

Proposed Resource Management Plan and Final Environmental Impact Statement for the Buffalo Field Office Planning Area

Volume 1 of 3
Chapters 1 - 3

May 2015

Buffalo Field Office

The BLM's multiple-use mission is to sustain the health and productivity of the public lands for the use and enjoyment of present and future generations. The Bureau accomplishes this by managing such activities as outdoor recreation, livestock grazing, mineral development, and energy production, and by conserving natural, historical, cultural, and other resources on public lands.

Proposed Resource Management Plan and Final Environmental Impact Statement for the Buffalo Field Office Planning Area

Volume 1 of 3 Chapters 1 - 3

**U.S. Department of the Interior
Bureau of Land Management
Buffalo Field Office, Wyoming**

May 2015

VOLUME 1 OF 3

Letter to the Reader	xli
Abstract.....	xlvi
Executive Summary	xlvi
Reader's Guide to this Document	lxiii
Acronyms and Abbreviations	lxv
1. Purpose and Need for Action	1
1.1. Introduction and Background.....	1
1.1.1. Land Ownership within the Planning Area	1
1.2. Purpose and Need for the Resource Management Plan Revision	4
1.2.1. Purpose.....	4
1.2.2. Need for Revising the Existing Plan	4
1.3. Planning Process	7
1.3.1. BLM Planning Process.....	7
1.3.2. Resource Management Plan Implementation.....	9
1.4. Decision Framework	9
1.4.1. Planning Issues.....	10
1.4.2. Planning Criteria	12
1.4.3. Major Statutes, Policies, and Regulations	14
1.4.4. Other Related Plans.....	15
1.5. Collaboration.....	16
1.5.1. Consultation and Coordination.....	17
1.6. National Greater Sage-Grouse Planning Strategy	19
1.7. Topics Not Addressed in this Resource Management Plan Revision	23
2. Resource Management Alternatives.....	25
2.1. Resource Management Alternatives	27
2.2. Summary of Changes Made Between the Draft RMP/EIS and the Proposed RMP/Final EIS ...	27
2.3. Alternatives Development Process	32
2.4. Alternative Components	34
2.4.1. Goals and Objectives	34
2.4.2. Allowable Uses and Management Actions	34
2.5. Greater Sage-Grouse Habitat Management	36
2.5.1. BLM Programs for Addressing Greater Sage-Grouse Threats	37
2.5.2. Range of Alternatives for Greater Sage-Grouse Management.....	50
2.5.3. Development of the BLM Proposed Plan for Greater Sage-Grouse Management.....	59

2.5.4.	BLM Proposed Plan for Greater Sage-Grouse Habitat Management	59
2.5.5.	Adaptive Management Strategy for Greater Sage-Grouse.....	75
2.5.6.	Regional Mitigation for Greater Sage-Grouse Habitat Management.....	78
2.5.7.	Greater Sage-Grouse Habitat Management Objectives.....	80
2.5.8.	Powder River Basin Restoration Program	89
2.5.9.	Monitoring Framework for Greater Sage-Grouse Habitat Management	92
2.6.	Alternatives Considered, but not Carried Forward for Detailed Analysis	94
2.6.1.	Physical Resources.....	94
2.6.2.	Mineral Resources.....	94
2.6.3.	Fire and Fuels Management	96
2.6.4.	Biological Resources.....	96
2.6.5.	Heritage and Visual Resources	97
2.6.6.	Land Resources	97
2.6.7.	Special Designations	99
2.6.8.	Socioeconomic Resources.....	99
2.7.	Management Actions Common to All Alternatives.....	99
2.7.1.	Physical Resources.....	99
2.7.2.	Mineral Resources.....	100
2.7.3.	Fire and Fuels Management	100
2.7.4.	Biological Resources.....	100
2.7.5.	Heritage and Visual Resources	101
2.7.6.	Land Resources	102
2.7.7.	Special Designations	102
2.7.8.	Socioeconomic Resources.....	103
2.8.	Summaries of the Alternatives	103
2.8.1.	Alternative A – Current Management (No Action).....	111
2.8.2.	Alternative B – Resource Conservation	114
2.8.3.	Alternative C – Resource Development.....	118
2.8.4.	Alternative D – Proposed RMP.....	122
2.9.	Detailed Alternative Descriptions by Resource	125
2.9.1.	1000 PHYSICAL RESOURCES	126
2.9.2.	2000 MINERAL RESOURCES.....	135
2.9.3.	3000 FIRE AND FUELS MANAGEMENT	144
2.9.4.	4000 BIOLOGICAL RESOURCES	150
2.9.5.	5000 HERITAGE AND VISUAL RESOURCES.....	222
2.9.6.	6000 LAND RESOURCES.....	232
2.9.7.	7000 SPECIAL DESIGNATIONS	266
2.9.8.	8000 SOCIOECONOMIC RESOURCES	272
2.10.	Summary of Environmental Consequences by Alternative	277
3.	Affected Environment	281
3.1.	Physical Resources.....	283
3.1.1.	Air Quality	283
3.1.1.1.	Regional Context	283
3.1.1.2.	Regulatory and Policy Framework	283
3.1.1.3.	Indicators	284
3.1.1.4.	Current Condition	289
3.1.1.5.	Trends	298
3.1.1.6.	Climate Change.....	318
3.1.2.	Geological Resources.....	324

3.1.2.1.	Regional Context	324
3.1.2.2.	Indicators	325
3.1.2.3.	Current Condition	325
3.1.2.4.	Trends	328
3.1.2.5.	Key Features	329
3.1.3.	Soil	329
3.1.3.1.	Regional Context	329
3.1.3.2.	Indicators	330
3.1.3.3.	Current Condition	330
3.1.3.4.	Trends	331
3.1.3.5.	Key Features	332
3.1.4.	Water Resources.....	333
3.1.4.1.	Regional Context	333
3.1.4.2.	Indicators	334
3.1.4.3.	Current Condition	334
3.1.5.	Cave and Karst Resources.....	378
3.1.5.1.	Regional Context	378
3.1.5.2.	Indicators	379
3.1.5.3.	Current Condition	379
3.1.5.4.	Trends	380
3.1.5.5.	Key Features	380
3.2.	Mineral Resources	380
3.2.1.	Locatable Minerals.....	383
3.2.1.1.	Regional Context	383
3.2.1.2.	Indicators	383
3.2.1.3.	Current Condition	384
3.2.1.4.	Trends	388
3.2.1.5.	Key Features	390
3.2.1.6.	Locatable Minerals – Bentonite	390
3.2.1.7.	Locatable Minerals – Gypsum	392
3.2.1.8.	Locatable Minerals – Uranium	393
3.2.2.	Leasable Minerals – Coal.....	398
3.2.2.1.	Regional Context	398
3.2.2.2.	Indicators	400
3.2.2.3.	Current Condition	400
3.2.2.4.	Trends	409
3.2.2.5.	Key Features	410
3.2.3.	Leasable Minerals – Fluids	410
3.2.3.1.	Regional Context	410
3.2.3.2.	Indicators	411
3.2.3.3.	Current Condition	411
3.2.3.4.	Trends	415
3.2.3.5.	Key Features	415
3.2.4.	Leasable Minerals – Other	416
3.2.4.1.	Regional Context	416
3.2.4.2.	Indicators	416
3.2.4.3.	Current Condition	416
3.2.4.4.	Trends	416
3.2.4.5.	Key Features	416
3.2.5.	Salable Minerals.....	417
3.2.5.1.	Regional Context	417

3.2.5.2.	Indicators	417
3.2.5.3.	Current Condition	418
3.2.5.4.	Trend.....	421
3.2.5.5.	Key Features	423
3.3.	Fire and Fuels Management.....	424
3.3.1.	Unplanned Fire (Wildfire).....	425
3.3.1.1.	Regional Context	426
3.3.1.2.	Indicators	426
3.3.1.3.	Current Condition	427
3.3.1.4.	Trends	429
3.3.1.5.	Key Features	429
3.3.2.	Planned Fire (Prescribed Fire).....	430
3.3.2.1.	Regional Context	431
3.3.2.2.	Indicators	431
3.3.2.3.	Current Condition	431
3.3.2.4.	Trends	431
3.3.2.5.	Key Features	432
3.3.3.	Stabilization and Rehabilitation	432
3.3.3.1.	Regional Context	432
3.3.3.2.	Indicators	433
3.3.3.3.	Current Condition	433
3.3.3.4.	Trends	433
3.3.3.5.	Key Features	433
3.4.	Biological Resources.....	434
3.4.1.	Vegetation – Forests and Woodlands.....	434
3.4.1.1.	Regional Context	434
3.4.1.2.	Indicators	434
3.4.1.3.	Current Condition	435
3.4.1.4.	Trends	436
3.4.1.5.	Key Features	436
3.4.2.	Vegetation – Grassland and Shrubland Communities.....	437
3.4.2.1.	Regional Context	437
3.4.2.2.	Indicators	437
3.4.2.3.	Current Condition	438
3.4.2.4.	Trends	443
3.4.2.5.	Key Features	443
3.4.3.	Vegetation – Riparian/Wetland Resources	444
3.4.3.1.	Regional Context	444
3.4.3.2.	Indicators	445
3.4.3.3.	Current Condition	446
3.4.3.4.	Trends	448

APPENDICES

(Electronic only)

