by the Bakken oil boom, which began in 2008 and drew workers to counties outside the analysis area, such as McKenzie and Williams Counties. Oil production peaked in 2012 and experienced intermittent declines due to a variety of factors. including international competition, reserve exhaustion, and the COVID-19 pandemic (Smith 2021; Williams-Derry and Kunkel 2021). Small-scale shifts in production patterns throughout the oil boom may have contributed to the diverging population growth trends at the county level between 2010 and 2021. Overall, the statewide population growth between 2010 and 2021 aligns with an increase in employment in the mining industry (including quarrying and oil and gas extraction), which grew from 2.8 percent of overall state employment in 2010 to 3.2 percent of state employment in 2021. Although mining constitutes a relatively small portion of employment in North Dakota, it is higher than the national average of less than 1 percent.

Table 2-11. North Dakota Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040
Bowman County	3,102	3,024	N/A	-2.5	N/A
Slope County	727	775	N/A	6.6	N/A
State of North Dakota	659,858	773,344	N/A	17.2	N/A

Source: US Department of Commerce 2022
N/A = Not available

The state unemployment rate steadily declined from 2016 through 2019. In 2020, unemployment in North Dakota more than doubled, when the COVID-19 pandemic triggered mass layoffs and disrupted the economy. The economy began to recover in 2021, as signified by a decline in the unemployment rate across the state (**Table 2-12**). In North Dakota, the largest nonfarm employment sectors include government, healthcare, and retail, representing 15.8 percent, 12.2 percent, and 10 percent, respectively. Government and government-based enterprises also represent the largest portion of personal wage income in North Dakota.

Table 2-12. North Dakota Analysis Area Unemployment

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Bowman County	1.8	2.2	1.7	1.7	1,5	3.4	2,5
Slope County	2.6	2.5	1.9	2.0	2.0	3.0	2.8
State of North Dakota	2.8	3.1	2.6	2.4	2.1	5.1	3.7

Source BLS 2023

Bowman County has the largest population within the North Dakota analysis area, while Slope County has the lowest population. With a 2021 population of 775 people, Slope County observed a 6.6 percent population increase between 2010 and 2021, whereas Bowman County, which had a 2021 population of 3,024 people, saw a population decrease of 2.5 percent during the same period. Both counties' population changes between 2010 and 2021 did not follow overall North Dakota state trends (US Department of Commerce 2022; **Table 2-11**). The difference in populations trends could be related to the role the mining industry played in each county compared to North Dakota, as the impact of the Bakken oil boom and the general importance of mining in local economies becomes more apparent at the county level.

In 2010, mining was a key industry for Slope County, with approximately 13.8 percent of total employment and 38.9 percent of labor income coming from the mining industry, compared to 2.8 percent of employment and 5.1 percent of nonfarming earnings in North Dakota (2021 employment and income data were not disclosed; see **Table A-12** in **Appendix A**). In Bowman County, jobs in mining and extraction sharply decreased by more than half (from 5.3 to 2.2 percent of employment), as did income for this industry. This decline in the mining industry in Bowman County may reflect a shifting nexus of oil and mining jobs to other counties, as well as short-term trends in oil industry patterns that depend on fluctuations in production and impacts from broader economic or geopolitical trends. Additionally, except for government, education, healthcare, and miscellaneous service sectors, all employment numbers in Bowman County decreased; this trend aligns with its declining population and suggests the dependence of the county's non-mining industries on its mining industries (**Table A-12** in **Appendix A**).

Table 2-12 shows that the North Dakota analysis area experienced rates of unemployment that are lower than the statewide rate for each year from 2015 to 2021. At the county level, Bowman County experienced a slight uptick in the unemployment rate in 2019, which coincides with the brief decline in the Bakken oil

boom that was caused by a drop in oil prices; then, the unemployment rate decreased until reaching its lowest unemployment rate in 2019 (1.5 percent; Scheyder 2016). From 2015 to 2021, Slope County experienced its lowest unemployment rate in 2017, after which the unemployment rate stagnated through 2019. The decline in unemployment could have attracted more people to the county, which would contribute to the population growth seen from 2010 to 2021. Both counties in the North Dakota analysis area experienced their highest unemployment rate in 2020 over the 7-year period due to restrictions and layoffs during the 2020 COVID-19; this was consistent with the state's unemployment trends but still lower than the overall state unemployment level.

Farming represents an important economic component of both analysis area counties. At 15.7 percent of all employment, farm employment in Bowman County measures over three times greater than the state statistic of 5 percent. Farm earnings comprise approximately 14 percent of Bowman County earnings, and the average farming labor income of $86,000 is higher than the county average of $58,000. Farming is also a major component of the economy in Slope County, representing 47.2 percent of all jobs and 29.3 percent of county income. Additionally, the average labor income for farming employment in Slope County is relatively high, at approximately $73,000, compared to the county average of $67,000. In both counties, farm employment declined at lower rates than overall private nonfarm employment (**Table A-12** in **Appendix A**). Farm employment remained roughly constant from 2010 to 2021 in both counties in the analysis area, while private, nonfarm employment declined by roughly 10 percent. This reflects the counties' continued reliance on agriculture and suggests that Bowman and Slope Counties could be sensitive to BLM decisions on livestock grazing in GRSG HMAs.

The largest nonfarm employment sectors in Slope County include government, real estate, and transportation, which represent 8.7 percent, 3.2 percent, and 3.0 percent of all employment (**Table A-12** in **Appendix A**). In Bowman County, government and government enterprises also constituted a relatively large proportion of employment and labor income, followed by several service sectors, including retail trade, wholesale trade, and healthcare (**Table A-13** in **Appendix A**). In both counties, labor income from retail trade is slightly low relative to its share of employment, indicating slightly lower labor wages. The average labor income in Slope County ($67,000) is slightly higher than the state average of $64,000, while in Bowman County it is lower, at $58,000. The differences in labor income could have been a factor contributing to the historical population growth in Slope County and population decline in Bowman County (**Table A-13** in **Appendix A**).

2.7 OREGON

The Oregon analysis area includes eight counties clustered in the southeast to central region of Oregon (see **Figure A-7** in **Appendix A**). The counties with the largest amount of BLM-administered surface acres in GRSG HMAs are Malheur, Harney, and Lake Counties, with about 4.3 million acres, 3.7 million acres, and 2.1 million acres of BLM-administered surface lands in GRSG HMAs, respectively. Additionally, the acres in GRSG HMAs make up over 80 percent of BLM-administered surface lands in all three counties. In Malheur County, GRSG HMAs acres represent about 76 percent of the total acres in the county (federal and nonfederal).

Oregon's population grew by about 445,000 people between 2010 and 2021, which is an increase of about 11.8 percent (see **Table 2-13**). This increase is projected to continue over the next 20 years, with the population increase estimated to be about 22.7 percent. Oregon's population increase was largely due to migration by residents from other states who were attracted by Oregon's economic expansion (Cunningham

Table 2-13. Oregon Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040
Baker County	16,150	16,539	15,156	2.4	-8.4
Crook County	21,515	24,300	31,410	12.9	29.3
Grant County	7,349	7,225	6,566	-1.7	-9.1
Harney County	7,364	7,454	7,537	1.2	1.1
Lake County	7,882	8,119	8,177	3.0	0.7
Malheur County	31,326	31,313	30,514	0.0	-2.6
Union County	25,373	26,255	27,482	3.5	4.7
Deschutes County	154,568	194,964	203,390	26.1	4.3
State of Oregon	3,761,925	4,207,177	5,164,041	11.8	22.7

Sources: Portland State University Population Research Center 2022; University of Virginia Weldon Cooper Center, Demographics Research Group 2018; US Department of Commerce 2022

2021). From 2010 to 2021, employment in Oregon grew by about 385,000 jobs; this was an increase of about 17.7 percent, larger than population growth. The largest percentage in employment increases occurred in the transportation and warehousing, health care and social assistance, and construction industries (see **Table A-14** in **Appendix A**).

The unemployment rate in Oregon steadily declined from 5.5 percent in 2015 to 3.7 percent in 2019. Consistent with the rest of the country, the unemployment rate across Oregon increased sharply in 2020 due to a large number of layoffs that occurred during the global COVID-19 pandemic; however, it decreased to below the 2015 unemployment rate in 2021 (see **Table 2-14**; BLS 2023). Real total earnings in the state increased from 2010 to 2021 by about 43 percent; however, per capita income in 2021 was slightly lower than the US average per capita income, which suggests that Oregon's population increase was not largely motivated by higher incomes (BEA 2021a, 2021b).

Table 2-14. Oregon Analysis Area Unemployment Rate

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Baker County	6.6	6.2	5.4	5.2	4.5	7.2	5.1
Crook County	8.2	6.8	6.2	5.8	5.1	8.8	6.7
Grant County	8.5	7.5	6.8	6.8	6.8	8.4	6.7
Harney County	7.0	6.1	6.2	5.8	5.2	5.9	5.1
Lake County	7.5	6.2	5.6	5.4	5.3	5.6	5.5
Malheur County	6.2	5.4	4.6	4.4	4.0	5.2	4.4
Union County	6.0	5.8	5.2	5.2	4.8	7.8	5.6
Deschutes County	5.7	4.8	4.2	4.1	3.9	8.0	5.3
State of Oregon	5.5	4.7	4.1	4.01	3.7	7.6	5.2

Source: BLS 2023

Across the Oregon analysis area, the population increased by about 45,000 people from 2010 to 2021, which is an increase of about 16.4 percent; this is a slightly larger growth rate than for the whole state of Oregon. Over the 11 years, the population in all Oregon analysis area counties increased or remained stagnant, except for Grant County. Grant County, which is the smallest county in the analysis area with a population of 7,225, had a very small decrease of over 100 people (a decrease of about 1.7 percent). The county with the largest percentage increase in population in the Oregon analysis area was Deschutes County, which had an increase of over 40,000 people (Deschutes County is also the most populous county in the Oregon analysis area, with a population of almost 195,000 people in 2021; see **Table 2-13**; US Department of Commerce 2022). Some counties in the Oregon analysis area are expected to see growth rates going

forward through 2040; however, the population growth is projected to slow in Deschutes County, with a forecasted change of 4.3 percent from 2021 to 2040. The population is expected to decline in Grant, Baker, and Malheur Counties by 9.1 percent, 8.4 percent, and 2.6 percent, respectively (see **Table 2-13**; Portland State University Population Research Center 2022).

The increase in population in the Oregon analysis area is likely correlated with employment, which increased by a similar amount to the populations from 2010 to 2021 (about 44,000 jobs), which was an increase of about 29 percent. All counties in the Oregon analysis area saw an increase in employment over the 11-year period. Deschutes County, which had the largest increase in magnitude of population, had the largest increase in employment across the analysis area, with over 40,000 additional jobs (a similar increase as the population). This increase in total employment was largely driven by an increase in employment in the health care and social assistance industry, which accounts for the largest percentage of total employees in Deschutes County at 12.5 percent. Grant County, which had the only population decline from 2010 to 2021, had the smallest increase in employment, with an increase of about 85 jobs (see **Table A-14** in **Appendix A**).

Unemployment rates across the Oregon analysis area generally decreased or were stagnant from 2015 to 2019. The unemployment rate in Deschutes County was similar to the unemployment rate across the state of Oregon; it steadily decreased from 5.7 percent in 2015 to 3.9 percent in 2019. The unemployment rate in Grant County was higher than the state of Oregon's, but it also decreased from 8.5 percent in 2015 to 6.8 percent in 2017 and remained stagnant through 2019. All the counties experienced an increase in the unemployment rate in 2020 during the COVID-19 pandemic (**Table 2-14**). However, in some counties, such as Harney, Lake, and Malheur Counties, the increase in unemployment rate in 2020 was small; this could be due to the reliance on the farm industry in these three counties and because farm workers were considered essential workers during the COVID-19 pandemic. All counties in the Oregon analysis area had a decrease in the unemployment rates from 2020 to 2021 as the local economies and businesses opened back up.

In addition to the number of job opportunities attracting people to move to the Oregon analysis area, labor income plays a part in encouraging population growth or decline. In 2021, Deschutes County, which had the highest increase in population and employment from 2010 to 2021, had the highest reported per capita income across all industries in the Oregon analysis area of almost $68,000 (over $6,000 more than the per capita income for the state of Oregon and over $3,000 more than the per capita income for the US; BEA 2021a, 2021b). Malheur County, which had a stagnant population from 2010 to 2021, had the lowest per capita income across all counties in the Oregon analysis area, with per capita income of almost $39,000 (about 33 percent less than the per capita income across the state of Oregon).

In Deschutes County, the key industries with the highest average earnings per employee (which is calculated by dividing total earnings by the total number of employees; see **Table A-15** in **Appendix A**; BEA 2021a, 2021b) were utilities, information, and construction. In Malheur County, the industries with the highest reported average earnings per employee were utilities, government and government enterprises, and manufacturing.

In 2021, the farming industry in Oregon represented about 2.7 percent of total employment and less than 1 percent of total earnings.[5] However, in the Oregon analysis area, which is on Oregon's eastern side,

[5] Farming employment includes the labor of farm proprietors, but not unpaid family labor; therefore, the statistics presented in this report do not include the total value of farming through employment.

farming plays an important role in the local economies. Farming employment makes up over 7 percent of total employment in all counties except Deschutes County. Farming was the second-largest industry for employment in Harney, Lake, and Grant Counties, with about 19.6 percent, 16.0 percent, and 13.0 percent of total jobs coming from farming, respectively (only falling below the government and government enterprises industry). Farming was the third-largest industry for employment in Malheur and Baker Counties, with 12.8 percent and 10.9 percent of total employment, respectively. In Union and Crook Counties, the farming industry was the fourth largest in terms of employment percentage, with 7.5 percent and 7.0 percent of total employment, respectively.

Farm earnings make up less of a percentage of the total earnings in most counties in the analysis area, but they still make up over 6 percent in Harney, Lake, and Malheur Counties. These three counties have a high percentage of BLM-administered lands in GRSG HMAs; therefore, these counties could be susceptible to impacts on farming, including potential changes to livestock grazing and ranching, from BLM decisions on GRSG HMAs (see **Chapter 3**, Livestock Grazing, in the EIS for more details on grazing and ranching use on BLM-administered lands in the Oregon analysis area).

Employment and earnings in the mining industry (including quarrying and oil and gas extraction) were either not disclosed, or they comprised a very small percentage (less than 1 percent) of total employment and earnings across the Oregon analysis area as well as the state of Oregon (see **Table A-15** in **Appendix A**; BEA 2021a, 2021b). This suggests that the economies in these two counties do not depend on the mining industry, and these economies would likely not be sensitive to changes in mineral development.

Recreation and tourism-related industries, such as the accommodation and food industry and retail trade industry, are other important industries within the Oregon analysis area. In Malheur, Baker, and Deschutes Counties, retail trade was the second-largest industry for employment, with 14.6 percent, 12.6 percent, and 11.4 percent, respectively, of total jobs coming from this industry. The percentages of total employment and earnings from these key industries across the Oregon analysis area have not changed substantially from the data included in the 2015 Sage-Grouse Plan Amendment EIS, which included data from 2010. This suggests that the economic significance of major industries in the Oregon analysis area have remained consistent over the past decade.

2.8 SOUTH DAKOTA

The South Dakota analysis area consists of Butte and Harding Counties, which lie in the state's northwestern corner (see **Figure A-8** in **Appendix A**). Including subsurface acreage, 10 percent of Butte County and 3 percent of Harding County fall within HMAs.

From 2010 to 2021, the population in South Dakota increased by 10.3 percent, or 82,785 people (**Table 2-15**). Total employment in South Dakota increased by a slightly smaller magnitude—about 64,000 jobs—which suggests there may be some correlation between the increase in population and the increase in employment (**Table A-16** in **Appendix A**). The employment increase was largely driven by the real estate and rental and leasing industry, which increased by about 10,000 jobs, and the health care and social assistance industry, which increased by over 9,000 jobs. In South Dakota, the percentages of employment by industry have remained relatively constant over the last decade, with a majority of employment occurring in government and government enterprises, health care and social assistance, and retail trade (**Table A-16** in **Appendix A**).

Table 2-15. South Dakota Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040
Butte County	9,888	10,167	N/A	2.8	N/A
Harding County	1,250	1,179	N/A	-5.7	N/A
State of South Dakota	799,462	881,785	N/A	10.3	N/A

Source: US Department of Commerce 2022
N/A = Not available

Butte County has the largest population within the South Dakota analysis area, while Harding County has the lowest population. Butte County, consisting of 10,167 people, observed a small population increase of about 2.8 percent between 2010 and 2021, whereas Harding County, with a population of 1,179 people, had a population decrease of 5.7 percent during the same period. The population changes in both counties in the South Dakota analysis area differed from the high population growth rate at the state level. This difference in population trends may be due to the rural character of the counties in the analysis area, as the state's population growth is concentrated in counties that contain or adjoin major urban centers, such as Sioux Falls and Rapid City (US Department of Commerce 2022).

Employment in both counties in the analysis area increased from 2010 to 2021. In Butte County, employment increased by about 200 jobs; in Harding County, employment increased by about 100 jobs (**Table A-16** in **Appendix A**). For both counties, the increase in employment was largely due to the retail trade industry, which accounted for an increase in about 100 jobs and 40 jobs in Butte and Harding Counties, respectively. In Butte County, the retail trade industry represented the largest nonfarm industry for employment, with about 14.7 percent of total employment. This was followed by government and government enterprises, with about 12.7 percent of jobs, and construction, accommodation, and other services, with about 7.2 percent for each of the three industries. In Harding County, the retail trade industry was the second-largest nonfarming industry for employment, with 9.2 percent of total jobs (only behind government and government enterprises with 10.3 percent of employment; see **Table A-16** in **Appendix A**).

Historical unemployment rates vary across the South Dakota analysis area. In Butte County, from 2015 to 2021, the unemployment rates were higher than they were for the state of South Dakota. In Harding County, the unemployment rates were lower than the unemployment rates for the state of South Dakota. Consistent with the rest of the US, the South Dakota analysis area and the state of South Dakota saw unemployment rates increase in 2020 during the COVID-19 pandemic. Unemployment rates in 2021 show that South Dakota's economy continues to recover from the economic effects of the COVID pandemic, with unemployment rates returning to similar levels to those experienced in 2015 (**Table 2-16**).

Table 2-16. South Dakota Analysis Area Unemployment

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Butte County	3.3	3.5	3.3	3.0	2.9	5.0	3.4
Harding County	2.4	2.9	2.8	2.2	2.3	3.4	2.8
State of South Dakota	3.0	3.0	3.1	2.8	2.8	4.3	3.1

Source: BLS 2023

The farming industry has played a key role in the economies across South Dakota, especially in the South Dakota analysis area. In Butte County, farm employment comprised 11 percent of all employment in 2021; this is a slight decrease from 12 percent in 2010 but more than double the state statistic in 2021 of 5 percent (**Table A-16** in **Appendix A**). Earnings from the farm industry represent about 6.2 percent of total earnings

in Butte County. In Harding County, the farm industry was the largest industry for employment, with 26.4 percent of the jobs in this industry. This percentage of employment in the farm industry was only a slight decrease from the percentage of farm employment in 2010 of 27.5 percent (**Table A-16** in **Appendix A**). Earnings from the farm industry represent about 32.3 percent of total earnings in Harding County, which is the largest sector for labor income in the county. The reliance on farming as a key industry for employment suggests that the South Dakota analysis area could be susceptible to BLM management decisions that impact farming, ranching, or livestock grazing.

In Butte County, the industries with the largest percentage of labor income were government and government enterprises, retail trade, and construction. In Harding County, the industries with the largest percentage of labor income were farming, government and government enterprises, and construction. This is due to the importance of these industries for the number of jobs in the area. In Butte County, the average earnings per employee in these sectors were about $49,000, $30,000, and $51,000 for government and government enterprises, retail trade, and construction jobs, respectively. The earnings per employee in the top sectors in Harding County were about $55,000, $53,000, and $67,000 for farming, government and government enterprises, and construction jobs, respectively. On the other hand, the industries with the highest earnings per employee were information in Butte County, with $79,000 per job, and mining (including quarrying and oil and gas extraction) in Harding County, with $109,000 per job (**Table A-17** in **Appendix A**).

2.9 UTAH

Nearly all of Utah, or 23 out of 29 of its counties, lies within the analysis area (see **Figure A-9** in **Appendix A**). Those counties not in the analysis area lie at the southeastern, southwestern, and northern-central areas of the state. Seven counties (Daggett, Morgan, Rich, Carbon, Beaver, Box Elder, and Piute Counties) contain BLM-administered lands that qualify as at least 33 percent GRSG HMAs. In Daggett, Morgan, and Rich Counties, which are in Utah's northeastern corner, nearly 100 percent of all BLM-administered surface acreage falls within HMAs, holding implications for BLM management decisions in these counties. In Carbon County, as well as the western counties of Beaver, Box Elder, and Piute, approximately one-third to half of BLM-administered surface acreage falls within GRSG HMAs. For all seven counties, close to one-quarter of the total county acreage consists of GRSG HMAs, holding implications for future land management decisions. Expanding development that typically accompanies population growth may be an important factor in planning for GRSG management in the near future.

Utah's population grew by 20.6 percent between 2010 and 2021 (**Table 2-17**). The most populous county within the Utah analysis area in 2021 was Cache County, with 137,255 people. Other counties with relatively large populations within this analysis area include Toole County (76,165 people), Box Elder County (59,220 people), Iron County (61,232 people), and Summit County (42,843 people). At 51.4 percent, Wasatch County had the largest percentage increase in population between 2010 and 2021; this was followed by Morgan County (33.2 percent), Iron County (32.4), Tooele County (30.5 percent), percent), and Cache County (21.1 percent). Population growth in Wasatch County was driven by migration, tourism, and the presence of the Wasatch Campus of Utah Valley University. By 2040, Wasatch County is predicted to have a population increase of almost 60 percent, while Morgan and Tooele Counties will experience similarly rapid population growth (University of Utah, Kem C. Gardner Policy Institute 2022; see **Table 2-17**).

Table 2-17. Utah Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040
Beaver County	6,645	7,156	8,777	7.7	22.7
Box Elder County	50,084	59,220	75,494	18.2	27.5
Cache County	113,307	137,255	185,948	21.1	35.5
Carbon County	21,390	20,488	20,689	-4.2	1.0
Daggett County	1,076	962	910	-10.6	-5.4
Duchesne County	18,689	19,738	19,351	5.6	-2.0
Emery County	10,991	9,885	9,674	-10.1	-2.1
Garfield County	5,167	5,079	5,294	-1.7	4.2
Grand County	9,227	9,705	11,375	5.2	17.2
Iron County	46,240	61,232	85,248	32.4	39.2
Juab County	10,260	12,049	17,586	17.4	46.0

More broadly, the three fastest-growing counties are all part of the Greater Salt Lake Region, a 12-county region that functions largely as a single consumption and labor market. The Greater Salt Lake Region is one of the urban areas driving Utah's population increase (**Table 2-17**; University of Utah, Kem C. Gardner Policy Institute 2022). Approximately 25 percent of the acreage in steadily growing Beaver, Box Elder, and Rich Counties falls within HMAs; an increasing population will have implications for future management decisions for GRSG.

The county that experienced the most population loss between 2010 and 2021 was Daggett County (10.6 percent), followed by Emery County (10.1 percent), Wayne County (9.8 percent), and Carbon County (4.2 percent) (**Table 2-17**). Except for Wayne County, all these counties are expected to either continue decreasing, or stagnate, in population through 2040. This may be due to their more rural nature or a higher-than-average unemployment rate encouraging residents to seek work elsewhere, or both. In Carbon and Emery Counties, declines in population and overall employment may be tied to unpredictable fluctuations in their coal-based economies amid changes in energy markets and growing competition from alternative sources of energy, including both renewables and fossil fuels (Gruenspecht 2019; Schott 2017; **Table 2-17**; **Table 2-18**; **Table A-18** in **Appendix A**). The economies in these counties could be sensitive to changes in industries, such as the mining industry, that might impact job availability and further encourage the population to move elsewhere for employment.

Table 2-18. Utah Analysis Area Unemployment Rate

Geographic Area	2015	2016	2017	2018	2019	2020	2021
Beaver County	3.7	4.8	3.9	3.3	3.0	4.0	2.8
Box Elder County	3.6	3.4	3.2	2.8	2.6	4.4	2.4

State of Utah	3.5	3.3	3.1	2.9	2.6	4.7	2.7

Source: BLS 2023

Although most analysis area counties experienced population growth (and will continue to expand through 2040), many experienced much higher rates of unemployment; others had unemployment rates about equal to or greater than those of Utah from 2015 to 2021 (**Table 2-18**). Cache, Morgan, and Summit Counties (besides anomalously high unemployment rates in 2020–2021 that were related to the COVID-19 pandemic). The data show that 12 counties in Utah experienced their lowest rates of unemployment in 2021, which were slightly greater than Utah's overall unemployment rate for 2021. Lower employment rates in 2021 could have been driven by an increase in the available workforce, similar to state trends.

Eleven counties experienced their lowest rate of unemployment in 2019, which were slightly greater than Utah's overall unemployment rate for 2019. During 2015, 2016, and 2020, 22 counties experienced their highest rates of unemployment, which were greater than Utah's unemployment averages for these years. At the county level, the lowest unemployment rate was in 2021 in both Cache County (2.0 percent) and Juab County (2.0 percent) and ranged to a high of 10.4 percent in Garfield County (**Table 2-18**). It should be noted that in all counties that experienced population growth, the total number of jobs increased, but unemployment remained above the state average (**Table 2-18**; **Table A-18 [Parts 1–4]** in **Appendix A**).

Service-based industries continue to represent a large portion of Utah's overall employment and labor income; these trends also exist at the county level. Since 2010, total employment has increased for almost all the counties in the analysis area (except for Carbon and Emery Counties), indicating that there has been somewhat of an economic expansion (**Table A-18 [Parts 1–4]** in **Appendix A**). The increase in total employment across the analysis area was largely due to increases in jobs in the manufacturing,

accommodation and food services, and construction industries, which grew by about 10,000 jobs, 9,000 jobs, and 8,500 jobs, respectively.

Declines in employment in Carbon and Emery Counties may be tied to changes in the potentially unpredictable coal economy (Schott 2017). Carbon County experienced a slight loss of jobs in mining (from 7.7 percent in 2010 to 7.0 percent in 2021), administrative and waste management services (5.4 percent to 3.1 percent), and wholesale trade (4.2 to 2.7 percent). Employment in Emery County decreased in the construction; manufacturing; transportation and warehousing; professional, scientific, and technical services; other services; and government and governmental enterprises industries (**Table A-18 [Parts 1–4]** in **Appendix A**).

Employment in the mining industry (including quarrying and oil and gas extraction) continues to represent a low portion of total employment. The exceptions are Sevier (5.0 percent), Duchesne (11.7 percent), Carbon (7.0 percent), Emery (6.2 percent), and Uintah (8.2 percent) Counties; in these counties, the employment in the mining industry was greater than Utah's state average (**Table A-18 [Parts 1–4]** in **Appendix A**). It is worth noting that in all counties where data are available, all underwent declines in mining employment. This is particularly apparent in Uintah County, where mining declined from 17.7 percent of employment in 2010 to 8.2 percent in 2021. The average labor income for mining in these counties ranges from $83,000 in Uintah County to $108,000 in Emery County; all fall below the average statewide labor income for mining (**Table A-18 [Parts 1–4]** in **Appendix A**). These counties that rely on mining for employment and labor income could be sensitive to BLM management decisions that limit mining in GRSG HMAs. Counties with the highest proportion of farm employment include Piute (23.5 percent), Beaver (14.6 percent), and Millard (14.3 percent) Counties. These numbers represent slight declines of approximately 1–2 percent from 2010 (**Table A-18** in **Appendix A**). In Morgan, Tooele, and Wasatch Counties, which are the three fastest-growing counties, farm employment represents a relatively low share of total employment, with 5.2 percent, 2.0 percent, and 2.3 percent, respectively. Farm employment has declined since 2010 in these counties. However, numbers for all three counties remain higher than the state average of less than 1 percent (**Table A-18** in **Appendix A**).

Growing employment sectors for these three counties include service industries like finance, professional services, and real estate, in addition to the non-service industry of construction (**Table A-18** in **Appendix A**). The decline in farm employment and simultaneous shift toward service industries may reflect diversifying and expanding economies as county populations continue to expand. However, farming plays an important role for Beaver, Iron, Piute, Rich, and Sanpete Counties, where the average earnings per employee for the farming industry are higher than the average earnings per employee across all industries, with about $70,000, $46,000, $117,000, $57,000, and $44,000 in earnings, respectively. Additional changes in the farming industry through BLM management decisions that impact livestock grazing would result in large impacts on these counties that have relied on farming for employment and labor income.

Government-based employment continues to represent a large portion of total employment on both the state and county level, with some counties, such as Piute (19.5 percent) and Sanpete (22.8 percent), having high percentages of government-based employment (**Table A-18** in **Appendix A**). Government-based employment is also responsible for a large percentage of total employment in Daggett (26.2 percent), Duchesne (21.1 percent), and Carbon Counties (19.0 percent). These percentages are greater than Utah's government employment average. In Daggett and Carbon Counties, the average wages for government employment ($69,000 and $56,000, respectively) fall below the state average of $75,000 for this sector (**Table A-19** in **Appendix A**).

2.10 WYOMING

The Wyoming analysis area encompasses 21 counties, spanning almost the entire state of Wyoming; the only excluded counties are Teton County on Wyoming's western border and Goshen County on Wyoming's eastern border. All analysis area counties contain BLM-administered acreages classified as at least 89 percent GRSG HMAs, except for Laramie and Platte Counties, where BLM-administered acreage classified as GRSG HMAs is closer to 50 percent. Counties with the highest percentage of GRSG HMAs overall include Big Horn, which is 65 percent HMAs, and Sweetwater and Washakie, which are both classified as 72 percent GRSG HMAs. Carbon, Fremont, Hot Springs, Lincoln, Natrona, and Sublette Counties are also significant counties for GRSG HMAs, having been classified as between 40 to 50 percent HMAs (see **Figure A-10** in **Appendix A**).

Between 2010 and 2021, the population in Wyoming grew by 3 percent. Statewide population is expected to increase from 580,390 to 614,820 people by 2040, which is a rate of 5.9 percent (**Table 2-19**). The county with the largest population in 2021 within the Wyoming analysis area was Laramie County with 100,900 people. Other counties with relatively high populations include Natrona County (78,810 people), Campbell County (45,450 people), Sweetwater County (42,440 people), and Albany County (39,250 people). Laramie and Lincoln Counties both experienced population growth of 10 percent between 2010 and 2021, and both counties are expected to continue increasing at slightly higher rates through 2040. Between 2015 and 2021, unemployment rates in both counties were consistently lower than or comparable to the state average, which may signal relatively stable economic conditions that are drawing workers (**Table 2-20**).

Table 2-19. Wyoming Analysis Area Population

Geographic Area	2010	2021	2040	% Change 2010–2021	% Change 2021–2040
Albany County	36,299	39,250	42,600	8.1	8.5
Big Horn County	11,668	11,900	12,230	2.0	2.8

Source: BLS 2023

Several counties declined in population between 2010 and 2021, with Washakie County undergoing the highest decline by 8.8 percent. Other counties that declined in population include Carbon, Hot Springs, and Niobrara Counties, which declined by 7.0 percent, 6.3 percent, and 5.4 percent, respectively. All three counties are expected to decline in population through 2040 (**Table 2-19**).

Key employment service sectors in Wyoming analysis area counties include retail trade, healthcare, and accommodation and food services. The retail and accommodation sectors, which yield average labor incomes of $37,000 and $32,000, respectively, tend to pay a below-average labor income compared to the overall state average of $59,000. Meanwhile, the average labor income for healthcare ($58,000) is more comparable to the state average. None of these three sectors experienced notable changes with respect to employment between 2010 and 2021. Among these three service sectors, employment tended to be concentrated in retail trade as well as accommodation and food services across all counties.

Mining (including quarrying and oil and gas extraction) is also a key industry for employment across Wyoming. Wyoming is one of the top coal and oil and gas producers, and it plays an important role in locatable mineral extraction. However, mining employment decreased from 8.0 percent in 2010 to 4.6 percent in 2021. Mining is especially important for employment in Campbell, Converse, Sublette, and Sweetwater Counties; mining holds the greatest proportions of private employment in these counties (**Table A-20** in **Appendix A**). However, the mining industry is susceptible to boom-and-bust cycles, and since 2010, employment has been decreasing in many counties across Wyoming. Notably, the proportion of mining jobs in Sweetwater County plummeted from 23.4 percent in 2010 to 9.3 percent in 2021, which aligns with its trend of above-average unemployment rates since 2015. This decrease is more drastic than the state-level trend.

Even with the decline in employment, mining still plays an important role in the regional economies. This is highlighted by the average labor wages for mining in these counties, which surpassed county averages across all industries. Moreover, mining represented over 20 percent of labor income in these counties, compared with the state average of 8.7 percent (**Table A-20** in **Appendix A**). This suggests that these counties that rely on mining could be impacted by BLM management decisions that restrict mining in GRSG HMAs.

Farming comprises 3.5 percent of employment at the state level. County-level numbers are roughly comparable, except for Niobrara County, which has the highest concentration of farming employment at 16.3 percent. In Big Horn, Crook, Niobrara, and Platte Counties, farming employment equals approximately 11 to 12 percent. Among these relatively farming-dependent counties, none experienced a meaningful change in employment between 2010 and 2021. The average farming labor income is relatively low, and it did not constitute a major proportion of total labor income for these counties. These counties with high reliance on farming for employment could be sensitive to BLM management decisions that impact livestock grazing.

This page intentionally left blank.

Chapter 3. BLM Land and Resource Use and Revenue

Resources and resources use data levels based on data from recent fiscal years are provided in the sections below for key resources with a potential to be impacted by proposed management, including mineral and energy development and livestock grazing.

Mineral development under the BLM is managed under three main categories: leasable, locatable, and salable minerals/mineral materials. Each is subject to different federal laws and implementing regulations.

3.1 LEASABLE MINERALS

Leasable minerals are a category of mineral resources made available for exploration and development by mineral leasing. They are specific types of mineral resources described by the Mineral Leasing Act of 1920. They include fluid minerals (such as crude oil and natural gas), solid energy minerals (such as coal), and select nonenergy minerals (such as sodium, phosphate, and potassium).

3.1.1 Fluid Minerals (Oil and Gas)

As mentioned in **Chapter 2**, Demographic and Economic Baseline Conditions, the mining industry is important for supporting the local economies in many communities in the analysis area, especially in areas where a large percentage of employment comes from the mining industry, and a large portion of the mining that occurs on federal lands is for fluid minerals (oil and natural gas). These areas include northwestern Colorado, southeastern Idaho, southeastern Montana, northeastern Nevada, southwestern North Dakota, central to eastern Utah, and northeastern and southwestern Wyoming In addition to these regions, oil and gas extraction is important throughout the states for providing funding for public services through royalties and taxes that are distributed to the states where the extraction occurred. Additionally, the jobs associated with mining, including oil and gas extraction and production, tend to be high paying compared with other types of employment in these rural communities (see **Chapter 2**, Demographic and Economic Baseline Conditions, for more details on employment and labor income by industry in each state).