Appendix A. Legislation and Policy Pertaining to Specific Resources	1771
Appendix B. Greater Sage-Grouse Implementation Framework	1779
B.1. COT Objective 1: Stop Population Declines and Habitat Loss	1781
B.1.1. Step 1 – Determine Proposal Adequacy.....	1783
B.1.2. Step 2 – Evaluate Proposal Consistency with LUP	1783
B.1.3. Step 3 – Apply Avoidance and Minimization Measures to Comply with Sage- Grouse Goals and Objectives	1792
B.1.4. Step 4 – Apply Compensatory Mitigation or Reject / Defer Proposal	1793
B.2. COT Objective 2: Implement Targeted Habitat Management and Restoration	1796
B.3. COT Objective 3: Develop and Implement State and Federal Conservation Strategies and Associated Incentive-based Conservation Actions and Regulatory Mechanisms	1796
B.3.1. Implementation Working Groups	1797
B.3.2. Implementation Tracking	1798
B.3.3. Public Involvement	1798
B.4. COT Objective 4: Proactive Conservation Actions	1799
B.5. COT Objective 5: Development of Monitoring Plans	1801
B.5.1. The Greater Sage-Grouse (GRSG) Monitoring Framework	1801
B.5.1.1. Introduction	1801
B.5.1.2. Broad and Mid-Scales	1804
B.5.1.3. Fine and Site Scales	1828
B.5.1.4. Conclusion	1830
B.5.1.5. The BLM Greater Sage-Grouse Disturbance and Monitoring Subteam Membership	1830
B.5.1.6. Literature Cited	1830
B.5.1.7. Attachments	1834
B.6. COT Objective 6: Prioritize, Fund and Implement Research to Address Existing Uncertainties	1837
B.6.1. Wyoming Greater Sage-Grouse Adaptive Management Plan	1837
B.6.1.1. Adaptive Management Triggers	1837
B.6.1.2. Adaptive Management Response	1838
B.6.1.3. EIS Level Projects	1839
B.6.1.4. Implementation Groups	1839
B.6.1.5. Small Leks	1840
Appendix C. Public Involvement, Consultation, and Coordination	1843
C.1. Introduction	1843
C.2. Public Involvement	1844
C.3. Consultation and Coordination	1847
C.4. Distribution List	1850
C.5. Consultation Letters	1855

Appendix D. Best Management Practices	1863
D.1. Bureau of Land Management (BLM) BMP Resources.....	1863
D.2. Other Agency BMP Resources	1865
D.3. Greater Sage-Grouse: Required Design Features and Best Management Practices	1866
D.3.1. Required Design Features	1866
D.3.2. Best Management Practices	1876
Appendix E. Livestock Grazing Allotments.....	1899
E.1. Livestock Grazing Allotments within the Buffalo Planning Area	1899
E.2. Standards and Guidelines Status	1910
E.3. Livestock Grazing Allotments Within Greater Sage-Grouse Habitat	1915
Appendix F. Maps	1931
Appendix G. Surface Disturbance and Reasonable Foreseeable Actions.....	1937
Appendix H. Fluid Mineral Lease Notices; Lease Stipulations; and the Process for Exceptions, Modifications, and Waivers	1959
H.1. Lease Notices	1959
H.2. Lease Stipulations	1962
H.3. Processing Exceptions, Modifications, and Waivers	2021
Appendix I. Biological Assessment	2025
I.1. Introduction.....	2025
I.2. Consultation and Biological Assessment Objectives	2028
I.3. Overview of the Planning Area.....	2029
I.4. Current Status and Habitat Requirements	2032
I.5. Methods and Context of the Analysis	2040
I.6. Analysis of Proposed Management Actions and Effects	2046
I.7. Summary of Cumulative Effects.....	2131
I.8. Summary of Effects Determinations.....	2132
I.9. Conservation Measures.....	2133
I.9.1. Proposed Protections under the Proposed RMP.....	2133
I.9.2. Conservation Measures from Other Sources.....	2135
Appendix J. Mitigation Guidelines for Surface-Disturbing and Disruptive Activities, Wyoming Bureau of Land Management.....	2155
J.1. Introduction.....	2155
J.1.1. Purpose.....	2156
J.2. Mitigation Guidelines	2156
J.2.1. Surface Disturbance Mitigation Guideline.....	2156
J.2.2. Wildlife Mitigation Guideline.....	2157
J.2.3. Cultural Resource Mitigation Guideline	2157

J.2.4. Special Resource Mitigation Guideline	2158
J.2.5. No Surface Occupancy Guideline.....	2159
Appendix K. Biological Resources Support Documents.....	2161
K.1. Biological Resources of the Buffalo Planning Area	2161
K.2. Raptor Management.....	2205
Appendix L. Lands Identified for Disposal Through Exchange or Sale	2211
Appendix M. Technical Support Document for Air Quality	2239
M.1. Introduction.....	2239
M.2. Study Area	2239
M.3. Pollutants Addressed in the Analysis.....	2239
M.4. Thresholds of Significance.....	2241
M.5. Emissions Calculations	2246
M.6. Summary of Emissions for All BLM Activities	2253
Appendix N. Buffalo Air Resource Management Plan	2479
N.1. Introduction.....	2479
N.1.1. Purpose.....	2479
N.1.2. Authority for Air Resource Management	2479
N.1.3. Background	2480
N.1.4. Characterization of Air Resources in the Environmental Impact Statement.....	2486
N.2. Air Resource Management Plan	2487
N.2.1. Coal Lease by Application.....	2487
N.2.2. Mineral and Energy Development Authorizations.....	2487
N.2.3. Monitoring	2488
N.2.4. Modeling.....	2488
N.2.5. Mitigation.....	2489
N.2.6. Contingency Plans.....	2493
Appendix O. Reclamation Policy for the Buffalo Field Office.....	2495
Appendix P. Wyoming Standards for Healthy Rangelands	2501
P.1. Introduction.....	2501
P.2. Standards for Healthy Public Rangelands.....	2503
P.2.1. Standard #1	2503
P.2.2. Standard #2	2503
P.2.3. Standard #3	2504
P.2.4. Standard #4	2505
P.2.5. Standard #5	2505
P.2.6. Standard #6	2506
P.3. BLM Wyoming Guidelines for Livestock Grazing Management.....	2506

P.3.1. Definitions.....	2507
Appendix Q. Fire and Fuels Management.....	2511
Q.1. Emergency Stabilization and Rehabilitation.....	2511
Q.2. Fire Management Policy for Wilderness Study Areas.....	2516
Appendix R. Travel and Transportation Management	2519
Appendix S. Areas of Critical Environmental Concern.....	2531
S.1. Proposed Areas of Critical Environmental Concern Designated by Alternative D	2531
S.1.1. Pumpkin Buttes.....	2531
S.1.2. Welch Ranch.....	2534
S.2. Proposed Areas of Environmental Concern not Designated by Alternative D	2536
S.2.1. Burnt Hollow.....	2536
S.2.2. Cantonment Reno.....	2537
S.2.3. Dry Creek Petrified Tree.....	2538
S.2.4. Fortification Creek Elk Area.....	2539
S.2.5. Hole-in-the-Wall.....	2539
S.2.6. Sagebrush Ecosystems	2540
Appendix T. Recreation Management Areas.....	2543
T.1. Burnt Hollow Management Area.....	2543
T.2. Dry Creek Petrified Tree Management Area	2548
T.3. Hole-in-the-Wall Management Area	2552
T.4. Middle Fork Powder River Management Area.....	2556
T.5. Mosier Gulch Management Area.....	2561
T.6. Welch Ranch Management Area	2567
T.7. Weston Hills Management Area	2572
T.8. Extensive Recreation Management Areas	2576
T.8.1. Cabin Canyon Management Area.....	2577
T.8.2. Face of the Bighorns/North Fork Extensive Recreation Management Area.....	2578
T.8.3. Gardner Mountain Extensive Recreation Management Area	2579
T.8.4. Kaycee Stockrest Extensive Recreation Management Area	2581
T.8.5. North Bighorns Extensive Recreation Management Area	2582
T.8.6. Powder River Basin Extensive Recreation Management Area.....	2583
T.8.7. South Bighorns Extensive Recreation Management Area	2585
T.8.8. Walk-in Area Extensive Recreation Management Area	2586
Appendix U. Economic Impact Analysis Methodology.....	2589
U.1. The IMPLAN Model.....	2589
U.2. Oil and Gas	2590
U.3. Livestock Grazing.....	2594
U.4. Recreation	2596

Appendix V. Oil and Gas Operations 2599

V.1. Geophysical Exploration.....	2599
V.1.1. Seismic Reflection Surveys	2599
V.2. Geophysical Management (Permitting Process)	2601
V.2.1. State Standards.....	2601
V.2.2. Mitigation.....	2602
V.3. Oil and Gas Leasing.....	2602
V.4. Drilling Permit Process	2603
V.4.1. Permitting.....	2603
V.4.2. Standard Drilling Conditions of Approval.....	2607
V.4.3. Surface Disturbance Associated With Oil and Gas Drilling	2610
V.4.4. Issuance of Rights-of-Way.....	2611
V.5. Drilling Operations	2611
V.5.1. Rotary Drilling	2612
V.5.2. Logging	2613
V.5.3. Casing	2614
V.5.4. Hydraulic Fracturing.....	2615
V.5.5. Oil and Gas Exploratory Units.....	2616
V.5.6. Field Development.....	2616
V.6. Production	2617
V.6.1. Gas Production (other than CBNG)	2617
V.6.2. Oil Production	2618
V.6.3. CBNG Production	2618
V.6.4. Water Production	2619
V.6.5. Production Problems	2619
V.6.6. Secondary and Enhanced Oil Recovery	2619
V.6.7. Gas Storage	2621
V.7. Plugging and Abandonment of Wells	2621

Appendix W. Buffalo Water Resources Management Plan..... 2623

W.1. Introduction.....	2623
W.1.1. Purpose.....	2623
W.1.2. Authority for Water Resource Management	2623
W.1.3. Background and Current Conditions.....	2625
W.1.3.1. Water Baseline	2625
W.1.3.2. Monitoring Programs	2647
W.1.3.3. Reclamation Efforts.....	2649
W.2. Water Resource Management Plan	2650
W.2.1. Locatable Mineral Development and Coal Lease by Application	2650
W.2.2. Mineral and Energy Development Authorizations.....	2651
W.2.3. Monitoring	2653
W.2.4. Mitigation.....	2653