Oil and Gas Production and Activity

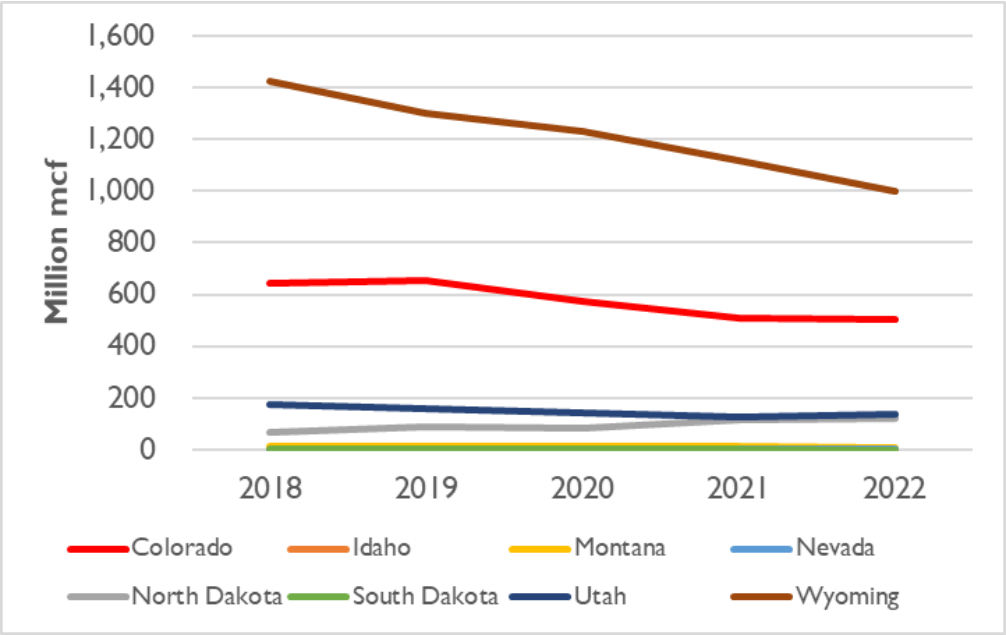
In 2022, the two biggest producers of natural gas on federal land were Wyoming and Colorado, with about 999 million thousand cubic feet (mcf) and 504 million mcf of gas for Wyoming and Colorado, respectively (see **Table A-22** in **Appendix A**, which shows oil and gas production from 2018 to 2022 on federal lands in the planning area as well as statewide totals, and **Figure 1** and **Figure 2**, which show the trends of gas production from 2018 to 2022 for the statewide total and the socioeconomic analysis, respectively). More than half of the federal natural gas production in Colorado occurs outside the Colorado socioeconomic analysis area, with a large portion of natural gas production occurring in Colorado's southwest, north, or northwest regions. However, there is still a large amount of federal natural gas production in the Colorado socioeconomic analysis area, especially in counties in the west-central region of Colorado, which includes Garfield and Mesa Counties.

More than half of the federal natural gas production in Wyoming occurs in Sublette, Sweetwater, and Fremont Counties, which are in the Green River Basin and the Wind River Basin, in Wyoming's southwestern region. These three counties in Wyoming have a large percentage of the BLM-administered

surface acres in GRSG HMAs, which suggests that these counties might be impacted by changes in BLM management decisions on GRSG.

From 2018 to 2022, there was no federal natural gas production in Oregon. Although there was federal natural gas production in California, none of it occurred in the socioeconomic analysis area.

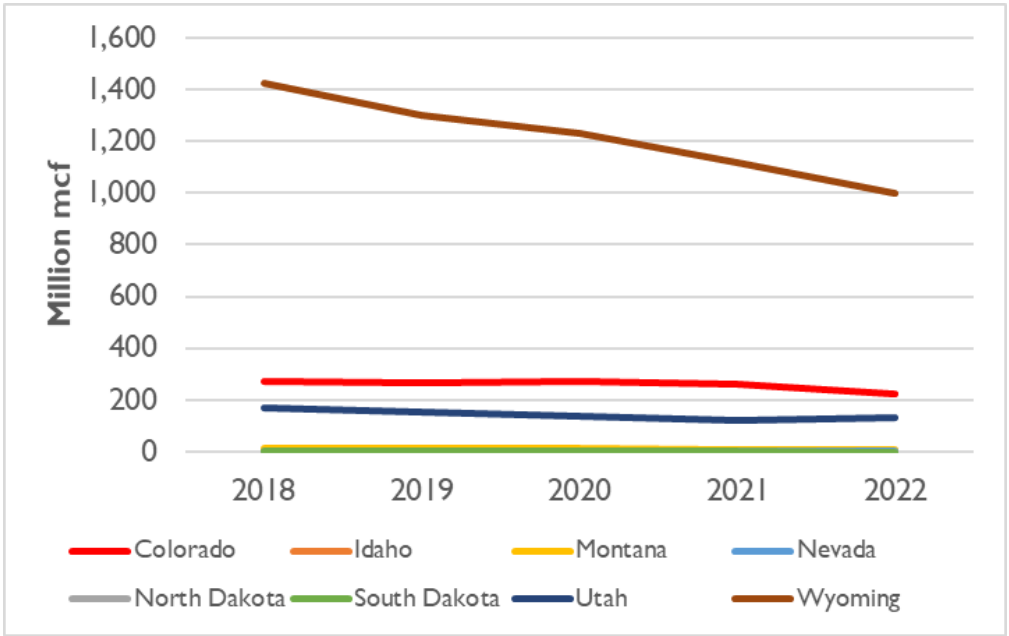
From 2018 to 2022, total gas production increased in North Dakota and Nevada by about 51 million mcf and 1,700 mcf, respectively (which was about a 76.3 percent and 87.2 percent increase, respectively). However, most of the increase in federal natural gas in North Dakota occurred outside the socioeconomic analysis area; all counties in the North Dakota analysis area saw a decrease in natural gas production. Total statewide federal natural gas production decreased in the rest of the states, with the biggest decrease occurring in Wyoming and Colorado, with a decrease of about 426 million mcf and 142 million mcf, respectively (which was a decrease of about 29.9 percent and 22.0 percent, respectively). The county with the largest reduction in magnitude of gas production from 2018 to 2022 was Sublette County in Wyoming, with a reduction of about 334 million mcf (a decrease of about 35.8 percent). The county with the largest increase in magnitude of gas production was Campbell County in Wyoming, with an increase of about 13.6 million mcf (an increase of about 31.3 percent; see **Figure 1** and **Figure 2**, below, and **Table A-22** in **Appendix A**).



In 2022, the two biggest oil producers on federal land were Wyoming and North Dakota, with about 48 million barrels (bbl) and 43 million bbl of oil, respectively (see **Table A-22** in **Appendix A** and **Figure 3** and **Figure 4**, below). However, most of the federal oil in North Dakota is produced outside the North Dakota socioeconomic analysis area, in the west-central region of North Dakota. The North Dakota socioeconomic analysis area, which is in the southwest corner of North Dakota, produces only about 1 percent of the total federal oil for the state. In contrast, most oil produced in Wyoming occurred in the Wyoming socioeconomic analysis area, largely concentrated in the Powder River Basin, Bighorn Basin, and Green River Basin.

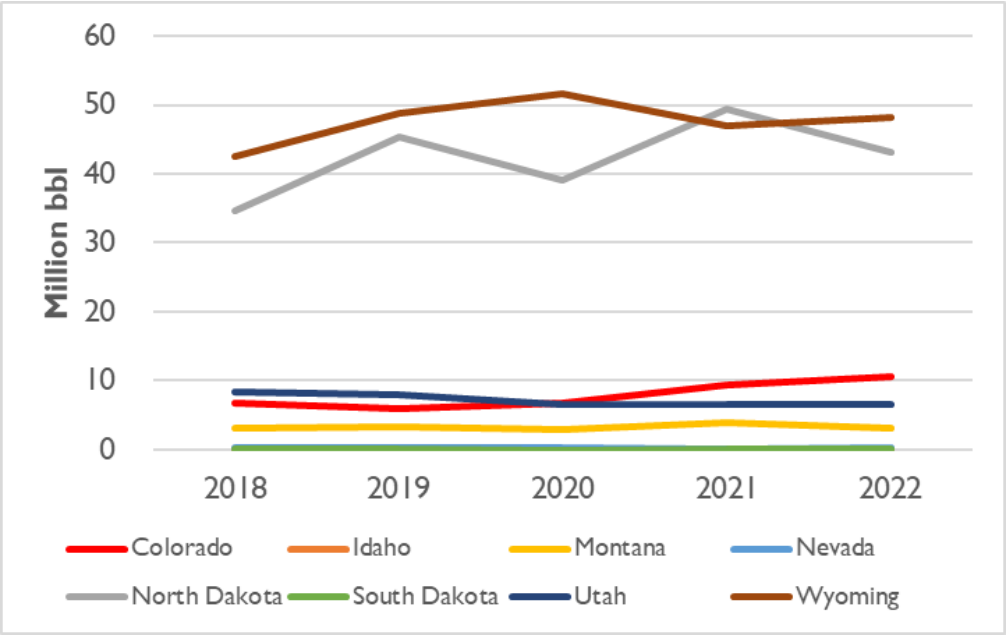
From 2018 to 2022, there was no federal oil production in Oregon. Although there was federal oil production in California, none of it occurred in the socioeconomic analysis area.

From 2018 to 2022, total oil production increased in Colorado, Montana, North Dakota, South Dakota, and Wyoming. The biggest increase in magnitude occurred in North Dakota and Wyoming, with 8.4 million bbl and 5.5 million bbl, respectively. However, except for the increase in oil production in Wyoming, almost all of the increase in federal oil occurred outside the socioeconomic analysis area (all counties in the Colorado, North Dakota, and South Dakota socioeconomic analysis areas and most of the counties in the Montana socioeconomic analysis area saw a decrease in oil production).



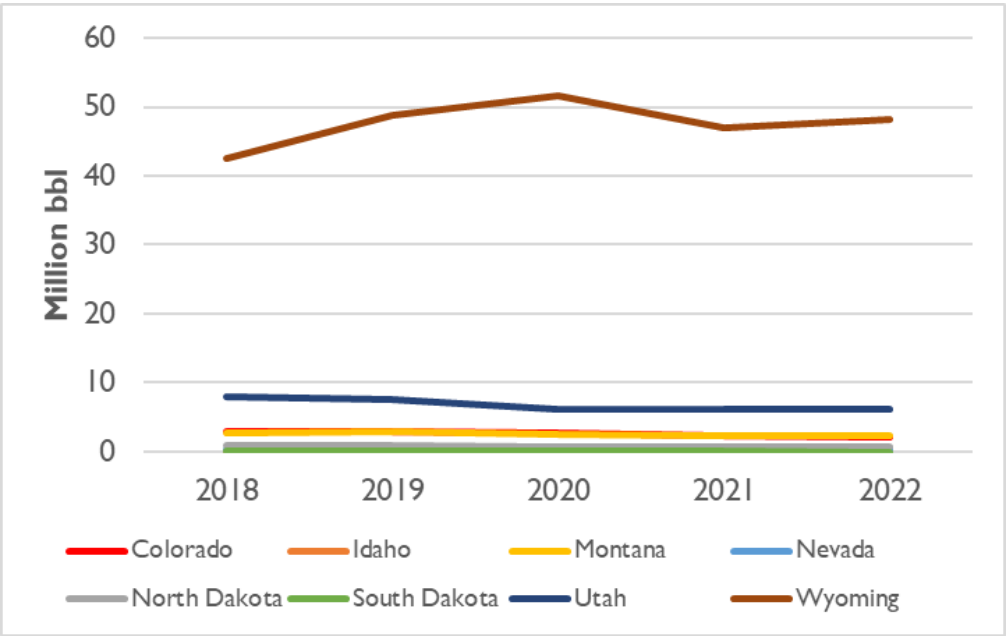
Total statewide federal oil production decreased in the remainder of the states (Idaho, Nevada, and Utah). The biggest decrease in magnitude of federal oil occurred in Utah, with a reduction of about 1.9 million bbl (a decrease of about 22.5 percent from 2018 levels). The county with the largest reduction in magnitude of oil production was Sublette County in Wyoming, with a reduction of about 2.9 million bbl (a decrease of about 49.0 percent). The county with the largest increase in magnitude of oil production was Converse County in Wyoming, with an increase of about 7.7 million bbl (an increase of about 70.1 percent; see **Figure 3** and **Figure 4**, below, and **Table A-22** in **Appendix A**).

Figure 1. Total Statewide Federal Natural Gas Production, 2018–2022



Note: From 2018 to 2022, there was no federal gas production in Oregon. Although there was federal gas production in California, none of it occurred in the socioeconomic analysis area. Therefore, Oregon and California are not included in the figure above.

Figure 2. Federal Natural Gas Production in the Socioeconomic Analysis Area for Each State, 2018–2022



Note: From 2018 to 2022, there was no federal gas production in Oregon. Although there was federal gas production in California, none of it occurred in the socioeconomic analysis area. Therefore, Oregon and California are not included in the figure above.

Figure 3. Total Statewide Federal Oil Production, 2018–2022

Note: From 2018 to 2022, there was no federal oil production in Oregon. Although there was federal oil production in California, none of it occurred in the socioeconomic analysis area. Therefore, Oregon and California are not included in the figure above.

Figure 4. Federal Oil Production in the Socioeconomic Analysis Area for Each State, 2018–2022

Note: From 2018 to 2022, there was no federal oil production in Oregon. Although there was federal oil production in California, none of it occurred in the socioeconomic analysis area. Therefore, Oregon and California are not included in the figure above.

Table 3-1 shows federal oil and gas activity, including cumulative producing leases and acres in producing status, as well as applications for permits to drill (APDs) received and approved in fiscal year 2021 and wells started and completed in fiscal year 2021. In 2021, Wyoming had the most activities on federal land overall, including the most acres in producing status (3.9 million acres), APDs approved (1,432 APDs), wells started (233 wells), and wells completed (1,069 wells). **Table 3-2** shows the historical average annual new federal wells spud[6] by state and area, broken out separately by oil and gas. The annual wells spud is averaged over two time periods: 2013–2014, which is prior to GRSG management changes from the previous 2015 Record of Decisions, and 2015–2022, which includes wells spud after GRSG management changes. On the total federal land in the planning area (on and off GRSG HMAs), the average annual spud rate decreased over the two time periods in every state, except oil wells in Idaho and gas wells in North Dakota.

Many factors not directly related to GRSG management changes contribute to the difference in annual spud rates, such as changes in demand and the price for oil and gas. For example, the crude oil market crash of 2016 and other external constraints, such as fluctuating litigation activities, have significantly affected federal oil and gas production. From 2015 to 2022, average annual spud rates for oil wells over the planning area ranged from less than 1 well per year in Idaho, Nevada, and Utah to about 881 wells per year in Colorado. Gas wells ranged from less than 1 well per year in Colorado to about 245 wells in Wyoming. Additionally, well spud rates on GRSG HMAs were lower than total spud rates; however, this is likely due to the difference in the size of the area.

Table 3-1. Oil and Gas Activity on Federal Land in the Planning Area (Fiscal Year 2021)

State	Cumulative Producible and Service Completions	Cumulative Producing Leases	Cumulative Acres in Producing Status	APDs Received in Fiscal Year 2021	APDs Approved in Fiscal Year 2021	Wells Started in Fiscal Year 2021	Wells Completed in Fiscal Year 2021
California	6,327	318	91,446	200	61	47	116
Colorado	7,397	2,159	1,476,291	82	282	161	133

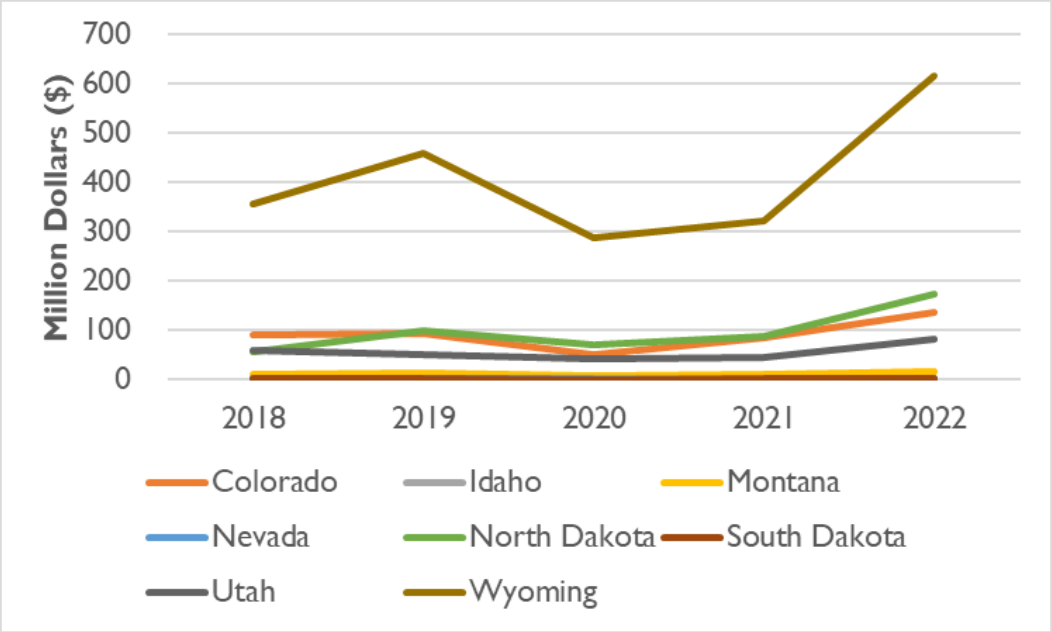
Federal Oil and Gas Disbursement Payments

The government collects revenues from leasable mineral extraction on public lands through bonuses, royalties, and rents paid by producers. These funds are collected and subsequently distributed to the federal and state government. The Department of the Interior, through the Office of Natural Resources Revenue (ONRR), collects a set percentage of the sales value of federal leasable minerals; this is known as a royalty. In August 2022, the US Congress passed H.R. 5376–Inflation Reduction Act of 2022 (the IRA), which updated federal oil and gas leasing terms, including the royalty rate, rental rate, and minimum bonus bid rate. The IRA increased federal royalty rates for new oil and natural gas leases from 12.5 percent to 16.67 percent.



Leaseholders can competitively bid, pay an initial bonus (that is, higher than the minimum bonus bids), and subsequently pay rent for the right to develop the resources on public lands (the IRA eliminated the option for noncompetitive lease sales). The IRA increased the annual rental rates for new competitive oil and gas leases from $1.50 per acre (or fraction thereof) in the first 5 years and $2.00 per acre each year thereafter to $3 per acre from the first 2 years, $5 per acre for years 3 through 8, and $15 per acre for years 9 and 10. After 10 years, those set rental rates will be the minimum. The IRA also increased the minimum bonus bid from $2 per acre to $10 per acre for 10 years; after 10 years, $10 per acre is the statutory minimum.

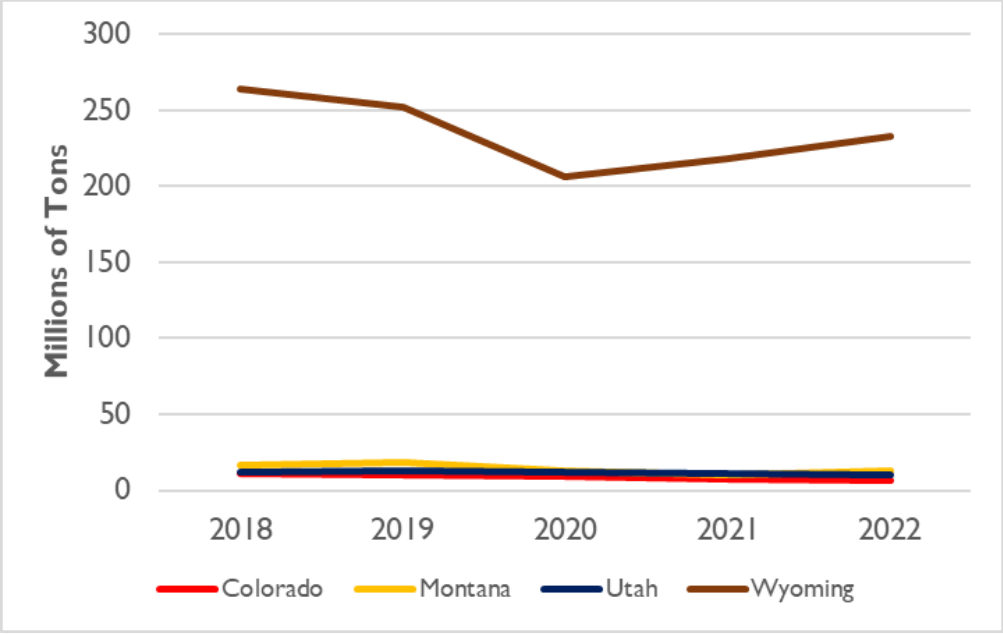
Other revenues that are not included in the royalty, rent, or bonus categories include settlement agreements and expression of interest fees. Approximately 50 percent of revenues collected from the leasing and production of federal minerals go to the US Treasury, and 49 percent of these mineral revenues are transferred to the state in which they were generated. The portion of revenue allocated to the state, in turn, is distributed to counties, cities, and school districts based on the state's own laws and policies (see **Table A-28** in **Appendix A**, which lists the policies for expenditures at the state level and distributions to local governments and school districts).

Lease revenues and royalties distributed to the state and county provide an additional economic contribution from mineral resource extraction. **Figure 5** shows the disbursement payments made to the states from federal oil and gas extraction from 2018 to 2022 (see **Table A-23** in **Appendix A** for the data).[7] Wyoming had the highest disbursement from oil and gas extractions, in 2022, with about $615 million. From 2018 to 2019, oil and gas disbursements made to the states increased in California, Colorado, Montana, North Dakota, and Wyoming, but decreased in Idaho, Nevada, South Dakota, and Utah. From 2019 to 2021, oil and gas disbursements declined for all states in the planning area. In 2022, disbursements increased and returned to 2019 levels or higher; however, disbursements in 2022 were lower than 2018 levels in Idaho, Nevada, and South Dakota.

Over the 5-year time period, Wyoming and North Dakota saw the largest magnitude increase in oil and gas disbursements, with an increase of about $260 million and $117 million, respectively. Nevada and South Dakota saw the largest magnitude decrease in disbursements of about $123,000 and $98,000, respectively. These decreases in disbursements could impact the local economies and public services such as education. If oil and gas disbursements continue to decline in Nevada and South Dakota, public services that are funded through oil and gas disbursements could be impacted.

Figure 5. Federal Disbursements to States from Oil and Gas Extraction, Fiscal Years 2018–2022

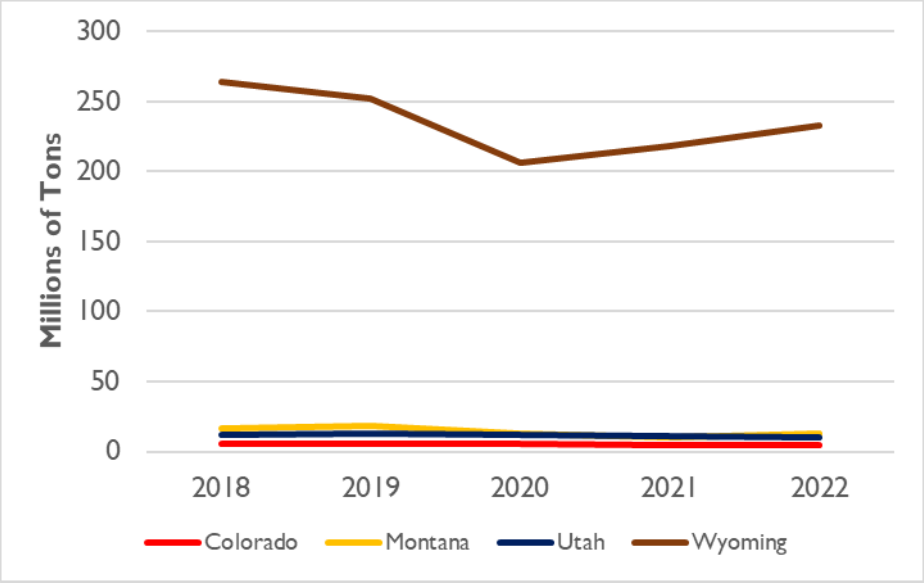
Note: From 2018 to 2022, there was no federal oil and gas production or disbursement made to Oregon. Although there was federal oil and gas production and disbursements made to California, none of the production occurred in the socioeconomic analysis area. Therefore, Oregon and California are not included in the figure above.



[7] The disbursements shown are from revenue prior to the passing and implementation of the IRA. While existing leasing will not be affected by the IRA, the new royalty rates, rental rates, and minimum bonus bids from the IRA will apply to new leases that are issued after the IRA passed. Revenue, production, and disbursements to states from new oil and gas leases are expected to change as a result of the IRA; however, the magnitude of this change is not yet known.

3.1.2 Coal

Coal Mines and Production



Coal is used primarily in the United States to generate electricity. Western coal-producing states with GRSG populations include Colorado, Montana, North Dakota, Utah, and Wyoming. In 2022, Wyoming and Montana were the largest producers of coal on federal lands across the socioeconomic analysis area (see **Table A-24** in **Appendix A**, which shows the coal production in counties included in each state's socioeconomic analysis area between 2018 and 2022, and see **Figure 6** and **Figure 7**, below, which show the total coal production for each state and each state's socioeconomic analysis area, respectively). From 2018 to 2022, there was no federal coal production in California, Idaho, Nevada, Oregon, and South Dakota; while there was federal coal production in North Dakota, none of it occurred in the socioeconomic analysis area.

Figure 6. Total Statewide Federal Coal Production, 2018–2022

Note: From 2018 to 2022, there was no federal coal production in California, Idaho, Nevada, Oregon, and South Dakota. Although there was federal coal production in North Dakota, none of it occurred in the socioeconomic analysis area. Therefore, these states are not included in the figure above.

Figure 7. Federal Coal Production in the Socioeconomic Analysis Area for Each State, 2018–2022

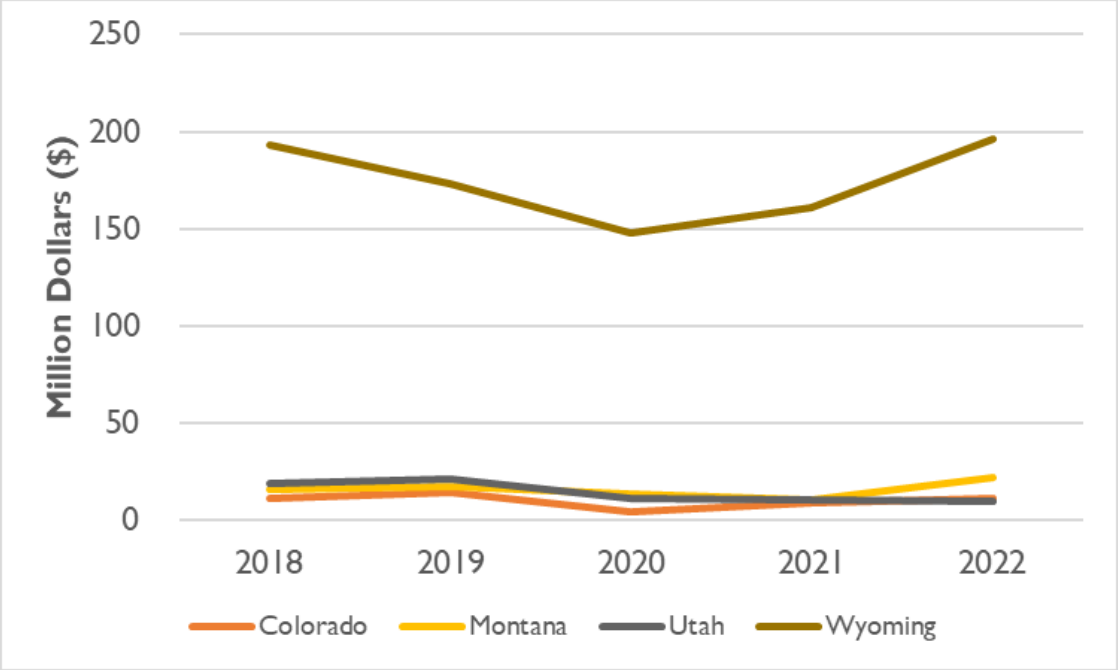
Note: From 2018 to 2022, there was no federal coal production in California, Idaho, Nevada, Oregon, and South Dakota. Although there was federal coal production in North Dakota, none of it occurred in the socioeconomic analysis area. Therefore, these states are not included in the figure above.

Coal production and development activities can be an important contributor to local jobs, labor income, and tax revenue, especially in rural communities. Additionally, the jobs associated with mining, including coal mining, tend to be high paying compared with other types of employment in these rural communities (see **Chapter 2**, Demographic and Economic Baseline Conditions, for more details on employment and labor income by industry in each state). However, due to a change in market conditions, there has been a recent decreasing trend in coal production. All states, except North Dakota, saw a decline in coal production from 2018 to 2022, with the largest percentage decline occurring in Colorado (with a reduction in production of about 77.9 percent over the 5-year period). This reduction of coal production was observed globally. The reduction was largely driven by the reduction in natural gas prices that increased the demand for natural gas and reduced the demand for coal (EIA 2021).[8]

In the coming decade, coal is expected to continue to decrease. The reduction in demand for coal is also expected to continue, and the US is expected to retire about half of its coal-fired capacity by 2026 (Institute for Energy Economics and Financial Analysis 2023).

Federal Coal Disbursement Payments

Due to the reduction in demand for coal-fired generation, many economies throughout the socioeconomic analysis area could face significant financial impacts from the loss of the associated coal mining jobs and tax revenue in the next decade. For example, Moffatt County, Colorado, received over $12 million in ad valorem taxes in 2018 from coal power plants and mines in the county (Mesa University, undated). In Wyoming, continued revenue decreases from coal production have spurred the review of funding mechanisms for state school systems and education services. The Wyoming School Capital Construction Account has been



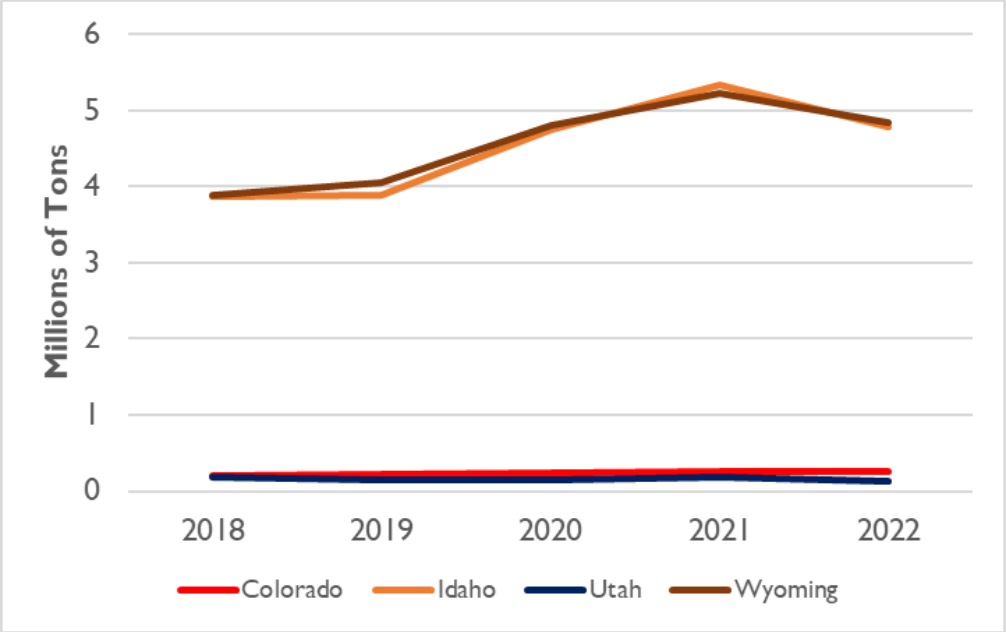
[8] Coal and natural gas are substitute goods and compete for the same demand for energy (Abraham 2018). This means that when the demand for one energy source increases (due to factors such as a decrease in price), the demand for the other energy source decreases.

historically funded through federal coal lease bonuses (see **Table A-25** in **Appendix A**). However, the federal coal lease bonuses in Wyoming peaked at $229.6 million in 2012–2013 and have declined since then, with no foreseeable return through at least 2026 (Wyoming Legislative Service Office 2022; Wyoming Consensus Revenue Estimating Group 2023).

Figure 8 shows the disbursements to the states in the planning area from federal coal extraction (see **Table A-25** in **Appendix A** for the data). Similar to oil and gas, the government collects royalties, rents, bonuses, and other revenues from coal production. Federal royalties for coal are set at a rate of 12.5 percent for surface coal and 8.0 percent for coal extracted from underground mines (US Department of the Treasury 2021). Federal coal leases require payment of an annual rental fee of not less than $3 per acre or fraction thereof (BLM 2022d). The revenues are disbursed to the states, and the states then allocate a portion of the disbursements to counties, local governments, municipalities, and school districts (see **Table A-28** in **Appendix A**, which lists the polices for expenditures at the state level and distributions to local governments and school districts).

All states in the planning area, except Montana and Utah, had stagnant disbursements from coal extraction over the last 5 years. Utah experienced a decline in disbursements of about 48 percent. Montana had a decline in disbursements from 2018 to 2021, but then disbursements increased from 2021 to 2022.

Figure 8. Federal Disbursements to States from Coal Extraction, Fiscal Years 2018–2022



Note: From 2018 to 2022, there was no federal coal production in or disbursement made to California, Idaho, Nevada, Oregon, and South Dakota. Although there was federal coal production in and disbursements made to North Dakota, none of the production occurred in the socioeconomic analysis area. Therefore, these states are not included in the figure above.

3.1.3 Nonenergy Leasable Minerals

Nonenergy Mineral Extraction

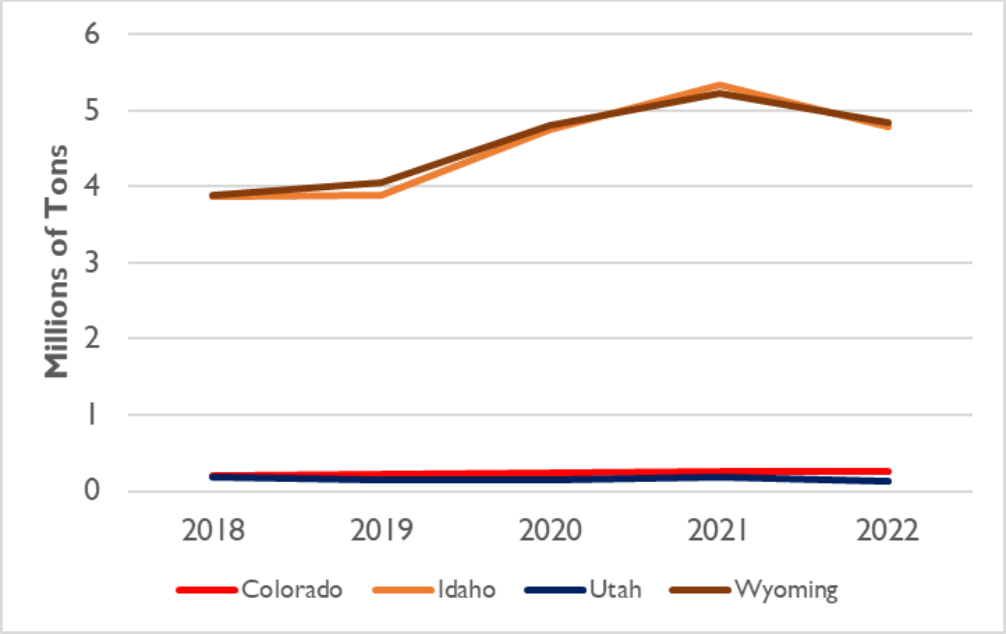


Figure 9 and **Figure 10**, below, show the total federal nonenergy mineral extraction for each state in the planning area and the nonenergy mineral extraction for the counties in each state's socioeconomic analysis area, respectively (see **Table A-26** in **Appendix A** for the data by county). In 2022, Wyoming and Idaho were the biggest producers of nonenergy minerals, with over 4.8 million tons of sodium bicarbonate, trona, soda ash, and sodium sesquicarbonate, as well as other by-products extracted in Wyoming and almost 4.8 million tons of phosphate extracted in Idaho. Nonenergy mineral extraction increased in both Wyoming and Idaho through 2021; it decreased slightly in 2022, but was still above 2018 levels by about 943,000 and 911,000 tons for Wyoming and Idaho, respectively. In Colorado, nonenergy mineral extraction, which is made up of sodium bicarbonate extractions, increased slightly (by about 60,000 tons) from 2018 to 2022. In the Utah, nonenergy mineral extraction, which is made up of clay and gilsonite extractions, decreased slightly from 2018 to 2022, with a reduction of about 54,000 tons.

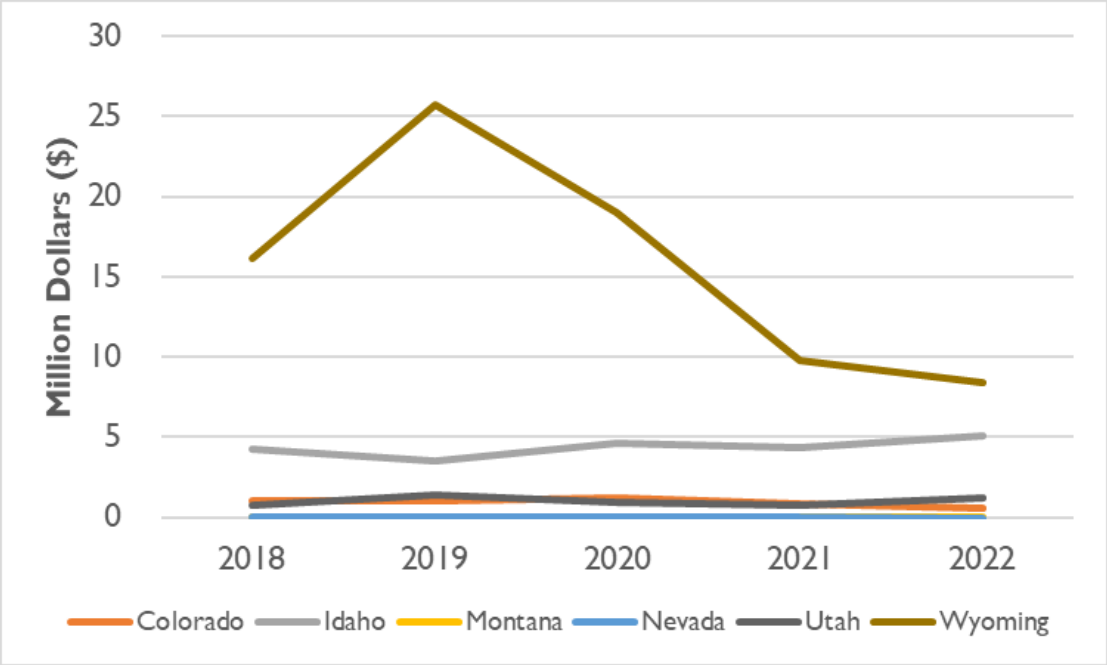
Figure 9. Total Statewide Federal Nonenergy Mineral Extraction, 2018–2022

Note: Montana, Nevada, Oregon, and South Dakota did not have any federal nonenergy mineral extraction from 2018 to 2022. Although there was federal nonenergy mineral extraction in California and North Dakota, the extraction occurred outside the socioeconomic analysis area. Therefore, these states are not included in the figure above.

Figure 10. Federal Nonenergy Mineral Extraction in the Socioeconomic Analysis Area for Each State, 2018–2022



Note: Montana, Nevada, Oregon, and South Dakota did not have any federal nonenergy mineral extraction from 2018 to 2022. Although there was federal nonenergy mineral extraction in California and North Dakota, the extraction occurred outside the socioeconomic analysis area. Therefore, these states are not included in the figure above.

Federal Nonenergy Mineral Disbursement Payments

Similar to oil, gas, and coal, the government collects revenue from nonenergy minerals. The BLM determines and discloses the royalty rate for nonenergy minerals before the lease is offered; the minimum royalty rates are 5 percent of gross value of output for phosphate and sulfur 2 percent of quantity or gross value of output for sodium and potassium, and 25 cents per ton for asphalt. Gilsonite and hard-rock minerals have no minimum royalty rate. A portion of the revenues collected by the government are disbursed to the states, and the states then allocate a portion of the disbursements to counties, local governments, municipalities, and school districts (see **Table A-28** in **Appendix A**, which lists the polices for expenditures at the state level and distributions to local governments and school districts).

Figure 11 shows the disbursements to the states in the planning area from all federal nonenergy extraction, including sodium, potassium, phosphate, hard rock, and gilsonite (see **Table A-27** in **Appendix A** for the data). Wyoming had the highest disbursement from nonenergy mineral extractions, in 2022, with about $8.4 million (all of which came from sodium-based minerals such as trona). However, these disbursements in Wyoming declined from 2019 to 2022 by over $7.7 million, which was the largest decline in magnitude across the planning area. All states, except Idaho and Utah, had either a decline in disbursements or stagnation in disbursements over the 2019–2022 period. Idaho has large deposits of phosphate and disbursements to Idaho over the last five years ranged from about $3.5 million in 2019 to $5.1 million in 2022. Disbursements in Idaho decreased from 2018 to 2019 but increased from 2019 to 2022, which raised the disbursements above 2018 levels by $863,000. Utah disbursements, which are largely from potassium and gilsonite, fluctuated between a low of about $739,000 in 2018 and a high of about $1.4 million in 2019.

Figure 11. Federal Disbursements to States from Nonenergy Leasable Mineral Extraction, Fiscal Years 2018–2022

Note: North Dakota, Oregon, and South Dakota did not have any disbursements from nonenergy minerals from 2018 to 2022. California received disbursements for federal nonenergy minerals extracted in the state; however, the minerals were extracted outside the California socioeconomic analysis area. Montana and Nevada received small disbursements for rents, bonuses, and other distributions from nonenergy minerals, but there were no nonenergy minerals extracted from 2018 to 2022. Therefore, these states are not included in the figure above.

California receives disbursements for nonenergy minerals produced in the state; however, minerals are extracted outside the California socioeconomic analysis area; therefore, changes in BLM management decision on GRSG HMAs would likely not impact disbursements for nonenergy minerals in California. Therefore, the disbursements are not included in this report.

In addition to the public services that nonenergy leasable minerals help support, mining jobs, including jobs associated with nonenergy leasable mining, tend to be some of the highest paying jobs in rural communities, especially in Idaho (see **Chapter 2**, Demographic and Economic Baseline Conditions, for more information on employment and wages in the mining industry).

3.2 Locatable Minerals

Locatable minerals are minerals for which the right to explore or develop the mineral resource on federal land is established by the location (or staking) of lode or placer mining claims and is authorized under the General Mining Law of 1872. Locatable minerals include metallic minerals, such as gold, silver, copper, lead, zinc, molybdenum, and uranium, and nonmetallic minerals, such as fluorspar, asbestos, talc, and mica.

Acquisition of locatable minerals is executed by staking a mining claim over the deposit and acquiring the necessary permits to explore or mine. Within a mining claim located after the Surface Resources Act of July 23, 1955, the surface lands remain open to the public for other multiple uses that do not materially interfere with exploration, mining, and reasonably incident activities. Miners locate claims to acquire the right to develop the mineral values in a specified area. For operations other than casual use, the claimant is required

to submit a notice or a plan of operations. Regulations require the claimant to prevent unnecessary or undue degradation of the land. The BLM may petition the Secretary of the Interior through the process outlined in Section 204 of FLPMA to withdraw areas from further location of mining claims or sites.

Locatable mineral exploration and production occur throughout the planning area, on and off GRSG HMAs. **Table 3-3** shows locatable minerals found in the planning area by state.

Table 3-3. Locatable Mineral Types on Federal Lands in the Planning Area*

States	Precious and Base Metals	Industrial Minerals
Colorado	Gold, molybdenum, and uranium	Gypsum
Idaho	Gold, silver, copper, lead, iron, molybdenum, beryllium, uranium, and vanadium	Limestone, bentonite, high-alumina clay, and gypsum
Montana	Gold, silver, and mercury	Bentonite and diamonds
Nevada	Gold, silver, copper, lithium, galena, iron, zinc, cobalt, vanadium, tungsten, antimony, and molybdenum	Gypsum, limestone, diatomite, bentonite, silica sand, magnesium, and barite
Oregon	Gold, silver, lead-silver-zinc, copper, uranium, iron, and arsenic	Borax, dimension stone, mercury, limestone, diatomaceous earth, zeolites, kaolinite, perlite, gemstones, and bentonite
Utah	Gold, silver, copper, lead, iron, molybdenum, beryllium, uranium, and vanadium	Limestone, bentonite, high-alumina clay, and gypsum
Wyoming	Uranium, gold, titanium, and lithium	Limestone, marble, bentonite, and jade

Source: BLM and Forest Service 2015; Muntean et. al 2022; USGS 2016
*This list includes locatable minerals commonly known to exist in the planning area. It is not an exhaustive list of all locatable minerals in the planning area. Inclusion on this list does not imply that these metals and minerals are being developed or extracted.

Nevada is one of the top hard-rock mining states. The General Mining Law does not require mines to report production or subject these minerals to royalty payments; therefore, production data is not available for all BLM administered lands. however, data on open claims for locatable minerals are available throughout the planning area. Within GRSG priority habitat management areas (PHMAs), Nevada and California, combined, have about 147,160 existing open claims across 21,167,000 acres of BLM-administered locatable minerals.[9] This is the most open claims in GRSG habitat of all the states in the planning area. In Colorado, there are about 552 existing open claims across 3,600,000 acres of BLM-administered locatable minerals on PHMAs. In Idaho, there are about 7,219 existing open claims across 10,203,000 acres of BLM-administered locatable minerals on PHMAs. In Montana, South Dakota, and North Dakota, combined, there are about 2,315 existing open claims across 8,371,000 acres of BLM-administered locatable minerals on PHMAs. In Oregon, there are about 4,993 existing open claims across 12,126,000 acres of BLM-administered locatable minerals on PHMAs. In Utah, there are about 6,418 existing open claims across 3,952,000 acres of BLM-administered locatable minerals on PHMAs. Finally, in Wyoming, there are about 33,401 existing open claims across 26,012,000 acres of BLM-administered locatable minerals on PHMAs (BLM 2023).

Regions in Idaho, Oregon, and Nevada have had sharp increases in the average number of annual claims since 2016. There could be a number of reasons for the increase, including a potential increase in demand for critical minerals in the area, a potential increase in the price of locatable commodities, or operators looking to secure claims, in the event the Secretary decides to withdraw the areas proposed in the 2016 SFA Withdrawal process which is currently underway.. Claims that exist in a withdrawal area before the date of

[9] As of November 2023, there were over 250,000 active mining claims across all BLM-administered lands in Nevada, on and off-PHMAs.

a withdrawal are not subject to the withdrawal and could potentially be developed in the future, subject to a validity examination. However, validity examinations typically cost at least $50,000 per claim to complete and have the potential to delay the start of locatable mineral development on a valid claim, which could add risks and costs to the operators (BLM 2023).

Locatable mineral production data is available for some BLM field offices, including those in Nevada, where locatable mineral production represents an important use. **Table 3-4** shows locatable minerals production by state for states and field offices where data is available.

Table 3-4. Locatable Mineral Annual Production in the Planning Area (Fiscal Year 2022)

Locatable Minerals	Colorado	Nevada	Wyoming
Bentonite (tons)	—	—	1,200
Cement (ton)	—	24,208	—
Dolomite	—	23,393	—

Source: BLM 2023

Note: Data provided are state-level data for all BLM-administered lands and minerals as available. Data are not reported for all states. No production data is available for California, Idaho, Montana, North Dakota, Oregon, South Dakota or Utah.

The value of minerals and their contribution to local and regional economies vary based on market conditions and the volume extracted. Within the planning area, all the states, except South Dakota and North Dakota, impose taxes on locatable hard-rock mining activities. The taxes in most states are collected regardless of landownership (see **Table A-29** in **Appendix A** for information on state taxes for hard-rock mining activities on all lands). The type of taxes and amount collected vary across states; however, the distributions of the taxes are important in supporting public services and infrastructure by providing funds for schools; local counties, cities, and towns; highways and road construction; and water infrastructure (State of Wyoming Legislature 2021). In addition to the public services that locatable minerals help support, mining jobs, including hard-rock mining jobs, tend to be some of the highest paying jobs in rural communities, especially in Nevada (see **Chapter 2**, Demographic and Economic Baseline Conditions, for more information on employment and wages in the mining industry).

Economic contributions from locatable mineral development for states in which production data on BLM administered lands is available are provided in **Table 3-5**, below.

Table 3-5. Locatable Mineral Annual Direct Economic Contributions in the Planning Area (Fiscal Year 2022)

Locatable Mineral	Impact	Colorado	Nevada	Wyoming
Bentonite	Direct Jobs	—	—	12
	Direct output ($)	—	—	4,147,821
Cement	Direct Jobs	—	140	—
	Direct output ($)	—	29,031,529	—

3.3 MINERAL MATERIALS

Salable minerals or mineral materials are common minerals sold or given away to local governments, other government entities, and nonprofit groups. Salable minerals are defined as lower-value, common-variety materials, such as rock, gravel, and soil. The term "salable minerals" is synonymous with "mineral materials" and can also be called "common-variety minerals." The BLM has discretion to manage the sale or removal of these materials, with the sale regulated by commercial permits. Salable minerals are also sometimes provided free of charge to local governments for public projects under free-use permits. The volume of material sold and used varies by state.

Table 3-6 shows the number of permits and quantity of federal salable minerals extracted in the 2021 fiscal year, separated out by free-use permits and exclusive and nonexclusive permits. Idaho had the largest number of existing free-use permits, with 93 permits and almost 78,000 cubic yards of extracted mineral materials. Nevada had the largest quantity of extracted mineral materials under free-use permits, with almost 95,000 cubic yards extracted across 78 permits. Wyoming had the largest number of new free-use permits issued in 2021, with 24 new permits and over 3,000 cubic yards of mineral materials extracted. Colorado had the largest quantity of extracted mineral materials under free-use permits, with over 2.1 million cubic yards of mineral materials across 9 permits.

Note: Materials were disposed of under the Materials Act of 1947 (61 Statute 681; 30 US Code 601), as amended by the Multiple-Use Mining Act of 1955 (69 Statute 367).

[a] The data are aggregated into eight standard material groups.

[b] New disposals this year showing the total quantity and value over the full term of the authorization.

[c] Reports show the quantity and dollar values of production this year from all new and previously issued sale contracts and permits.

[d] Includes sales and permit data originally reported in both tons and cubic yards. For this table, all data have been converted automatically to cubic yards.

[e] Total exclusive and nonexclusive numbers are combined together.

[f] Includes North Dakota and South Dakota

[g] Includes Washington

[h] Includes Nebraska

[i] The sum of each state's exclusive and nonexclusive totals

Nevada had the largest number of existing exclusive and nonexclusive permits and the largest quantity of mineral materials extracted across these permits, with 438 existing permits and almost 3.2 million cubic yards of mineral materials. Nevada also had the largest quantity of mineral materials extracted under new existing exclusive and nonexclusive permits, with almost 7.7 million cubic yards. Utah had the largest number of new existing exclusive and nonexclusive permits, with 362 total permits.

Because mineral materials generally do not represent scare commodities, they can be found throughout the analysis areas, on and off GRSG HMAs. Sand and gravel, used often as construction aggregate, are an extremely important resource. The extraction of these resources varies directly with the amount of development—road building and maintenance, and urban development—nearby; this is because sand and gravel are necessary for the development of that infrastructure. The proximity of both transportation and markets are key elements in the potential for deposits to be developed, even more so than for other types of mineral deposits (Burgex Mining Consultants 2023).

Future demand for mineral materials will vary depending on market conditions, which differ according to economic conditions and construction activity. One major driver of construction activity is road and well pad construction for oil and gas exploration and development and residential and commercial construction projects. As new oil and gas development continues to occur, it is expected that mineral materials activity will continue. Another driver of demand for mineral materials is to improve road access for fire suppression activities. The construction, maintenance, and effectiveness of fuel breaks can be impacted by availability of mineral material pits.

Community pits are sites established by governmental agencies for the public to acquire mineral materials through sales contracts. Local government agencies and nonprofit organizations may obtain these materials free of cost for community purposes. County and state road construction divisions are the significant users of gravel and sand resources. A negotiated sale is an exclusive site proposed by a single party, often commercial, as the party must pay for the BLM to process the permit. The number of sales out of a community pit varies by site, from less than one to more than 50 per year. Most sales are for less than 1 ton. Free-use permit sites are used sporadically and may be scattered throughout a field office (FO) or district office; this way, when the county needs material, it has a nearby source, thereby reducing haul costs. A pit may be inactive for several years before it is needed for a road project in the area.

Mineral material extraction and mining is an important part of many local economies, and jobs associated with mining, including mineral materials extraction and mining, tend to be high paying compared with other types of employment in these rural communities (see **Chapter 2**, Demographic and Economic Baseline Conditions, for more details on employment and labor income by industry in each state).

3.4 RENEWABLE ENERGY

3.4.1 Geothermal Energy

Geothermal reservoirs are naturally occurring areas of hydrothermal resources, where the natural heat of the earth's interior heats groundwater in porous or fractured rock. This geothermal hot water and steam can be harnessed as a source of renewable energy when they are brought to the surface, either naturally or by drilling. The most active natural reservoirs tend to occur close to the boundaries of tectonic plates. The areas in the US with the highest potential for geothermal power are in western states where large areas have hydrothermal resources near the earth's surface and can be accessed more economically. More than 90 percent of all US geothermal power generation occurs in California and Nevada (NREL 2021). Other states in the planning area with geothermal production are Idaho, Oregon, and Utah. However, only Nevada and Utah had geothermal production with a federal stake that was in the counties within the socioeconomic analysis area; therefore, the focus of this discussion is on Nevada and Utah (see **Table 3-7**).

Geothermal resources exist in significant portions of the Nevada socioeconomic analysis area. Based on US Geological Survey data, the highest potential for geothermal development likely occurs along Nevada's western border, which is outside GRSG HMAs. However, there is also moderate to high potential for geothermal development in northeastern Nevada, which contains a high percentage of land in GRSG HMAs (Williams et al. 2008). Nevada currently has 25 operating geothermal power plant units in 18 locations (State of Nevada Commission on Mineral Resources 2023). Twenty-two of these operating geothermal units are in counties within the analysis area, and 10 of these plants are within or near GRSG PHMAs.

Table 3-7. Total Geothermal Electrical Generation with a Federal Stake, 2018–2022 (kWh)

State	County	2018	2019	2020	2021	2022

Source: ONRR 2023

Note: The data include all planning area counties for which the ONRR reported data; while there was geothermal production in California, no geothermal production occurs in the California socioeconomic analysis areas.

Between 2015 and 2019, geothermal project development growth in Nevada surpassed growth in all other states; five new geothermal plants came online in Nevada during this period (NREL 2021) Nevada's geothermal electricity generation was the second highest in the US, after California. In 2021, geothermal power plants in Nevada collectively produced 825 megawatts (MW) of electricity (State of Nevada Commission on Mineral Resources 2021).

Table 3-7 shows the total electrical generation from geothermal resources administered by the BLM from 2018 to 2022. In Nevada, geothermal energy increased from 2018 to 2022 by about 375 million kilowatt-hours (kWh), which was an increase of about 16.3 percent. This increase in geothermal energy in Nevada is a trend that has continued since the 2015 Record of Decisions. Of the counties in the analysis area, Lander County in Nevada had the largest increase in the amount of generation, with an increase of about 368 million kWh (an increase of about 52.7 percent).

Table 3-8 shows the historical average annual new geothermal wells spud with a federal stake in Nevada, broken out by total land area and limited to only on GRSG HMAs. The annual wells spud is averaged over two time periods: 2013–2014, which is prior to GRSG management changes from the previous 2015 Record of Decisions, and 2015–2022, which includes wells spud after GRSG management changes. The average annual spud rate for geothermal wells in Nevada increased slightly over the two time periods across the total land in the analysis area (on and off GRSG HMAs), and the annual spud rate decreased over the two time periods on GRSG HMAs. However, the differences between spud rates across the two time periods were minimal, with changes of less than one well per year.

Table 3-8. Average Annual New Wells Spud with a Federal Stake in Nevada, by Area

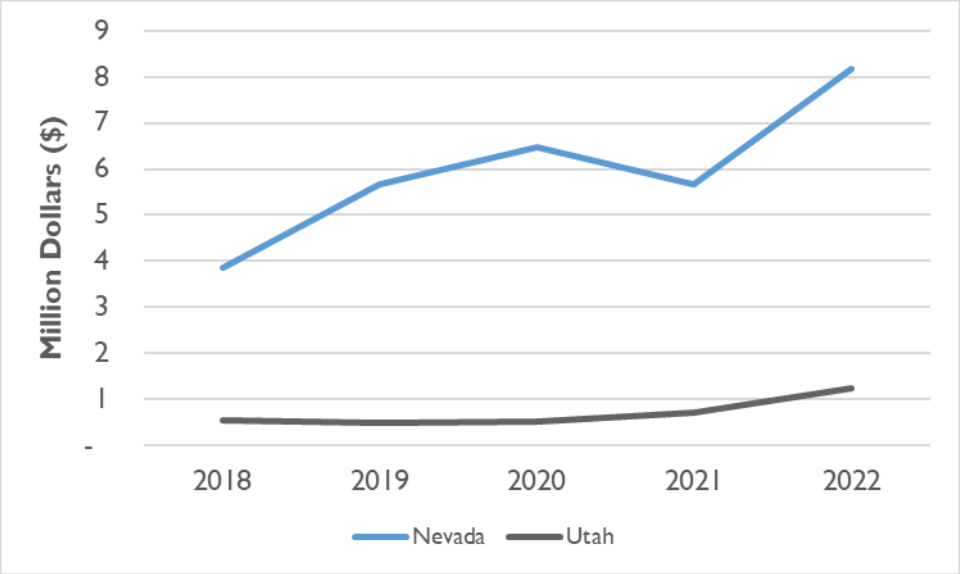
Area	2013–2014 Average	2015–2022 Average
GRSG HMAs	2.00	1.37
Total	2.00	2.75

Source: BLM 2023

Over the next 20 years, there could be about 20 power plants developed on federal leases in the GRSG planning area, which would amount to about 589 MW of geothermal generation capacity (BLM 2023e).

Geothermal resources in Utah are plentiful in the middle and northern portions of the state, although a lack of transmission capacity may hinder development, especially in the northwest corner. Geothermal resources in Utah have been estimated to have the potential to supply 15,000 MW of electricity. There are currently three geothermal power plants in Utah with capacity of 72.5 MW (BLM 2023h). Two of the three geothermal power plants in Utah (Blundell and Cove Fort-Sulpherdale power plants) are partially on BLM-administered lands with federal geothermal leases.

Table 3-7 shows the total geothermal electrical generation with a federal stake, from 2018 to 2022, in counties in the Utah analysis area and the total for the state of Utah. Although generation has fluctuated from year to year, both counties in the analysis area that produced geothermal generation, as well as the state of Utah, saw a reduction in geothermal generation in 2022 from 2019 levels. Beaver County in Utah saw the largest reduction in magnitude of geothermal generation, with a decrease of nearly 13 million kWh from 2018 to 2022 (a reduction of about 11.7 percent over the 5-year period).



There are areas with moderate levels of geothermal energy development potential within the GRSG HMAs in Beaver and Iron Counties in southwestern Utah and Carbon, Uintah, Duchesne, and Grand Counties in the eastern region of the state. These overlapping areas are small, and there are other nearby areas that could have better potential for geothermal energy development that are not on GRSG HMAs; however, there could be up to one 30 MW geothermal power facility developed on BLM-administered lands in GRSG HMAs over the next 20 years (BLM 2015a, 2023h).

Industry surveys show geothermal power plants employ about 0.74–1.17 people per MW to maintain and operate a facility; an additional 0.96 secondary jobs per MW are generated for every power plant built. Additionally, there are temporary jobs in the manufacturing and construction sectors created by the construction of new power plants. Over the 17–33 months in which an average plant is constructed, about 3.1 people per MW of full-time employment are needed to construct the plant, and 3.3 people per MW are needed to manufacture the plant equipment (Geothermal Energy Association 2015).

Federal Geothermal Disbursement Payments

The government collects revenues from leasable mineral extraction and geothermal production on public lands, which are subsequently distributed to the federal, state, and local governments. These revenues that are distributed to the state and county provide important economic contributions that often support public services, like education. **Figure 12** shows the disbursement payments made to the states from geothermal with a federal stake from 2018 to 2022 (see **Table A-23** in **Appendix A** for the data). In 2022, Nevada and Utah saw disbursements of about $8.2 million and $1.2 million, respectively. Over the 5-year time period, the disbursements from geothermal with a federal stake in Nevada and Utah increased by over two times.

Figure 12. Disbursements to States from Geothermal with a Federal Stake, Fiscal Years 2018–2022

Note: From 2018 to 2022, there was no geothermal production with a federal stake in Colorado, Idaho, Montana, North Dakota, Oregon, South Dakota, and Wyoming. Although there was federal oil and gas production and disbursements made to California, none of the production occurred in the socioeconomic analysis area. Therefore, only Nevada and Utah are included in the figure above.

3.4.2 Wind and Solar

Wind and solar projects on BLM-administered lands are authorized under right-of-way (ROW) leases or grants. A ROW is a permit that authorizes the use of a specific parcel of BLM-administered land for projects, such as renewable (wind or solar) energy sites. A ROW authorizes the holder to construct, operate, maintain, and terminate a facility for the life of the project.

Table 3-9 shows the number of Federal Land Policy and Management Act of 1976 ROWs for energy only, which includes wind and solar projects. Northeastern California and Nevada reported the largest number of ROWs for energy projects, with 48 ROWs and 16 ROWs, respectively. As of 2021, five wind projects were operating on public lands in the analysis area (in Nevada, Oregon, Utah, and Wyoming), and one project (in Wyoming) was pending construction (BLM 2021). As of 2022, there were only two solar projects operating on public lands in the analysis area (in Nevada and Wyoming), and one project (in Utah) was pending construction (BLM 2022e).

Chapter 2, Demographic and Economic Baseline Conditions, discusses the jobs in key sectors for each state in the analysis area, and **Table A-2** through **Table A-21 (Part 3)** in **Appendix A** of this document show the number of jobs and labor income by sector county in each state of the analysis area, as reported by the US Bureau of Economic Analysis. Renewable energy, such as wind and solar development and operations and maintenance, support jobs in various industries, such as the construction industry, so the US Bureau of Economic Analysis includes the jobs that are supported through renewable energy in the employment numbers for these various industries rather than reporting jobs for renewable energy separately.

Table 3-9. Number of Federal ROWs for Energy (Solar and Wind), Fiscal Year 2021

Administrative State	Total ROWs for Energy	Solar ROWs in Analysis Area Counties (Operating and Pending Construction)	Wind ROWs in Analysis Area Counties (Operating and Pending Construction)
California	61	0	0
Colorado	1	0	0
Idaho	9	0	0
Montana	0	0	0
Nevada	28	1	1
North Dakota	0	0	0
Oregon	2	0	1

3.5 LIVESTOCK GRAZING

The BLM administers public land grazing primarily in accordance with the 1934 Taylor Grazing Act, 1976 Federal Land Policy and Management Act, and 1978 Public Rangelands Improvement Act. Grazing use on public land is administered through grazing authorizations (leases or permits) issued by FOs to qualified applicants, who are assigned grazing preference. Preference is expressed in animal unit months (AUMs) or the amount of forage consumed by one cow and calf for 1 month.

Table 3-10 shows the 5-year average billed AUMs associated with the total permitted allotments and permitted allotments with greater than 15 percent PHMA land on BLM-administered lands in the planning area, by allotment type. Wyoming and Nevada had the most total billed AUMs on average, with about 1.4 million AUMs and 1.2 million AUMs, respectively. In Wyoming, 98 percent of the billed AUMs are on allotments with greater than 15 percent of PHMA land. In Nevada, about 87.6 percent of billed AUMs are on allotments with PHMA land. This suggests that BLM management decisions that affect livestock grazing could impact these states.

The species (type) and age (class) of livestock that graze across the planning area vary across FOs; however, they are primarily cow-calf pairs or yearling cattle in all states. Some allotments graze other kinds of livestock, including sheep, goats, bison, and horses.

Table 3-10. 5-Year Average Livestock Grazing Billed AUMs on BLM-Administered Lands (2018–2022)

State	Livestock Type	5-Year Average Billed AUMs (2018–2022)	5-Year Average Billed AUMs on Allotments with Greater than 15 Percent PHMA Land	Percentage of Billed AUMs on Allotments with Greater than 15 Percent PHMA Land

Source: BLM 2023

The BLM-administered lands and other public and private lands support values to the local economies across the socioeconomic study area by providing forage for local farmers to raise their cattle, sheep, goats, bison, and horses. These, in turn, provide food to the farmers, their families, and the surrounding communities. Under the Taylor Grazing Act, a portion of BLM grazing revenue is returned to the county of origin; 50 percent of Section 15[10] fees collected are returned to counties, and 12.5 percent of Section 3[11] fees are returned to counties. Grazing revenue and the disbursement that is returned to the county vary by county and may have a higher level of importance at the local level for some communities. In addition, the lands provide value through the social and cultural connections with livestock grazing in the analysis areas; these values are discussed in **Chapter 4**, Social Setting and Nonmarket Values.

Across the US there are different types of farms and ranches that operate and make business decisions in different ways. The USDA Economic Research Service developed a classification, or "typology", of farms and ranches based on annual gross cash farm income (the ranch or farm's revenue prior to deducting expenses), primary occupation of the operator, and ownership of the farm or ranch. Farms and ranches are broadly categorized into family and non-family ranches based on whether the majority of the ranching business is owned by the primary operator and relatives of the primary operator (non-family ranches are those where the operator and individuals who are related to the operator do not own a majority of the business). Family ranches are further categorized by size and primary occupation of the operator as described below (USDA Economic Research Service 2024):

- Small family ranches are those that have gross cash farm income of less than $350,000 per year. These ranches are broken into four types based on the primary occupation of the operator and size of the ranch: retirement ranches (where the operators are retired but continue to ranch on a small scale), off-ranch primary occupation (where the operators report a primary occupation other than farming or ranching), ranch primary occupation with low sales (where the operators report that farming or ranching is their primary occupation and the gross cash farm income of their farm is less than $150,000), and ranch primary occupation with moderate sales (where the operators report that farming or ranching is their primary occupation and the gross cash farm income of their ranch is at least $150,000 but less than $350,000).
- Midsize family ranches are those that have gross cash farm income of at least $350,000 but less than $1 million.
- Large family ranches are those that have gross cash farm income of at least $1 million but less than $5 million.
- Very large family ranches are those that have gross cash farm income of at least $5 million.

[10] Section 15 lands are public lands that lie outside a grazing district administered by the BLM under Section 15 of the Taylor Grazing Act. The BLM authorizes livestock grazing on these lands by issuing leases to private parties.
[11] Section 3 of the Taylor Grazing Act concerns grazing permits issued on BLM-administered lands within the grazing districts established under the act. It gave leasing preference to landowners and homesteaders in or adjacent to the grazing district lands.

Table 3-11 shows the percentage of farms and ranches in the beef cattle ranching and farming or sheep goat farming industries by the ranch typology described above for each state in the analysis area. The data provided include farms and ranches in as well as outside of the analysis area and on and off BLM-managed lands; however, the data can be used for illustrative purposes to examine how different types of farms and ranches might be impacted by the BLM-management decisions differently. Additionally, the data shown is for farms and ranches that produced or sell at least $1,000 of agricultural products per year, so it does not include very small farms and ranches that produce less than $1,000 of agricultural products or where the operators normally consume the products that are produced. In all of the states in the analysis area, except California, the largest percentage of ranches fell in the category of small family ranch with off-ranch primary occupation (with percentages ranging from 24.7 percent of ranches in Montana to 45.4 percent of ranches in Utah). Ranches that fell into the category of small family ranch with ranch primary occupation and low sales made up a large percentage of total ranches, especially in Colorado, Montana, North Dakota, South Dakota, and Wyoming, where the percentages of this type of ranch was above 20 percent. Furthermore, when considering all small family ranches where ranching is the primary occupation (both low sales and moderate sales together), the percentage was larger than small family off-ranch primary occupation ranches in Montana, North Dakota, South Dakota, and Wyoming (USDA National Agricultural Statistics Service 2012, 2024). The BLM-management decisions that impact livestock grazing would likely have a greater effect on small family ranches where ranching is the primary occupation than other types of ranches. This is because small family ranches where ranching is the primary occupation rely more heavily on ranching than other types of small family ranches and they tend to have less flexibility and resources for modifying business practices based on the BLM-management decisions than larger ranches (for example, they have less ability to absorb higher costs, if ranching costs were to increase).

Table 3-11. Percentage of Beef Cattle and Sheep and Goat Farms and Ranches by Ranch Type for Each State in the Analysis Area (2024)

Ranch Size	Ranch Type	California	Colorado	Idaho	Montana	Nevada	North Dakota	Oregon	South Dakota	Utah	Wyoming	US Total
Small family ranches	Retirement ranch[1]	35.3	24.3	25.3	15.6	28.6	11.0	36.7	9.9	27.3	16.3	33.9
	Off-ranch primary occupation[1]	34.9	37.7	43.5	24.7	31.7	30.1	38.8	28.5	45.4	28.5	45.8
	Ranch primary occupation with low sales[1]	16.3	21.1	18.8	21.8	14.6	22.5	15.4	21.2	13.2	18.5	17.3
	Ranch primary occupation with moderate sales	4.7	6.6	5.1	14.9	7.2	16.8	3.0	17.5	3.8	14.1	0.7
Midsize family ranches		2.9	4.1	2.8	13.3	7.7	13.4	2.6	15.4	3.2	11.5	0.3
Large-scale family ranches		1.3	1.2	1.1	3.2	2.9	3.7	1.0	3.8	0.8	3.7	0.1
Very large-scale family ranches		0.4	0.2	0.2	0.2	0.4	0.1	0.1	0.2	0.0	0.2	0.0
Non-family ranches		4.2	4.8	3.3	6.3	6.8	2.4	2.6	3.4	6.3	7.2	1.8
Total		100	100	100	100	100	100	100	100	100	100	100

Source: USDA National Agricultural Statistics Service 2012, 2024

[1]Data from the 2022 Census of Agriculture did not break out small family farms with low sales into separate categories for retirement ranches, off-ranch primary occupation, and ranch primary occupation with low sales, so these percentages were estimated based on data from the 2012 census, which was the last year data was reported for these categories separately.

3.6 WILD HORSE AND BURROS

The Wild Free-Roaming Horses and Burros Act of 1971, as amended by the Federal Land Policy and Management Act of 1976 and the Public Rangeland Improvement Act of 1978, directs the protection and management of wild horses and burros on BLM-administered lands. Responsibility for wild horse and burro management is governed by 43 Code of Federal Regulations 4700. One of the BLM's top priorities is to ensure the health of the public lands so that the species depending on them, including the nation's wild horses and burros, can thrive. The BLM policies and regulations also direct that wild horses and burros are to be managed as self-sustaining populations of healthy animals.

The 53.8 million acres across the western US where wild horses or burros were found roaming at the time the 1971 Wild Free-Roaming Horses and Burros Act was passed are known as herd areas. A subset of these areas (approximately 31.6 million acres nationwide) have been determined suitable for long-term management of wild horses and burros and are known as herd management areas (WHB HMAs). Wild horses and burros within WHB HMAs are managed with the goal of maintaining sustainable ecological conditions and multiple-use relationships on federal lands. Both herd areas and WHB HMAs can include private or state lands, but the BLM has management authority only over public lands.

To carry out its duties under the 1971 law, the BLM periodically evaluates each herd area to determine whether it has adequate food, water, cover, and space to sustain healthy and diverse wild horse and burro populations over the long term. The BLM may designate an appropriate management level (AML) and specify an allowable range in horse numbers for each WHB HMA, based on the available forage and other resources necessary to sustain the horse or burro populations, as well as resource objectives and other designated uses of the BLM-administered lands.

In the planning area, there are approximately 15 million acres of wild horse and burro WHB HMAs. The BLM administers 168 WHB HMAs within California, Colorado, Idaho, Montana, Nevada, Oregon, Utah, and Wyoming. Current conditions within the planning area show that wild horse populations continue to grow, often exceeding AMLs. As wild horse and burro populations exceed AMLs, wild horses and burros can be causal factors for failing to meet applicable standards (**Table 3-12**).

Table 3-12. Wild Horse and Burro Herd Management Areas by State

State	Acres of WHB HMAs	Statewide "High" AML	Estimated Current Population	Percent above AML
California	2,053,082	2,200	10,140	361
Colorado	365,988	827	1,873	126
Idaho	383,894	617	555	0
Montana	27,094	120	195	63
Nevada	14,032,947	12,811	46,570	264
Oregon	2,733,577	2,700	4,532	68
Utah	3,644,013	3,795	4,017	6
Wyoming	26,917,766	2,200	4,734	115
Total	**50,158,361**	**25,270**	**72,616**	**208**

Source: BLM 2022

Wild horses are often termed "living symbols of the historic and pioneer spirit of the West." (16 U.S.C. § 1331). As such, some stakeholders place a social value on horses related to this symbolism. Wild horses may also hold value for some due to an emotional connection related to the long history of human-horse interactions throughout civilization (Scasta, Henning and Beck 2018).