Appendix X. Federal Oil and Gas Operations on Split Estate Lands..... 2661

X.1. Purpose.....	2661
X.2. Definitions.....	2661
X.3. General.....	2662
X.4. Operations.....	2662
X.5. References.....	2668

Appendix Y. Comment Analysis 2671

Y.1. Introduction.....	2671
Y.2. Comment Analysis Process.....	2671
Y.2.1. Analysis Process	2672
Y.3. Commenter Demographic.....	2674
Y.3.1. Geographic Representation	2674
Y.3.2. Organizational Affiliation	2676
Y.3.3. Public Comment Document Method of Delivery	2677
Y.3.4. Form Letters.....	2678
Y.4. Analysis of Comments.....	2678
Y.4.1. Comment Submittals by Issue Category	2679
Y.4.2. Substantive Comment Summary and Response.....	2682
Y.4.3. Non-Substantive Comments	2746
Y.5. Conclusion	2746

Letter to the Reader

United States Department of the Interior

BUREAU OF LAND MANAGEMENT

Buffalo Field Office
1425 Fort Street
Buffalo, WY 82834

In reply refer to:
1610 (WY930)

Dear Reader:

Enclosed is the Proposed Resource Management Plan (PRMP) and Final Environmental Impact Statement (FEIS) for the Buffalo Field Office. The Bureau of Land Management (BLM) prepared the PRMP/FEIS in consultation with cooperating agencies, taking into account public comments received during this planning effort. The PRMP provides a framework for the future management direction and appropriate use of the Buffalo planning area, located in Campbell, Johnson, and Sheridan Counties, Wyoming. The document contains land use planning decisions to guide the BLM's management of the Buffalo planning area.

This PRMP/FEIS is one of fifteen sub-regional planning efforts being conducted as part of the BLM's National Greater Sage-Grouse Planning Strategy. The PRMP identifies conservation measures to conserve, enhance and/or restore Greater Sage-Grouse (GRSG) habitat in response to the US Fish and Wildlife Service's (USFWS) March 2010 "warranted, but precluded" Endangered Species Act listing petition. The USFWS found that the inadequacy of regulatory mechanisms was identified as a significant threat to GRSG in their finding on the petition to list the GRSG. RMP conservation measures were identified as the BLM's principal regulatory mechanism.

This PRMP and FEIS have been developed in accordance with the National Environmental Policy Act of 1969, as amended, and the Federal Land Policy and Management Act of 1976, as amended. The PRMP is largely based on Alternative D, the preferred alternative in the Draft Resource Management Plan/Environmental Impact Statement (DRMP/DEIS), which was released on June 28, 2013. The PRMP/FEIS contains the Proposed Plan, a summary of changes made between the DRMP/DEIS and PRMP/FEIS, impacts of the Proposed Plan, a summary of the written and verbal comments received during the public review period for the DRMP/DEIS, and responses to the comments.

Pursuant to BLM's planning regulations at 43 CFR 1610.5-2, any person who participated in the planning process for this PRMP and has an interest which is or may be adversely affected by the planning decisions may protest approval of the planning decisions within 30 days from date the Environmental Protection Agency (EPA) publishes the Notice of Availability of the FEIS in the Federal Register. For further information on filing a protest, please see the accompanying protest regulations in the pages that follow (labeled as Attachment # 1). The regulations specify the required elements of your protest. Take care to document all relevant facts. As much as possible, reference or cite the planning documents or available planning records (e.g., meeting minutes or summaries, correspondence, etc.).

Emailed protests will not be accepted as valid protests unless the protesting party also provides the original letter by either regular mail or overnight delivery postmarked by the close of the protest period. Under these conditions, the BLM will consider the emailed protest as an advance copy and will afford it full consideration. If you wish to provide the BLM with such advance notification, please direct emailed protests to: protest@blm.gov.

All protests must be in writing and mailed to one of the following addresses:

Regular Mail:

Director (210)
Attn: Protest Coordinator
P.O. Box 71383
Washington, D.C. 20024-1383

Overnight Delivery:

Director (210)
Attn: Protest Coordinator
20 M Street SE, Room 2134LM
Washington, D.C. 20003

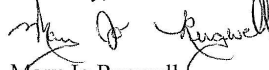

Before including your address, phone number, email address, or other personal identifying information in your protest, be advised that your entire protest – including your personal identifying information – may be made publicly available at any time. While you can ask us in your protest to withhold from public review your personal identifying information, we cannot guarantee that we will be able to do so.

The BLM Director will make every attempt to promptly render a decision on each protest. The decision will be in writing and will be sent to the protesting party by certified mail, return receipt requested. The decision of the BLM Director shall be the final decision of the Department of the Interior on each protest. Responses to protest issues will be compiled and formalized in a Director's Protest Resolution Report made available following issuance of the decisions.

Upon resolution of all land use plan protests, the BLM will issue an Approved RMP and Record of Decision (ROD). The Approved RMP and ROD will be mailed or made available electronically to all who participated in the planning process and will be available on the BLM website at <http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo.html>.

Unlike land use planning decisions, implementation decisions included in this PRMP/FEIS are not subject to protest under the BLM planning regulations, but are subject to an administrative review process, through appeals to the Office of Hearings and Appeals (OHA), Interior Board of Land Appeals (IBLA) pursuant to 43 CFR, Part 4 Subpart E. Implementation decisions generally constitute the BLM's final approval allowing on-the-ground actions to proceed. Where implementation decisions are made as part of the land use planning process, they are still subject to the appeals process or other administrative review as prescribed by specific resource program regulations once the BLM resolves the protests to land use planning decisions and issues an Approved RMP and ROD. The Approved RMP and ROD will therefore identify the implementation decisions made in the plan that may be appealed to the Office of Hearing and Appeals.

Sincerely,

Mary Jo Rugwell
Acting State Director

Attachment 1

Protest Regulations

[CITE: 43CFR1610.5-2]

TITLE 43--PUBLIC LANDS: INTERIOR
CHAPTER II--BUREAU OF LAND MANAGEMENT, DEPARTMENT OF THE INTERIOR
PART 1600--PLANNING, PROGRAMMING, BUDGETING--Table of Contents
Subpart 1610--Resource Management Planning
Sec. 1610.5-2 Protest procedures.

- (a) Any person who participated in the planning process and has an interest which is or may be adversely affected by the approval or amendment of a resource management plan may protest such approval or amendment. A protest may raise only those issues which were submitted for the record during the planning process.
- (1) The protest shall be in writing and shall be filed with the Director. The protest shall be filed within 30 days of the date the Environmental Protection Agency published the notice of receipt of the final environmental impact statement containing the plan or amendment in the Federal Register. For an amendment not requiring the preparation of an environmental impact statement, the protest shall be filed within 30 days of the publication of the notice of its effective date.
- (2) The protest shall contain:
 - (i) The name, mailing address, telephone number and interest of the person filing the protest;
 - (ii) A statement of the issue or issues being protested;
 - (iii) A statement of the part or parts of the plan or amendment being protested;
 - (iv) A copy of all documents addressing the issue or issues that were submitted during the planning process by the protesting party or an indication of the date the issue or issues were discussed for the record; and
 - (v) A concise statement explaining why the State Director's decision is believed to be wrong.
- (3) The Director shall promptly render a decision on the protest.
- (b) The decision shall be in writing and shall set forth the reasons for the decision. The decision shall be sent to the protesting party by certified mail, return receipt requested. The decision of the Director shall be the final decision of the Department of the Interior.

Abstract

Lead Agency: United States (U.S.) Department of the Interior, Bureau of Land Management (BLM)

Type of Action: Administrative (Final)

Jurisdiction: Portions of Campbell, Johnson, and Sheridan counties, Wyoming

Abstract: This Proposed Resource Management Plan (RMP) and Final Environmental Impact Statement (EIS) describes and analyzes alternatives for the planning and management of public lands and resources administered by the BLM, within the Buffalo planning area. The planning area is located in north-central Wyoming and consists of approximately 7.4 million acres of federal, state, and private land. Within the planning area, the BLM administers approximately 780,000 acres of surface lands and 4.8 million acres of federal mineral estate.

BLM-administered lands within the planning area are currently managed according to the 1985 Buffalo RMP as updated by the 2001 Buffalo RMP Update and amended by the 2003 RMP Amendment for the Powder River Basin Oil and Gas Project. When approved, this RMP and EIS will replace these existing plans. As part of the RMP revision process, the BLM conducted a scoping period to solicit input from the public and interested agencies on the nature and extent of issues and impacts to be addressed in the Draft RMP and EIS. Planning issues identified for this RMP revision focus on soils and watershed management, energy and minerals management, fire and fuels management, invasive species, wildlife and special status species habitat, cultural and paleontological resources, management of visual resources, land ownership adjustments, access to public lands and travel, recreation and visitor use, livestock grazing, special designations, and socioeconomic conditions.

The Draft RMP and EIS presented alternatives A through D. **Alternative A** is a continuation of current management (No Action Alternative). Under this alternative, use of public lands and resources would continue to be managed under the existing RMP, as amended. **Alternative B** emphasizes the greatest protection of physical, biological, and heritage resources, while providing for limited development. **Alternative C** emphasizes resource development, while limiting protection of physical, biological, and heritage resources. **Alternative D** balances protection of physical, biological, and heritage resources, while providing for sustainable development.

After careful consideration of both public and internal comments received on the Draft RMP and EIS, adjustments and clarifications have been made to the document, including Alternative D. As modified, Alternative D is now presented as the Proposed RMP in the Final EIS.

Protests: Protests must be postmarked or received no later than 30 days after publication of the U.S. Environmental Protection Agency Notice of Availability in the *Federal Register*.