As discussed in Rodriguez (2020) people's emotional responses to horses as well as the increasing need for management of wild populations have resulted in controversy about this issue throughout the West (Michaels 2018; Scasta, Henning and Beck 2018; Scasta 2019) Concerns over increasing wild horse and burro populations and program costs have prompted discussions, studies, and proposals. The BLM uses wild horse and burro funding for a variety of activities, including off-range holding activities, gathers, and other activities. For fiscal year 2021, expenditures totaled an estimated $122.2 million (CRS 2022).

3.7 PUBLIC FINANCES

A summary of revenue collected from BLM mineral and energy development and public finances related to BLM public land use are included below.

3.7.1 State and Local Revenues

State and local governments collect a variety of revenues related to the use of natural resources. These revenues could be indirectly impacted by BLM management decisions on GRSG HMAs, if the decisions affect the level of use of natural resources. The following is a description of major sources of revenue and the potential link to BLM resources and resource uses.

Tax revenue at the state level is collected from various sources, including the following:

- State business income taxes and personal income taxes on employee earnings are collected for earnings on employment and industries in certain states (there is no state income tax in Wyoming).
- Severance tax is imposed on nonrenewable natural resources that are removed from the earth. Natural resources that are subject to severance taxation include metallic minerals, molybdenum, oil and gas, oil shale, and coal. Rates of taxation vary by mineral resource and state (see **Table 3-13** for the severance tax rates for oil and gas for each state in the planning area).
- State sales tax is imposed on purchases directly or indirectly associated with BLM-administered lands and resource uses (for example, purchases of household goods by livestock operators on BLM-administered lands).
- Other state revenue sources include sources such as State Conservation Fees or Wyoming's Impact Assistance Tax Program, which require developers on public lands to pay impact assistance payments as warranted by the application/plan of development approval (State of Wyoming 2021).

Table 3-13. Severance Tax Rate by State, 2023

State	Tax Type	Severance Tax (as a percentage of production revenue)	Severance Tax (per bbl of oil)	Severance Tax (per 50,000 cubic feet of gas)
California	Oil and Gas Production Assessment	N/A	$0.5038349	$2.52
Colorado[1]	Severance Tax	2.0 to 5.0	N/A	N/A
Idaho	Oil and Gas Conservation Tax	2.5	N/A	N/A
Montana	Natural Gas and Oil Production Tax	9.19 (for oil) and 9.79 (for natural gas)	N/A	N/A
Nevada	Oil and Gas Conservation Fee	N/A	$0.15	$0.15
North Dakota	Oil and Gas Gross Production Tax	5.0 (for oil production)	N/A	$3.53 (for gas production)
Oregon	Oil and Gas Production Tax	6.0	N/A	N/A

State	Tax Type	Severance Tax (as a percentage of production revenue)	Severance Tax (per bbl of oil)	Severance Tax (per 50,000 cubic feet of gas)
South Dakota	Energy Minerals Severance Tax	4.5	N/A	N/A
Utah[1]	Oil and Gas Severance Tax	3.0 to 5.0	N/A	N/A
Wyoming	Oil and Natural Gas Severance Tax	6.0	N/A	N/A

Source: National Conference of State Legislatures 2018
N/A = data not applicable
[1]The calculations of revenues from severance tax in the impacts analysis assumed a rate of 5 percent for Colorado and Utah (see Appendix 18, Appendix 10, and Chapter 4 for more details on the impacts analysis on economic conditions, including impacts on revenue from taxes and fees associated with oil and gas activity).

Tax rates can vary widely across local taxing entities within a state, and a county often includes many different taxing entities (e.g., counties, school districts, municipalities, special districts). At the local level, taxes that can be impacted by BLM-administered land uses include the following:

- Local sales tax is imposed at a variable rate based on jurisdiction. It is imposed on purchases directly or indirectly associated with BLM-administered lands and resource uses.
- Ad valorem and other property taxes, which are determined based on local mill levy rates, property valuations, and the gross value of minerals produced within their jurisdiction (including federal minerals located within their jurisdiction).

In addition to state and local taxes, states and local governments receive revenue sharing payments associated with mineral development and grazing on BLM-managed lands and minerals.

As discussed in **Section 3.1**, the leasing and development of minerals and geothermal resources generates federal revenues through rents and royalties. The Office of Natural Resource Revenue collects, accounts for, and verifies energy and mineral revenues and distributes a portion of these funds to states and counties in accordance with governing laws. As shown below, ONRR distributes millions of dollars back to mineral and energy producing states each year. The allocation of these federal disbursements between state expenditures, local distributions, and savings is dictated by statutes in each State.

Table 3-14. Office of Natural Resource Revenue Disbursements to State and Local Governments

State	2018	2019	2020	2021	2022
Utah	$76,192,140	$71,694,837	$53,902,022	$55,144,537	$89,592,227
Idaho	$4,368,184	$3,713,807	$4,575,241	$4,328,968	$4,990,428
Colorado	$112,567,174	$108,050,475	$57,115,433	$90,875,874	$142,599,470
North Dakota	$53,223,775	$93,654,132	$66,717,834	$83,389,365	$163,646,101
Nevada	$5,352,679	$6,813,611	$7,750,788	$6,712,843	$9,380,215
Wyoming	$563,955,988	$641,109,256	$457,474,034	$479,888,613	$785,726,557

Source: Office of Natural Resource Revenue: Disbursements FY 2018 - 2022 (accessed from https://revenuedata.doi.gov/query-data#)

Since fiscal revenues are collected from federal mineral extraction at multiple levels, revenue associated with federal mineral leasing and production can account for a significant portion of annual budgets at both the State and local level. Even if a State is not heavily reliant on revenues from federal mineral production, the mining sector (including oil and gas extraction) may account for a greater percentage of the local tax base

and local funding for schools, roads, and a variety of public services within communities may be more closely tied to the collection of ad valorem taxes.

In additional to federal mineral and energy revenue sharing payments, a portion of BLM grazing receipts are returned to county of origin. Under the Taylor Grazing Act, 50 percent of Section 15[12] fees collected are returned to counties, and 12.5 percent of Section 3[13] fees are returned to counties. Grazing revenue and the disbursement that are returned to the county vary by county and may have a higher level of importance at the local level for some communities.

Payments in Lieu of Taxes (PILTs)

PILTs are federal payments to local governments that help offset losses in property taxes due to nontaxable federal lands within their boundaries.[14] However, PILTs are not guaranteed and are subject to annual congressional budget appropriations.

BLM-administered lands fall under Section 6902 of the PILT law, which establishes a formula for calculating payments for qualifying acres of entitlement lands. Payment is typically made directly to the eligible local government. Section 6902 of the PILT act states that PILTs may be used by recipients (usually counties) for any governmental purpose; they are not required to be further distributed to other local government units.

The Department of the Interior computes payments authorized under Section 6902 of the act using the greater of the following two alternatives: (1) $2.94 (in 2022) multiplied by the number of acres of qualified federal surface land, reduced by the amount of funds received by the locality in the prior fiscal year, such as from the Secure Rural Schools program or the mineral leasing program; or (2) $0.42 (in 2022) multiplied by the number of acres of qualified federal surface land in the unit of local government, with no deduction for the prior year's payments. Both alternatives are subject to a population ceiling limitation computed by multiplying the county population by a corresponding dollar value (adjusted annually for inflation) contained in the act. Mineral revenue-sharing programs are factored in the PILT calculations, which means that BLM management decisions that impact mineral extractions and operations could impact PILTs disbursed to local governments.

PILTs are transferred to county or local governments, as applicable, and are in addition to other federal payments, including those from grazing fees. Counties in the Utah analysis area received about $38.2 million in PILTs in 2023 for nearly 27.9 million acres of federal lands. About 70.5 percent of the federal land in the Utah analysis area was BLM-administered land. After applying the calculated payment per acre of federal land for each county to the BLM acres, the estimated BLM-related portion of PILT revenue in the Utah analysis area was about $24.7 million. This was the highest BLM-related portion of PILT revenue to counties across all states in the analysis areas (see **Table 3-15**).

[12] Section 15 lands are public lands that lie outside a grazing district administered by the BLM under Section 15 of the Taylor Grazing Act. The BLM authorizes livestock grazing on these lands by issuing leases to private parties.
[13] Section 3 of the Taylor Grazing Act concerns grazing permits issued on BLM-administered lands within the grazing districts established under the act. It gave leasing preference to landowners and homesteaders in or adjacent to the grazing district lands.
[14] Public Law 94-565, dated October 20, 1976, was rewritten and amended by Public Law 97-258 on September 13, 1982, and was codified at 31 US Code 69. The law recognizes that local governments' inability to collect property taxes on federally owned land can create a financial impact. PILTs are in place to help mitigate the financial impact. See Public Law 94-565 and Public Law 97-258 for more details on limits and appropriations.

Chapter 4. Social Setting and Nonmarket Values

4.1 Social Conditions and Community Interests

The 10-state range-wide planning area encompass a diverse landscape of social conditions, including both rural and urban populations. The socioeconomic analysis areas for each state where GRSG HMAs are located tend to be more rural areas of each state; however, the attitudes, beliefs, values, opinions, and perceptions about BLM-managed public resources and the effects of policies and actions can vary substantially across social and geographic groups around and associated with the socioeconomic analysis areas. These views and beliefs of residents, visitors, commercial users, traditional or subsistence users, tribes, and interest-based or place-based groups reflect different cultural and economic linkages that people have with BLM-administered lands. Those with common interests can typically be defined by communities of place or communities of interest, or both, as detailed below.[15]

4.1.1 Communities of Place

Communities of place are communities of people who are bound together because of where they reside, work, visit, or otherwise spend a continuous portion of their time. The various communities in the socioeconomic study areas share a strong link to the land and natural resources. Due to the size of the planning area, a narrative is not included here for all relevant communities of place. Please see state-specific discussions of key geographic areas in the 2015 Sage-Grouse Plan Amendments /EISs (BLM 2015a, 2015b, 2015c, 2015d, 2015e, 2015f, 2015g). While some changes to the population and economic conditions have occurred in communities (as described in **Chapter 2** at the county level), the key communities and concerns described in the previous plans are still applicable.

Some key concerns expressed in public comments and outlined in 2015 revolved around concern for the preservation of rural characteristics and values. For example, a shift toward larger, more mechanized agricultural operations, as well as the increasing diversification of local economies, have challenged traditional ways of life in many communities. Nevertheless, farming and ranching remain important parts of the economy, society, and culture across the socioeconomic study areas.

In some areas, particularly those with scenic and recreational amenities, farmlands and ranches are being sold and used for recreational purposes or subdivided for homesites. This is part of a larger trend in which many rural communities in the western United States have witnessed "migration turnaround," which is a reversal of the rural-to-urban migration that characterized much of the United States prior to the 1970s. Some rural areas are now experiencing a significant increase in population after decades of stability or decline.

Despite population increases across many regions of the study areas, some rural communities continue to lose population. This is due, in part, to the out-migration of young people and the aging of the existing population. In contrast to communities where in-migration is occurring, residents of these communities

[15] Additional information on social characteristics of counties in Nevada can be found in the county-level socioeconomic baseline reports published by the Nevada Economic Assessment Project, accessed here: https://extension.unr.edu/neap/about-neap-program.aspx.

may be more concerned about the economic survival of their communities. Multiple-use management of and access to BLM-administered lands, which comprise a large portion of lands in many counties, are cited as paramount concerns in these areas (BLM 2006a).

Residents expressed some similar themes during public scoping and the June 2012 Economic Strategies Workshop (BLM and Forest Service 2012; BLM 2012b). Comments supported maintaining or expanding access to BLM-administered lands for grazing, recreational purposes, and mineral extraction. Many expressed concern that placing additional constraints on these activities might create economic hardship within their communities and alter traditional cultural values and lifestyles. Additionally, some argued that constraints on livestock grazing would exacerbate existing trends of conversion of ranch lands to agricultural and residential uses, perhaps with the unintended consequence of decreasing open space and wildlife habitat.

4.1.2 Communities of Interest

Communities of interest are organizations and groups of individuals who have common interests and views in the use and management of BLM-managed public resources. Many organizations or groups of individuals may belong to or share values with more than one community of interest. While the specific relevant communities of interest, and the relative importance of these groups in a given area, vary through the planning area, key overall groups have been identified based on input from the 2015 Sage-Grouse Plan Amendments/EISs and public input. These are summarized below.

Habitat and resource conservation communities of interest are organizations and groups of individuals who have a number of conservation objectives; most believe broadly that protecting at-risk species and maintaining habitats and ecosystems for all species, including GRSG habitats, are fundamental values that should be a high priority in public policy (Brown et al. 2015). Within the socioeconomic analysis areas, many conservation communities believe in the intrinsic value of GRSG and well-functioning, healthy sagebrush ecosystems. Conservation communities could also include persons and organizations concerned with protecting wild horses and burros. These communities emphasize the need to safeguard nonuse values associated with natural resources, as further described in the section below.

Other interest groups with ties to use values of GRSG include those who hunt GRSG for recreational purposes and those who hunt GRSG for subsistence use. While the rational for valuation of the species may vary from those groups who emphasize conservation, both groups are generally supportive of management that would provide for sustained habitat to support the species for the long term.

Mineral development and production communities of interest are organizations and groups of individuals who believe mineral development is a vital component of national, state, and local economies—creating jobs, generating income, and contributing tax and royalty payments to all levels of government. Throughout the socioeconomic analysis areas, many of these communities also believe mineral development and production are socially important, because they support the social systems of local communities by providing private sector livelihoods and revenues to governments. With respect to oil and gas production, these communities believe that domestic development and production are important to national energy security. They believe that many years of compatible development have been achieved in the area, providing significant benefits to the local and regional economy. This group can also include businesses with a tie-in to oil and gas development and production. Those with development as a common interest are likely to prioritize management that emphasizes continued economic contributions associated with this use.

Intertwined with the above communities of shared interest are state, county, and local governments and local residents. State, county, and local governments strive to protect the interests of the residents, and they support various communities by funneling tax revenue into important public infrastructure and services. Some residents across the socioeconomic analysis areas seek to preserve the historical agricultural setting of the community and are reluctant to embrace change, especially changes that could impact the way of life and the character of the community. Some residents are concerned about increased demands on local government services and infrastructure. Other residents are concerned about changes that could impact economic and business opportunities, in the form of changes in employment and earnings. Local chambers of commerce are another example of a specific group with an interest in economic tie-ins with GRSG management.

Other specific types of business groups with a tie-in to GRSG management include those associated with real estate, tourism, and recreation. These groups would benefit from management that allows for continued or increased recreational and tourism activities on BLM-administered lands. In addition, individuals and groups who represent farming and ranch operators can be impacted by GRSG management decisions, which impact the level and locations of grazing on BLM-administered lands and the jobs and socioeconomic contributions associated with these uses.

Academic institutions work to preserve, learn, and pass on knowledge about natural resources, such as GRSG, and represent a group with common interests.

Federally recognized tribes are sovereign nations who value public land and resources for their cultural and spiritual significance. For tribal members, protecting cultural resources, combined with maintaining access to traditional cultural sites, is extremely important. These cultural sites include areas of past occupation and also areas where traditional practices, such as plant gathering and hunting, have occurred. Other groups and individuals with interests in archaeology and history also value cultural resources, though these should not be conflated with the unique relationships and responsibilities upheld by the BLM with tribal nations.

The factors that interest groups perceive as impacting GRSG, and the ways in which GRSG management is seen as impacting communities, may vary by the community of interest. One recent study examined different stakeholder groups and their perspectives on factors most important for GRSG species management. Viewpoints toward the role of climate change and predators in sage-grouse management varied most among stakeholder groups, while less division was present related to the importance of sod-busting (breaking up new ground for cultivation) and concerns for the economic impacts of listing GRSG as an endangered species.

4.2 NONMARKET VALUES

BLM-administered lands provide a range of goods and services that benefit society in a variety of ways. Some of these goods and services, such as solid and fluid minerals, are bought and sold in markets; hence, they have a readily observed market value. Others have a less clear connection to market activity, even though society derives benefits from them. In some cases, goods and services have both market and nonmarket values. This section provides an overview of several nonmarket values associated with GRSG management.

For the purposes of this effort, the BLM defines "value" as the combination of all benefits that people receive from BLM-managed lands and resources. Total value is the sum of market value from economic activities and nonmarket value. However, it is important to note that nonmarket values, in the discussion below, are not directly comparable to the previous sections that describe various resource uses and revenue on BLM-administered lands. The market indicators discussed above describe the effects on economic (market) activity in the region, and the market values of many of the activities are monetized. However, nonmarket

values tend to differ across groups and individuals based on preferences, so there are challenges associated with monetizing nonmarket values. Therefore, nonmarket values are discussed qualitatively.

The nonmarket values associated with GRSG management on BLM-administered lands include both use (direct and indirect) and nonuse values (such as existence values and bequest values held by the general public from self-sustaining populations of GRSG; BLM 2013). This section provides an overview of the use and nonuse nonmarket values that may be affected by management of GRSG HMAs.

Nonmarket values associated with GRSG and GRSG habitat can also be viewed through the lenses of ecosystem services. Ecosystem services, or the benefits that people receive from nature, are commonly classified within four major categories: regulating, provisioning, cultural, and supporting (Millennium Ecosystem Assessment 2005). Sagebrush environments, which support GRSG populations, provide numerous ecosystem services, such as providing services associated with food products from livestock production; hunting; other recreational opportunities; and the provision of water for municipal, industrial, and irrigation uses. In addition, intact sagebrush ecosystems reduce wildfire return intervals and host many species of wildlife, including game animals and other sensitive, threatened, and endangered species. Healthy sagebrush ecosystems sequester carbon, which can be enhanced through conservation efforts on public lands (Bennett and Pierce 2020).

People also receive intrinsic benefits from nature that are diverse in inspiration but consistently highly valued. These could be intrinsic benefits from seeing or knowing a flourishing, biodiverse sagebrush ecosystem exists; intrinsic benefits from feeling secure such habitats will exist for the enjoyment and health of future friends and family members; or intrinsic benefits from preserving ancestral/heritage/cultural connections established through sagebrush ecosystems and the GRSG species. Comparatively, there are others whose non-market values associated with public lands, including intrinsic and bequest values, are threatened by land use restrictions associated with GRSG HMAs.

4.2.1 Mineral Extraction and Development (including Leasable Minerals, Locatable Minerals, and Mineral Materials)

Most of the value associated with mineral extraction is economic value from the market activities. However, many mine operators and workers gain additional value through the lifestyle of working at a mine. Many mine workers come from generations of people who work in mines, and there can be social cohesion from families of mine workers.

4.2.2 Livestock Grazing

Public lands managed for livestock grazing provide both market values (for example, forage for livestock) and nonmarket values. The ranching community benefits from multiple sagebrush ecosystem services, including supporting services that provide forage for livestock, which in turn allow for provisioning services, such as beef production.

However, many ranchers value the ranching lifestyle more than the income generated by their ranching operations. Beyond jobs and income associated with ranching, the lands associated with ranching also contribute to the quality of life and enjoyment for many area residents and visitors by supporting open space, wildlife habitat, working landscapes, and a rural lifestyle (Brymer et al. 2018). One primary reason ranchers indicate they own land is for the "tradition, values and culture" rather than primarily for profit (Tanaka et al. 2005).

In a survey of 645 ranchers in the western United States (not exclusive to sagebrush areas), participants identified the cultural values of maintaining their families' traditions and values as the most important reason for owning a ranch, followed by passing on the ranch and ranch lifestyle to future generations (Tanaka and Maczko 2017). Many public land ranchers work elsewhere part-time and rely on the ranch for only 20 percent of their income (Hanus 2011), relying instead on outside jobs or other savings to support their ranching operation. Families that work off the ranch may do so for health insurance reasons as well as supplemental income. Income from outside of the ranch may also be needed due to increased pressure of government regulation. Changes related to regulation and management practices of grazing affect ranching operations, ability to operate, and the continued activity of ranching in the West.

Some studies have found nonmarket values of ranching associated with use values to residents (Mangun et al. 2005) and tourists in the form of open space and western ranch scenery (Ellingson et al. 2006). Others see nonmarket opportunity costs associated with livestock grazing that may, depending on management methods and other variables, reduce native plant species and forage for wildlife (Todres et al. 2003).

4.2.3 Wild Horse and Burros

Values associated with wild horses and burros vary depending on the viewpoints of different individual groups. Some groups highly value horses and consider them as beloved animals that should receive a greater share of BLM resources. Groups valuing wild horses and burros emphasize the importance of the existence value associated with the preservation of free-roaming populations; they often note factors such as historical and cultural values and view wild horses as a symbol of the West.

Other groups view free-roaming horses as interlopers that place additional stress on fragile ecosystems, and compete with livestock and native wildlife for forage and water (National Academies of Sciences, Engineering, and Medicine 2013).

Most WHB HMAs contain GRSG habitat in a sagebrush vegetation community. Overall management direction is to manage for healthy populations of wild horses and burros to achieve a thriving natural ecological balance with respect to wildlife, livestock use, and other multiple uses. Protecting areas from surface-disturbing activities for the purpose of protecting GRSG would also protect forage for wild horses and burros and limit conflicts with humans or surface disturbance. BLM management decisions that restrict WHB HMAs for the protection of GRSG might increase the cost associated with managing wild horses, but impacts are not likely to be material.

4.2.4 Greater Sage-Grouse Conservation

Economists have long recognized that wildlife species, especially rare, threatened, and endangered species, have economic values beyond just viewing. This is supported by a series of legal decisions and technical analyses. The US Court of Appeals in 1989 first clarified that the Department of the Interior, in assessing damages in Natural Resource Damage Assessment cases, should include what it termed as "passive use values" (that is, existence values provided to nonusers of the species) as a compensable value in addition to any use value. These passive use values are also included in Oil Pollution Act damage assessments. The term "passive use values" is interchangeable with the previously defined term "nonuse values." This ruling and subsequent analysis for Natural Resource Damage Assessment and Oil Pollution Act assessments are consistent with well-established economic theory showing that people derive value from passive use or nonuse as well as active uses of resources (Krutilla 1967). Economists have devoted a great deal of theoretical and empirical work to refining concepts and developing methods to measure these passive use values.

The BLM conducted a literature search to demonstrate the potential range of values that could be associated with species that are candidates for listing as threatened or endangered, such as GRSG populations. Analysts first verified there are no existing studies on the total economic value or nonuse valuation specific to the GRSG. This is not an uncommon occurrence, as there are dozens of rare or potentially threatened species that have not been studied, despite the very high policy relevance of the species and the large magnitude of economic value at stake in these policy decisions.

The BLM used three criteria to identify studies that are most applicable to the current analysis: (1) whether the species valuation study was located in the same geographic region as the GRSG HMAs; (2) whether the species was listed as threatened or endangered; and (3) whether the species was hunted (implying a mix of use and nonuse values). No studies met all three criteria, as there are no other species in the literature in the geographic region (intermountain) for a species that is both hunted and listed as sensitive.

The primary article used by the BLM was the peer-reviewed journal article by Richardson and Loomis (2009), which is a compilation of the economic values of threatened, endangered, and rare species. A literature review was also conducted to determine whether there had been any recent studies on GRSG or closely related species provides a summary of the studies with features most similar to the GRSG species.

Table 4-1. Existing Estimates of the Annual Total Nonmarket Value of Protecting Habitat for Species Similar to GRSG

Region	Species	Listed	Hunted	Annual Value per Household[b]	Change Valued
Four Corners (Arizona, Colorado, New Mexico, and Utah)	Mexican spotted owl	Yes	No	$77.20	Avoid extinction in 15 years in the Four Corners region
New England	Wild turkey	No	Yes	$22.07	Avoid extinction in New England
Texas (also Louisiana, New York City, Chicago, and Atlanta)	Whooping crane	Yes	No	$57.67	Avoid extinction
Maine	Peregrine falcon	Yes	No	$42.72	Restore self-sustaining population
South Carolina and the rest of the US	Red-cockaded woodpecker	Yes	No	$19.39	Restore habitat to increase the chance of survival to 99 percent
Atlantic coast	Atlantic red knot	Yes	No	$21.64	Avoid extinction

Sources: Loomis and Ekstrand 1997 (Mexican spotted owl); Stevens et al. 1991 (New England wild turkey); Bowker and Stoll 1988 (whooping crane); Kotchen and Reiling 2000 (peregrine falcon); Reaves et al. 1999 (red-cockaded woodpecker); Myers 2014 (Atlantic red knot)
All these sources, with the exception of Myers 2014, are as cited in Richardson and Loomis (2009). Myers 2014 is cited in Subroy et al. 2019.
Notes: Stated preference values for households may have a degree of hypothetical bias that could overstate the actual monetary amount households would pay by a factor of two to three. All values are adjusted to $2023.

Chapter 5. Environmental Justice

5.1 Introduction

This section supports the environmental justice screening of the GRSG range-wide analysis area, focusing on the counties within California, Colorado, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, Utah, and Wyoming that encompass a substantial amount of BLM-administered acres in GRSG HMAs, as detailed in **Chapter 1**, Introduction.

Environmental justice embodies the principle of fair treatment and meaningful involvement for all individuals, regardless of their race, color, national origin, or income, in relation to the formulation, execution, and enforcement of environmental laws, regulations, and policies. It underscores the essential concept that no specific group, whether defined by race, ethnicity, or socioeconomic status, should disproportionately bear the adverse environmental impacts arising from industrial, municipal, or commercial activities, or the implementation of federal, state, local, and tribal programs and policies (BLM 2005).

Executive Order (EO) 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations (1994), mandates federal agencies to identify and address disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations in the United States. The EO mandates that each federal agency "make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations" (59 *Federal Register* 7629 [1994]). EO 14096, Revitalizing Our Nation's Commitment to Environmental Justice for All, enacted on April 21, 2023, complements EO 12898.

Furthermore, the BLM Land Use Planning Handbook (BLM 2005), emphasized by the significance outlined in Instruction Memorandum 2022-059, reinforces the BLM's dedication to environmental justice. This commitment is evident in providing substantial opportunities for low-income, minority, and American Indian and Alaska Native populations to meaningfully participate and in considering these populations when developing mitigation measures, as appropriate.

5.2 Environmental Justice Screening Criteria

For this analysis, the BLM analyzed minority populations, low-income populations, and American Indian and Alaska Native populations within each applicable county within each state, as identified above, using the definitions and thresholds outlined in guidance documents from the Council on Environmental Quality (CEQ) and the BLM Instruction Memorandum 2022-059 (CEQ 1997; BLM 2022a).

The CEQ defines minorities as individuals who identify as American Indian or Alaska Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic. A minority environmental justice population is recognized if the percentage of minority individuals constitutes greater than or equal to 50 percent of the total population within a given area or if the minority population percentage is "meaningfully greater" than the minority population percentage in a reference area (CEQ 1997). To determine whether a minority population is "meaningfully greater," the minority population percentage in the reference area is multiplied by 1.1 (equivalent to 110 percent) to calculate a threshold value (BLM 2022a). Subsequently, each county's minority population percentage within that state is compared against this calculated threshold. Counties with

minority populations meeting or exceeding this threshold are identified as having potential environmental justice populations.

This comprehensive approach ensures that both clear numerical benchmarks and relative comparisons are considered in identifying minority environmental justice populations. For the purposes of this analysis, the state serves as the reference area. In California and Nevada, which are states with large urban metropolitan areas, the percentage of the population in non-metropolitan areas of the state are used as the reference area populations. GRSG HMAs are largely in rural areas, so non-metropolitan areas would allow a more consistent comparison of regions without including any outliers in demographic data from metropolitan areas.

Low-income populations are defined relative to the annual statistical poverty thresholds from the US Census Bureau (CEQ 1997). The CEQ guidance does not provide criteria for determining low-income populations as explicitly as it does for minority populations; however, the BLM defines low-income individuals as people whose income is less than or equal to twice (200 percent of) the federal poverty level (BLM 2022a). For this analysis, low-income populations were identified following guidance in BLM IM 2022-059. A county is considered to have a significant low-income population and contain environmental justice populations when its low-income population percentage is greater than or equal to 50 percent of the overall population or if the low-income population percentage is greater than or equal to the low-income population percentage of a reference area. Similar to minority populations, the state is used as the reference area for low-income populations except as noted above.

American Indian and Alaska Native individuals are defined as those who identify as American Indian and Alaska Native alone or in combination with one or more races, or they are part of a federally recognized tribe. American Indian and Alaska Native populations are included in minority populations; however, to explore key issues and resources in the analysis areas that are important to individuals who identify as American Indian and Alaska Native, this analysis uses a more sensitive threshold than the threshold for minority populations to identify American Indian and Alaska Native environmental justice populations separately from minority environmental justice populations. For the purposes of this analysis, American Indian and Alaska Native environmental justice populations are considered present when the percentage of American Indian and Alaska Native individuals in a county is greater than or equal to 50 percent or greater than or equal to the percentage of American Indian and Alaska Native individuals in the reference area. As with minority and low-income populations, the reference area for comparing American Indian and Alaska Native populations is the state. Non-metropolitan data are used for American Indian and Alaska Native populations in California and Nevada to exclude any outliers in demographic data from metropolitan areas.

The CEQ instructs agencies to seek tribal representation in a manner that is consistent with the government-to-government relationship between the United States and tribal governments, the federal government's trust responsibility to federally recognized tribes, and any treaty rights (CEQ 1997; see Section 5.2.1 of the 2024 Greater Sage-Grouse Draft Resource Management Plan Amendment and Final Environmental Impact Statement for more details on tribal consultation for this effort).

Appendix A includes tables showing the percentage of minority, low-income, and American Indian and Alaska Native populations for each state in the range-wide planning area. They include each county in the analysis area with a large portion of BLM-administered lands in GRSG HMAs. The tables also indicate whether the county met the threshold for minority, low-income, and/or American Indian and Alaska Native populations and is therefore identified as an environmental justice population. **Appendix A** also includes

figures of each state that indicate which counties in the analysis areas are identified as an environmental justice population.

Both counties included in the California analysis area for having a large area of BLM-administered land in GRSG HMAs were identified as containing environmental justice populations (see **Table A-30** and **Figure A-11** in **Appendix A**). The state of California overall has a non-metropolitan minority population of 29.3 percent, and the threshold for a minority environmental justice population is 32.2 percent. In the California analysis area, Lassen County exceeds the threshold for minority populations, with a minority population of 36 percent, and qualifies as a minority environmental justice population. The low-income threshold in California is 29 percent. Both Lassen County and Modoc County exceed the threshold for low-income populations and are identified as environmental justice populations. California has a non-metropolitan American Indian and Alaska Native population of 5.9 percent; however, neither county in the California analysis area exceeds the threshold for American Indian and Alaska Native populations.

Overall, seven of the eight counties in the Colorado analysis area were identified as having environmental justice populations (see **Table A-31** and **Figure A-12** in **Appendix A**). The minority population in Colorado is 33.2 percent, and the threshold for minority populations is 36.5 percent. Notably, none of the counties within the Colorado analysis area meet the criteria for a "meaningfully greater" minority population, which would classify them as environmental justice populations. However, the Colorado analysis area does encompass seven counties where the low-income population equals or exceeds the state's designated low-income threshold of 23.6 percent. Furthermore, Moffat County and Rio Blanco County have American Indian and Alaska Native populations that exceed the state's American Indian and Alaska Native population threshold of 2.5 percent, highlighting their significance in relation to American Indian and Alaska Native communities.

In the Idaho analysis area, 25 of the 27 counties meet the criteria for containing environmental justice populations that could face disproportionate and adverse impacts from BLM management decisions on GRSG HMAs (see **Table A-32** and **Figure A-13** in **Appendix A**). In Idaho, the minority population constitutes 19.4 percent of the total population, and the threshold for minority environmental justice populations is 21.3 percent. Fourteen counties surpass the meaningfully greater threshold for a minority population, designating them as environmental justice populations. Across the Idaho analysis area, 24 counties have a low-income population equal to or exceeding the state threshold of 31.3 percent. Additionally, 14 counties in the analysis area have American Indian and Alaska Native populations that meet or exceed the threshold for environmental justice populations, which is 2.6 percent for the state of Idaho.

In the Montana analysis area, 18 of the 26 counties were identified as environmental justice populations that could be adversely affected by BLM management decisions on GRSG HMAs (see **Table A-33** and **Figure A-14** in **Appendix A**). For minority populations, seven counties exceed the threshold for a meaningfully greater minority population of 16.4 percent, marking them as environmental justice populations. Across the analysis area, 18 counties demonstrate a higher low-income population than the state threshold of 31.1 percent. Seven counties also meet or exceed the state threshold of 8.2 percent for American Indian and Alaska Native environmental justice populations. Examining geographic clusters and their connection to the GRSG HMAs is pivotal to understanding the impacts of BLM management decisions on GRSG HMAs. These 18 counties are largely located in central Montana, as well as along Montana's southern, eastern, and western borders.

The entire Nevada analysis area is identified as containing environmental justice populations that could be impacted by BLM management decisions on GRSG HMAs (see **Table A-34** and **Figure A-15** in

Appendix A). The non-metropolitan population for minority populations in Nevada is 28.8 percent, with a threshold for minority populations of 31.7 percent. In the Nevada analysis area, four counties—Elko, Humboldt, Pershing, and Washoe Counties—surpass the threshold for a meaningfully greater minority population, marking them as environmental justice populations. Five counties—Eureka, Humboldt, Lander, Nye, and Pershing Counties—have low-income populations equal to or exceeding the state average of 31.2 percent. All 10 counties in the Nevada analysis area meet or exceed the threshold of 2.5 percent for American Indian and Alaska Native populations.

No county in the North Dakota analysis area is identified as containing an environmental justice population (see **Table A-35** and **Figure A-16** in **Appendix A**). In North Dakota, the minority population constitutes 16.9 percent of the total population, and the threshold for minority populations is 18.6 percent. No counties in the North Dakota analysis area surpass the threshold for a meaningfully greater minority population. No counties in the North Dakota analysis area demonstrate a low-income population exceeding the state threshold of 25.2 percent. Also, no counties include a higher American Indian and Alaska Native population than the state threshold of 6.8 percent.

Overall, seven of the eight counties in the Oregon analysis area were identified as environmental justice populations (see **Table A-36** and **Figure A-17** in **Appendix A**). In Oregon, the minority population is 25.9 percent of the total population, with a threshold for a minority population of 28.5 percent. Only one county in the Oregon analysis area, Malheur County, surpasses the threshold, designating it as an environmental justice population. For low-income populations, seven counties in the Oregon analysis area contain low-income populations equal to or exceeding the state average of 28.7 percent. These counties are Baker, Crook, Grant, Harney, Lake, Malheur, and Union Counties. For American Indian and Alaska Native populations, three counties in the Oregon analysis area meet or exceed the state threshold of 3.3 percent: Harney, Lake, and Malheur Counties. These counties identified as environmental justice populations could be impacted by BLM management decisions on GRSG HMAs.

One county in South Dakota's analysis area, Butte County, is identified as containing an environmental justice population, and the environmental justice population in this county could be impacted by the BLM management decisions regarding GRSG HMAs (see **Table A-37** and **Figure A-18** in **Appendix A**). No county in the South Dakota analysis area exceeds the threshold for a meaningfully greater minority population of 21.1 percent or the threshold for American Indian and Alaska Native populations of 10.4 percent. However, Butte County has a higher low-income population than the state's threshold of 29.0 percent. These data indicate that while there are not environmental justice populations based on minority population in South Dakota, attention should be given to the county with a meaningfully greater low-income population to assess its relationship to the GRSG HMAs and potential environmental justice impacts.

Across the Utah analysis area, 18 of the 23 counties are identified as environmental justice populations (see **Table A-38** and **Figure A-19** in **Appendix A**). The minority population in the state of Utah is 22.7 percent, and the threshold for minority population is 25.0 percent; however, no counties in the Utah analysis area surpass the threshold for a meaningful greater minority population. For low-income populations, 17 counties have a higher low-income population than the state's threshold of 24.7 percent. For American Indian and Alaska Native populations, 10 counties meet or exceed the American Indian and Alaska Native population threshold of 2.0 percent. These counties that are identified as containing environmental justice populations could experience impacts from BLM management decisions on GRSG HMAs.

In the Wyoming analysis area, 15 of the 21 counties are identified as containing environmental justice populations (see **Table A-39** and **Figure A-20** in **Appendix A**). Six of these counties surpass the

threshold for a meaningfully greater minority population of 17.6 percent, designating them as environmental justice populations. Moreover, 12 counties in the analysis area contain a higher low-income population than the state threshold of 26.5 percent. For American Indian and Alaska Native populations, two counties, Fremont County and Weston County, exceed the American Indian and Alaska Native population threshold of 3.7 percent. These counties that are identified as containing environmental justice populations could be impacted by the BLM management decisions regarding GRSG HMAs. These data underscore the presence of environmental justice populations and a heightened low-income population in multiple counties in Wyoming, indicating a need for specific attention to these populations in the context of GRSG HMAs and potential environmental justice impacts.