Refer to the instructions in the letter preceding this abstract for additional information on how to protest. The close of the protest period will be announced in news releases, newsletters, and on the project website at <http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo.html>.

Executive Summary

EXECUTIVE SUMMARY

ES.I INTRODUCTION

The Federal Land Policy and Management Act of 1976 (FLPMA) directs the United States (US) Department of the Interior (DOI), Bureau of Land Management (BLM) to develop and periodically revise or amend its resource management plans (RMPs), which guide management of BLM-administered lands. This RMP and Environmental Impact Statement (EIS) describes and analyzes alternatives for the future management of public lands and resources the BLM administers in the Buffalo Field Office (BFO) in north-central Wyoming.

The BLM Buffalo Proposed Plan provides a layered management approach that offers the highest level of protection for Greater Sage-Grouse (GRSG) in the most valuable habitat. Land use allocations in the Proposed Plan would limit or eliminate new surface disturbance in Priority Habitat Management Areas (PHMA), while minimizing disturbance in General Habitat Management Areas (GHMA).¹ In addition to establishing protective land use allocations, the Proposed Plan would implement a suite of management tools, such as disturbance limits, GRSG habitat objectives and monitoring, mitigation approaches, adaptive management triggers and responses, and other protective measures throughout the range. These overlapping and reinforcing conservation measures will work in concert to improve and restore GRSG habitat condition and provide consistency in how the BLM will manage activities in GRSG habitat in the planning area.

¹ For the Proposed RMP and Final EIS, Greater Sage Grouse habitat nomenclature has been changed from Core Areas to Priority Habitat Management Areas (PHMA) and Non-Core Sage Grouse Habitat to General Habitat Management Areas (GHMA).

ES.1.1 Rationale and Relationship to the Greater Sage-Grouse Planning Strategy

The Buffalo RMP addresses the March 2010 US Fish and Wildlife Service (USFWS) 12-Month Finding for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered (75 *Federal Register* 13910, March 23, 2010). In that finding, the USFWS concluded that GRSG was “warranted, but precluded” for listing as a threatened or endangered species. A “warranted, but precluded” determination is one of three results that may occur after a petition is filed by the public to list a species under the Endangered Species Act (ESA). This finding indicates that immediate publication of a proposed rule to list the species is precluded by higher-priority listing proposals; that is, a species should be listed based on the available science, but listing other species takes priority because they are more in need of protection.

The USFWS reviewed the status of and threats to the GRSG in relation to the five listing factors provided in Section 4(a)(1) of the ESA. Of the five listing factors reviewed, the USFWS determined that Factor A, “the present or threatened destruction, modification, or curtailment of the habitat or range of the GRSG,” and Factor D, “the inadequacy of existing regulatory mechanisms,” posed “a significant threat to the GRSG now and in the foreseeable future” (75 *Federal Register* 13910, March 23, 2010). The USFWS identified the principal regulatory mechanisms for the BLM as conservation measures in land use plans (LUPs).

The Buffalo RMP is one of the 15 LUP revisions and amendments and EISs being prepared by the BLM as part of the National Greater Sage-Grouse Planning Strategy (BLM 2011).² These documents provide a set of management alternatives focused on specific conservation measures across the range of the GRSG (see **Figure ES-1**, Greater Sage-Grouse Planning Strategy Boundaries).

Science-based decision making and collaboration with state and local partners are fundamental to the National Greater Sage-Grouse Planning Strategy. The 15 Greater Sage-grouse RMP/EISs address threats to GRSG identified by state fish and wildlife agencies, the BLM National Technical Team, and the USFWS in the context of its listing decision and the Conservation Objectives Team (COT) report. The COT report was prepared by wildlife biologists from state and federal agencies and provides a blueprint for the overall conservation approach set forth in the BLM GRSG LUP/EISs (USFWS 2013). Where consistent with conservation objectives, the GRSG LUP/EISs adopt unique state- and stakeholder-developed approaches and priorities. Additional science-based reviews by the US Geological Survey and related scientific literature provided further guidance on specific issues that arose in developing the final BLM and Forest Service GRSG LUP/EISs. In addition, regular meetings with the Western

Governors Association Sage-Grouse Task Force provided additional opportunities for coordination with member states.³

Figure ES-1

ES.1.2 Description of the Planning Area and Habitat Management Areas

The planning area is the geographic area within which the BLM will make decisions during this planning effort. The planning area boundary includes all lands regardless of jurisdiction. The Buffalo RMP planning area covers approximately 7.4 million acres of federal, state, and private lands in 3 counties (Campbell, Johnson, and Sheridan). Of the total area, approximately 780,000 acres are BLM-administered surface lands and 4.8 million acres are federal mineral estate.

While the planning area consists of all lands regardless of ownership, decisions resulting from the Buffalo RMP/EIS would apply only to BLM-administered lands, including surface and split-estate lands with federal mineral estate. **Chapter 3, Affected Environment**, describes the current resource and resource use conditions in the planning area.

³ The Western Governors Association Sage-Grouse Task Force works to identify and implement high priority conservation actions and integrate ongoing actions necessary to preclude the need for the GRSG to be listed under the ESA. The Task Force includes designees from the 11 western states where GRSG is found as well as representatives from USFWS, BLM, Natural Resources Conservation Service, Forest Service, United States Geological Survey, and Department of the Interior.

As part of the National Greater Sage-Grouse Planning Strategy, GRSG habitat on BLM-administered lands in the decision area consists of lands allocated as PHMA and GHMA (**Figure ES-2**, Greater Sage-Grouse Habitat Management Areas – Buffalo RMP EIS, and **Table ES-1**, Habitat Management Areas in the Buffalo Planning Area). PHMA and GHMA are defined as follows:

- PHMA (137,400 acres): BLM-administered and National Forest System lands identified as having the highest value to maintaining sustainable GRSG populations. The boundaries and management strategies for PHMA are derived from and generally follow the Core Area boundaries identified in the Draft RMP/EIS. PHMA was identified in coordination with the State of Wyoming. Areas of PHMA largely coincide with areas identified as Priority Areas for Conservation in the COT report.
- GHMA (628,200 acres): BLM-administered lands that require some special management to sustain GRSG populations. GHMA was identified in coordination with the State of Wyoming.

The planning area includes other BLM-administered lands that are not allocated as habitat management areas for GRSG. These lands would be managed as described in **Chapter 2**.

Table ES-1
Habitat Management Areas in the Buffalo Planning Area

Habitat Management Area	Acres of BLM-administered Lands	Percent of BLM-administered Lands in Planning Area
PHMA	137,400	18
GHMA	628,200	80
Other BLM-administered lands	16,500	2

ES.2 PURPOSE AND NEED

BLM-administered lands within the planning area are currently managed according to the 1985 Buffalo RMP as updated by the 2001 Buffalo RMP Update and amended by the 2003 Record of Decision (ROD) and RMP Amendment for the Powder River Basin Oil and Gas Project (existing plan). Since the ROD for the existing plan, new data have become available and laws, regulations, and policies regarding management of these public lands have changed. In addition, decisions in the existing plan do not satisfactorily address all new and emerging issues in the planning area. These changes and potential deficiencies created the need to revise the existing plans. The revised RMP will address the changing needs of the planning area and select a management strategy that best achieves a combination of the following elements:

- Employing a community-based planning approach to seek broadly supported solutions to issues, and collaborate with federal, state, and local cooperating agencies.
- Establishing goals and objectives for managing resources and resource uses in the approximately 780,000 surface acres and 4.2 million acres of federal mineral estate in the Planning Area administered by the BLM BFO in accordance with the principles of multiple use and sustained yield.
- Identifying land use plan decisions to guide future land management actions and subsequent site-specific implementation decisions.
- Identifying management actions and allowable uses anticipated to achieve the established goals and objectives and reach desired outcomes.
- Providing comprehensive management direction by making land use decisions for all appropriate resources and resource uses the BLM administers in the Planning Area.
- Providing for compliance with applicable tribal, federal, and state laws, standards, and implementation plans, and BLM policies and regulations.
- Recognizing the Nation's need for domestic sources of minerals, food, timber, and fiber.
- Retaining flexibility to adapt to new and emerging issues and opportunities and to provide for adjustments to decisions over time based on new information and monitoring.
- Striving to be compatible with the plans and policies of adjacent local, state, tribal, and federal agencies and consistent with federal laws, regulations, and BLM policies; and be flexible enough to adapt to future BLM policy and guidance updates.

- Identify and incorporate appropriate conservation measures to conserve, enhance, and restore GRSG habitat by reducing, minimizing, or eliminating threats to that habitat.

The BLM currently administers public lands in the Planning Area according to the Buffalo RMP (BLM 1985, as amended). Although this existing plan has been updated since the BLM adopted it, new data have become available, and laws, regulations, and policies regarding management of these public lands have changed. In addition, decisions in the existing plan do not satisfactorily address all new and emerging issues in the Planning Area. These changes and potential deficiencies created the need to revise the existing plan.

This RMP with associated EIS is needed to respond to the USFWS's March 2010 "warranted, but precluded" ESA listing petition decision (75 Federal Register 13910, March 23, 2010). The USFWS identified inadequacy of regulatory mechanisms as a significant factor in its finding on the petition to list the GRSG. In its listing decision, the USFWS noted that changes in management of GRSG habitats are necessary to avoid the continued decline of GRSG populations. Changes in land allocations and conservation measures in the BLM RMPs provide a means to implement regulatory mechanisms to address the inadequacy identified by the USFWS.