The findings of areas containing environmental justice populations in the analysis areas for each state were instrumental in evaluating potential disparities in the impacts of various alternatives on minority and low-income populations. Because counties were identified as containing environmental justice populations, as discussed above, the BLM management decisions on GRSG HMAs could impact environmental justice populations disproportionately. The following section includes a discussion of environmental justice issues of concern raised in the previous efforts in 2015.

5.3 Environmental Justice Issues of Concern

As discussed above, Environmental justice includes the principle of meaningful involvement for all individuals, regardless of their race, color, national origin, or income. In 2022 through 2024, the BLM initiated formal consultation with tribes and outreach and meetings with the public, including those who meet the criteria for environmental justice consideration that have interests or traditional cultural properties in the analysis area. In January 2022, the BLM held two virtual public scoping meetings at different times during the day to encourage public participation across a wide group of people in various locations and to accommodate various needs. The meetings were recorded and shared on the project's ePlanning website for those who were unable to attend. In 2012, the BLM and the Forest Service conducted an economic strategies workshop to identify public concerns related to potential social, economic, and environmental justice impacts resulting from management alternatives (BLM and Forest Service 2012; BLM 2012; see Chapter 5, Consultation and Coordination, for more detail on government-to-government consultations with tribes as well as meetings and outreach to the public for this effort).

The BLM maintains the project's ePlanning website as well as a national GRSG conservation website that aims to help the public learn how BLM is working on maintaining and restoring GRSG. These sites provide background information, updated documents, information on public meetings, and contact information.

Comments that the BLM received during these outreach efforts helped guide resource and impact analysis considerations. Additionally, the agencies reviewed the scoping report for the current EIS to identify comments related to environmental justice issues. This section summarizes findings from those efforts and discusses the issues that will be addressed in the impacts analysis on environmental justice populations.

A key issue of concern relating to environmental justice populations for many of the states, including California, Nevada, Colorado, Idaho, Montana, Oregon, South Dakota, and Utah, largely pertained to the interests of those who identify as American Indian and Alaska Native, the cultural significance of the GRSG to American Indian and Alaska Native populations, and the importance of hunting and subsistence. Some concerns revolved around the viability of GRSG populations. Historical records highlight the importance of GRSG to individuals who identify as American Indian and Alaska Native across the planning area who traditionally relied on GRSG as a vital food source. GRSG has played a vital role in traditions and customs, and it has served as inspiration for ceremonial dances.

It was noted that the preservation of GRSG habitat would have beneficial effects for those who identify as American Indian and Alaska Native who hold cultural value for the bird (BLM and Forest Service 2012). American Indian and Alaska Native populations across the planning area engage in hunting and subsistence activities on federal lands outside the boundaries of their reservations. Access to hunting and subsistence resources is a concern for many environmental justice populations within the state analysis areas, especially for American Indian and Alaska Native populations. The profound connection between the GRSG habitat and Native American culture underscores the importance of considering these aspects in the planning and decision-making processes. On the other hand, some comments expressed concern that habitat conservation in some alternatives could negatively impact road realignment projects near their reservation and plans to expand their reservation boundaries; this is because their reservation is surrounded by PHMAs.

Another issue of concern for environmental justice populations was regarding economic impacts on environmental justice populations from greater restrictions on livestock grazing and mineral, oil and gas, and renewable energy development. This issue was especially of concern in counties with high poverty rates and declining economic opportunities (BLM 2013b). However, at the time this report is being published, there is a lack of evidence that the types of operations that are most likely to be impacted by BLM management decisions employ a higher percentage of people who identify as a minority, low-income, or American Indian and Alaska Native. These types of operations that are most likely to be impacted by BLM management decisions include mining, renewable energy, and ranching and livestock operations—especially small family-owned ranches and livestock operations (see Section 3.5, Livestock Grazing, in this Appendix for more information on ranch types that are most likely to be affected by BLM decisions).[16] Therefore, there is not evidence that impacts on economic conditions due to BLM decisions will lead to disproportionate impacts on environmental justice populations, and economic impacts on environmental justice populations will not be carried forward in the impacts analysis on environmental justice populations. Impacts on economic conditions may occur across the analysis area, and these impacts on economic conditions from restrictions on livestock grazing and mineral, oil, and gas development are analyzed and discussed in the impacts analysis on social and economic conditions as it relates to all populations in surrounding communities. Additional screening and consideration of environmental justice populations and analysis of any disproportionate and adverse impacts will occur at the implementation stage at a scale commensurate with the scope and scale of management actions being considered to provide additional protections for local GRSG populations. Depending on conditions at that time, communities with environmental justice concerns may change

In Wyoming and Idaho, issues of concern were brought up relating to impacts on food prices and availability due to restrictions on grazing and mineral development (especially trona mining, which is used in household and food products). These comments were brought up in the context of economic conditions; however, increases in food prices and decreases in food availability tend to disproportionately impact low-income individuals who have more limited means for finding alternatives; therefore, this issue of concern will be carried forward and examined in the impacts analysis on environmental justice populations.

The 2015 EISs contained issues that were not brought up in public comments but were considered important issues for environmental justice populations; these issues were analyzed in the impacts analysis on environmental justice populations. One of these issues was the impact on environmental justice populations from changes in availability for firewood permits. The current BLM management decisions, however, will not

[16] Small family-owned ranches and livestock operations tend to employ more family workers and fewer wageworkers than agricultural and crop farms. Wageworkers, such as grader and sorter farm laborer, tend to include high percentages of individuals who identify as part of an environmental justice population (USDA Economic Research Service 2023).

change the availability for firewood permits; therefore, this issue of concern will not be carried forward in the impacts analysis.

Visual and auditory impacts on environmental justice populations from mining development and operations and travel management decisions were other issues that were considered in the 2015 EISs. The previous 2015 plans included specific management decisions that could impact areas used for spiritual and religious practices, but these types of site-specific decisions are not included in the current effort. Therefore, impacts on environmental justice populations from visual and auditory disruptions will not be carried forward in the impacts analysis. Impacts on visual and auditory resources will be considered for potential inclusion in the implementation-level NEPA analysis.

In addition to the issues raised by the public, as discussed above, the BLM will consider and analyze other issues of concern for environmental justice populations. These issues include impacts on environmental justice populations from potential changes in water quality, air quality, and climate change from potential mineral development under alternatives with less restrictions. These issues were not analyzed in the 2015 EISs; however, they are considered important to the analysis in the current efforts.

Table A-1. Analysis Areas Overview

Analysis Area	BLM Management Unit(s)	Counties*
California	Eagle Lake FO	Lassen
	Applegate FO	Modoc
Colorado	Colorado River Valley FO	Eagle, Garfield, Routt
	Grand Junction FO	Mesa
	Kremmling FO	Garfield, Grand, Jackson
	Little Snake FO	Moffatt, Routt
	White River FO	Garfield, Rio Blanco
Idaho	Bruneau FO	Owyhee
	Burley FO	Cassia, Minidoka, Twin Falls
	Challis FO	Custer, Lehmi
	Four Rivers FO	Washington, Elmore, Adams, Gem, Payette
	Jarbidge FO	Owyhee, Twin Falls, Elko
	Owyhee FO	Owyhee
	Pocatello FO	Oneida, Power, Bear Lake, Bingham, Caribou, Bonneville
	Salmon FO	Lehmi
	Shoshone FO	Blaine, Camas, Butte, Elmore, Gooding, Jerome, Lincoln, Minidoka, Power
	Upper Snake FO	Bingham, Blaine, Bonneville, Butte, Clark, Custer
Montana	Miles City FO	Big Horn, Carter, Custer, Dawson, Fallon, Garfield, McCone, Power River, Prairie, Roosevelt, Rosebud, Treasure, Valley, Wibaux
	Lewistown FO	Chouteau, Fergus, Meagher, Petroleum
	Dillion FO	Beaverhead, Madison
	Havre FO	Blaine, Phillips, Chouteau
	Malta FO	Phillips
	Glasgow FO	Valley
	Billings FO	Bighorn, Carbon, Golden Valley, Musselshell, Stillwater, Sweetgrass, Wheatland, Yellowstone
	Butte FO	Park, Gallatin, Deer Lodge
	Upper Missouri River FO	Blaine, Chouteau, Fergus, Phillips
North Dakota	North Dakota FO	Slope, Bowman
Nevada	Mountain Lewis FO	Lander, Eureka, Nye, White Pine
	Tonopah FO	Nye
	Sierra Front FO	Washoe
	Stillwater FO	Mineral, Churchill, Nye, Lander
	Tuscarora FO	Elko, Eureka, Lander
	Wells FO	Elko
	Caliente FO	Lincoln, Nye
	Wells FO	Elko
	Black Rock FO	Humboldt, Washoe, Pershing
	Humboldt River FO	Humboldt, Washoe, Pershing
	Bristlecone FO	White Pine, Nye
	Eagle Lake FO	Washoe
	Basin and Range FO	Lincoln, Nye
Oregon	Lakeview DO	Harney, Lake
	Prineville DO	Crook, Deschutes, Harney, Lake
	Vale DO	Union, Malheur, Harney, Grant, Baker
	Burns DO	Crook, Grant, Harney, Lake, Malheur
South Dakota	South Dakota FO	Butte, Harding

Analysis Area	BLM Management Unit(s)	Counties*
Utah	Salt Lake FO	Box Elder, Morgan, Rich, Summit, Tooele, Wasatch, Cache
	Cedar City FO	Beaver, Iron
	Fillmore FO	Juab, Millard
	Kanab FO	Garfield, Iron, Kane
	Moab FO	Grand
	Price FO	Carbon, Emery
	Richfield FO	Garfield, Piute, Sanpete, Wayne
	Vernal FO	Daggett, Duchesne, Uintah
Wyoming	Casper FO	Converse, Goshen, Natrona, Platte
	Newcastle FO	Campbell, Crook, Niobrara, Weston
	Worland FO	Big Horn, Hot Springs, Park, Washakie
	Rawlins FO	Carbon, Fremont, Laramie, Sweetwater
	Rock Springs FO	Fremont, Lincoln, Sublette, Sweetwater, Uinta
	Cody FO	Bighorn, Park
	Buffalo FO	Campbell, Johnson, Sheridan
	Lander FO	Carbon, Fremont, Hot Springs, Natrona, Sweetwater

Source: ONRR 2023a

N/A = percent change not available due to no federal production reported in 2018

Note: Includes all planning area counties for which the ONRR reported data. Oregon did not have any federal oil or natural gas production from 2018 to 2022; although there was federal oil and gas production in California, the production occurred outside the socioeconomic analysis area. Therefore, the data are not included in this report.

Table A-23. Federal Disbursements to States from Oil and Gas Extraction, Fiscal Years 2018–2022

State	2018 ($)	2019 ($)	2020 ($)	2021 ($)	2022 ($)	Change 2018–2022 ($)	% Change 2018–2022

Wyoming	355,777,987	458,184,527	285,683,930	319,770,982	615,497,307	259,719,320	73.0

Source: ONRR 2023b

Note: Oregon did not have any disbursements from oil and gas from 2018 to 2022. California received disbursements for federal oil and gas produced in the state; however, the minerals were produced outside the California socioeconomic analysis area. Therefore, California disbursements for federal oil and gas are not included in this report.

Table A-24. Coal Production by County on Federal Land in the Planning Area, 2018–2022 (Tons)

Source: ONRR 2023

Note: Includes all planning area counties for which the ONRR reported data. California, Idaho, Nevada, Oregon, and South Dakota did not have any federal coal extraction from 2018 to 2022; while there was federal coal extraction in North Dakota, the production occurred outside the socioeconomic analysis area. Therefore, the data are not included in this report.

Table A-25. Federal Disbursements to States from Coal Extraction

State	2018 ($)	2019 ($)	2020 ($)	2021 ($)	2022 ($)	Change 2018–2022 ($)	% Change 2018–2022
Colorado	11,293,401	14,554,781	4,222,405	9,280,605	11,696,818	403,417	4

Source: ONRR 2023

Note: Includes all planning area counties for which the ONRR reported data. Montana, Nevada, Oregon, and South Dakota did not have any federal nonenergy mineral extraction from 2018 to 2022. Although there was federal nonenergy mineral extraction in California and North Dakota, the extraction occurred outside the socioeconomic analysis area. Therefore, the data are not included in this report.

Table A-27. Federal Disbursements to States from Nonenergy Mineral Extraction

State	2018 ($)	2019 ($)	2020 ($)	2021 ($)	2022 ($)	Change 2018–2022 ($)	% Change 2018–2022
Colorado	980,929	1,012,120	1,167,651	824,188	542,777	(438,152)	-45
Idaho	4,237,741	3,529,543	4,656,285	4,380,755	5,101,091	863,350	20
Utah	738,527	1,374,179	921,871	748,658	1,227,146	488,620	66
Wyoming	16,131,318	25,736,670	18,948,857	9,794,050	8,402,061	(7,729,258)	-48

Source: ONRR 2023b

Note: North Dakota, Oregon, and South Dakota did not have any disbursements from nonenergy minerals from 2018 to 2022. California received disbursements for federal nonenergy minerals extracted in the state; however, the minerals were extracted outside the California socioeconomic analysis area; therefore, California disbursements for federal nonenergy minerals are not included in this report. Montana and Nevada received small disbursements for rents, bonuses, and other distributions from nonenergy minerals, but there were no nonenergy minerals extracted from 2018 to 2022. Therefore, because these disbursements were not material and not likely to be impacted by the BLM's management decisions, they are not included in this report.

Table A-28. State Policies for Distributions of Federal Mineral Revenue

State	State Expenditures	Local Distributions	Savings
California	California deposits royalties from federal mineral leasing into the State School Fund	N/A	N/A
Colorado	Fifty percent of bonus disbursements are allocated to the Higher Education Federal Mineral Lease Revenues Fund Colorado allocates 48.3 percent of non-bonus disbursements (up to 104 percent of the previous year's transfer amount) to the state's Public School Fund.	Twenty percent of non-bonus revenue is allocated to federal lease districts, counties, and municipalities based on data, including the proportion of original lease payments and employees in the natural resource sectors. Colorado distributes 1.7 percent of non-bonus disbursements to local school districts. Twenty percent of non-bonus revenue is allocated as grants by the Colorado Department of Local Affairs to assist local governments' processes for planning, public engagement, or collaboration with federal land managers.	Ten percent of non-coal bonus disbursements are transferred to the Colorado Water Conservation Board. Fifty percent of bonus disbursements are allocated into the Local Government Permanent Fund.
Montana	Seventy-five percent of disbursements are allocated to the state's General Fund.	Twenty-five percent of disbursements are allocated to the county of origin.	N/A
Nevada	The first $7 million of disbursements are deposited directly into the State Education Fund. Spillover amounts are deposited into the Account for Revenue from the Lease of Federal Lands. Of these spillover disbursements, 43.75 percent are allocated to the State Education Fund.	Of the spillover disbursements deposited in the Account for Revenue from the Lease of Federal Lands, 56.25 percent are then allocated to the county of origin.	N/A
North Dakota	N/A	Fifty percent of disbursements are allocated to school districts. Fifty percent of disbursements are allocated to the county of origin.	N/A

State	State Expenditures	Local Distributions	Savings
Utah	Utah allocates 2.25 percent of non-bonus disbursements to the Utah Geological Survey. Utah allocates 2.25 percent of non-bonus disbursements to the Utah State University Water Research Lab. Thirty percent of bonus payments in the Mineral Bonsu Account are allocated to the Wildland Fire Suppression Fund.	Forty percent of non-bonus disbursements are allocated to counties and special service districts. Five percent of disbursements are allocated to special service districts through the Department of Workforce Services. Disbursements are used to pay PILTs to local governments for state-owned lands. Utah allocates 32.5 percent of non-bonus disbursements and spillover amounts and 70 percent of non-bonus disbursements to the Permanent Community Impact Fund and distributes them to socially and economically impacted areas.	N/A
Wyoming	Wyoming allocates $2 million of disbursements (of the first $200 million) to the state's General Fund for administration. Of the coal bonus disbursements, 12.5 percent are allocated to the Highway Fund. Ten percent of bonus disbursements are allocated to the Community College Commission, and unspent and spillover amounts are allocated to the School Capital Construction Account. Of the non-bonus disbursements, 44.8 percent are allocated to the School Foundation Program Account as are 33 percent of the disbursements after the first $200 million. Of the non-bonus disbursements, 6.75 percent are allocated to the University of Wyoming.	Forty percent of coal bonus disbursements and 2.7 percent of non-bonus disbursements are allocated to the School Capital Construction Account. Wyoming allocates 37.5 percent of coal bonus disbursements and 3.75 percent of non-bonus disbursements to the Capital Construction Account. Of the non-bonus disbursements, 31.375 percent are allocated to the Highway Fund. Of the non-bonus disbursements, 9.375 percent are allocated to municipalities based on the general and school populations.	Wyoming allocates 66.6 percent of the disbursements after the first $200 million to the Budget Reserve Account. Spillover amounts from the distributions to the School Foundation Program Account are allocated to the Common School Permanent Fund.

Table A-29. State Taxes Assessed on Hard-Rock Mining Activities on Land Types, including Federal Lands (as of 2019)

State	Tax Name	Type of Mines or Minerals Assessed	Type of Tax	Tax Rate
Colorado	Severance tax—metallic minerals	Metallic minerals, all other minerals except molybdenum, oil, gas, coal, oil shale, rock, sand, gravel, stone products, earth minerals, limestone, carbon dioxide, and dolomite	Modified gross revenue	2.25 percent of gross income above $19 million per year
	Severance tax—molybdenum	Molybdenum ore	Unit based	$0.05 per ton above 625,000 tons per calendar quarter
Idaho	Mining license tax	Gold, silver, copper, and lead	Net proceeds	1 percent of net value of royalties paid or ore mined or extracted
Montana	Mining license tax—metal mine	Gold, silver, or any other metals or precious or semiprecious gems or stones	Net smelter returns	Percentage of gross value, less first $250,000, as follows: For gold, silver, or any platinum group metal-processed concentrates shipped to a refinery, 1.6 percent of gross value minus $250,000; For mineral concentrates shipped to smelter, mill, or reduction works, 1.81 percent of gross value minus $250,000
	Mining license tax—micaceous mines	Vermiculite, perlite, kerrite, maconite, or any other micaceous minerals	Unit based	$0.05 per ton of concentrate mined, extracted, or produced
	Resource indemnity and groundwater assessment tax	Includes any precious stones or gems, gold, silver, copper, lead, uranium, vermiculite, limestone, or other nonrenewable, merchantable products	Metals—net smelter returns; selected minerals—gross revenue with reference price	Default rate: $25 plus 0.5 to 1 percent of gross value greater than $5,000; For garnets: $25 plus 1 percent of gross value greater than $2,500; For limestone: $25 plus 10 percent of gross value greater than $250; For vermiculite: $25 plus 2 percent of gross value greater than $1,250

State	Tax Name	Type of Mines or Minerals Assessed	Type of Tax	Tax Rate
Nevada	Net Proceeds of Minerals Taxes	All minerals	Net proceeds	Based on a sliding scale between 2 percent and 5 percent, depending on the ratio of net proceeds to gross proceeds.
Utah	Severance tax on metals and metalliferous minerals	Ore, metal, or other substance containing 57 listed minerals, including gold, iron, mercury, nickel, and uranium extracted from all lands; does not include gemstones, potash, sand and gravel, oil, gas, and coal, and others	Net proceeds	2.6 percent of taxable value, which is the gross proceeds of sale (sale of yellowcake in the case of a sale of uranium concentrates) less $50,000 per year per mine and standard deduction
	Severance tax—beryllium	Beryllium	Other (cost based)	2.6 percent of taxable value; taxable value is 125 percent of direct mining costs
Wyoming	Mining severance tax—uranium	Uranium	Modified net smelter returns	4 percent of value of gross product, which is fair market value of minerals at mouth of mine, not including processing; fair market value is calculated by multiplying sales of yellowcake less royalties, ad valorem production taxes, and severance taxes; the result is multiplied by the industry factor
	Mining severance tax—other	Valuable deposits other than coal, oil and gas, trona, bentonite, uranium, and sand and gravel	Modified net smelter returns	2 percent of the value of the gross product, which is fair market value of minerals at mouth of mine, not including any processing

Source: GAO 2019

Note: California also charges taxes for hard-rock mining; however, there were no locatable mineral types on federal lands (see **Table 3-3**). Therefore, information on taxes in California were not included above. Nevada and Oregon only charge royalties for minerals extracted on state lands; therefore, data from Nevada and Oregon are not included above.

Table A-30. Disbursements to States from Geothermal with a Federal Stake

State	2018 ($)	2019 ($)	2020 ($)	2021 ($)	2022 ($)	Change 2018–2022 ($)	% Change 2018–2022
Nevada	3,854,581	5,665,406	6,483,864	5,680,458	8,185,231	4,330,649	112
Utah	538,739	491,491	528,661	716,894	1,247,237	708,498	132

Source: ONRR 2023b

Note: From 2018 to 2022, there was no geothermal production with a federal stake in Colorado, Idaho, Montana, North Dakota, Oregon, South Dakota, and Wyoming. Although there was federal oil and gas production and disbursements made to California, none of the production occurred in the socioeconomic analysis area. Therefore, only Nevada and Utah are included in the table above.

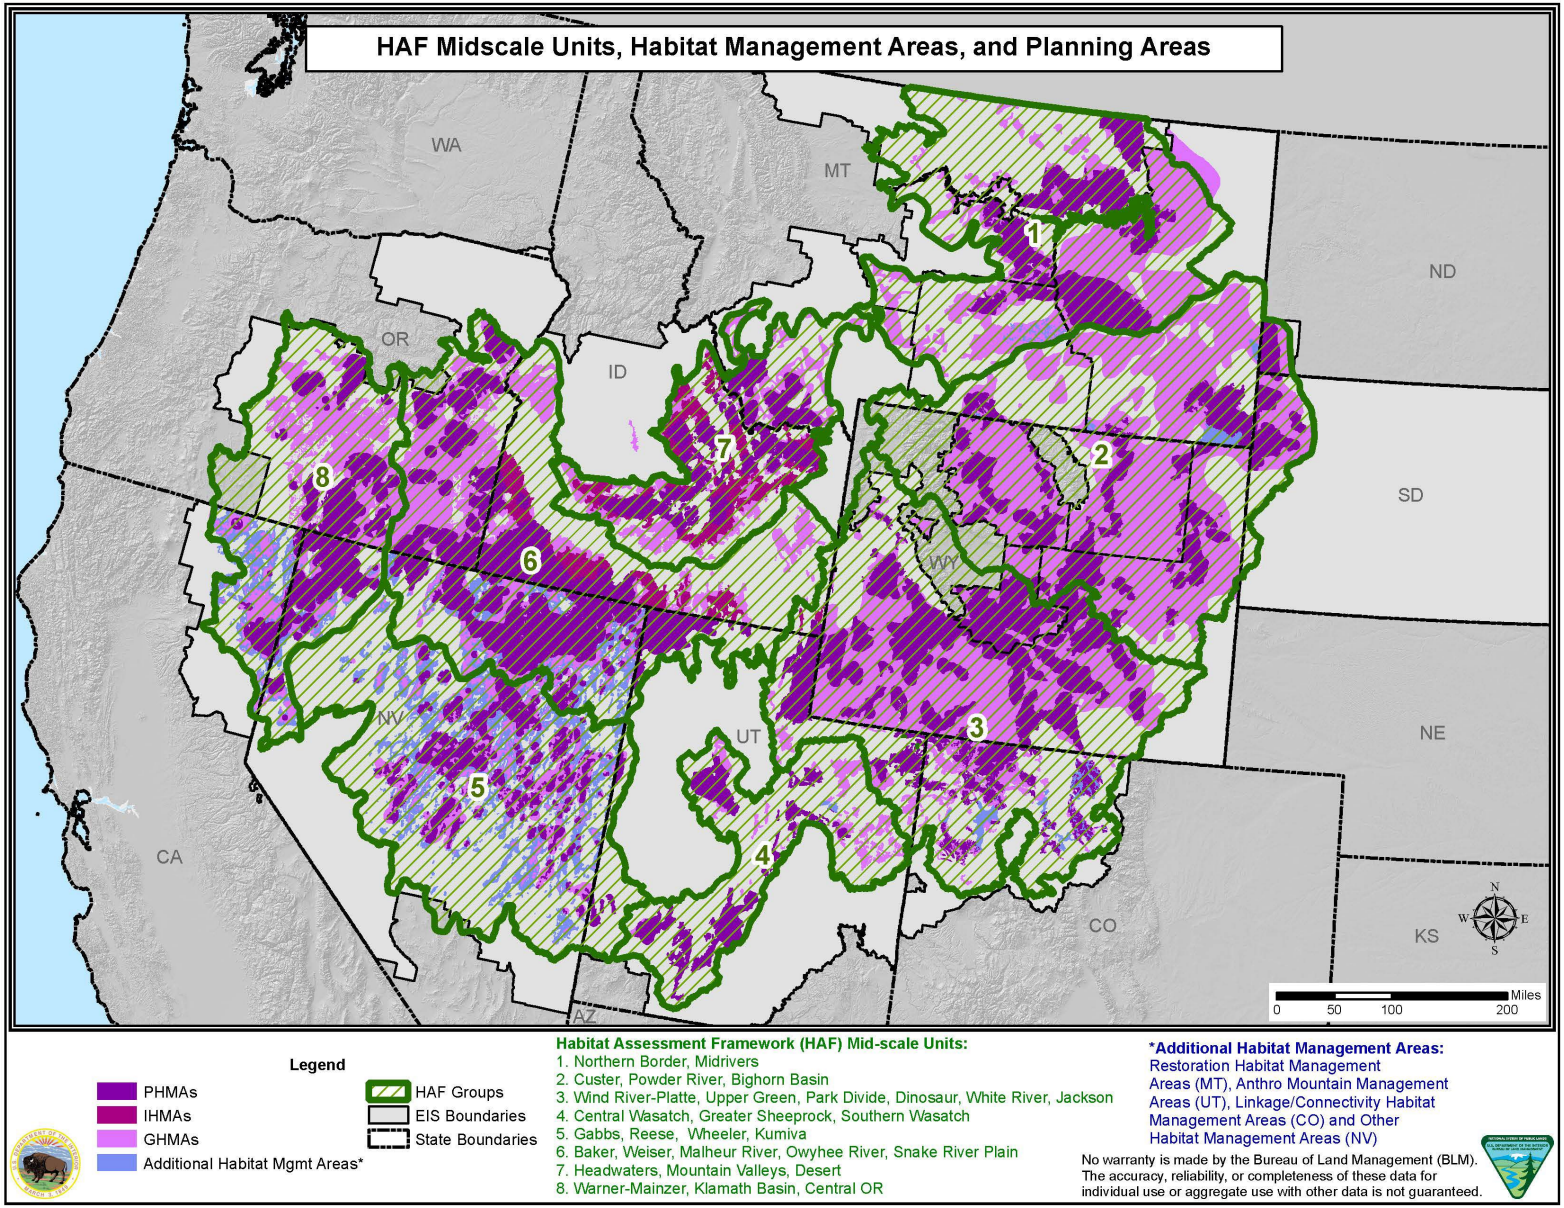
14-1 HAF Midscale Units, Habitat Management Areas, and Planning Areas 14-2

Appendix 14. Environmental Consequences Supporting Information



14.1 HAF Groupings

The Habitat Assessment Framework (HAF) is a tool to measure the suitability of GRSG habitat at multiple scales. Mid-scale (second order) HAF areas are conceptually linked to GRSG dispersal capabilities in population and subpopulation areas as described by Connelly and others (2004). Mid-scale HAF delineations also conceptually provide the life requisite space for GRSG dispersal, allowing for migration movements (presumably between seasonal habitats) based on the following key inputs:

- availability of sagebrush habitat,
- size and number of habitat patches,
- connectivity of habitat patches,
- characteristics of linkage areas between patches,
- landscape matrix and edge effects, and
- anthropogenic disturbances.

The mid-scale HAF delineations identified by the BLM capture a conceptual biologically meaningful unit. In addition, recent genetic analyses (Oyler-McCance et al. 2022) delineated sub-population clusters across GRSG range based on data collected between 2005 and 2015. These sub-population delineations indicate movement of GRSG within these areas (either in the past or currently), indicating a cumulative effects analysis on those units would have a biological basis. As such, the BLM combined habitat information using mid-scale HAF and results from the lek persistence model (Wann et al. 2022) with genetic information from Oyler-McCance et al. (2022), to group mid-scale HAF units within the genetic subpopulation boundaries. Given the divisions between subpopulation groupings are not distinct, groupings are based on the preponderance of genetic and habitat information. The resulting eight GRSG HAF groupings are shown in **Figure 14-1**. The allocation acres for Habitat Management Areas (HMAs), locatable minerals, and fluid minerals are provided for each of the eight mid-scale HAF groups by alternative in **Section 14.4**. These allocation acres for the locatable minerals and fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals for the purposes of GRSG conservation are only proposed and considered under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

Figure 14-1. HAF Midscale Units, Habitat Management Areas, and Planning Areas

14.2 CUMULATIVE EFFECTS

A cumulative impact on the environment is one that results from the incremental impact of the given alternative when added to other past, present, and reasonably foreseeable actions, regardless of what agency (federal or nonfederal) or person undertakes such actions. Cumulative impacts can result from actions that have individually minor impacts, but when taken collectively over time, their combined effects may be significant. The cumulative impacts resulting from the implementation of the alternatives in this RMPA/EIS may be influenced by other actions, as well as activities and conditions on other public and private lands, including those beyond the planning area boundary. As a result, the sum of the effects of these incremental impacts involves determinations that often are complex, limited by the availability of information, and, to some degree, subjective.

Because of the programmatic nature of an RMPA/EIS and cumulative impacts assessment, the analysis tends to be broad and generalized. This allows BLM to examine the impacts that could occur from a reasonably foreseeable management scenario, combined with other reasonably foreseeable activities or projects; consequently, this assessment is primarily qualitative for most resources because of a lack of detailed project-scaled information at the planning stage. A quantitative comparison of geospatial management decisions on public lands across the greater sage-grouse (GRSG) range is presented in **Section 14.3** below.

The cumulative effects analysis in Chapter 4 and supported by the information in this appendix assesses the magnitude of cumulative impacts by comparing the environment in its baseline condition with the expected impacts of the alternatives and other actions in the same geographic area. The magnitude of an impact is determined through a comparison of anticipated conditions against the baseline, as depicted in the affected environment, or the long-term resilience of a resource or social system.

The following factors were considered in cumulative impact assessment:

- Federal, Tribal, nonfederal, and private actions
- Potential for combined impacts or combined interaction between impacts
- Potential for impacts across political and administrative boundaries
- Other spatial and temporal characteristics of each affected resource
- Comparative extent of cumulative impacts across alternatives

14.3 STATE AND LOCAL CONSERVATION PLANS AND EFFORTS

This RMPA is considering changes to GRSG habitat management on public lands and provides direction for if and/or how future developments may occur. This RMPA is limited to planning-level decisions; in other words, it does not authorize any specific project but establishes the conditions under which future actions would be considered in GRSG habitat on public lands. Because of the nature of this decision, the greatest equivalent corresponding actions to consider in cumulative impacts is from actions of a similar scale. The most critical of these types of actions/plans are state GRSG plans, executive orders, statures, and related conservation efforts. Across the landscape, the BLM's RMPAs for public lands will be added to the management from the State plans/efforts. States have legal jurisdiction for managing GRSG populations, as well as having permitting authority over several types of potentially impactful land uses both on non-BLM-administered lands (e.g., oil and gas development on private lands), as well as for some uses on public lands (e.g., locatable mineral mines). Because of this, the State plans/efforts have the greatest potential for a similarly scaled cumulative effect when combined with the BLM's RMPAs.

In addition to the State plans, many counties and conservation districts also include GRSG management in their local plans. There is substantial variability in the level of detail and regulatory nature of the decision in

these plans across the GRSG range. This includes providing recommendations for GRSG habitat management on public lands and may also include specific management for land uses for which the county has permitting authority.

Each State with GRSG has developed a specific approach for conserving those populations and providing or recommending management of uses that could impact GRSG and their habitat. The following sections summarize each state's plan and related efforts.

14.3.1 Colorado

Colorado GRSG Conservation Plan, EO 2015-004, Greater Sage Grouse Stewardship Action Plan, SB 19-181. GRSG habitat conservation in Colorado spans across federal, state, local and private management. In 2008, the State of Colorado published the Colorado Greater Sage-Grouse Conservation Plan (CCP) which built on conservation plans developed by local working groups. The CCP provides an extensive literature review of GRSG in Colorado and overarching conservation strategy to support conservation of the species and avoid or minimize impacts. The CCP contains voluntary management guidelines that may be applied across land ownerships and many land uses (Colorado Greater Sage-grouse Steering Committee 2008). Implementation of the CCP guidelines is not mandatory.

Through implementation of the CCP, the State of Colorado has funded and completed over 146,000 acres of habitat improvements in GRSG habitat and supported numerous conservation easements (Conservation Efforts Database).

In 2015 Colorado's governor issued Executive Order 2015-004 to strengthen the CCP. Under the order, the state oil and gas permitting agency would evaluate its existing wildlife siting rules for potential improvement and consult with Colorado Parks and Wildlife when considering actions that impact GRSG or GRSG habitat. The order also prioritized the completion of the Colorado Habitat Exchange, a voluntary compensatory mitigation program. The Colorado Habitat Exchange has not been fully implemented largely due to changing market conditions that devalued the credit/debit system. There are no other statewide mitigation exchanges or banks in place.

Oil and gas operations in Colorado, regardless of ownership, are subject to the rules and regulations overseen by the Colorado Energy & Carbon Management Commission (ECMC, formerly Oil and Gas Conservation Commission). In 2019, Colorado Senate Bill 19-181 was signed into law, amending the Oil and Gas Conservation Act. SB 19-181 ensures that oil and gas development including flowline operations in Colorado are regulated in a manner that protects public health, safety, welfare, the environment and wildlife resources (§34-60-101 et seq.). Subsequent approved rulemaking for SB 19-181 included substantial updates to the 300 Series (consultations), 400 Series (Noise & Lighting Requirements), and 1200 Series regulations, which dictate the protection of wildlife resources. The 1200 Series regulations require wildlife mitigation plans for new or amended oil and gas locations, or for previously permitted locations that would cause the density of oil and gas locations to exceed 1 per square mile in PHMA. The wildlife mitigation plans must have written concurrence from CPW. New ground disturbance within 1 mile of GRSG lek sites, among other high priority habitats, is precluded except under certain circumstances outlined in the regulations. Any direct and/or indirect impacts resulting from development triggers compensatory mitigation requirements (monetary fees or operator-completed projects) which are intended to provide a conservation benefit for the population(s) impacted. Mitigation under the SB 19-181 is enforceable by ECMC but is limited to oil and gas development and flowline operations.

State trust land represents approximately 10 percent of the GRSG habitat in Colorado. In 2016 the State Land Board issued the Greater Sage Grouse Stewardship Action Plan (SAP) for an original term of 4 years and re-issued the SAP in 2020 for an additional 5 years. The SAP describes the current uses of the state trust lands, the quality of these lands for GRSG habitat, sets prescriptions for both surface and mineral ownership, and clarifies GRSG habitat mitigation and adaptive management (Colorado State Land Board, 2016). Some management actions described in the SAP are required to hold leases on state trust lands, such as a set of required and voluntary grazing best management practices. In coordination with CPW, the State Land Board applies stipulations to fluid mineral leases including no surface occupancy in PHMA, no surface occupancy within 2 miles of a lek in GHMA, and timing limitations in all designated habitat. The State Land Board also applies the 3 percent disturbance cap and the average of one facility per 640-acre density cap described in the BLM 2015 ARMPA. To date, the State Land Board has foregone 6 oil and gas, 1 solid mineral, 3 solar, and 9 wind energy leases to conform with the SAP (Annual Stewardship Report 2023). The State Land Board has implemented $82,000 worth of habitat enhancement projects associated with the SAP since 2016 (Colorado State Land Board 2023).