ES.3 PROPOSED ACTION

The proposed federal action is the Proposed Plan, which identifies resource management actions in accordance with the multiple-use and sustained-yield mandates of FLPMA. The proposed action is also intended to provide a consistent framework for managing GRSG and its habitat on BLM-administered land. The alternatives, including the Proposed Plan, comprise desired future outcomes and a range of management actions, allowable uses, and land use allocations that guide management on BLM-administered lands. The Proposed Plan (see **Section ES.6**, Greater Sage-Grouse Habitat Management Proposed Plan and Environmental Effects) represents the agency's approach for addressing the purpose and need.

ES.4 DEVELOPMENT OF THE RMP/EIS

ES.4.1 Scoping

A Notice of Intent (NOI) published in the Federal Register on November 14, 2008, formally announced the BLM's intent to revise the existing plan and prepare the associated EIS. Publication of the NOI initiated the scoping process and invited affected and interested agencies, organizations, and the general public to participate in determining the scope and issues to be addressed by alternatives and analyses in the EIS. The scoping period was from November 14, 2008 to January 5, 2009, during which time the BLM hosted five public meetings attended by 129 people. The scoping meetings provided the public an opportunity to learn about the project, ask questions, and provide their issues and concerns to the BLM. Information obtained by the BLM during scoping,

along with issues identified by the BLM and other agencies, was used to form the scope of the EIS. The BLM also held two open house meetings in December 2009 in Buffalo and Gillette, Wyoming. Similar to the public scoping meetings, the open house meetings provided the public an opportunity to ask questions of BLM staff and learn about the progress of the project. The final Scoping Summary Report, available online at <http://www.blm.gov/wol/st/en/prog/more/sagegrouse.html>, prepared in conjunction with all the GRSG LUPAs, summarizes the scoping and issue-identification process and describes 13 broad issue categories identified during the scoping process.

ES.4.2 Cooperating Agency Collaboration

The BLM invited local, state, federal, and tribal representatives to participate as cooperating agencies on the Buffalo RMP/EIS. The BLM invited these entities to participate because they have jurisdiction by law or because they could offer special expertise. The State of Wyoming, other federal agencies, Campbell, Crook, Johnson, and Sheridan County Commissions, three local conservation districts, and the Northern Cheyenne Tribe agreed to participate as cooperating agencies in the RMP revision. Cooperating agencies participated in a series of alternative formulation workshops, reviewed draft information and documents, and periodically met with BLM management and resource specialists throughout the revision process to discuss planning issues and provide input to the process. Cooperating agencies helped the BLM develop the alternatives identified in this Proposed RMP and Final EIS.

Consultation with Native American tribes is part of the NEPA scoping process and a requirement of FLPMA. The BLM took multiple steps to contact the tribes and include them in the scoping process. The BLM sent letters to multiple tribes inviting them to be part of the planning process through consultation and public scoping meetings, as well as requesting information to be considered in the planning process.

ES.4.3 Development of the Draft RMP/EIS

Development of Management Alternatives

In accordance with NEPA and the Council on Environmental Quality (CEQ) implementing regulations (40 Code of Federal Regulation 1500), the planning team considered public input and developed a reasonable range of alternatives for the Draft RMP/EIS.

The planning team developed four unique alternatives, including one No Action Alternative and three action alternatives, which were subsequently analyzed in the Draft RMP/EIS. Each of the preliminary action alternatives was designed to:

- Address the 12 planning issues
- Fulfill the purpose and need for the RMP
- Meet the multiple-use and sustained-yield mandate of FLPMA

- Respond to USFWS-identified issues and threats to GRSG and its habitat, including specific threats identified in the COT report

Collectively, the three action alternatives (Alternatives B, C, and D) analyzed in the Draft RMP/EIS offered a range of possible management approaches for responding to the purpose and need as well as the planning issues and concerns identified through public scoping. While the overarching goal of the long-term conservation of GRSG and its habitat is the same across alternatives, each alternative contains a discrete set of objectives and management actions, which if selected as the final plan, would constitute a unique RMP.

Publication of Draft RMP/EIS

Public Comment Period

The Notice of Availability (NOA) for the Buffalo Draft RMP/EIS was published in the Federal Register on June 28, 2013, initiating the 90-day public comment period. The BLM held four public meetings in Buffalo, Gillette, Sheridan, and Kaycee, Wyoming in August 2013. Written public comments were reviewed and considered by the BLM.

Comment Analysis

During the public comment period, the BLM received comment letters by mail and email, which contained over 2,000 substantive comments. Comments covered a wide spectrum of thoughts, opinions, ideas, and concerns. The BLM considered all substantive comments received and revised the plan based on certain issues raised in the comments, as presented in this Proposed RMP and Final EIS. **Appendix C**, Coordination and **Appendix Y**, Comment Analysis, describe the comment analysis methodology and responses to the public comments, respectively.

ES.5 RMP/EIS ALTERNATIVES AND ENVIRONMENTAL EFFECTS

ES.5.1 Alternative A

The No Action Alternative represents continuation of current management and provides a baseline from which to identify potential environmental consequences when compared to the action alternatives. The No Action Alternative describes current resource and land management direction as represented in the Buffalo RMP (BLM 1985, as amended), and associated habitat management plans, maintenance actions, and updates. Current management identifies constraints on mineral leasing and other activities in the Planning Area to protect resource values. Current management does not include any Areas of Critical Environmental Concern (ACECs), National Scenic or Back Country Byways, or Wild and Scenic Rivers (WSRs). There are three WSAs and a segment of the Middle Fork Powder River that is eligible for WSR designation. The BLM considers Special Recreation Management Area (SRMA) on a case-by-case basis, generally manages the planning area as one Extensive Recreation Management Area (ERMA) under Alternative A, and allows livestock grazing on

all but 4,000 acres of BLM-administered lands in the Big Horn Mountains. Current management includes stipulations and seasonal restrictions for surface-disturbing and disruptive activities to protect sensitive wildlife areas and other values that are incompatible with mineral resources activity.

GRSG habitat would continue to be managed under current management direction.

ES.5.2 Alternative B

Alternative B is based on the conservation measures developed by the BLM National Technical Team (NTT) planning effort described in Instruction Memorandum (IM) No. WO-2012-044. As directed in the IM, the conservation measures developed by the NTT must be considered and analyzed, as appropriate, through the land use planning and NEPA processes by all BLM state and field offices that contain occupied GRSG habitat. Alternative B would emphasize conservation of physical, biological, heritage and visual resources, and lands with wilderness characteristics with constraints on resource uses. Alternative B would conserve large areas of land for physical, biological, and heritage resources; designates 8 ACECs; and places a number of restrictions on motorized vehicle use and mineral development. Alternative B would evaluate roads within the planning area for designation as National Back Country or Scenic Byways. All lands with wilderness characteristics under Alternative B would be specifically managed to preserve their wilderness characteristics. Alternative B also applies additional constraints on resource uses within the three VSAs in comparison to Alternative A. Resource use constraints would remain in the VSAs even if Congress decides not to designate those areas as Wilderness. The BLM would designate 8 SRMAs and 2 ERMA's under Alternative B, and prohibits livestock grazing where it has been determined to be incompatible with other uses. New transmission lines would only be allowed in designated corridors and would be required to be placed underground. The number of designated corridors under Alternative B is less than any other alternative.

This alternative would restore vegetation in GRSG habitat on BLM-administered lands. Restrictions on surface-disturbing and disruptive activities in sensitive wildlife habitats are generally more prohibitive under Alternative B than Alternative A, and the size of protective buffers is increased around areas of specific management concern such as occupied GRSG leks. Alternative B would also enlarge and enhance habitat areas and habitat for connectivity.

ES.5.3 Alternative C

Alternative C would emphasize resource uses and reduce constraints on resource uses to protect physical, biological, and heritage and visual resources. Compared to other alternatives, Alternative C would conserve the least land area for physical, biological, and heritage resources; designates six SRMAs; and does not designate any ACECs. Alternative C would be the least restrictive to

motorized vehicle use and ROW and mineral development. All areas would be managed as open to fluid, coal, and locatable mineral exploration and development subject to varying levels of constraints for fluid minerals. Renewable energy development and aboveground transmission lines would be allowed within the planning area consistent with other resource values. The BLM manages lands with wilderness characteristics consistent with other resource objectives and only prohibits livestock use where it is currently prohibited under Alternative A. Alternative C limits off-highway vehicle (OHV) use to designated roads and trails, closes 28,900 acres, and seasonally closes 723,500 acres in big game crucial winter range. The BLM would allow land disposals, which could fragment native plant communities.

The emphasis on resource uses under Alternative C would reduce the amount of habitat protection for GRSG and its habitat. Impacts on GRSG under Alternative C would be similar to Alternative A (current management).

ES.5.4 Alternative D (Proposed RMP)

Compared to the other alternatives, Alternative D would generally allow resource use if the activity could be conducted in a manner that would conserve physical, biological, and heritage and visual resources. Alternative D would designate the second most lands as SRMAs and ACECs, while emphasizing moderate constraints on resource uses to reduce impacts on resource values. Alternative D places few universal constraints on resource uses and instead allows activities if they meet certain requirements designed to mitigate impacts on resource values. Under Alternative D, mineral resource uses are subject to less extensive constraints than under Alternative B but more than either Alternatives A or C. Alternative D would emphasize the use of designated corridors for major above- and below-ground infrastructure and would manage fewer acres as ROW exclusion for renewable energy development compared with Alternative B. Alternative D would also designate two new ACECs. Lands with wilderness characteristics would be managed to protect wilderness characteristics and emphasize ecosystem health, natural values, and primitive recreational opportunities. Alternative D limits OHV use to designated roads and trails on 661,700 acres and seasonally closes 18,300 acres in wintering big game habitat.

Compared to current management (Alternative A), Alternative D generally applies greater restrictions on surface disturbance and disruptive activities to protect sensitive wildlife habitats, including occupied GRSG leks. Alternative D implements the State of Wyoming's Core Area Strategy. For GRSG, constraints on resource uses are greater within PHMA than outside PHMA. For example, the BLM would apply an NSO stipulation within 0.6 mile of GRSG leks within PHMA and within 0.25 mile of occupied GRSG leks outside of PHMA.

ES.6 GREATER SAGE-GROUSE HABITAT MANAGEMENT PROPOSED PLAN AND ENVIRONMENTAL EFFECTS

In consideration of public comments, best science, cooperating agency coordination, and internal review of the Draft RMP/EIS, the BLM developed this Proposed Plan for Greater Sage-Grouse Habitat Management (Proposed Plan). The Proposed Plan represents the BLM's proposed approach for meeting the purpose and need consistent with the agency's legal and policy mandates.

The BLM Proposed Plan addresses threats to GRSG and its habitat identified by the USFWS in the March 2010 listing decision that apply to the Buffalo planning area as well as threats described in the COT report. The Proposed Plan seeks to provide greater regulatory certainty for management actions intended to conserve the GRSG (see **Table ES-2**, Key Components of the Buffalo Proposed Plan Addressing COT Report Threats). In making its determination of whether the GRSG is warranted to be listed as threatened or endangered under the ESA, the USFWS will evaluate the degree to which land use planning decisions proposed in this RMP/EIS address threats to GRSG and its habitat.

The Proposed Plan would maintain and enhance GRSG populations and habitat. The Proposed Plan benefits GRSG populations by eliminating disturbance near leks and other key areas.

The Proposed Plan establishes conditions, subject to valid existing rights, for new anthropogenic activities to ensure a net conservation gain to GRSG in PHMA. The Proposed Plan would reduce habitat disturbance and fragmentation through limitations on surface-disturbing activities, while addressing changes in resource condition and use through monitoring and adaptive management. The Proposed Plan provides a framework for prioritizing areas in PHMA for wildfire, invasive annual grass, and conifer treatments, which will maintain and enhance GRSG habitat.

The Proposed Plan is built upon the foundation for GRSG management established by and complementary to the Governor's Executive Order 2011-05, Greater Sage Grouse Core Area Protection (Core Area Strategy) (Wyoming Office of the Governor 2011) by establishing similar conservation measures and focusing restoration efforts in the same key areas most valuable to the GRSG.

For a full description of the Proposed Plan, see **Chapter 2**.

Table ES-2
Key Components of the Buffalo Proposed Plan Addressing COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Component of the Buffalo Proposed Plan
All Threats	<ul style="list-style-type: none"> • Implement the Adaptive Management Plan, which provides regulatory assurance that unintended negative impacts to GRSG habitat will be addressed before consequences become severe or irreversible. • PHMA: Require and ensure mitigation that provides a net conservation gain to GRSG. • Monitor implementation and effectiveness of conservation measures in GRSG habitats according to the Habitat Assessment Framework. • Apply Required Design Features (RDF) when authorizing actions in GRSG habitat. • Prioritize the leasing and development of fluid mineral resources outside GRSG habitat.
All development threats, including mining, infrastructure, and energy development	<ul style="list-style-type: none"> • PHMA: Implement an anthropogenic disturbance cap of 5% at the project-area scale. With Core Areas of PHMA, limit disturbance to 1 energy or mining facility per 640 acres. • PHMA: Implement a density cap of an average of 1 energy and mining facility per 640 acres. • PHMA: Surface occupancy and surface-disturbing activities would be prohibited on or within a 0.6-mile radius of the perimeter of occupied GRSG leks. • GHMA: Surface occupancy and surface-disturbing activities would be prohibited on or within a 0.25-mile radius of the perimeter of occupied GRSG leks.
Energy Development—Fluid Minerals	<ul style="list-style-type: none"> • PHMA: Open to fluid mineral leasing subject to No Surface Occupancy (NSO) stipulation within 0.6 miles of an occupied lek, and Timing Limitation (TL) stipulation from March 15 to June 30. • GHMA: Open to fluid mineral leasing subject to NSO within 0.25 miles of an occupied lek and TL stipulations.
Energy Development—Wind Energy	<ul style="list-style-type: none"> • PHMA: Avoidance area (may be available for wind energy development with special stipulations)
Infrastructure – major Rights-of-Way (ROW)	<ul style="list-style-type: none"> • PHMA: Avoidance area (may be available for major ROWs with special stipulations)
Infrastructure – minor ROWs	<ul style="list-style-type: none"> • PHMA: Avoidance area (may be available for minor ROWs with special stipulations)
Mining—locatable minerals	<ul style="list-style-type: none"> • Apply RDFs to locatable minerals consistent with applicable law.
Mining—coal	<ul style="list-style-type: none"> • PHMA is essential habitat for GRSG for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).
Livestock Grazing	<ul style="list-style-type: none"> • Prioritize the review and processing of grazing permits/leases in PHMAs. • The NEPA analysis for renewals and modifications of grazing

Table ES-2
Key Components of the Buffalo Proposed Plan Addressing COT Report Threats

Threats to GRSG and its Habitat (from COT Report)	Key Component of the Buffalo Proposed Plan
	<p>permits/leases will include specific management thresholds, based on the GRSG Habitat Objectives Table, Land Health Standards, and ecological site potential, to allow adjustments to grazing that have already been subjected to NEPA analysis.</p> <ul style="list-style-type: none"> • Prioritize field checks in PHMAs to ensure compliance with the terms and conditions of grazing permits.
Free-Roaming Equid Management	<ul style="list-style-type: none"> • Not applicable to the planning area.
Range Management Structures	<ul style="list-style-type: none"> • Allow range improvements which do not impact GRSG, or which provide a conservation benefit to GRSG such as fences for protecting important seasonal habitats.
Recreation	<ul style="list-style-type: none"> • PHMA: Do not construct new recreation facilities.
Fire	<ul style="list-style-type: none"> • PHMA: Prioritize suppression immediately after life and property to conserve the habitat. • GHMA: Prioritize suppression where wildfires threaten PHMA.
Nonnative, Invasive Plants Species	<ul style="list-style-type: none"> • Improve GRSG habitat by treating annual grasses. • Treat sites in PHMA and GHMA that contain invasive species infestations through an integrated pest management approach.
Sagebrush Removal	<ul style="list-style-type: none"> • PHMA: Maintain a minimum of 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover. • All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives for GRSG.
Pinyon and/or Juniper Expansion	<ul style="list-style-type: none"> • Remove conifers encroaching into sagebrush habitats, prioritizing occupied GRSG habitat.
Agricultural Conversion and Ex-Urban Development	<ul style="list-style-type: none"> • Retain the majority of PHMA in federal management.

ES.7 SUMMARY

Since the release of the Draft Buffalo RMP/EIS, the BLM has continued to work closely with a broad range of governmental partners, including the United States Department of Agriculture Natural Resources Conservation Service, the USFWS and US Geological Survey in DOI, Indian tribes, governors, state agencies, and county commissioners. Through this cooperation, the BLM has developed the Proposed Plan that, in accordance with applicable law, achieves the long-term conservation of GRSG and its habitat.

Conservation of GRSG is a large-scale challenge that requires a landscape-scale solution that spans 11 western states. The Buffalo RMP/EIS would achieve the consistent, range-wide conservation objectives as outlined below. Additionally, the Buffalo RMP/EIS would align with the State of Wyoming's priorities and land management approaches.

Minimize additional surface disturbance. The most effective way to conserve the GRSG is to protect existing, intact habitat. The BLM would aim to reduce habitat fragmentation and protect key habitat areas. The Buffalo RMP/EIS would minimize surface disturbance on over 700,000 acres of BLM-administered lands by allocating lands as PHMA and GHMA with decisions that aim to conserve GRSG habitat.

The limitations on mineral and ROW development along with the disturbance cap, lek buffers, and adaptive management would result in a net conservation gain for GRSG. The Proposed Plan prioritizes oil and gas development outside of GRSG habitat and focuses on a landscape-scale approach to conserving GRSG habitat. In the context of the planning area, land use allocations under the Proposed Plan would limit or eliminate new surface disturbances in PHMA.

The BLM also updated the Proposed Plan to reflect new GRSG state conservation strategies, including recent State Executive Orders. The objectives of these documents are consistent with the State of Wyoming's Core Area Strategy, which is designed to protect GRSG and its habitat within core areas using a suite of tools and mechanisms that work in concert to conserve GRSG by reducing habitat loss and fragmentation through lek buffers, disturbance limits, excluding activities, and a sophisticated mapping utility to monitor the amount and density of disturbance.

Improve habitat condition. While restoring lost sagebrush habitat can be very difficult in the short term, particularly in the most arid areas, it is often possible to enhance habitat quality through purposeful management. The Buffalo RMP/EIS commits to management actions necessary to achieve science-based vegetation and GRSG habitat management objectives established in the Proposed Plan.

Habitat restoration and vegetation management actions would improve GRSG habitat and prioritize restoration to benefit PHMA. As a result, the restoration and management of vegetation actions would focus on GRSG. For mitigation, the BLM would coordinate with the Wyoming Sage Grouse Implementation Team for application of the "avoid, minimize, compensate" process to ensure anthropogenic activities result in a net conservation gain for GRSG habitat. The Proposed Plan also includes a process for monitoring and adapting to changing conditions on the landscape. Using monitoring data for population and sagebrush canopy cover, the adaptive management strategy would apply more restrictive management where there is a consistent downward trend. The cause

of the downward trend (e.g., anthropogenic disturbance, fire, disease, etc.) would be identified through monitoring data.

Reduce threat of rangeland fire to sage-grouse and sagebrush habitat

Rangeland fire can destroy sagebrush habitat and lead to the conversion of previously healthy habitat into landscapes dominated by invasive species. The Buffalo RMP/EIS incorporates Secretarial Order 3336 and sets forth protocols to improve the BLM's ability to protect GRSG habitat from damaging wildfire. Prescribed fire would only be used to improve or maintain habitat for GRSG and would be only be used to meet specific fuels objective standards.