Additionally, several regional plans provide important GRSG conservation strategies in Colorado. This includes the Middle Park Greater Sage-Grouse Conservation Plan (CPW 2000) which covers the upper Colorado River drainage in north-central Colorado and include portions of Grand and Summit counties and the northeast corner of Eagle County; the Northern Eagle/Southern Routt Greater Sage-Grouse Conservation Plan (CPW 2004) which addresses Northern Eagle and southern Routt counties north of Eagle River; the North Park Greater Sage-Grouse Conservation Plan (CPW 2001) which covers Jackson County in the northern tier of Colorado; the Parachute-Piceance-Roan Plateau Greater Sage-Grouse Conservation Plan (CPW 2008b) and the Parachute-Piceance-Roan Plateau Sage-Grouse Work Group (CPW 2008c) which addresses the Parachute-Piceance-Roan area in western Garfield and Rio Blanco counties.

14.3.2 Idaho

Policy for GRSG Management in Idaho and EO 2022-03. With Executive Order 2022-003 "Adopting Idaho's 2021 Sage-Grouse Management Plan and Idaho Sage-Steppe Mitigation Process," the State of Idaho updated its GRSG management plan. The State plan guides GRSG management and provides recommendations across all ownerships. The State plan identifies policy direction and recommendations for GRSG conservation and management on federal lands and actions with a federal nexus within the Sage-grouse Management Area. The State plan may also apply to management of State Endowment Lands (a decision by the Idaho Board of Land Commissioners); it is non-binding on private lands.

The objectives of the Idaho Plan are to: (1) implement policy mechanisms to conserve and manage GRSG habitats, populations, and connectivity; (2) monitor habitat and population trends; and (3) use adaptive regulatory triggers to prevent further loss and stabilize habitats and populations in PHMA and IHMA.

The State plan focuses on management and direction for large-scale anthropogenic disturbance, as well as priorities for habitat management and restoration. Under the State plan, habitat disturbance from wildfire and fuels management, maintenance and operation activities by utility companies, and infrastructure related to homes or small-scale agricultural businesses are exempt from restrictions for large-scale anthropogenic disturbance.

Idaho's GRSG management is based on the three-tiered approach to Habitat Management Areas (HMA), ranging from Priority, Important, and General HMA (i.e. PHMA, IHMA, and GHMA) in terms of habitat quality, breeding bird densities, and connectivity. Guidance for management from the most to least restrictive also follows this order. The State plan focuses on conserving primarily PHMA, followed by IHMA. This 3-

tiered HMA approach facilitates multiple-use activities in lower quality habitats, e.g. disturbed or fragmented, in GHMA.

Executive Order 2022-03 also adopted the Idaho Sage-Steppe Mitigation Principles that guide compensatory mitigation, albeit voluntary. The overall strategy is to primarily avoid, then minimize impacts to GRSG, and lastly, to mitigate for unavoidable impacts. Mitigation efforts would focus on increasing the resiliency and productivity of GRSG populations and habitats, particularly in PHMA and IHMA. The State will work with federal land management agencies and project proponents to use the Habitat Quantification Tool (HQT) to measure and quantify the impact of new anthropogenic disturbance on GRSG, and, if needed, provide mitigation recommendations.

BLM Idaho has a Memorandum of Understanding (MOU ID SO-2022-09: Idaho Greater Sage-grouse Implementation Team) with several partner federal and state agencies to develop conservation strategies and make recommendations pertaining to adaptive management, review of new anthropogenic disturbance, and mitigation. The State makes recommendations on mitigation largely based on the Idaho Sage-steppe Mitigation Principles document and results from the HQT. The Implementation Team review proposals for new anthropogenic disturbance and makes recommendations to the BLM Authorizing Officer.

The State of Idaho has several ongoing efforts that contribute to GRSG conservation:

- **Sage-Grouse Actions Team** (SGAT) is comprised of representatives from state and federal agencies and NGOs who collaborate on habitat restoration efforts. It is overseen by the Idaho Governor's Office of Species Conservation. The SGAT specifically targets work on invasives, juniper removal, wet meadow and riparian restoration, wildfire prevention (e.g., strategic fuel breaks, wildland fire engine fill stations), and wildfire rehabilitation. Annual funding annually is typically a mix of state or federal funds. Each winter project proposals from agencies and individual landowners are evaluated. Projects have been funded since 2016. In 2022, through the SGAT, approximately 8,000 acres of habitat were treated, leks monitored, and funding assistance for GRSG coordinator positions. Many on-the-ground projects have been completed to-date, including those complementing efforts by various agencies or landowners in Idaho.
- Idaho **Cheatgrass Challenge** (CC) is a multiagency partnership lead by the Natural Resource Conservation Service (NRCS) whose focus is to proactively maintain healthy landscapes, free of invasive annuals grasses (IAG) (cheatgrass, medusahead wildrye, ventenata and other invasive weeds), reduce IAG distribution in transitional areas, and mitigate the adverse effects in areas they dominate. The CC was formed in 2018 and consists of representatives from multiple federal and state agencies, as well as Pheasants Forever and the Idaho Rangeland Conservation Partnership. Projects are funded annually. A review team evaluates the applications based in factors such as treatment effectiveness, collaboration across landownerships, and leveraging of funding and in-kind efforts.

14.3.3 California

GRSG Conservation Plan for northeastern California (NV/CA Sub-region). The State of California has not developed a plan or established a mitigation strategy for GRSG. In lieu of a state mitigation strategy in California, the BLM coordinates with the Sagebrush Ecosystem Technical Team (SETT) on site-specific projects which require mitigation, as appropriate. The SETT runs a "table-top" analysis established in the Conservation Credit System (CCS; State of Nevada, 2022) to determine the impacts of the site-specific projects. The BLM uses this information to determine the appropriate mitigation measures required

to off-set impacts to GRSG and their habitat and remain consistent with mitigation measures applied on lands in Nevada.

In November of 2022, a petition was submitted to the California Fish and Game Commission (Commission) requesting the Commission list GRSG as threatened or endangered under the California Endangered Species Act (CESA). Based on the information contained in the petition and other relevant information, it was determined that there was sufficient information to indicate the petitioned action may be warranted. A one-year status review of GRSG by the California Department of Fish and Wildlife (CDFW) commenced in June of 2023. During the review period, GRSG will receive the same protections as a CESA-listed species throughout California.

On California BLM-managed lands in Nevada, the California BLM utilizes the Nevada Greater Sage-grouse Conservation Plan (State of Nevada, 2019), CCS and abides by the State of Nevada's Regulations (2022 Nevada Revised Statutes (NRS) Chapter 232-State Departments NRS 232.162) regarding GRSG mitigation, which applies to lands in GRSG habitat across all land ownership. See the "GRSG Conservation Plan for Nevada" below for additional information on the State of Nevada's GRSG conservation plan, CCS and mitigation strategy.

Additional ongoing efforts that contribute to GRSG conservation in California include the Buffalo Skedaddle Working Group. The group is named after a GRSG Population Management Unit (PMU) which is managed by the Eagle Lake and Applegate Field Offices. The group has been working for over a decade addressing ways to conserve habitats that are important for GRSG within the Buffalo Skedaddle PMU. The working group consists of wildlife biologists, rangeland management specialists, ecologists, private landowners, and permittees. The group represent the BLM, CDFW, Nevada Department of Wildlife, US Fish and Wildlife Service, Forest Service, Natural Resources Conservation Service, and the ranching community.

The group has been focused on implementing the conservation goals and habitat restoration targets established in the 2006 Buffalo Skedaddle Conservation Plan (currently under revision). The group works on projects focused on the habitat needs of GRSG including all seasonal habitats, wildfire rehabilitation, riparian restoration and protection, fuels reduction, control of invasive species and several multi-year research projects in conjunction with USGS, CDFW, NDOW and universities. The Plan includes strategies to manage uses such as livestock and wild horse and burro in ways that benefit GRSG and its habitat. It also recognizes the critical connection of public and private lands and the essential partnership among the land managing agencies and landowners.

14.3.4 Nevada

GRSG Conservation Plan for Nevada. On March 30, 2012, Governor Brian Sandoval fortified Nevada's commitment to GRSG conservation by issuing Executive Order 2012-09, which established the Governor's Greater Sage-grouse Advisory Committee (Advisory Committee) with a directive to provide updated recommendations for GRSG conservation in Nevada to preclude the need for listing GRSG under the Endangered Species Act (ESA) and provide a GRSG alternative in the Nevada BLM/ USFS Land Use Plan (or Resource Management Plan) revision process. Those efforts resulted in the Strategic Plan for Conservation of Greater Sage-Grouse in Nevada (2012 State Plan), completed on July 31, 2012, which consisted of a list of primary threats to GRSG in Nevada and recommendations to the Governor on strategies and actions to conserve GRSG in Nevada.

One of the main recommendations of the 2012 State Plan was the creation of the Sagebrush Ecosystem Program (SEP), which would consist of the Sagebrush Ecosystem Council (SEC) and the Sagebrush Ecosystem

Technical Team (SETT). The SEC was originally established under Executive Order 2012-19, on November 19, 2012, and later codified under Nevada Revised Statutes Chapter 232.162. The SETT began work on February 11, 2013. On April 22, 2013, the SEC directed the SETT to further develop the recommendation in the 2012 State Plan into a more comprehensive and detailed strategy. The SEC considered proposed revisions over a series of meetings starting in July 2013. The result of those efforts was the 2014 Nevada Greater Sage-grouse Conservation Plan (State Plan).

The State Plan, as updated in 2019, is based on available scientific information and stakeholder input to apply a GRSG conservation plan specific to Nevada. This is meant to be a "working document" that will be updated as new science emerges and lessons are learned through implementation of the State Plan, using an adaptive management framework.

In addition to the State Plan, the SEP developed the Nevada Sage-grouse Strategic Action Plan (SAP). The State Plan provides broad goals, objectives, and management actions to ameliorate the primary threats to GRSG in Nevada. The SAP is a companion document to the State Plan and goes into greater detail identifying areas in which to focus conservation efforts to achieve the broad goals and objectives outlined in the State Plan. The SAP identifies funding sources to implement the management actions recommended in the State Plan. The SAP also identifies where the primary threats to GRSG habitat are located across the landscape and provides specific guidance on how to ameliorate these threats based on local area conditions, resistance and resilience regimes, and ecological site descriptions. The SAP helps guide how and where the management efforts identified in the State Plan are prioritized to achieve landscape-scale conservation of GRSG and the sagebrush (*Artemisia* spp.) ecosystem.

Nevada Conservation Credit System. Administered by the Sagebrush Ecosystem Technical Team (SETT), the Nevada Conservation Credit System (CCS) is an approach to GRSG habitat protection that provides for fully compensating habitat impacts from man-made disturbances by long-term enhancement and protection of habitat to result in an overall benefit for the species, while allowing for anthropogenic disturbances that support the Nevada economy. The CCS was developed to meet requirements established by Nevada Revised Statutes Chapter 232.162 to fulfill compensatory mitigation requirements for anthropogenic disturbances to GRSG habitat on public lands in Nevada. The use of the CCS to offset impacts to GRSG became mandatory in Nevada with the adoption of Nevada Administrative Code 232.400-232.480 in 2019. The CCS is used to offset impacts from anthropogenic disturbances through habitat enhancement and protection that results in a net conservation benefit for GRSG habitat in Nevada. The CCS quantifies verified functional habitat value in the form of credits and quantifies the verified functional habitat value of impacts, both direct and indirect, in the form of debits.

The CCS fulfills the November 3, 2015, Presidential Memorandum: *Mitigating Impacts on Natural Resources from Development and Encouraging Related Private Investment* directive to ensure that federal policies are clear, work similarly across agencies, and are implemented consistently. The CCS meets the objective of encouraging private investment to achieve public natural resource conservation as an innovative way to finance successful stewardship and restoration projects that demonstrate a measurable net conservation gain of sagebrush habitat in Nevada.

The CCS is designed to accommodate private land credits in the system and the State Plan currently allows for credits to be generated on public land. However, procedures and instructions have not been adopted for federal agency engagement with the CCS to verify and enroll credits on public land.

14.3.5 Montana

Montana GRSG Habitat Conservation Program and EO 12-2015. In Montana, the GRSGS Conservation strategy is overseen by the Montana Sage-Grouse Oversight Team and the Sage-grouse Habitat Conservation Program, working to implement Executive Order 12-2015 and the Greater Sage-grouse Stewardship Act. Executive Order 12-2015 establishes specific requirements and limitations on development, being most restrictive in core areas near leks and less restrictive in general habitat and connectivity areas. Other components establish general practices that apply to everyone. The EO applies to all state agencies and all programs and activities of state government, including permitting programs, grant programs, and internal agency programs.

The MT Habitat Conservation Program facilitates implementation by consulting with permit applicants and project proponents to help applicants avoid negative impacts of development through minimization of impacts and address compensatory mitigation for impacts that can't be avoided or minimized. The mitigation hierarchy is applied by first working to avoid impacts and core area, then minimization through onsite practices, and as a last resort, compensatory mitigation to replace lost habitat. The Program will make recommendations to the applicant and the permitting agency.

While the MT HCP provides advice, and is not a regulatory entity, compliance with the EO is achieved through the issuing of state permits, grants or technical assistance, which contain requirements. In cases where exceptions or waivers to the EO are requested, these are decided by the Montana Sage Grouse Oversight Team. Implementation is mandatory for state agencies and federal agencies have committed to align their work to the approach, consistent with "all hands, all lands."

The compensatory mitigation aspects of the Montana Sage-Grouse Conservation Strategy are established through a Montana Sage Grouse Oversight Team (MSGOT) approved, Montana Mitigation System Policy Guidance Document for Greater Sage-Grouse and the Habitat Quantification Tool Technical Manual (HQT). The HQT and mitigation policy took effect January 12, 2019. The System draws on findings and science from the U.S. Fish and Wildlife Service's (USFWS) Conservation Objectives Report (COT), the 2015 USFWS Not Warranted Finding, and the recommendations of the Montana Greater Sage-Grouse Habitat Conservation Advisory Council. The approach relies on best available science, should incorporate new information, and is based on deliberations of the Montana Mitigation Stakeholders Team (Stakeholders Team). The HQT calculates the functional acres lost on a debit project and gained on a credit project. Functional acres are based on the quality and quantity of affected habitat. The policy guidance document applies multipliers for development projects to incentivize voluntary conservation and consistency with the Montana Sage-Grouse Habitat Conservation Plan or specific provisions of federal land use plans.

The Montana Policy Guidance defines the processes and information necessary to create, buy, or sell mitigation credits suitable for meeting sage grouse mitigation requirements within the State of Montana. The HQT calculates the functional acres lost on a debit project and gained on a credit project. Functional acres are based on the quality and quantity of affected habitat.

In 2005, Montana Fish Wildlife and Parks (FWP), released the Management Plan and Conservation Strategy for Sage-grouse in Montana, a product crafted in partnership with other key entities. The plan describes GRSG habitat, population dynamics, and provides a framework for developing local working groups. Overall, the plan outlines the envisioned approach for conservation and enhancement of sage-grouse habitats. This plan, along with newer science and information was used as key information in the development of the MT GRSG Conservation Strategy.

Montana FWP also manages the Upland Game Bird Enhancement Program which provides funds for various conservation actions including management changes, restoration projects, and easements. In addition, the department provides technical assistance to aid in the development and application of GRSG related conservation projects from federal, local, and non-profit partner organization programs.

14.3.6 North Dakota

Management Plan and Conservation Strategies for GRSG in North Dakota. The State of North Dakota Game and Fish Department released the Management Plan and Conservation Strategies for Greater Sage-Grouse in North Dakota in 2014. The plan provides recommendations on how to meet objectives from the FWS COT Report (2013). While the plan does not regulate development in sage-grouse habitat, it provides a framework for habitat conservation efforts across the varied ownership in ND GRSG habitat. The plan recommends a conservation hierarchy, starting with avoidance, and where that is not possible, minimization and mitigation.

In addition, the ND Game and Fish Department runs a Private Land Initiative program, that includes programs such as Conservation Reserve Cost Sharing, Working Lands, and Habitat Plots. These initiatives fund various conservation actions, including ones in GRSG habitats.

14.3.7 South Dakota

South Dakota GRSG Action Plan 2022-2026. GRSG are listed as a species of greatest conservation need in the 2014 South Dakota Wildlife Action Plan. Habitat areas, management approaches, population dynamics, and additional management options were part of the Sage-grouse Management Plan for South Dakota 2014 – 2018. The management plan was updated in 2022 with the release of Management of Greater Sage-Grouse in South Dakota. Information from the management plan was used to craft the South Dakota Greater Sage-Grouse Action Plan (2022-2026) which was released in early 2022. The plan recommends three priorities: core area mapping; habitat management; and collaboration. While the plan is not regulatory, it does provide both internal guidance to SD Game Fish & Parks and identifies the need for collaboration, establishment of good faith efforts, and environmental review to facilitate the common interest of GRSG conservation.

Additional contributions by the state for GRSG conservation are focused on providing capacity for collaborative habitat-related programs. SD GFP contributes funding to multiple partner efforts that overlap and work to leverage federal, state, and additional funding sources to apply restoration, enhancement, and protection actions to GRSG habitats in South Dakota.

14.3.8 Oregon

Oregon Sage-Grouse Action Plan and EO 15-18. The State of Oregon is in the process of updating its Oregon Sage-Grouse Conservation Assessment and Strategy. Oregon Department of Fish and Wildlife (ODFW) first developed a plan for the conservation and management of GRSG in Oregon in 2005. This document, the Greater Sage-Grouse Conservation Assessment and Strategy for Oregon (or "CAAS"), was last updated in 2011. The 2011 update to the CAAS included a process for defining and delineating the most important sage-grouse habitats in Oregon. These "Priority Areas for Conservation" (PACs) are necessary to conserve 90% of Oregon's GRSG population and include both core and low-density habitats. ODFW updated the GRSG habitat designation maps, and consequently the Oregon Fish and Wildlife Commission approved them in December 2023, which was not in time incorporation into the BLM's Draft analysis; it will be incorporated into the Final EIS.

The State plan implements direction from State EO 15-18 (September 15, 2015). ODFW Greater Sage-Grouse Conservation Strategy (Oregon Administrative Rules OAR 635-140-0000 – 0025) rules identify GRSG habitat, target population objectives, and mitigation hierarchy with specific information regarding mitigation. The State's Land and Conservation Development Commission (LCDC) also enacted OAR 660-023-0115 for GRSG conservation, which is the regulatory rule. All state agencies that carry out, fund, or permit actions within GRSG habitat were required to adopt OAR-660-023-0115.

Oregon has a Sage-grouse Mitigation Program, which is a product of Oregon's GRSG conservation efforts and addresses the threat of increasing development pressure in GRSG habitat. Proposed development projects in GRSG habitat that require a county or state permit, which includes private lands, and are identified as a conflicting use (e.g., any non-agriculture development over 5 acres), as outlined in OAR 660-023-0115(7), must coordinate with the Mitigation Program to ensure the Mitigation Hierarchy outlined in both OAR 660-023-0115 and OAR 635-140-0025 has been achieved. "Compensatory mitigation" is the third step in the mitigation hierarchy and means the replacement or enhancement of the function of habitat capable of supporting GRSG in greater numbers than predicted to be impacted by a development. ODFW operates a Habitat Quantification Tool (HQT), which was developed to measure projected outcomes of both new development and habitat restoration projects and to help target siting of credit and debit projects in the most beneficial locations for GRSG .

In 2012, the Oregon Sage-grouse Conservation Partnership (SageCon) was convened at the request of the Governor's office to formulate an "all lands, all threats" approach to GRSG conservation. This effort was to address both USFWS' GRSG listing decision in 2015 and support long-term community sustainability in central and eastern Oregon. SageCon continues to convene the partners involved in Oregon's sagebrush rangelands. The ODFW 2011 Conservation and Assessment Strategy and the 2015 Oregon Sage-grouse Action Plan identified Local Implementation Teams (LITs) for 5 geographic areas to be the hub of locally-led collaboration to achieve coordinated and supported implementation of strategic conservation actions on-the-ground. These LITs and other local entities work closely with BLM district and field offices to coordinate cross-jurisdictional activities to benefit GRSG habitat.

Additionally, private landowners are able to make a long-term commitment through CCAA's. Voluntary conservation agreements through Sage-Grouse Candidate Conservation Agreements with Assurances (CCAAs) are designed to support the ecological integrity and uplift of Oregon's privately owned sagebrush habitats. In these 30-year agreements between US Fish & Wildlife Service and a local entity (Soil & Water Conservation District or Watershed Council), enrolled properties are assessed for risks to sage-grouse and their habitat, and actions are identified to address those threats. Implementation funds can then be applied for from USDA NRCS and the Oregon Watershed Enhancement Board (OWEB).

14.3.9 Utah

Utah Conservation Plan for GRSG (January 2019) and EO/2015/002. The State of Utah updated its Conservation Plan for Greater Sage-Grouse in 2019. The plan implements direction from State EO 2015/002. The State plan identifies 11 Sage-Grouse Management Areas that encompass more than 90 percent of Utah's breeding GRSG populations. The plan notes that GRSG habitats outside the SGMAs are not required for long-term conservation of the species. The State's EO and associated plan combines voluntary and incentive-based programs on private, local government, State Trust lands, and state lands– with reasonable and cooperative regulatory programs on federally managed lands. The EO mandated that all relevant State agencies participate in the implementation of the Plan. State agencies have developed MOUs

with the Utah Division of Wildlife Resources and Public Lands Policy Coordinating Office. Those agreements set agency-specific directives related to the implementation of the executive order and the Plan.

The State of Utah also has a Compensatory Mitigation Program that was established, in part, by the Utah Legislature, Utah Administrative Rule (Compensatory Mitigation Program), and the State's Plan. The program includes rules, definitions and mechanisms for developing and tracking mitigation credits and debits. During project coordination, the Plan recommends that the regulatory entity or project proponent voluntarily implement the compensatory mitigation. The Program is administered by Utah's Department of Natural Resources, and recommends that for every one acre of functional GRSG habitat permanently disturbed, four acres of functional habitats or corridors should be created, restored and/or preserved.

Since 1996, the State has coordinated with Utah State University to facilitate local working group meetings in communities with occupied GRSG habitat. These groups have developed local GRSG conservation plans and meet regularly to coordinate and shape the state and national policies that directly affect them.

14.3.10 Wyoming

Greater Sage-grouse Core Area Protection Executive Order (2019-3). The State of Wyoming manages GRSG through Executive Order as the State's primary regulatory mechanism to conserve GRSG. The Executive Order establishes a conservation framework implemented at the scale of the State with the goal of precluding the need to list GRSG as threatened or endangered under the Endangered Species Act (ESA). Governor Freudenthal signed the first GRSG Core Area Protection Executive Order (SGEO) in 2008 (SGEO 2008-2) which was updated in 2010 (SGEO 2010-4). Each successive administration has updated and signed a new SGEO (Governor Mead SGEO 2011-5 and 2015-4; Governor Gordon SGEO 2019-3).

Wyoming's SGEO 2019-3 coordinates GRSG conservation actions across jurisdictional boundaries (i.e., "all lands approach"). The SGEO directs agencies and departments of the State of Wyoming to follow, consistent with statutory authority, the procedures outlined in the SGEO. On private lands incorporated into the strategy, only those activities which state agencies are required by state or federal law to review or approve are subject to the SGEO. Core population areas, connectivity areas and winter concentration areas identified as distinct habitat designations in the SGEO encompass approximately 15 million acres of GRSG habitat and 84% of the GRSG breeding population in the State. The SGEO recognizes and supports enrollment and expanded coverage of voluntary conservation programs such as USFWS's Candidate Conservation Agreements with Assurances (CCAA) and NRCS's Sage-Grouse Initiative (SGI). A statewide umbrella CCAA designed to promote conservation measures that reduce or remove threats to GRSG and to increase landowner participation by streamlining the CCAA enrollment process has been in effect in Wyoming since 2013. The State has distributed >$100M (since inception of the GRSG core area protection strategy) for on-the-ground projects, research and monitoring specific to GRSG conservation; these funds have generally been funneled through the Wyoming Wildlife and Natural Resource Trust (WWNRT) or the GRSG Local Working Groups (LWG).

The conservation framework established in the SGEO follows an avoidance, minimization, and compensatory mitigation (where appropriate) approach to GRSG conservation. Compensatory mitigation is required by statute for activities requiring a state permit that do not comply with the stipulations of the SGEO. The State's compensatory mitigation framework details the biological, replacement, durability, and additionality requirements for a parcel of land to be considered as a GRSG "conservation credit." The mitigation framework additionally defines "restoration credits" as a means of incentivizing the restoration of GRSG habitats that have been lost or severely impacted. Debit requirements for activities that exceed thresholds in core population areas are established by disturbance type and range from 5 to 10 debits per acre or per

type. Currently, a single GRSG mitigation bank on Pathfinder Ranches (Sweetwater River Conservancy) is functional in Wyoming, although several additional GRSG mitigation bank proposals are under consideration by the State.

14.4 Habitat Management Area, Locatable Mineral, and Fluid Mineral Allocation Information by Mid-scale HAF Group

When assessing the cumulative impact of the RMPA/EIS on GRSG and its habitat, there are multiple geographic scales that the BLM has considered. In 2015 and 2019, cumulative impacts to GRSG were analyzed using Management Zones identified by the Western Association of Fish and Wildlife Agencies (WAFWA). The WAFWA Management Zones were based on floristic provinces. Based on information that has become available since the previous efforts,

II. Locatable Minerals

Table 14-2. Locatable Minerals Decisions within HAF 1

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-3. Fluid Minerals (Oil & Gas) Decisions within HAF 1

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. Calculations reflect only the portions of the HAF where data was available. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Forseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land owerships for each alternative.

II. Locatable Minerals

Table 14-5. Locatable Minerals Decisions within HAF 2

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-6. Fluid Minerals (Oil & Gas) Decisions within HAF 2

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Foreseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land ownership for each alternative.

Table 14-8. Locatable Minerals Decisions within HAF 3

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-9. Fluid Mineral (Oil & Gas) Decisions within HAF 3

Percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Foreseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land ownership for each alternative.

II. Locatable Minerals

Table 14-11. Locatable Minerals Decisions within HAF 4

Acreages and Percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-12. Fluid Mineral (Oil & Gas) Decisions within HAF 4

Percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Foreseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land ownership for each alternative.

II. Locatable Minerals

Table 14-14. Locatable Minerals Decisions within HAF 5

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-15. Fluid Mineral (Oil & Gas) Decisions within HAF 5

Percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Foreseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land ownership for each alternative.

II. Locatable Minerals

Table 14-17. Locatable Minerals Decisions within HAF 6

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-18. Fluid Mineral (Oil & Gas) Decisions within HAF 6

Percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Foreseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land ownership for each alternative.

II. Locatable Minerals

Table 14-20. Locatable Minerals Decisions within HAF 7

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-21. Fluid Mineral (Oil & Gas) Decisions within HAF 7

Percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Foreseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land ownership for each alternative.

II. Locatable Minerals

Table 14-23. Locatable Minerals Decisions within HAF 8

Acres and percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. The acres for the locatable minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. For example, for locatable minerals, proposed mineral withdrawals are only proposed and considered for GRSG conservation under Alternative 1 and Alternative 3 in this RMP Amendment. All the other existing and proposed withdrawal acreage that is identified under other alternatives represent proposed or existing withdrawals that are either being proposed in other RMP efforts or existing withdrawals that are already in place. The information is provided for context and to facilitate the analysis of effects.

III. Fluid Minerals (Oil & Gas)

Table 14-24. Fluid Mineral (Oil & Gas) Decisions within HAF 8

Percentages reflect BLM managed lands. Percentages may not total to 100% due to rounding. All figures and tables are intended for Habitat Assessment Framework summary purposes only. These acres for fluid minerals represent a combination of existing allocations in existing Resource Management Plans (RMPs) and allocations identified under the alternatives in this RMP Amendment. The information is provided for context and to facilitate the analysis of effects. It is important to note that just because an area is open to leasing does not mean that it will be developed. Any development must be in conformance with the stipulations which may preclude development in some areas. The stipulation information has been considered in context with mineral potential, and drilling and economic trends to develop the Reasonably Foreseeable Development Scenario (see **Appendix 12**) which estimates the amount of development anticipated across all land ownerships for each alternative.

14.5 PAST, PRESENT, AND REASONABLY FORESEEABLE ACTIONS

Beyond the state and local plans, there are other actions that have occurred in GRSG habitat in the past, are currently taking place or being considered, and activities which may be reasonably foreseeable. **Table 14-25** represents many of these actions across the entire range for GRSG, which are separated by state.

As noted in section 14.1, those actions that are at a similar level of decision-making to this RMPA are most likely to have a cumulative impact with the actions considered in the alternatives. Most prominently, this includes U.S. Forest Service GRSG plan amendments from 2015, as well as any other changes to those plans currently being considered. Other efforts with similar levels of decisions include other BLM planning efforts that affect similar geographic areas or land uses as what is being considered in this RMPA effort.

Additionally, BLM Colorado has developed the Fluid Mineral Specialist Report on Concurrent Land Use Planning Efforts in Colorado (BLM 2024b) to support the cumulative impacts analysis for several concurrent land use planning efforts in Colorado. The report provides an overview of how the land use planning decision areas overlap across the BLM administrative units (field offices) and where fluid mineral resources may be available as a result of all planning efforts. The report provides a geospatial analysis of fluid mineral topics and a discussion on potential impacts to air quality and greenhouse gas emissions, socioeconomic impacts, and communities that are most likely to be impacted by the concurrent and overlapping land use plans. That report is incorporated by reference here.

In addition to the various planning efforts, there are a variety of actions being considered within the planning area. There are also a wide variety of actions the BLM considered during implementation of the RMPs. The intent of **Table 14-25** and the related cumulative impacts analyses is not to analyze every potential future land use in GRSG habitat. Each action conducted on public lands must go through its own analysis, including consideration of the direct, indirect, and cumulative effects associated with that project. As the level of decision-making gets more specific, the level of analysis correspondingly gets more specific, as the level of uncertainty or speculation is reduced.

It is also critical to note that all actions authorized on public lands must document conformance with RMP goals, objectives, and decisions. Any project identified below that occurs on public lands – or any other action that may occur that is not noted in the table – must align with the direction in the current land use plans (if authorized before completion of this effort), or with the direction associated with whatever decision comes from this effort (if authorized after a decision is made in this effort). Additionally, any proposed action

that includes state or county permits must also be in conformance with those plans. As such, the intent of **Table 14-25** and the corresponding analyses is not to present or analyze every potential project that may occur, or even all those listed in the table, as some of those projects would not be in conformance with some of the alternatives being considered. The effect of the management of the alternatives and their impacts direct, indirect, and cumulative on GRSG and its habitat, the various land uses, and corresponding effects to socioeconomics are described in **Chapter 4**.

Table 14-25. Past, Present, and Reasonably Foreseeable Actions

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Multi-State				
Lands and Realty	California, Colorado, Idaho, Montana, Nevada, Oregon, Utah, Wyoming	West-wide energy corridors (Section 368 energy corridors)	In accordance with Section 368(a) of the Energy Policy Act of 2005, the BLM designated 5,000 miles of energy corridors for potential placement of future oil, natural gas and hydrogen pipelines, and electricity transmission and distribution infrastructure. The BLM is currently conducting an amendment effort that is considering adjustments to some of the corridors.	Ongoing and Proposed changes to some corridors
Lands and Realty	California, Colorado, Idaho, Montana, Nevada, Oregon, Utah, Wyoming	Solar Programmatic EIS	The BLM is considering updates to its 2012 Western Solar Plan and is considering expanding its solar planning to include five additional states: Idaho, Montana, Oregon, Washington, and Wyoming	Ongoing
Multiple	All (except Dakotas and Washington)	21 Restoration Landscapes	Work in Restoration Landscapes will coordinate and sequence different types of investments and treatments from across the BLM – including fuels, rangelands, wildlife, forestry, aquatics and recreation.	Proposed
Locatable Minerals	California, Idaho, Montana, Nevada, Oregon, Utah, Wyoming	SFA Withdrawal Project	The BLM is considering withdrawal from location and entry under the Mining Act of 1872 for Sagebrush Focal Areas (SFAs) from the 2015 GRSG plans. This EIS is providing the additional and more specific analyses prior to a final decision of whether to withdraw some, none, or all of the SFAs.	Proposed
Lands and Realty	Idaho, Wyoming	Gateway West 230/500 Transmission Line Project	Rocky Mountain Power and Idaho Power to build and operate approximately 1,000 miles of new high-voltage transmission lines. Project has been authorized and is being implemented, with construction underway and ongoing, moving east to west	Ongoing
Vegetation	All	Vegetation Treatments Using Herbicides	The BLM approved an addition to its list of approved herbicides, 7 active ingredients including Indaziflam, Aminocyclopyrachlor, Clethodym, and Flumioxazin, among others.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Lands and Realty	Montana, North Dakota, Wyoming, Utah, Colorado, Nebraska, Arizona	Sentinel (Ground Based Strategic Deterrent (GBSD)) Program Deployment and Minuteman III Decommissioning and Disposal	The Department of the Air Force (DAF) issued a Record of Decision (ROD) in May 2023 to document its decision to implement actions to deploy the Sentinel (formerly known as the Ground Based Strategic Deterrent [GBSD]) intercontinental ballistic missile (ICBM) system and to decommission and dispose of the Minuteman III (MMIII) ICBM system. The ROD includes establishing approximately 3,126 miles of new utility corridors throughout the F.E. Warren AFB, Malmstrom AFB, and Minot AFB missile fields in Colorado, Nebraska, North Dakota, Montana, and Wyoming, for which the government would acquire the necessary property easements/ROWs. The new corridors would supplement the existing utility connections. Sentinel maintenance, training, storage, testing and support actions will occur also at Hill AFB, Utah; Utah Test and Training Range, Utah; Camp Guernsey, Wyoming; and Camp Navajo, Arizona.	Proposed
Lands and Realty	Wyoming, Colorado, Utah	Energy Gateway South Transmission Line	650-mile 500 kV transmission line. Begins in south central Wyoming, crosses Utah diagonally from northeast to southwest, and ends in Mona, Utah. Includes GRSG mitigation.	Ongoing
Lands and Realty	Wyoming, Colorado, Utah, Nevada	TransWest Express	725-mile 600 kV transmission line. Begins in south-central Wyoming, crosses Utah diagonally from northeast to southwest, and ends south of Las Vegas	Ongoing
Lands and Realty	Idaho, Oregon	Boardman to Hemingway Project	The Boardman to Hemingway Transmission Line Project is a 500 kilovolt (kV) transmission line, beginning at a substation near Boardman, Oregon, and extending south and east to the existing Hemingway Substation near Melba, Idaho, a distance of approximately 300 miles. The transmission line will provide additional electrical capacity between the Pacific Northwest region and the Intermountain region of southwestern Idaho.	Ongoing
Vegetation	Idaho, Oregon, Nevada, northeastern California, Utah, and eastern Washington	Programmatic EIS for Fuel Breaks in the Great Basin	This programmatic environmental impact statement (PEIS) evaluates creating and maintaining a system of fuel breaks in the Great Basin region. The project area, covering nearly 224 million acres, includes portions of California, Idaho, Nevada, Oregon, Utah, and Washington. The fuel breaks would be placed along a subset of available linear features, such as roads and rights-of-way (ROWs) on Bureau of Land Management (BLM)-administered lands within sagebrush communities; these potential treatment areas cover approximately 38 million acres within the project area boundary.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Vegetation	Idaho, Oregon, Nevada, northeastern California, Utah, and eastern Washington	Programmatic EIS for Fuels Reduction and Rangeland Restoration in the Great Basin	This landscape scale Programmatic Environmental Impact Statements (EIS) to analyzes potential effects of reducing fuel loading and restoring rangeland productivity within the Great Basin Region (Idaho, Oregon, Nevada, northern California, Utah, and eastern Washington) in order to protect and conserve the sagebrush-steppe ecosystem from loss as a result of wildfires.	Ongoing
Lands and Realty	Nevada, Utah	Cross-Tie kV Transmission Project	The Project proposed by TransCanyon, LLC (TransCanyon) includes a 214-mile, single-circuit, 1,500-megawatt, 500-kilovolt (kV), high voltage alternating current (HVAC) overhead transmission line that would be located on BLM-managed public land, USDA Forest Service National Forest System Land, state land, and private land in Beaver, Juab, and Millard Counties, Utah; and White Pine County, Nevada. The proposed route would cross a total of 137 miles in Utah and 77 miles in Nevada. Approximately 165 miles, or 77 percent, of the proposed route would be on BLM-managed public land, approximately 9 miles (4 percent) on National Forest System Land, approximately 11 miles (5 percent) on state land, and the remaining approximately 29 miles (14 percent) on privately owned land. TransCanyon would obtain these land rights through ROW grants from the BLM, a SUP from the USDA Forest Service, and easements or fee purchases for non-Federal lands.	Proposed
Lands and Realty	Idaho, Nevada, Utah	Southwest Intertie Project (SWIP)	LS Power Company proposes to construct and operate a 500kV transmission line from their Midpoint Substation near Shoshone, Idaho to a new proposed substation in the Dry Lake Valley northeast of Las Vegas, Nevada. A crosstie route would also be constructed from the Ely, Nevada area to a point near Delta, Utah. New substations would be required near Ely, Las Vegas, and Delta, and a series of compensation stations would be needed midway between the Midpoint Substation and Ely, Nevada, and between Ely and Dry Lake. New microwave facilities would be required on the route from Midpoint to Dry Lake.	Ongoing
Wildfires and Fuels Management	Idaho, Oregon	Tri-state Fuel Breaks Project	The Tri-state Fuel Breaks Project includes a system of roadside fuel breaks (987 miles; approx. 435 miles in Idaho and 550 miles in Oregon) that reduce fuel loading along established roads to improve suppression coordination and response across a 3.6-million-acre project area spanning the southeastern corner of Oregon and southwestern corner of Idaho and connect to existing fuel breaks within northern Nevada.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Northwest Colorado				
Federal Resource Management / Land Use Plans	Colorado	Big Game RMP Amendment	The BLM will consider whether to incorporate new or changed oil and gas management decisions in existing land use plans, such as limits on high-density development, including facility and route density limitations, and other lease stipulations that would incorporate conservation measures for important big game habitat areas in Colorado.	Ongoing
Federal Resource Management / Land Use Plans	Colorado	Gunnison Sage-Grouse RMP Amendment	The BLM is preparing an Environmental Impact Statement to determine whether to amend the land use plans of BLM field offices, national monuments, and national conservation areas containing occupied and unoccupied habitat for the threatened Gunnison sage-grouse (*Centrocercus minimus*) as identified by the U.S. Fish and Wildlife Service in the 2020 Final Recovery Plan.	Ongoing
Federal Resource Management / Land Use Plans	Colorado	Colorado River Valley Field Office and Grand Junction Field Office Supplemental EIS	The purpose of this supplemental EIS is to broaden the range of alternatives in the 2015 CRVFO and GJFO Approved RMPs with respect to the lands that are allocated as open or closed for oil and gas leasing. The purpose is also to provide additional air quality analysis for the fluid mineral management alternatives considered in the 2014 CRVFO Final EIS and the 2015 GJFO Final EIS and in this supplemental EIS.	Ongoing
Lands and Realty	Colorado	Blue Valley Land Exchange	Proposed exchange of 1,652 acres of federal lands in the Kremmling Field Office for 2,005 acres of nonfederal lands in Grand and Summit Counties, Colorado. A Notice of Decision approving the Blue Valley Land Exchange was issued in January 2023, followed by a 45-day protest period. KFO is in the process of protest response.	Ongoing
Lands and Realty	Colorado	Wolf Creek Reservoir EIS/ RMP Amendment	Rio Blanco Water Conservancy District (RBWCD) filed an application for a right-of-way (ROW) for "White River Regional Water Supply Project" and specifically for the Wolf Creek Reservoir. RBWCD obtained a conditional water right decree for 66,720 acre-feet for use in a proposed reservoir location. The majority of the project would occur on public land managed by the BLM. Other affected property includes the Middle Wolf Creek State Trust Land parcel and a private parcel owned by RBWCD.	Proposed
Lands and Realty	Colorado	Axial Basin Solar Development	Private land within LSFO. Axial Basin Solar LLC, a subsidiary of juwi, inc., is developing the Axial Basin Solar Project in Moffat County, Colorado. The utility-scale solar development is expected to be sited on 3,500 acres of private land.	Proposed