Reader's Guide to this Document

Chapter 1. Purpose and Need for Action. This chapter introduces the Proposed Resource Management Plan (RMP) and Final Environmental Impact Statement (EIS), describes the purpose and need to which the Bureau of Land Management (BLM) is responding, provides an overview of the BLM planning process, identifies planning issues and criteria, summarizes consultation and coordination, and identifies topics not addressed by this RMP revision.

Chapter 2. Resource Management Alternatives. Chapter 2 describes how the four alternatives (A through D) were developed, the components and content of each alternative, and discusses the alternatives considered but eliminated from further consideration. It also presents a comparative summary of impacts of each alternative. Resource discussions in chapters 2, 3, and 4 are organized according to the following eight resource topics:

1000. Physical Resources – Air Quality, Geological Resources, Soil, Water Resources, and Cave and Karst Resources

2000. Mineral Resources – Locatable, Leasable, and Salable Minerals

3000. Fire and Fuels Management – Unplanned Fire (Wildfire), Planned Fire (Prescribed Fire), and Stabilization and Rehabilitation

4000. Biological Resources – Vegetation, Fish and Wildlife, and Special Status Species

5000. Heritage and Visual Resources – Cultural, Paleontological, and Visual

6000. Land Resources – Forest Products, Lands and Realty, Renewable Energy, Rights-of-Way and Corridors, Travel and Transportation Management, Recreation, Lands with Wilderness Characteristics, and Livestock Grazing Management

7000. Special Designations – Areas of Critical Environmental Concern, Scenic or Back Country Byways, Wild and Scenic Rivers, and Wilderness Study Areas

8000. Socioeconomic Resources – Social and Economic Conditions, Health and Safety, Environmental Justice, and Tribal Treaty Rights

Chapter 3. Affected Environment. This chapter describes the planning area and the existing environmental conditions that could be impacted by the alternatives.

Chapter 4. Environmental Consequences. Chapter 4 forms the scientific and analytic basis for comparing environmental impacts of each alternative. Impacts generally are described in terms of direct or indirect and short-term or long-term, when applicable. Potential cumulative and unavoidable impacts and irreversible and irretrievable commitments also are discussed in this chapter.

Chapter 5. References. This chapter provides full citation information for all references cited within the document.

Chapter 6. List of Preparers. This chapter provides a list of the names and project roles of the individuals involved in the preparation of this document.

Glossary. The glossary defines select terms used throughout this document.

Appendices. The appendices include documents that support existing resource conditions or situations, substantiate analyses, provide resource management guidance, explain processes, or provide information directly relevant or supporting conclusions in the Proposed RMP and Final EIS. Maps referenced in the Proposed RMP and Final EIS are included as a separate appendix. In hardcopy documents, maps are included at the end of Volume 3 and the other appendices can be found on a compact disk (CD) attached to the inside back cover of the document. For CD versions of the document, the maps and appendices are provided as separate files on the CD. Electronic versions of the maps and appendices are also available on the project website: <http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo.html>. Twenty-five appendices are included.

Chapter 1. Purpose and Need for Action

This page intentionally
left blank

1.1. Introduction and Background

This Proposed Resource Management Plan (RMP) and Final Environmental Impact Statement (EIS) describes and analyzes alternatives for the future management of public lands and resources administered by the United States Department of the Interior (DOI) Bureau of Land Management (BLM) within the Buffalo Field Office (BFO). Located in north-central Wyoming (Figure 1.1, “Buffalo Field Office Resource Management Plan Planning Area” (p. 3)), the planning area covers approximately 7.4 million acres of federal, state, and private land in three adjacent counties. Of the total area, approximately 780,000 acres are BLM-administered federal surface lands and 4.8 million acres are BLM-administered federal mineral estate.

BLM-administered lands within the planning area are currently managed according to the 1985 Buffalo RMP as updated by the 2001 Buffalo RMP Update and amended by the 2003 Record of Decision (ROD) for the Powder River Basin Oil and Gas Project and Decision Record for the 2011 Fortification Creek RMP Amendment/Environmental Assessment (EA) (BLM 2011c). Shaded text in this document identifies substantive changes between the Draft RMP and EIS and the Proposed RMP and Final EIS. The Buffalo RMP revision is anticipated to be completed by fall 2014.

1.1.1. Land Ownership within the Planning Area

As defined by Federal Land Policy and Management Act (FLPMA), “... public lands means any land and interest in land owned by the United States within the several states and administered by the Secretary of the Interior through the Bureau of Land Management ...” The BFO is responsible for managing public lands in Wyoming’s Campbell, Johnson, and Sheridan counties. County governments have land use planning responsibility for the private lands located within their jurisdictions.

BLM surface exists in scattered tracts throughout the planning area with the largest blocks of contiguous BLM-administered surface lands existing in the center and southwest portions of the planning area (Map 1). There are also large portions of the planning area with intermingled mineral ownerships.

The mineral estate under BLM surface in the planning area is generally federally owned. Mineral estate (shown on Map 2) is determined based on the content of patent documents. The following are common abbreviations used on BLM Master Title Plats (MTPs) to indicate the federal ownership of particular minerals for surface estate that is not federally owned: “All Min” (all minerals), “Coal” (only coal), “Coal OG” (only coal, oil, and gas), “OG” (only oil and gas), and “Coal OG Sod Pot” (only coal, oil, gas, sodium, and potassium). There may also be other abbreviations used to denote other federal mineral ownerships, but are much less common (see Chapter 3 — *Minerals*).

The federal government classifies minerals into locatables, leasables, and salables. The federal government owns all locatable minerals and salable minerals in lands with federal mineral ownership type “All Min.”

Leasable mineral estate can be held for a particular mineral or group of minerals. For example, federal coal includes ownership types “All Min,” “Coal,” “Coal OG,” and “Coal OG Sod Pot,” and federal oil and gas includes ownership types “All Min,” “Coal OG,” “OG,” and “Coal OG Sod Pot.” Leasable minerals other than coal and oil and gas are mentioned in Chapter 3 – *Minerals*.

Lands where the ownership of the surface estate and mineral estate differ are referred to as split estate. In these situations, mineral rights are considered the dominant estate, meaning they take precedence over other rights associated with the property, including those associated with owning the surface. The areas with scattered surface land ownership patterns and varied mineral ownerships, along with split estate lands, affect BLM management options. See Appendix X (p. 2661) for additional information.

Table 1.1, “Acreage of Surface Lands Within Each Jurisdiction of the Buffalo Planning Area” (p. 2) and Table 1.2, “Acreage of BLM-administered Mineral Estate within Each County in the Planning Area” (p. 2) provide summaries of the surface and mineral estate and administrative relationships for the planning area. The Approved RMP will not include planning and management decisions for lands or minerals administered by other federal agencies, privately owned, or owned by the State of Wyoming or local governments.

Table 1.1. Acreage of Surface Lands Within Each Jurisdiction of the Buffalo Planning Area

Agency	Campbell County	Johnson County	Sheridan County	Total
Bureau of Land Management	224,010	504,368	53,724	782,102
Department of Defense	0	0	4,166	4,166
Bighorn National Forest	0	328,220	389,228	717,447

State	195,332	220,908	122,366	538,606
Water	0	2,148	0	2,148
Total	3,066,940	2,670,098	1,619,337	7,356,374

Source: BLM 2012f

Table 1.2. Acreage of BLM-administered Mineral Estate within Each County in the Planning Area

Mineral	Campbell County	Johnson County	Sheridan County	Total
Total ¹	2,418,761	1,682,668	701,848	4,803,277
Locatables	1,599,141	1,412,726	336,254	3,348,121
Leasable – Coal	2,411,562	1,663,142	700,432	4,775,136
Leasable – Fluids	1,611,915	1,434,092	340,523	3,386,530
Salables	1,599,141	1,412,726	336,254	3,348,121

Source: BLM 2012f

¹Acreage values are not cumulative. As described below, the federal government may manage multiple mineral resources on a given land parcel.