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Lands and Realty	Colorado	Big Cat Solar Development	Big Cat Solar LLC a subsidiary of Apex Clean Energy Holdings LLC is proposing a 200MWac solar photovoltaic generation facility for up to 200 MW of battery energy storage and ancillary facilities on approximately 2,793 acres of public lands in the Grand Junction Field Office. The project would include a project substation and a line tap to the existing 230 kV generation interconnection transmission line running through the project area.	Proposed
Lands and Realty	Colorado	Book Cliffs Solar Development	Book Cliffs Solar Farm LLC a subsidiary of Scout Clean Energy LLC is proposing a 210 MW solar photovoltaic generation facility for up to 210 MW of photovoltaic module arrays, collection system, a control house and a collector substation on approximately 2,621 acres of public land in the Grand Junction Field Office. The project would utilize the existing 230 kV generation transmission line running through the project area.	Proposed
Lands and Realty	Colorado	Nannie Blaine Solar PV Park (State of Colorado land)	SolarGen is proposing the Nannie Blaine Solar PV Park which is a 48 MW photovoltaic array on 151 acres of State of Colorado lands located north of I-70 and just east of the Grand Junction Motor Speedway.	Proposed
Lands and Realty	Colorado	Xcel 6670 Rebuild	Xcel is proposing a rebuild of the 6670 Rifle-Ute to DeBeque 69 kilovolt (kV) Transmission Line (6670 transmission line) located in Mesa and Garfield Counties, Colorado. Transmission line 6670 is planned to continue to be operated at 69 kV but will be designed to accommodate 115 kV for future needs. The existing 30 to 50-foot-wide permanent right-of-way (ROW) would be widened to 75 feet to accommodate design upgrades.	Proposed
Wild Horse and Burro	Colorado	Piceance-East Douglas Herd Management Area Horse Gather (2024)	The White River Field Office plans to conduct a gather in the Piceance-East Douglas Herd Area in 2024. The Appropriate Management Level (AML) for the HMA is between 135-235 horses.	Proposed
Wild Horse and Burro	Colorado	Little Book Cliffs Herd Management Area Horse Gather (2024)	The Grand Junction Field Office plans to conduct a gather in the Little Book Cliffs Herd Management Area in 2024. The Appropriate Management Level (AML) for the HMA is between 90-150 wild horses. The last gather in the Little Book Cliffs occurred in 2018, during which 96 horses were gathered and 41 were returned to the range.	Proposed
Wildfires and Fuels Management	Colorado	GRSG habitat burned 2018-2022	A total of 66,647 acres of GRSG habitat in CO burned between 2018 and 2022. Of those, 26,412 acres were on BLM land.	Past
Wildfires and Fuels Management	Colorado	Northwest Colorado Programmatic Vegetation Treatment Environmental Assessment (2017)	The plan takes a programmatic approach to vegetation treatments and installation of erosion/stabilization structures to work towards the vegetation management goals of the GJFO, KFO, WRFO, CRVFO, and LSFO RMPs to promote healthy, productive, and diverse vegetation communities.	Past

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Wildfires and Fuels Management	Colorado	Conducting Mechanical Vegetation Treatments During Drought Conditions (2020)	This plan analyzed the consequences of conducting mechanical vegetation treatments during drought conditions in GJFO, KFO, WRFO, CRVFO, and LSFO.	Past
Vegetation and GRSG Habitat Management	Colorado	Conducting Mechanical Vegetation Treatments During Drought Conditions (2021)	This plan analyzed the consequences of conducting mechanical vegetation treatments during drought conditions in GJFO, KFO, WRFO, CRVFO, and LSFO.	Past
Vegetation and GRSG Habitat Management	Colorado	Programmatic Environmental Assessment for Vegetation Treatments and Installation of Stabilization/Erosion Control Structures in Northwest Colorado (2017)	This programmatic EA evaluated vegetation treatments and erosion control structures in the WRFO, KFO, LSFO, CRVFO, and GJFO.	Past
Recreation	Colorado	South Sand Wash Open OHV Area Recreation Area Management Plan	The BLM is working with Craig Chamber of Commerce to develop a recreation management plan for the Sand Wash Basin Special Recreation Management Area. The plan will identify the types and locations of improvements needed to provide for OHV recreation opportunities within the SRMA.	Ongoing
Idaho				
Energy and Mining	Idaho	Husky 1 North Dry Ridge Phosphate Mine	The Husky 1 North Dry Ridge Phosphate Mine is an approximately 1,146-acre open pit phosphate mine in Caribou County, Idaho. The mine occurs on lands managed by the National Forest Service, Caribou-Targhee National Forest. Mining operations will occur over an estimated 13 years and total project duration with reclamation is 15 years.	Ongoing
Energy and Mining	Idaho	Caldwell Canyon Mine	The Caldwell Canyon Mine is an approximately 1,530-acre proposed open pit phosphate mine in Caribou County, Idaho. Mine facilities (ore stockpile, tipple, water management infrastructure, offices) would be located in the previously inactive Dry Valley Mine (East Caldwell Area) in Dry Valley. Mining operations would be conducted over an estimated 40-year period using a pit panel mining method.	Ongoing
Energy and Mining	Idaho	Rasmussen Valley Mine	The Rasmussen Valley Mine is an approximately 540-acre open pit phosphate mine in Caribou County, Idaho. The life of mining activities is 5 years and total project duration with reclamation is 7 years.	Ongoing
Energy and Mining	Idaho	East Smoky Panel Mine Project	The East Smoky Panel Mine is an approximately 850-acre open pit phosphate mine in Caribou County, Idaho. The life of mining activities is up to 12 years and total project duration with reclamation approximately 15 years.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Energy and Mining	Idaho	Dairy Syncline Mine Project	The Dairy Syncline Mine is an approximately 2,830-acres open pit phosphate mine in Caribou County, Idaho. The life of the mining activities is approximately 30 years.	Ongoing
Energy and Mining	Idaho	Smoky Canyon Mine Panels F and G Lease and Mine Modification Project	The existing Smoky Canyon Mine, located in Caribou County, Idaho, was authorized in 1982. Mining operations began in Panel A in 1984 and have continued ever since using standard open pit techniques in seven mine panels (Panels A-G). Mining operations are complete in Panels A, C, D, and E, and mining activities associated with Panel F and G were initiated in 2008 and are ongoing. Lease and mine modifications for Panels F and G mining and reclamation were approved in a 2015 Record of Decision.	Ongoing
Lands and Realty	Idaho	Lava Ridge Wind Project	The proposed Lava Ridge Wind Project could consist of up to 400 wind turbines and associated infrastructure, with an estimated generation capacity of 1,000 megawatts or more. The project area spans 197,474 acres and all project components would be sited within a series of approximately one-half mile wide corridors (approx. 84,385 acres). The project infrastructure proposed within the corridors is estimated to have a 2,374-acre footprint and a total disturbance area of 9,114 acres.	Proposed
Vegetation and GRSG Habitat Management	Idaho	Bruneau-Owyhee Sage-Grouse Habitat Project	The BLM is removing encroaching Western juniper to improve and maintain sagebrush-steppe habitat on about 726,000 acres within a 1.67 million-acre area of Owyhee County.	Ongoing
Lands and Realty	Idaho	Pending renewable energy development ROWs	There are 13 renewable energy development ROW applications (11 solar, 2 wind) and 2 renewable energy testing ROW applications (1 solar, 1 wind) pending review and analysis.	Proposed
Land Use Plan	Idaho	Four Rivers Field Office Resource Management Plan	The Four Rivers Field Office Resource Management Plan provides guidelines and objectives for renewable energy development, fish and wildlife habitat, outdoor recreation, livestock management, and other uses across approximately 783,000 acres of public lands and more than 1.17 million acres of Federal mineral estate in southwest Idaho.	Ongoing
Nevada and Northeast California				
Energy and Mining	Eureka County, Nevada	Gibellini Vanadium Project	The Project consists of construction and operation of an open pit mine, rock disposal area, crushing facilities and stockpile, heap leach pad, process facility, process and make-up water ponds, borrow areas, mine and access roads, water and power supply lines, ancillary facilities, and continued exploration activities on public lands within the Project area in Eureka County, Nevada. The mine life consists of 1.5 years of construction, 7 years of operation, 4 years of active reclamation and closure, and up to 30 years of post-closure monitoring.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Energy and Mining	Lander and Eureka Counties, Nevada	Goldrush Mine Project	The Goldrush Mine Plan of Operations boundary encompasses approximately 19,895 acres, of which 772 acres are on private land controlled by NGM and 19,123 acres of public lands administered by the BLM Mount Lewis Field Office and BLM Elko District, Tuscarora Field Office. The Goldrush Mine includes approximately 1,717.4 acres of new proposed disturbance and approximately 1,036.8 acres of existing/authorized and reclassified disturbance, for a total disturbance of approximately 2,754.2 acres. The underground mining and surface support activities for the Goldrush Mine include a materials handling system for transporting ore and waste rock from the underground workings to the surface and transporting aggregate and supplies to the underground workings and surface backfill plant; a dewatering system (including wells, pipelines, and pipeline corridors); a water treatment plant (WTP); rapid infiltration basins (RIBs); a multi-use shop; contact water pipeline; ventilation raises; a backfill aggregate paste plant and crusher; a shotcrete/cemented rock fill (CRF) plant; two new power lines (a 120-kilovolt (kV) power line with two switching stations, and a 13.8-kilovolt (kV) power line); new ancillary surface facilities (including bulk material storage, access roads, power supply, stormwater controls, laydown and parking areas, lighting, growth media stockpiles, dewatering and monitoring wells, gravel pit expansion, potable water and septic systems, dry facilities (i.e., change rooms), service boreholes for electrical and fuel delivery, fire suppression system, water truck refill stations, emergency helipads, fencing, and modular information technology (IT) and communications buildings); dual use of existing facilities within the nearby Cortez Mine Plan boundary; and continued surface and underground exploration activities. The Goldrush Mine would operate 24 hours per day, 365 days per year for approximately 24 years.	Ongoing
Energy and Mining	Washoe County, Nevada	Hog Ranch Mineral Exploration Project	The Hog Ranch Mineral Exploration Project is an expansion of current mineral exploration activities at the former Hog Ranch Mine in Northern Washoe County, Nevada. The approved mineral exploration on 200 acres of public land includes construction of drill pads, new access roads, and staging areas in support of exploratory drilling,	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Energy and Mining	Elko County, Nevada	South Railroad Valley Gold Mine	The Project is an open-pit gold mine operation that will include the following major components: • Four open pits; • Three waste rock disposal facilities (WRDFs); • Ore crushing and conveying system; • Lime and cement silos and ore agglomeration facility; • Ore stockpiles; • Clay stockpile; • Growth media stockpiles; • On-Site Power Plant and Sub-Station; • A limestone quarry area; • A heap leach facility (HLF) with solution channels, associated process solution tanks, and ponds; • Water Supply and Dewatering System; • Stormwater diversion ditches and stormwater sediment basins; • Water Treatment Plant Processing facilities comprised of pumps and pipelines, adsorption desorption and recovery (ADR) plant, refinery, and an assay laboratory; • Access and haul roads; • Ancillary facilities that include the following: ready line; maintenance area; reagent and fuel storage; storage and laydown yards; explosive magazines; meteorological station; warehouse; truck maintenance shop; truck wash; offices, warehouse and workshop, change/lunch facilities; administration/security building; and solid and hazardous waste management facilities; • Exploration in the vicinity of the open pits to better define and expand the ore body; and • Reclamation and closure, including the development of evapotranspiration (ET) cells. GSV proposes to mine approximately 52.1 million tons of heap leach ore and 159 million tons of waste rock (for a maximum total of 211 million tons of material). The material (both ore and waste) will be extracted from the open pits using conventional open pit mining methods of drilling, blasting, loading, and hauling. In addition to the construction of operating facilities, proposed exploration activities within the Project Area are estimated to disturb up to 150 acres.	Proposed
Energy and Mining	White Pine County, Nevada	Bald Mountain Mine, Juniper Expansion Project	The Juniper Project would modify and expand operations on BLM-administered lands within the North Operations Area (NOA) of the existing Bald Mountain Mine, resulting in approximately 3,969 acres of new surface disturbance and extension of the NOA mine life by 11 years.	Proposed
Energy and Mining	Lander and Eureka, Counties, Nevada	Ormat Crescent Valley Geothermal Development Project	The proposed Crescent Valley Geothermal Project considers the construction, operation, maintenance and eventual reclamation of a geothermal energy production facility and associated transmission line totaling approximately 2,040 acres on public and privately leased lands. The transmission line would support an approximate 30-megawatt net rated geothermal power generating facility, operated by Ormat Nevada, Inc.	Proposed

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Energy and Mining	Elko County, Nevada	Long Canyon Mine Project	The Project will be located in the Pequop Mountains and Goshute Valley, in Elko County, Nevada, approximately 75 miles east of Elko, Nevada. The Project will be an open-pit gold mine.	Proposed
Lands and Realty	Washoe, Lyon, Storey, Churchill, Mineral, Nye, Esmeralda, and Clark Counties, Nevada	Reno to Las Vegas Fiber Optic Project	The proposed buried fiber optic project would be located within existing highway rights-of-way that predominantly follow U.S. Highways 50 and 95; Nevada State Highways 160, 839, and 439; and County-maintained roads from Reno to Las Vegas.	Proposed
Energy and Mining	White Pine County, Nevada	White Pine Pumped Storage Hydroelectric Power Project	A 1,000 megawatt energy storage project under development in White Pine County, Nevada. The project facilities include two reservoirs, underground generation equipment, and a new transmission line. One of the reservoirs will be in the Duck Creek Range, and the other in the Steptoe Valley near Highway 93. Energy for pumping, and power generated by the project, will be delivered through a new 25-mile-long transmission line connecting the project with the Robinson Summit Substation. The remainder of the facilities will consist of access roads to the reservoirs, a transmission switch-station, and the entrance to the access tunnels.	Proposed
Lands and Realty	Eureka, White Pine, Lander, Churchill, and Lyon Counties, Nevada	Greenlink North Transmission Project	The Bureau of Land Management (BLM) Nevada Renewable Energy Coordination Office is evaluating two SF-299 applications [one application for a permanent right-of-way (ROW), one application for a short-term ROW] submitted by NV Energy for Transportation and Utility Systems and Facilities on Federal Lands. The proposed Greenlink North Project would span approximately 235 miles from Ely, Nevada to Yerington, Nevada through White Pine, Eureka, Lander, Churchill, and Lyon Counties and would involve construction of the following components: • Robinson Summit 525/345-kV Substation Expansion • New Lander 525/230-kV Collector Station. • New Fort Churchill-Robinson Summit 525-kV Transmission Line. • Fort Churchill 525/345-kV Substation Expansion.	Proposed
Lands and Realty	Clark, Nye, Esmeralda, Mineral, Lyon, Storey, and Washoe Counties, Nevada	Greenlink West Transmission Project	The Greenlink West Project would be a system of new 525-kilovolt (kV), 345-kV, 230-kV, and 120-kV electric transmission facilities on private, state, and federal lands. The project will run from North Las Vegas to Reno.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Energy and Mining	Humboldt County, Nevada	Thacker Pass Lithium	The proposed project consists of an open pit lithium mine, processing facilities, and continued exploration of adjacent lands located in northern Humboldt County, Nevada, approximately 17 miles northwest of Orovada, 53 miles north-northwest of Winnemucca, and 20 miles south of the Oregon state border. The proposed project will have a life expectancy of approximately 41 years.	Ongoing
Federal Resource Management Plans	Nevada, California	Greater Sage-Grouse Bi-State Distinct Population Segment	The approved Nevada California Greater Sage Grouse Distinct Population Segment Land Use Plan Amendment (LUPA) and Record of Decision (ROD) amends the Carson City Field Office Consolidated Resource Management Plan (RMP) and the Tonopah Field Office RMP. The BLM was a cooperating agency on the United States Forest Service (USFS) led planning effort and the LUPA was developed using a collaborative planning process that included input from the Nevada Department of Wildlife and the United States Fish and Wildlife Service. The LUPA/ ROD adds goals, objectives, action, and best management practices specifically designed to conserve, enhance, and/or restore habitats to provide for the long-term viability of the Greater Sage Grouse Bi-State Distinct Population Segment (BSSG). The LUPA provides direction at the land use plan level to include regulatory mechanisms for the management and conservation of BSSG habitats within the BLM Carson City and Battle Mountain Districts to support the BSSG population management objectives within the states of Nevada and California.	Ongoing
Mining and Energy	Washoe and Churchill Counties, Nevada	Juniper Geothermal Development Project	The Project proposes to include the construction and operation of up to two geothermal power production facilities, geothermal fluid production and injection wells and well pads, access roads, geothermal fluid pipelines, and ancillary support facilities. Electrical power generated at this facility would be sold on the commercial market.	Proposed
Mining and Energy	Pershing County, Nevada	Colado Geothermal	Drilling/exploration program to evaluate geologic structure, measure pressure – temperature gradients, and test the well to determine reservoir characteristics. Includes well pad construction, etc.	Proposed
Mining and Energy	Humboldt County, Nevada	Pinto Hot Springs Geothermal Exploration	—	Proposed
Mining and Energy	Pershing County, Nevada	Spring Valley Gold Mine	Proposed gold mine (baseline surveys currently underway)	Proposed
Lands and Realty	White Pine County, Nevada	Stagecoach Wind Development Project	Stagecoach Wind Development Wind Energy ROW is a 11,035-acre pending wind energy zone in White Pine County, Nevada.	Proposed
Lands and Realty	White Pine County, Nevada	Pantheon Solar	Pantheon Solar Project would be built on 8,086 acres of public lands, partially located in GRSG habitat.	Proposed

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Mining and Energy	Eureka County	Ruby Hill Mine	Expanded drill program at existing Ruby Hill Mine	Ongoing
Mining and Energy	Lander County, Nevada	Robertson Gold Mine	Mining development and exploration operations by Nevada Gold Mines LLC (NGM) on 5,990 acres, consisting of approximately 5,822 acres of public lands administered by the Bureau of Land Management (BLM) and 168 acre of private land in Lander County, Nevada.	Proposed
Vegetation	Eureka County, Nevada	Three Bars Ecosystem and Landscape Restoration Project	The 3 Bars Ecosystem in central Eureka County, Nevada spans approximately 725,000 acres and includes portions of three major mountain ranges (Roberts Mountain, Simpson Park Range, and Sulphur Spring Range). Many factors are contributing to the overall decline in land condition of this area. The gradual loss of sagebrush, bitterbrush, and mountain shrub communities impact wildlife species such as sage grouse, pygmy rabbit, and mule deer. Compromised riparian habitats impact the threatened Lahontan cutthroat trout and other aquatic species. Factors contributing to the overall decline in land health include increasing incidence and severity of wildfire, increasing expansion of downy brome (cheatgrass), increasing expansion and densification of pinyon pine and Utah juniper woodlands, and increasing human impacts.	Ongoing
Mining and Energy	Lander County, Nevada	McGinness Hills Geothermal Complex	The McGinness Hills Geothermal Complex is a complex of 3 geothermal power stations located in a valley between the Toiyabe Range and Simpson Park Range in Lander County, Nevada. It is the largest geothermal complex in Nevada and the fourth largest in the United States. The complex consists of two 45 MW geothermal power stations that were commissioned in July 2012, as well as a third 48 MW geothermal power station that was commissioned on 20 December 2018. The entire complex is owned by Ormat.	Ongoing
Livestock Grazing	Battle Mountain, Carson City, Elko, Ely, and Winnemucca Districts	Targeted and Prescribed Grazing of Annual Grasses in Great Basin Ecosystems in Nevada	Targeted grazing treatments for reduction of annual invasive grasses in a variety of Disturbance Response Groups on BLM managed public lands throughout the Great Basin ecoregions in Nevada. The project purpose is to manage invasive annual grasses by using a variety of livestock grazing practices in the Great Basin ecoregions of Nevada	Ongoing
Energy and Mining	White Pine Co, Nevada	Sage City Solar	Proposes solar facility is 16 miles west of Ely, NV on 6,790 acres, with a projected output of 800 MW.	Proposed
Energy and Mining	White Pine Co, Nevada	Robinson Solar Project	Project proposes a 750MW Solar PV facility with Battery Storage. The Solar Project would consist of 2 years of construction, 30 years of operation, with an option to renew.	Ongoing
Energy and Mining	White Pine Co, Nevada	Tromso Solar	Proposed solar facility 17 miles west of Ely, NV with a10,000 acre project area.	Proposed
Energy and Mining	White Pine Co, Nevada	Spring Valley Wind	Spring Valley Wind Generation Project has 63 2.4 Mitsubishi wind turbines currently working.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Energy and Mining	White Pine Co, Nevada	Aquilo Wind	The proposed project is for wind development within an application area totaling 18,744 acres, with a projected output of 700 MW.	Proposed
Energy and Mining	White Pine Co, Nevada	CGI Wind Testing	This project is located 15 miles west of Ely, NV and has an application area of 46,205 acres.	Proposed
Energy and Mining	White Pine Co, Nevada	CGI Solar Testing	This project is located 15 miles west of Ely, NV and has an application area of 15,728 acres.	Proposed
Energy and Mining	White Pine Co, Nevada	Scout Wind	This project is located in Spring Valley and has an application area of 2,965 acres.	Proposed
Energy and Mining	Lander Co, Nevada	Wildcat Solar	This project is located 13 miles southeast of Austin, NV with an application area of 21,668 acres, and a projected output of 400 MW.	Proposed
Energy and Mining	Lander Co, Nevada	Lonely Solar	This project is located 15 miles southwest of Austin, NV with an application area of 4,686 acres, and a projected output of 500 MW.	Proposed
Energy and Mining	Washoe Co, Nevada	Dodge Flat II Solar	This project is located 4 miles northwest of Fernley, NV with an application area of 917 acres.	Proposed
Livestock Grazing	Battle Mountain, Carson City, Elko, and Winnemucca Districts	Flexibility in Grazing Authorizations to Improve Lahontan Cutthroat Trout in Nevada	This project would modify grazing permits to create flexibility in livestock management to improve Lahontan cutthroat trout (*Oncorhynchus clarki henshawi*, LCT) habitat on BLM Nevada-administered grazing allotments. The project area includes 40 allotments administered through 43 permits, containing approximately 368 miles of occupied LCT stream habitat and approximately 875 acres of occupied LCT lake habitat in 4 Districts.	Proposed
Energy and Mining	Elko Co, Nevada	Tabor Flats Wind Test	This proposed project is 13 miles northwest of Wells, NV. No other information at this time.	Proposed
Lands and Realty	Lassen Co, California	Fourth Element 345 kV Transmission Line	Fourth Element is proposing to build a 345 kV transmission line to connect a wind energy generation facility to the power grid. The line would be 22 miles long, with 17.23 miles on BLM land.	Proposed
Vegetation	Washoe Co, Nevada	Dry Valley Rim Herbicide and Seeding	The BLM is treating 20,500 acres of the Dry Valley Rim with aerial herbicide with Imazapic and reseeding the area.	Ongoing
Montana, North Dakota, and South Dakota				
Land Use Plan	North Dakota	North Dakota Resource Management Plan (RMP) Revision	The North Dakota Bureau of Land Management (BLM) is revising its 32-year old Resource Management Plan (RMP) to provide goals, objectives, and direction for approximately 58,500 acres of BLM managed public lands and approximately 4.1 million acres of subsurface BLM managed federal mineral estate in North Dakota.	Proposed

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Energy and Mining	Montana	Miles City FO Resource Management Plan Supplemental EIS/Plan Amendment	BLM Montana/Dakotas has prepared a Supplemental EIS and Proposed Resource Management Plan Amendment due to a court order issued by the United States District Court of Montana (Western Organization of Resource Councils, et al. v. BLM; CV 4:20-CV00076-GF-BMM; 8/3/2022). Pursuant to the Order, the BLM completed a new coal screening and remedial NEPA analysis that considers no-leasing and limited coal leasing alternatives and discloses the public health impacts (both climate and non-climate) of burning fossil fuels (coal, oil, and gas) from the planning area. The Supplemental EIS and potential Resource Management Plan Amendment alternatives vary the amount of BLM-administered federal coal authorized to be available for leasing within the planning area.	Proposed
Lands and Realty	Montana, North Dakota	North Plains Connector Transmission Line	The North Plains Connector is a proposed 525 kilovolt high voltage direct current (HVDC) transmission line connecting the U.S. eastern and western electric grids in Montana and North Dakota. The North Plains Connector would be approximately 385 miles long, extending from an existing substation in Colstrip, Montana, to an existing substation in Center, North Dakota, and a new substation in Morton County, North Dakota. The application package is currrently under review.	Proposed
Energy and Mining	Montana	Denbury Carbon Solutions, LLC, Deep Permanent CO2 Geologic Sequestration Project	The application involves approximately 100,190 acres of BLM-administered lands. The project includes access roads, well pads for 15 underground injection wells (12 on BLM, 3 on State), powerlines, substation, main bulk line, flowlines, temporary use areas, underground pore space, and two pump stations. It is estimated that over a 20-year injection time period the project area has a potential storage of approximately 409.5 million metric tons of CO2 on federal land that CO2 would be injected by the 15 proposed wells over a 20-year period. This project (if approved) when fully operational would offset greenhouse gas emissions. This would be responsive to the US 2050 net-zero goal outlined in EO 14008.	Proposed

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Oregon				
Land Use Plan	Oregon	Southeast Oregon RMP Amendment	On June 16th, 2023, the BLM published in the Federal Register a Notice of Availability the Southeastern Oregon Proposed Resource Management Plan Amendment (PRMPA) and Final Environmental Impact Statement (FEIS) for the Southeastern Oregon planning area of the Vale District. This planning process proposes to amend the long-term management of the Southeastern Oregon planning area. The planning area encompasses approximately 4.6 million acres for the Malheur Field Office of the Vale District BLM. The Proposed RMP Amendment would prioritize protection of thirty-three areas (approx. 420,000 acres found by BLM to possess wilderness characteristics (outside of existing Wilderness Study Areas). Management of protected areas would emphasize maintenance and/or enhancement of the wilderness resource. In addition, the amendment would designate approximately 320,000 acres that are currently Open to cross-country off-highway vehicle (OHV) use as Limited to existing roads and primitive routes. Also addressed are rangeland health, grazing permit relinquishment and livestock grazing issues.	Ongoing
Land Use Plan	Oregon	Lakeview RMP Amendment	A Notice of Intent to prepare an EIS was published in the Federal Register. The Plan amendment will address the management of Lands with Wilderness Characteristics on about 1.65 million acres within the 3.2 million acre Lakeview planning area.	Ongoing
Vegetation and GRSG Habitat Management	Oregon	Northwest Malheur County Greater Sage-Grouse Habitat Restoration Project	Implementation started in 2017 and is ongoing. The BLM is using a combination of prescribed fire, silvicultural thinning, and herbicide and mechanical invasive species treatments that include western juniper removal, to maintain and restore habitat for GRSG and other sagebrush species in a 258,556-acre project area.	Ongoing
Energy and Mining	Oregon	Jindalee Hi-Tech Lithium Project	The Jindalee Hi-Tech Lithium Project is proposed lithium exploration using multiple bore holes. It encompasses 7,200-acres and would authorize 100 areas of disturbances from 267 exploration drill sites, the construction of 30.2 miles of a new access routes, and other temporary disturbances to store exploration activity equipment. Subsurface hydrological, geophysical, and geochemical data may be collected during the propose drilling activities.	Proposed
Utah				
Federal Resource Management / Land Use Plans	Utah	Grand Staircase-Escalante National Monument Resource Management Plan	Resource Management Plan revision for the Grand Staircase-Escalante National Monument in Kane and Garfield counties, Utah.	Ongoing

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Habitat Management	Utah	Utah Watershed Restoration Initiative	A partnership based program in Utah to improve high priority watersheds throughout the state.	Ongoing
Lands and Realty	Utah	Pine Valley Water Supply Project	Central Iron County Water Conservancy District proposes to develop and transport water from Pine Valley, southwest of Milford, Utah, to their existing system in central Iron County, Utah.	Proposed
Lands and Realty	Utah	Dingell Act – Emery County Land Exchange	Implementing an exchange of federal and non-federal land as directed by the Dingell Act. An agreement to initiate (ATI) an exchange was prepared in November 2021. The land exchange would include public and state lands located across up to 18 counties in Utah: Beaver, Carbon, Emery, Grand, Iron, Juab, Kane, Millard, Rich, San Juan, Sevier, Summit, Tooele, Uintah, Utah, Wasatch, Washington, and Wayne Counties. Under the land exchange, the Secretary of the Interior, acting through the BLM, would convey to the State of Utah School and Institutional Trust Lands Administration (SITLA) approximately 89,700 acres of federal lands or interests in land. In exchange for the BLM lands, SITLA would convey to the BLM approximately 116,000 acres of non-federal lands or interests therein. The SITLA parcels are located within newly created wilderness areas, the San Rafael Swell Recreation Area, the Green River Wild and Scenic Rivers (WSR) Corridor in Emery County, and the John Wesley Powell National Conservation Area (NCA) in Uintah County. Additional SITLA lands located within wilderness areas or NCAs in Washington County could be included in the land exchange if needed to equalize values.	Proposed
Wyoming				
Wildland Fires 2018-2022	Wyoming	BLM: Past – Acres burned on BLM administered land	Approximately 150,954 acres of HMA burned between 2018 and 2022. Post fire restoration and habitat treatments are being implemented, as described below, to diminish impacts of habitat lost to wildland fire.	Past
Fire Restoration (Emergency Stabilization and Rehabilitation)	Wyoming	BLM: Past and Present – Habitat restoration following wildland fires	0 acres of BLM-administered habitat are either currently being treated or scheduled to be treated according to specific prescriptions outlined in Emergency Stabilization and Burned Area Rehabilitation plans following wildfire.	Past/ongoing
Habitat Treatments	Wyoming	BLM: Past – Habitat improvement projects	Approximately 434,704 acres of Greater Sage-Grouse habitat were treated between 2018 and 2022 to maintain or improve conditions for Greater Sage-Grouse. Treatments included conifer removal, fuel breaks, invasive species removal and habitat protection/ restoration.	Past

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
Land Use and Realty (issued and pending) 2018-2022	Wyoming	BLM: Past Non-Renewable Energy Development ROWs Issued on BLM-Administered Public Land	BLM Wyoming issued approximately 2,428 non-renewable energy ROWs in the planning area during calendar years 2018-2022. This includes amendments and reauthorizations, which may not have resulted in new disturbance. For ROWs occurring in sage grouse habitat, effects were offset by the management prescriptions in the RMPs and ARMPA, and through the application of mitigation to conserve Greater sage-grouse and their habitats on non-federal lands in coordination with State and federal partners.	Past
—	Wyoming	BLM: Past Renewable Energy Development ROWs Issued on BLM-Administered Public Land	BLM Wyoming issued two renewable energy development ROWs in the planning area during calendar years 2018-2022 (one solar, one wind) and six renewable energy testing/monitoring ROWs (all wind). ROW authorizations conformed to the approved RMPs, including applicable Greater Sage-Grouse conservation measures, and were coordinated with State and federal partners to address effects from appurtenant project facilities and operations on non-federal lands.	Past
—	Wyoming	BLM: Pending Non-Renewable Energy Development ROWs	From this same period, there are approximately 469 non-renewable energy ROW applications pending review and analysis. No additional cumulative impacts are anticipated beyond those described.	Proposed
—	Wyoming	BLM: Pending Renewable Energy Development ROWs	There are nine renewable energy development ROW applications (four solar, five wind) and two renewable energy testing/monitoring ROW applications (both wind) pending review and analysis. No additional cumulative impacts are anticipated beyond those described.	Proposed
Oil and Gas	Wyoming	BLM: Past	BLM Wyoming has offered for lease approximately 2,123,417 acres; 1,748,733 acres of that total was leased from February 2019 to July 2023. Leases followed management prescriptions in the RMPs and ARMPA and stipulations apply as described in the leases according to HMA category.	Past
—	Wyoming	BLM: Pending	BLM Wyoming has a scheduled lease sale in each quarter of the year, as described in the Minerals Leasing Act (MLA).	Proposed
Locatable Mineral Projects	Wyoming	BLM: Past and Present	Between 2018-2022, the BLM has approved 27 new mines and/or expansions within the planning area (including non-habitat).	Past/ongoing
—	Wyoming	BLM: Pending	The BLM is currently reviewing 15 plans of operation for new mines and/or mine expansions. This number also includes 10 pending mine patents, which are in the process of being patented into private ownership.	Proposed
Leasable Mineral Projects (Coal)	Wyoming	BLM: Past	One coal lease modification was issued in 2018, totaling 450 acres. For lease modifications occurring in sage grouse habitat, effects were offset by the management prescriptions in the RMPs and ARMPA.	Past

Project Type	Project Location - State(s)	Project, Plan or Action	Description	Project Status[1]
—	—	BLM: Pending	BLM Wyoming is currently reviewing two coal lease applications / modifications totaling 313 acres.	Proposed

[1] Project status definitions: Past: project is completed; Proposed: project is in the planning stages but has not yet been approved; Ongoing: project has been approved and is being implemented.

Appendix 15

Livestock Grazing Best Management Practices and Design Features and Supplemental Information

This page intentionally left blank.

Appendix 15. Livestock Grazing Best Management Practices and Design Features and Supplemental Information

15.1 Livestock Grazing Management Best Management Practices and Design Features

The following best management practices (BMP) provide a list of strategies, practices, or design features to be considered during implementation of the Proposed RMP Amendment. These measures are not required in every instance but are useful to aid in proper livestock grazing management in GRSG habitats. The applicability and overall effectiveness of each BMP cannot be fully assessed until the project level when the project location and design are known. Because of site-specific circumstances, some BMPs may not apply to some projects (e.g., a resource is not present on a given site) and/or may require slight variations. For example, variations could be required for the following reasons:

- A specific BMP is documented to not be applicable to the site-specific conditions of the project/activity. Economic considerations, such as increased costs, do not necessarily require that a BMP be varied or rendered inapplicable.
- An alternative BMP, a state-implemented conservation measure, or plan-level protection is determined to provide equal or better protection for GRSG or its habitat.
- A specific BMP will not avoid or minimize impacts to GRSG or its habitat.

15.1.1 Coordination

- 43 CFR 4100 regulations direct BLM to consult, cooperate and coordinate with affected grazing permittees, the state having lands or responsible for managing resources within the area, and the interested public when engaging in program work such as changes in permitted use, Allotment Management Plans, Range Improvements, issuance and/or modification of a grazing authorization. The BLM coordinates with Federal, State, county, Indian tribal and local governmental entities, institutions, organizations, corporations, associations, and individuals when authorizing grazing on BLM lands. In GRSG habitat management areas, these communication efforts should include coordination on how livestock grazing practices could be managed across both BLM-administered lands and non-BLM-administered lands, in partnership with interested permittees and lessees, to improve GRSG habitat conditions.

15.1.2 Best Management Practices for Livestock Grazing Management

- Set priorities for grazing management activities (e.g., monitoring, authorization renewals, field checks, etc.) following direction in agency policy, including IM 2018-024 as amended or superseded. When considering competing priorities in GRSG habitat, considerations should include level of management priority (priority vs general habitat management areas) and focusing on areas where current livestock grazing management is a significant causal factor to not meeting or making significant progress towards meeting the special status species (SSS) land health standard, and those containing riparian areas, including wet meadows. Other criteria for prioritization can include the need to respond to urgent natural resource concerns (e.g., fire) and legal obligations.

- When current livestock management practices are determined to not be meeting or making progress towards meeting the SSS land health standard (following appropriate consultation, cooperation and coordination, consistent with BLM Handbook H-4180-1), implement changes in grazing management through grazing authorization modifications, or allotment management plan implementation. Potential modifications, either within the existing terms and conditions or considered as additional alternatives in grazing authorization NEPA analysis as a threshold/response, (not presented in any priority order) could include, but are not limited to, changes in:
  - Season or timing of use;
  - Numbers of livestock;
  - Distribution of livestock use;
  - Duration and/or level of use;
  - Kind of livestock (e.g., cattle, sheep, horses, or goats) (Briske et al. 2011); and
  - Range improvements.
- Locate supplements (salt, mineral, protein, etc.) away from water sources, meadows, riparian areas, swales, and GRSG leks in locations that increase livestock distribution unless effective control of livestock to avoid detrimental impairment of any riparian area or GRSG habitats can be ensured.
- When using salt or mineral supplements, place them outside intact sagebrush stands to reduce impacts to GRSG breeding habitat. For example, place supplements in existing disturbed sites, areas with reduced sagebrush cover, to reduce impacts on GRSG breeding habitat; where feasible use salts or mineral supplements to improve management of livestock for the benefit of GRSG habitat.
- During the lekking season, encourage minimal vehicle use and maintenance activities associated with livestock management during lekking hours (before 9 am and after 6 pm) within 0.6 miles of a lek.
- To decrease attracting predators or decreasing water quality, whenever found and wherever possible, remove dead livestock from public land and dispose of in ways that do not shift the impact to non-public land. If it is not possible to entirely remove livestock carcasses, they should, at a minimum, be removed from riparian areas and water sources.
- In PHMA, IHMA (in Idaho), and GHMA, areas that have received vegetation treatments should be rested from livestock grazing until resource monitoring data verifies the treatment objectives specific to the purposes of the treatment are being met and an appropriate grazing regime has been developed. Examples of vegetation treatments include seedings, hazardous fuels reduction treatments, emergency stabilization and rehabilitation efforts.
- Avoid disturbing lekking and roosting GRSG from human, guard animal, and sheep activities by trailing, overnighting, watering, and bedding sheep on public lands at least 0.6 miles from occupied leks (dates of lek activity determined locally, approximately March 15–May 1 in lower elevations and March 25–May 15 in higher elevations).
- When trailing livestock during the lekking or nesting season, use roads or existing trails, to the extent possible.
- When available, use GRSG habitat use-pattern mapping or habitat monitoring to strategically adjust livestock distribution to benefit occupied GRSG breeding habitat, include herding, salting, and water-source management (e.g., turning troughs/pipelines on/off and extending pipelines/moving troughs) in grazing programs.
- Ensure that permittees are informed of management and movement requirements related to avoiding recent burns, habitat rehabilitation, or other restoration sites.
- Identify and, when feasible, establish strategically located forage reserves, focusing on areas where restoration to GRSG habitat is unlikely or lower priority habitat restoration areas.

15.1.3 Design Features for Range Developments

- When installing new range improvement projects in PHMA/IHMA, avoid construction during the applicable seasonal use periods associated with lekking, nesting, or brood rearing seasonal habitats (March 1 – July 15, or as identified for local variability in coordination with the state wildlife agency or other appropriate agency with management expertise and authority).
- Use temporary range infrastructure, such as troughs, fences, and supplements, where feasible and appropriate, to meet management objectives.
- Install shutoff valves at spring sources and troughs. Unless needed for wildlife habitat or water, ensure shutoff valves are closed and troughs are drained when livestock are not utilizing the pasture, as consistent with the water laws of the State within which the land is located.
- Install lids on spring collection boxes.
- Limit structures taller than adjacent vegetation and existing structures that could provide perching opportunities for avian predators. Where they are necessary, place them near taller natural features or partially/entirely bury them if possible.
- Install floats in troughs to prevent overflow and keep water at spring sources, as consistent with the water laws of the State within which the land is located.
- Ensure that new and existing livestock troughs and open water storage tanks are fitted with ramps to facilitate the use of and escape from troughs by GRSG and other wildlife; do not use unsecured, unstable, or ineffective items such as floating boards or similar objects.
- Locate troughs outside meadows, swales, and riparian areas.
- Design new water developments to maintain hydrologic function of spring sources, water courses and associated riparian habitat, as consistent with the water laws of the State within which the land is located.
- Consider virtual fencing opportunities, as appropriate.
- To minimize risk of noxious or invasive plant spread, require all heavy equipment used in construction of range improvements to be thoroughly cleaned of all soil and plant material prior to entering public lands.
- To minimize livestock concentration impacts on nesting and early brood rearing sage-grouse, locate new livestock handling facilities (such as corrals) away from active leks and outside of nesting habitat at least by 1.2 miles (Manier et al. 2014).
- Identify and close roads and trails that are not needed for range development maintenance.
- Where livestock handling and/or watering facilities result in lowering the downstream water table and dewatering of wet meadows or mesic habitat, relocate or remove these facilities when doing so will halt or reverse the dewatering, consistent with applicable laws.
- Design new and maintain existing water projects to avoid standing pools of shallow water that could spread West Nile Virus.

15.1.4 Drought Response

- When completing a fully processed grazing authorization in GRSG habitat, incorporate strategies for livestock management during drought conditions.
- During drought conditions use a recognized drought indicator, such as the Drought Monitor, Vegetation Drought Response Index, or Palmer Drought Severity Index, to determine when

abnormally dry or drought conditions are developing, present, or easing. When such conditions are developing or present:
  - Conduct pre-season assessments prior to livestock turn out.
  - Monitor vegetation conditions during authorized livestock use periods to determine need for early removal and/or other changes to meet seasonal RMP objectives.
- During drought periods, prioritize evaluating effects of drought in PHMA relative to GRSG needs for food and cover (including riparian areas); ensure that post-drought management allows for vegetation recovery, based on ecological potential, that meets GRSG needs in priority GRSG habitat areas. Where ESDs or STMs are lacking for an area, the best available information to achieve the GRSG needs should be used.
- If livestock grazing is deferred due to drought, reevaluate vegetation and GRSG habitat indicators that measure GRSG habitat prior to reauthorization of grazing.

15.1.5 From the BLM National Sage-Grouse Habitat Conservation Strategy of 2004

- Use prescriptive livestock grazing, where appropriate, to reduce annual grass production and the spread of wildfire into sagebrush communities. Timing of grazing and effects on residual native plants need to be carefully evaluated.
- Use grazing practices that promote the growth and persistence of native shrubs, grasses and forbs needed by sage-grouse for seasonal food and concealment. Grazing practices include changing season of use, numbers of livestock, grazing intensity, distribution of livestock use, and type of livestock (sheep, cattle or horses). Altering season of grazing may help to favor perennial plants in areas where native perennials and cheatgrass occur together in the plant community. Vegetation structure (height) should be managed so as to provide adequate cover for sage-grouse during the nesting period.
- Coordinate with state wildlife agencies where concentrations of grazing wildlife detrimentally affects sage-grouse habitat quality.
- Maintain seeps, springs, wet meadows, and riparian vegetation in a functional and diverse condition for young sage-grouse and other species that depend on forbs and insects associated with these areas. Consider fencing if vegetation associated with these wet areas cannot be maintained with current livestock, wildlife or wild horse and burro use and the impacts of the fence are outweighed by the improved habitat quality.
- Where other grazing management options are not achieving, or cannot achieve, the desired objectives, a short-term option may be livestock exclusion. Temporary exclusion can provide the plant community the opportunity to progress toward a point where grazing can again be reintroduced once desired conditions are reached. Removing livestock may not reverse the condition of severely altered habitats and often must be combined with reseeding and other rehabilitation methods to restore appropriate sagebrush habitat.

15.1.6 Nevada Specific BMPs

If results from the GRSG Habitat Assessment Framework indicate that GRSG habitat benchmarks are found to be un-suitable, and the land health evaluation results in a finding that Standards are not met or progress made towards meeting, and the determination concludes that current livestock grazing is a causal factor, and until appropriate modifications are incorporated through the grazing authorization renewal process, the

following management strategies could be considered that may include, but are not limited to, the following, with considerations to site specific seasonal date restrictions:

- Provide periods of rest or deferment during critical growth periods of key vegetation species
- Manage grazing duration and intensity to allow plant growth sufficient to meet or make progress towards meeting GRSG habitat objectives (Table 2-2)
- Employ herd management techniques to minimize impacts of livestock on breeding, nesting, and brood-rearing habitat during the breeding season (March 1 to June 30; Lek—March 1 to May 15, and Nesting—April 1 to June 30)
- Consider any temporary projects that can avoid, minimize, or mitigate livestock impacts (e.g., temporary fencing or temporary water hauling locations;
- To prevent impacts to nesting GRSG, work with permittees to avoid concentrated turn-out locations for livestock within 4 miles of active and pending leks from March 1 to June 30 with consideration of quality of site-specific habitat, current bird activity, probability of sage-grouse nesting within the radius area, and duration intensity of the use.
- Avoid domestic sheep use and bedding areas and herder camps within 2 miles of active and pending leks from March 1 to June 30
- Utilizing land features and roads on maps provided to the permittee to help delineate livestock use avoidance areas

15.2 SUPPLEMENTAL INFORMATION: ACTION ALTERNATIVES ADDRESSING LIVESTOCK GRAZING

The USFWS 2013 Greater Sage-grouse (Centrocercus urophasianus) Conservation Objectives: Final Report (COT Report) notes that "livestock grazing is the most widespread type of land use across the sagebrush biome and almost all sagebrush areas are managed for livestock grazing" (USFWS 2013). The COT Report also includes tables that characterize threats to GRSG by population throughout its range (see COT Report, Table 2, pages 16 through 29). One of the threats assessed included grazing, with the report noting the threats from improper livestock grazing varied by population from "present and widespread," to "present but localized," and "not known to be present."

To address the threat of improper livestock grazing, the COT Report recommended a conservation objective to "conduct grazing management…in a manner consistent with local ecological conditions that maintains or restores healthy sagebrush shrub and native perennial grass and forb communities and conserves the essential habitat components for sage-grouse (e.g. shrub cover, nesting cover)" (COT Report, page 45). It goes on to note that "areas which do not currently meet this standard should be managed to restore these components." It concludes that "livestock…numbers must be managed at levels that allow native sagebrush vegetative communities to minimally achieve Proper Functioning Conditions (PFC; for riparian areas) or Rangeland Health Standards (RHS; uplands). The specific management (e.g., type of livestock, numbers, seasons, rotation, etc.) will depend on the local ecological factors and current condition of land health. The COT Report also recommends a conservation objective for range management structures ("avoid or reduce the impact of range management structures on sage-grouse"), and fences ("minimize the impact of fences on sage-grouse populations").

As part of this planning effort livestock/range management actions were reviewed to determine which specifically address COT objectives. The prior GRSG plan amendment efforts included several management actions in the livestock grazing section that are addressed in existing agency regulations, policies, or that are duplicative of management actions in other sections of the ARMPA or the original RMPs. Since these actions

would continue to be implemented whether they appear in the RMP, they are being considered for removal in Alternatives 4, 5, 6, and the Proposed RMP Amendment. Further, most of these actions address management on livestock grazing in general, rather than focusing on conducting livestock grazing in a manner that reduces the potential for improper livestock grazing. Finally, some of the management actions did not contain specific direction, but provided a series of suggestions of what kind of activities or adjustments may be considered during future grazing management decisions, with specific decisions deferred to the implementation level. Alternatives 4, 5, 6, and the Proposed RMP Amendment consolidate the livestock grazing decisions to focus on conducting livestock grazing in a manner that would reduce the potential for improper livestock grazing in GRSG habitat and relocate or remove actions that are not required to be in the RMP to implement.

The following table compares livestock grazing management actions from each of the BLM amendment efforts from 2015, with changes made in 2019 (if applicable) displayed in strike-out (for deletions) or underlines (for additions). The right-hand column identifies a summary statement for the row, with similar concepts between the states grouped. The column also identifies whether the concepts in the row are addressed by management in Alternatives 4, 5, 6, and the Proposed RMP Amendment in the EIS Chapter 2 and Appendix 21, whether the concept was retained as a livestock grazing best management practices, or if it is proposed to not be carried forward in this planning effort.

2015 RMP Amendment Livestock Grazing Management Direction with Updates from 2019 Amendment Identified							
Colorado	**Idaho**	**Montana/Dakotas**	**Nevada/California**	**Oregon**	**Utah**	**Wyoming**	**NOTES**
Objective RM-1: GRSG objectives and well-managed livestock operations are compatible because forage availability for livestock and hiding cover for GRSG are both dependent on healthy plant communities. Agreements with partners that promote sustainable GRSG populations concurrent with sustainable ranch operations offer long-term stability. In the context of sustainable range operations, manage the range program to: 1) maintain or enhance vigorous and productive plant communities; 2) maintain residual herbaceous cover to reduce predation during GRSG nesting and early brood-rearing; 3) avoid direct adverse impacts to GRSG-associated range project infrastructure; and 4) employ grazing management strategies that avoid concentrating animals on key GRSG habitats during key seasons.	—	**North Dakota Management Direction LG-1.3:** Within PHMA, incorporate GRSG habitat objectives and management considerations into all BLM grazing allotments through AMP or permit renewals. Develop standards with State of North Dakota and USFWS.	**Objective LG 1:** Manage permitted livestock grazing to maintain and/or enhance PHMAs and GHMAs to meet or make progress towards meeting all GRSG life-cycle requirements and habitat objectives (Table 2-2), based on site potential.	**Objective LG 1:** Manage livestock grazing to maintain or improve Greater Sage-grouse habitat by achieving Standards for Rangeland Health (SRH).	—	—	Summary statement: • Manage grazing to achieve GRSG habitat/objectives and/or land health standard • Avoid direct adverse GRSG impacts from range infrastructure Applicability for RMPs? There is a regulatory requirement to achieve land health standards (4180), and it is a common objective/desired condition for public lands. In this effort, we want to focus on an objective specific to maintaining/improving GRSG habitat. This concept is included in chapter 2 (see also Appendix 21, Section 21.1.10) in Objective RM-1.

2015 RMP Amendment Livestock Grazing Management Direction with Updates from 2019 Amendment Identified							
Colorado	**Idaho**	**Montana/Dakotas**	**Nevada/California**	**Oregon**	**Utah**	**Wyoming**	**NOTES**
—	**MD LG 1**: Maintain existing areas designated as available or unavailable for livestock grazing. Existing active AUMs for livestock grazing within the planning area will not be changed at the broad scale, though the number of AUMs available on an allotment may be adjusted based on site-specific conditions to meet management objectives during term permit renewals, AMP development, or other appropriate implementation planning. Additionally, temporary adjustments can be made annually to livestock numbers, the number of AUMs, and season of use in accordance with applicable regulations.	**Dillon MD LG 1**: Maintain existing areas designated as available or unavailable for livestock grazing. Existing active AUMs for livestock grazing within the planning area will not be changed at the broad scale, though the number of AUMs available on an allotment may be adjusted based on site-specific conditions to meet management objectives during term permit renewals, AMP development, or other appropriate implementation planning. Additionally, temporary adjustments can be made annually to livestock numbers, the number of AUMs, and season of use in accordance with applicable regulations. **Lewistown Action LG-1.2:** The area will remain available for livestock grazing.	—	**Objective LG 2:** On BLM-managed lands, 12,~~083~~105,~~622~~581 acres will continue to be available for livestock grazing in Greater Sage-grouse habitat. Table 2-6 is no longer applicable and is therefore deleted ~~In key RNAs, 22,765 acres will be unavailable to livestock grazing. See Table 2-6, Key ACECs and RNAs for ARMPA~~. MD LG 1 is deleted. Livestock grazing management in the 13 key RNAs returns to being governed by applicable district RMPs as amended by the 2015 Oregon Greater Sage-Grouse ROD/ARMPA goals, objectives, and management decisions. ~~**MD LG 1:** All or portions of key RNAs will be unavailable to grazing (Table 2-6). Determine whether to remove fences, corrals, or water storage facilities (e.g. reservoirs, catchments, ponds).~~	~~**MA LG 1:** PHMA and GHMA will be available for livestock grazing (Figure 2-3, Livestock Grazing [Appendix A]). Active animal unit months (AUMs) for livestock grazing will be 329,521 on BLM lands. Make adjustments to permitted AUMs consistent with regulation and the remaining grazing direction. In addition, on an annual basis livestock numbers and the season of use can be adjusted within the terms and conditions of the permit.~~ ~~Make adjustments to permitted use and annual adjustments to levels of livestock use consistent with regulation and the direction identified below where livestock grazing is identified as a causal factor to not meeting standards or habitat objectives.~~	—	Summary statement: • Available/unavailable allocation decision. Applicability for RMPs? One of the primary decisions an RMP is supposed to make is whether a given area is available for livestock grazing. Included in chapter 2 (see also Appendix 21, Section 21.1.10) as Allocation RM-1.
MD RM-1: (ADH) Within ADH, incorporate GRSG habitat objectives and management considerations into all BLM grazing allotments through Allotment Management Plans.	—	—	—	—	—	—	Summary statement: • Manage grazing to achieve GRSG habitat/objectives and/or land health standards Applicability for RMPs? Duplicative with other decisions. Consolidate decisions that incorporate habitat objectives into one. See chapter 2 (see also Appendix 21, Section 21.1.10) grazing decision RM-1 or Application of Habitat Objectives – Objective SSS Y and actions SSS Y1 and SSS Y2.

2015 RMP Amendment Livestock Grazing Management Direction with Updates from 2019 Amendment Identified							
Colorado	**Idaho**	**Montana/Dakotas**	**Nevada/California**	**Oregon**	**Utah**	**Wyoming**	**NOTES**
MD RM-2: (ADH) Work cooperatively on integrated ranch planning within GRSG habitat. Develop management strategies that are seamless with respect to actions on public and private lands within BLM grazing allotments.	**MD LG 3**: Where opportunities exist, coordinate with other land managers to encourage livestock operations that utilize mixed federal, private and/or state land to be managed at the landscape scale to benefit GRSG and their habitat across land ownerships.	**Dillon MD LG 3**: Where opportunities exist, coordinate with other land managers to encourage livestock operations that utilize mixed federal, private and/or state land to be managed at the landscape scale to benefit GRSG and their habitat across land ownerships. **Billings Management Direction LG-1.4:** In PHMA, work cooperatively on integrated ranch planning within GRSG habitat so operations with deeded/BLM allotments can be planned as single units. **Lewistown Action LG-1.4:** In PHMA, cooperate with ranchers and other agencies on integrated ranch planning so operations with intermingled land ownerships within BLM allotments can be planned as single units.	—	—	~~**MA LG 3**: In PHMA, consult, cooperate, and collaborate with other land owners and management agencies (e.g., private and SITLA) to develop plans which provide for landscape level approaches to habitat improvement. Manage unfenced private and SITLA lands within a grazing allotment that are under exchange of use agreements or percent public land use as a single unit that will have the same management as the public lands.~~	**MD LG 2:** Within PHMA the BLM will work cooperatively with permittees, lessees, and other landowners to develop voluntary grazing management strategies that integrate both public and private lands into single management units to improve Greater Sage-Grouse habitat.	Summary statement: • Coordinate with partners/neighbors Applicability for RMPs? 43 CFR 4100 regulations direct BLM to consult, cooperate and coordinate with affected grazing permittees, the state having lands or responsible for managing resources within and the interested publics when engaging in program work such as changes in permitted use, Allotment Management Plans, Range Improvements, issuance and/or modification of a grazing permit. Because regulations already require coordination, and conducting such coordination does not require an RMP decision to implement, it would be removed from the RMP-decision section for Alternatives 4, 5, 6 and the Proposed RMP Amendment. However, coordination language has been added specific to managing GRSG habitat across multiple ownership as a BMP in the appendix.

2015 RMP Amendment Livestock Grazing Management Direction with Updates from 2019 Amendment Identified							
Colorado	**Idaho**	**Montana/Dakotas**	**Nevada/California**	**Oregon**	**Utah**	**Wyoming**	**NOTES**
MD RM-3: (PHMA) The BLM will prioritize: 1. the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and 2. the processing of grazing permits/leases in PHMA. In setting workload priorities, precedence will be given to existing permits/leases in these areas not meeting Land Health Standards, with focus on those containing riparian areas, including wet meadows. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (e.g., fire) and legal obligations.	**MD LG 15**: Generally, t~~T~~he BLM will prioritize (1) the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and (2) the processing of grazing permits/leases based on land health conditions or concerns related to rangeland health standards. If similar issues are found in both PHMA and IHMA, then those in PHMA should be addressed first. ~~in Sagebrush Focal Areas (SFA) followed by PHMA outside of the SFA.~~ In setting workload priorities, precedence will be given to existing permits/leases in these areas not meeting Land Health Standards and that have declining Greater Sage-Grouse populations, defined by a soft or hard population adaptive management trigger being engaged. Greater Sage-Grouse populations that are stable or trending upward will be a lower priority for permit renewal and the assessment process~~, with focus on those containing riparian areas, including wet meadows. Management and conservation action prioritization will occur at the Conservation Area (CA) scale and be based on GRSG population and habitat trends: Focusing management and conservation actions first in SFA followed by areas of PHMA outside SFA~~. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (e.g., fire) and legal obligations. **MD LG 2**: Prioritize BLM land health assessments and processing of BLM grazing	**Dillon MD LG 15**: The BLM will prioritize (1) the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and (2) the processing of grazing permits/leases in Sagebrush Focal Areas (SFA) followed by PHMA outside of the SFA. In setting workload priorities, precedence will be given to existing permits/leases in these areas not meeting Land Health Standards, with focus on those containing riparian areas, including wet meadows. Management and conservation action prioritization will occur at the Conservation Area (CA) scale and be based on GRSG population and habitat trends: Focusing management and conservation actions first in SFA followed by areas of PHMA outside SFA. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (e.g., fire) and legal obligations. **MD LG 2:** Prioritize BLM land health assessments and processing of BLM grazing permits consistent with management area prioritization (MD SSS 4), unless other higher priority considerations exist (MD LG 15) or other factors such as threatened, endangered and proposed species habitat that livestock grazing can affect. Where possible, conduct land health assessments at the watershed, or other meaningful landscape-scale. **Billings MD LG-14**: The BLM will prioritize (1) the review of grazing permits/leases, in particular to determine if	**MD LG 2:** The BLM will prioritize (1) the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and (2) the processing of grazing permits/leases in ~~SFA followed by~~ PHMAs ~~outside of the SFA~~. In setting workload priorities, precedence will be given to existing permits/leases in these areas not meeting land health standards, with focus on those containing riparian areas, including wet meadows. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (e.g., fire) and legal obligations.	**MD LG 11:** Sagebrush Focal Areas will be prioritized for management and conservation actions, including, but not limited to review of livestock grazing permits/leases. **MD LG 12:** The BLM will prioritize (1) the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and (2) the processing of grazing permits/leases in Sagebrush Focal Areas (SFA) followed by PHMA outside of the SFA. In setting workload priorities, precedence will be given to existing permits/leases in these areas not meeting Land Health Standards, with focus on those containing riparian areas, including wet meadows. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (e.g. fire) and legal obligations.	~~**MA LG 2**: The BLM will prioritize~~ ~~(1) the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and~~ ~~(2) the processing of grazing permits/leases in SFA first followed by PHMA outside SFA.~~ ~~In setting workload priorities, precedence will be given to existing permits/leases in these areas not meeting Land Health Standards, with focus on those containing riparian areas, including wet meadows. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (ex., fire) and legal obligations.~~	**MD LG 5 (cont.):** The BLM would prioritize (1) the review of grazing permits/leases, in particular to determine if modification is necessary prior to renewal, and (2) the processing of grazing permits/leases in ~~SFAs followed by~~ PHMA ~~outside of the SFAs~~. In setting workload priorities, precedence would be given to existing permits/leases in these areas not meeting LHSs, with focus on those containing riparian areas, including wet meadows. The BLM may use other criteria for prioritization to respond to urgent natural resource concerns (e.g., fire) and legal obligations.	Summary statement: • Prioritize review/processing of grazing permits Applicability for RMPs? Prioritization is not an RMP decision. It depends on staffing, budget, and the consideration of other resource issues that include, but are not limited to GRSG, other listed species, LHS, wildfire, or other resource concerns. Previous national level guidance for prioritization of renewals has always been to look at high resource value areas first. IM's such as WO 2009-018 and WO 2018-024 gave guidance on prioritization. The 2015 FWS listing determination cited the prioritization for reviewing grazing permits and conducting monitoring to determine if changes may be needed to meet GRSG habitat conditions – though it also noted that other criteria could be considered. Retained language related to prioritization in the livestock grazing BMP appendix. It can help inform and guide during implementation, though it is not needed as an RMP-level decision.

Colorado	**Idaho**	**Montana/Dakotas**	**Nevada/California**	**Oregon**	**Utah**	**Wyoming**	**NOTES**
MD RM-4: (ADH) Conduct land health assessments that include (at a minimum) indicators and measurements of vegetation structure/condition/composition specific to achieving GRSG habitat objectives (Doherty et al. 2011). If local/state seasonal habitat objectives are not available, use GRSG habitat recommendations from Connelly et al. 2000 and Hagen et al. 2007.	**MD LG 4**: PHMA & IHMA: During the land health assessment process, identify the type(s) of seasonal habitat the assessed areas are capable of supporting. Utilize the habitat assessment framework, (Stiver et al. 2015) or other BLM approved methodology, in accordance with current policy and guidance to determine whether vegetation structure, condition and composition are meeting GRSG habitat objectives including riparian and lentic areas (Objective SSS 2; Table 2-2). Use appropriate Ecological Site Descriptions, reference sheets and state and transition models to inform desired habitat conditions and expected responses to management changes for the land unit being assessed.	**Dillon MD LG 4**: PHMA & IHMA: During the land health assessment process, identify the type(s) of seasonal habitat the assessed areas are capable of supporting. Utilize the habitat assessment framework, (Stiver et al. 2015) or other BLM approved methodology, in accordance with current policy and guidance to determine whether vegetation structure, condition and composition are meeting GRSG habitat objectives including riparian and lentic areas (Objective SSS 2; Table 2-2). Use appropriate Ecological Site Descriptions, reference sheets and state and transition models to inform desired habitat conditions and expected responses to management changes for the land unit being assessed. **Lewistown Action LG-1.2**: In PHMA and GHMA, conduct land health evaluations and determinations that include (at a minimum) indicators and/or measurements of structure/condition/ composition of vegetation specific to achieving GRSG habitat objectives. Management actions will be developed and implemented within one year if land health determinations indicate that an allotment is not meeting standards due to current livestock grazing. Appendix D addresses mid-scale monitoring. **Lewistown Action LG-1.6**: Allotments that have the best opportunities for conserving, enhancing, or restoring habitat for GRSG will receive high priority for monitoring, evaluation, and management.	**MD LG 4:** Complete land health assessments in PHMAs and GHMAs to identify whether or not GRSG habitat objectives (Table 2-2) are being met. The priority order for completing land health assessments in GRSG habitat is: • ~~Allotments containing SFA that have never been evaluated;~~ • ~~Allotments containing SFA that have not been re-evaluated in 10 or more years;~~ • Allotments containing PHMAs that have never been evaluated; • Allotments containing PHMAs that have not been re-evaluated in 10 or more years; • Allotments containing GHMAs that have never been evaluated; • Allotments containing GHMAs that have not been re-evaluated in 10 or more years.	**Objective LG 3:** Complete rangeland health assessments for grazing permits/leases that have not been renewed and prioritized by Allotment Categories I, M, and C. The priority order for completing rangeland health assessments in Greater Sage-grouse habitat is: 1. Allotments containing SFA that have never been evaluated. 2. Allotments containing SFA that have not been re-evaluated in 10 or more years. 3. Allotments containing PHMA that have never been evaluated. 4. Allotments containing PHMA that have not been re-evaluated in 10 or more years. 5. Allotments containing GHMA that have never been evaluated. 6. Allotments containing GHMA that have not been re-evaluated in 10 or more years.	~~**MA LG-5:** In PHMA and GHMA, conduct land health assessments that include indicators and measurements of structure, condition, composition, etc., of vegetation specific to achieving GRSG habitat objectives (Objective SSS-3), including within wetlands and riparian areas. Prioritize land health assessments in SFA, followed by PHMA outside of the SFA. Conduct land health assessments at the watershed scale and use the GRSG habitat objectives when assessing the applicable standard in GRSG habitats.~~	**MD LG 1**: The BLM policy in WO-IM-2009-007 and BLM Handbook H-4180-1 will be used to evaluate land health standards achievement in PHMA (core only) and, where not achieved, to determine if existing grazing management practices or levels of grazing use on public lands are significant factors in failing to achieve the standards and conform with the guidelines, which through this process will identify appropriate actions to address nonachievement and nonconformance.	Summary statement: • Land health assessments: include habitat indicators, ecological site descriptions, state and transition, priorities Applicability for RMPs? Prioritization is not an RMP decision. It depends on staffing, budget, and the consideration of other resource issues that include, but are not limited to GRSG, other listed species, LHS, wildfire, or other resource concerns. Previous national level guidance for prioritization of renewals has always been to look at high resource value areas first. IM's such as WO 2009-018 and WO 2018-024 gave guidance on prioritization. The 2015 FWS listing determination cited the prioritization for reviewing grazing permits and conducting monitoring to determine if changes may be needed to meet GRSG habitat conditions – though it also noted that other criteria could be considered. Retained language related to prioritization in the livestock grazing BMP appendix. It can help inform and guide during implementation, though it is not needed as an RMP-level decision.

2015 RMP Amendment Livestock Grazing Management Direction with Updates from 2019 Amendment Identified							
Colorado	**Idaho**	**Montana/Dakotas**	**Nevada/California**	**Oregon**	**Utah**	**Wyoming**	**NOTES**
MD RM-5: (ADH) Develop specific objectives—through NEPA analysis conducted in accordance with the permit/lease renewal process—to conserve, enhance, or restore GRSG habitat. Base benchmarks on Ecological Site/Range Site Descriptions. When existing on Ecological Site/Range Site Descriptions have not been developed, or are too general to serve adequately as benchmarks, identify and document local reference sites for areas of similar potential that exemplify achievement of GRSG habitat objectives and use these sites as the benchmark reference. Establish measurable objectives related to GRSG habitat from baseline monitoring data, ecological site descriptions, or land health assessments/evaluations, or other habitat and successional stage objectives.	—	**Billings: MD LG-12**: Site specific Greater Sage-Grouse habitat and management objectives will be developed for BLM land within Greater Sage-Grouse PHMA. These objectives will be incorporated into the respective allotment management plans (AMPs) or livestock grazing permits as appropriate. **Lewistown Action LG-1.2:** Site-specific Greater Sage-Grouse habitat and management objectives will be developed for BLM land and incorporated into the respective AMPs or livestock grazing permits as appropriate. Third order (fine-scale) and fourth order (site-scale) habitat indicators and characteristics for sage-grouse habitat seasonal use areas as described in the Sage-Grouse Habitat Assessment Framework (Stiver, et al. 2015) will be used to quantify habitat objectives. **HiLine MD-36**: Consideration will be given to incorporating fine-scale and site-specific Greater Sage-Grouse habitat and management objectives as appropriate to the area into AMPs or livestock grazing permits.	**MD LG 8:** Within PHMAs and GHMAs, incorporate terms and conditions into grazing permits to meet GRSG habitat objectives (Table 2-2), specific terms and conditions will be based on rangeland health assessments (and subsequent monitoring data).	**MD LG 4:** When fine and site-scale Greater Sage-grouse habitat assessment and monitoring is needed or required, (e.g., as a component of a rangeland health assessment), measure the Greater Sage-grouse habitat suitability indicators for seasonal habitats identified in Table 2-2. Site suitability values may be adjusted regionally where there is scientific justification for doing so. When using the indicators to guide management actions or during land health assessments, consider that the indicators are sensitive to the ecological processes operating at the scale of interest and that a single habitat indicator does not necessarily define habitat suitability for an area or particular scale.	~~**MA-LG-4:** Evaluate Utah's Rangeland Health Standards and process grazing permits. Focus monitoring and management activities on allotments found not to be achieving Utah's Rangeland Health Standards where livestock grazing is identified as a causal factor and that have the best opportunities for conserving, enhancing or restoring habitat for GRSG.~~ ~~Use ecological site descriptions and/or other appropriate information to determine the desired plant community within proper functioning ecological processes for conducting land health assessments to evaluate the achievement or non-achievement of rangeland health standards.~~	**MD LG 4:** Within PHMA, ~~all BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives. I~~if monitoring data show the wildlife/special status species standard ~~habitat objectives have~~ has not been met nor progress being made toward meeting ~~them~~ that standard, there will be an evaluation and a determination made as to the cause. If it is determined that the current authorized livestock use is a significant causal factor in failing to achieve the wildlife/special status species standards, the BLM would address the achievement or progress toward achieving the LHSs (43 CFR 4180.2) and, if needed, Greater Sage-Grouse habitat maintenance or improvement ~~for healthy rangelands, the use will be adjusted by the response specified in the instrument that authorized the use~~.	Summary statement: • Manage grazing to achieve GRSG habitat/objectives and/or land health standards Applicability for RMPs? Developed a consolidated action (Management Action RM-1 in chapter 2 and Appendix 10) to consider GRSG habitat benchmarks via HAF to inform LHS. The action connects GRSG habitat benchmarks for suitable habitat via HAF to inform land health special status species standard, and then the regulatory requirement to meet LHS (see Management Action RM-1 in chapter 2 and Section 21.1.10 in Appendix 10).