BLM Bureau of Land Management

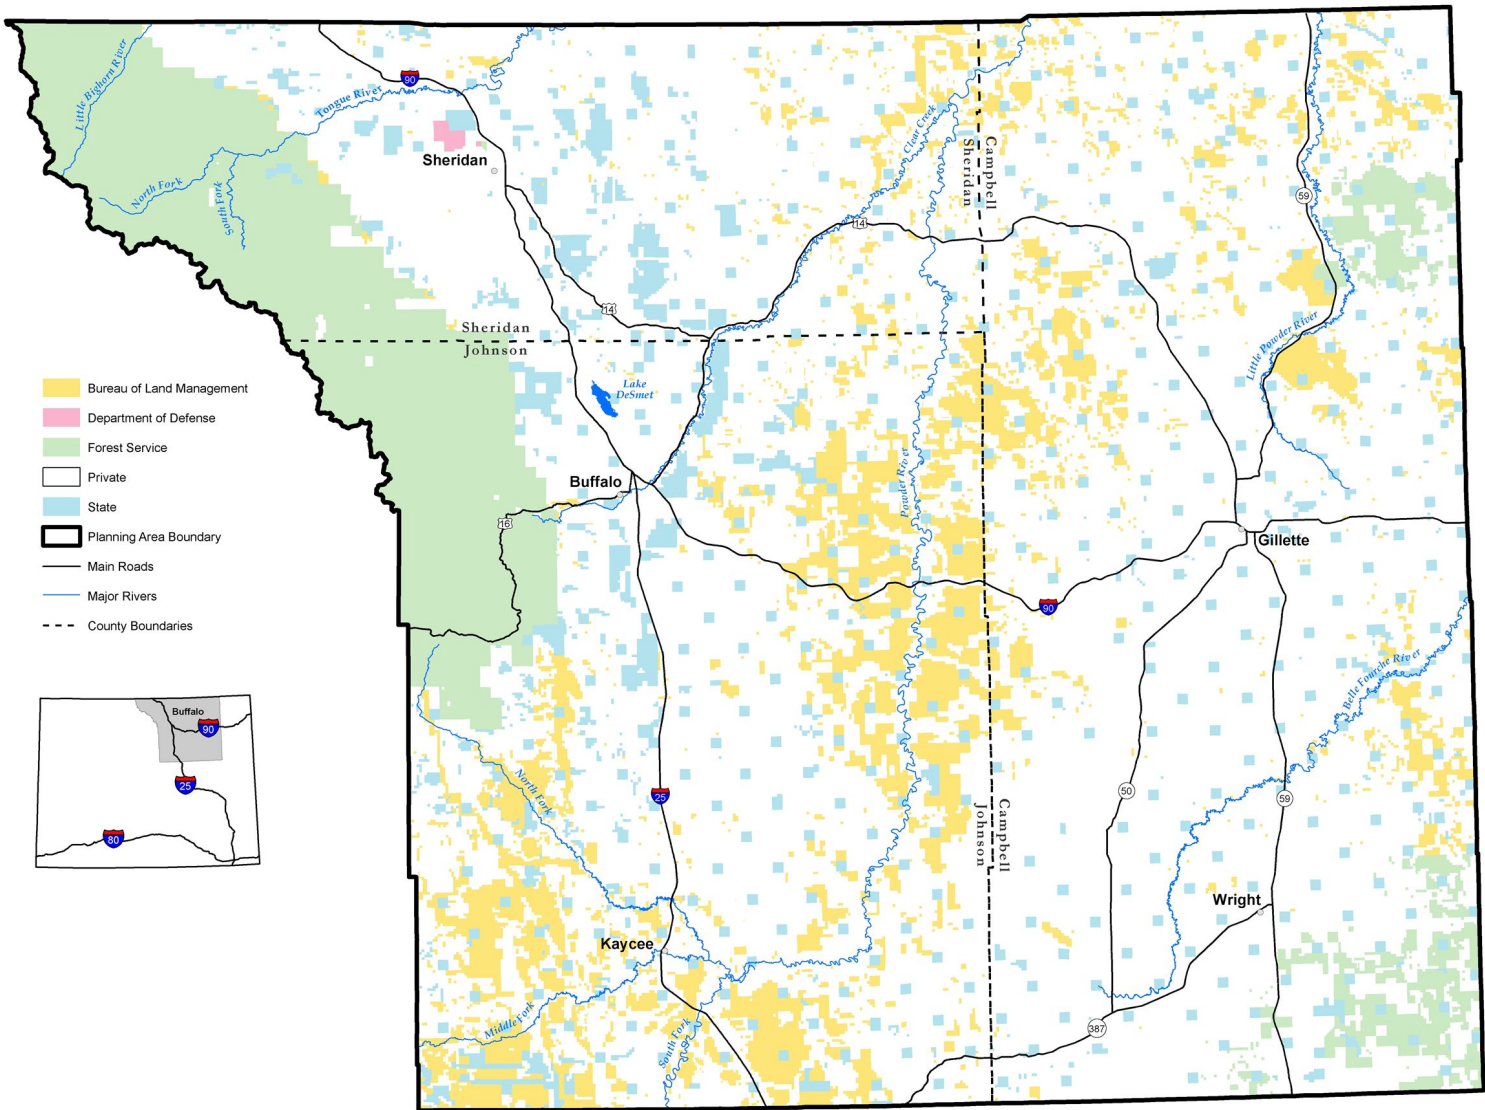

Figure 1.1. Buffalo Field Office Resource Management Plan Planning Area

1.2. Purpose and Need for the Resource Management Plan Revision

1.2.1. Purpose

An RMP is a land use plan that provides direction for managing public lands administered by the BLM in accordance with its multiple use mandate. The FLPMA directs the BLM to develop such land use plans to provide for appropriate uses of public land. Decisions in land use plans guide future land management actions and subsequent site-specific implementation decisions. The RMP establishes goals and objectives (desired outcomes) for resource management and the measures needed to achieve them. These measures are expressed as management actions and allowable uses (i.e., lands that are open or available for certain uses [including any applicable restrictions] and lands that are closed to certain uses). The purpose of revising the existing plan is to address conditions within the planning area that have changed and to evaluate new information in order to develop a management strategy that achieves a combination of the following:

- Employ a community-based planning approach to seek broadly supported solutions to issues, and collaborate with federal, state, and local cooperating agencies.
- Establish goals and objectives (desired outcomes) for management of resources and resource uses within the approximately 780,000 surface acres and 4.8 million acres of federal mineral estate in the planning area administered by the BLM in accordance with the principles of multiple use and sustained yield.
- Identify land use plan decisions to guide future land-management actions and subsequent site-specific implementation decisions.
- Identify management actions and allowable uses anticipated to achieve the established goals and objectives and reach desired outcomes.
- Provide comprehensive management direction by making land use decisions for all appropriate resources and resource uses administered by the BLM in the planning area or by updating existing decisions.
- Provide for compliance with applicable tribal, federal, and state laws, standards, implementation plans, and BLM policies and regulations.
- Recognize the Nation's needs for domestic sources of minerals, food, timber, and fiber, and incorporate requirements of the Energy Policy Act of 2005 (Pub. L. 2005).
- Retain flexibility to adapt to new and emerging issues and opportunities and to provide for adjustments to decisions over time based on new information and monitoring.
- Strive to be compatible with existing plans and policies of adjacent local, state, tribal, and federal agencies while complying with federal law, regulations, and BLM policy.

1.2.2. Need for Revising the Existing Plan

New data have become available, and laws, regulations, and policies regarding management of these public lands have changed. For example; the revised RMP will incorporate appropriate management actions and practices to conserve Greater Sage-Grouse and its habitat on BLM managed lands. In addition, the existing plan's decisions do not satisfactorily address all of the new and emerging issues in the planning area. These changes have resulted in the need to revise the existing plan. The BLM identified the need, or requirement, to revise the existing plan through a formal evaluation of the existing plan, consideration of the Analysis of the Management Situation (AMS) (BLM 2009h), examination of issues identified during the public involvement

process known as scoping, and through collaboration with cooperating local, state, and federal agencies.

New Data

Monitoring, availability of new information, and advances in science and technology provide new data to consider in the revision of the existing plan. Select new data can be found in the following documents and sources:

- BLM Assessing the Potential for Renewable Energy on Public Lands (BLM 2003a)
- Buffalo RMP Revision Analysis of the Management Situation (BLM 2009h)
- Buffalo Mineral Occurrence and Development Potential Report (BLM 2009c)
- BLM Wyoming Statewide Programmatic Endangered Species Act (ESA) Consultations:

- Fortification Creek RMP Amendment/EA (BLM 2011c)
- Energy Policy Act of 2005
- BLM Manual 6320 – Considering Lands with Wilderness Characteristics in the BLM Land Use Planning Process (BLM 2012b)
- DOI Order 3294 – Energy Management Reform (DOI 2010b)

New and Revised Policies

Numerous policies either have been revised or developed since the ROD for the existing plan was signed. A complete list of relevant policies, including new and revised policies, and their effective dates is identified in Appendix A (p. 1771).

The BLM released Handbook H-8320-1, Planning for Recreation and Visitor Services on August 22, 2014. The handbook assists BLM staff in the planning and management of recreation and visitor services on public land. The release of the handbook coincided with the final development of the Proposed RMP/Final EIS. Accordingly, not all recreation and visitor services decisions in this Proposed RMP/Final EIS follow the recommended format provided in the handbook. However, the Proposed RMP/Final EIS complies with the requirements for establishing desired conditions, allowable uses and actions related to the management of recreation and visitor services as discussed in Handbook H-8320-1.

Emerging Issues and Changing Circumstances

Emerging issues and changes in local, regional, and national circumstances to consider when revising the existing plan include the following:

- Increasing and conflicting demands on the planning area's resources
- Increasing complexity of resource management issues
- Changes in resource and resource condition monitoring tasks and the entities conducting monitoring
- Changes in the legal status of plants and wildlife occurring or potentially occurring in the planning area
- Increasing conflicts between resource uses and protection of specific wildlife and wildlife habitat
- Greater Sage-Grouse population viability
- Maintaining public access to public lands
- The spread of invasive plant and animal species on public lands
- Changing demand for energy and minerals development
- Increased interest in renewable energy development across the nation
- The management of riparian areas and water quality concerns
- Fire and fuels management practices and changes in national fire policy
- Changes in livestock grazing practices and rangeland conditions
- Changes in recreation and visitor use levels and locations
- The management and protection of recently discovered cultural and paleontological resources
- Addressing travel management, including increases in off-highway vehicle (OHV) use
- The appropriateness of certain withdrawals, land tenure adjustments, land use authorizations, and Rights-of-Way (ROWs) to include utility corridors ROWs
- Cumulative increase in surface disturbance due to mining and oil and gas activities
- Achieving reclamation success after mineral development activities
- Identification of unique or sensitive areas that meet the criteria for special designation
- Increasing air quality issues affecting human health and regulatory compliance
- Changes to visual resources classifications

Greater Sage-Grouse Management

In March, 2010 the U.S. Fish and Wildlife Service (USFWS) published its decision that listing of the Greater Sage-Grouse as a threatened or endangered species under the ESA was "Warranted but Precluded." Inadequacy of regulatory mechanisms was identified as a major threat in the USFWS finding on the petition to list the Greater Sage-Grouse. The USFWS has identified the

principal regulatory mechanism for the BLM as conservation measures in RMPs. Based on the identified threats to the Greater Sage-Grouse and the USFWS timeline for making a listing decision on this species, the BLM needs to incorporate objectives and adequate conservation measures into RMPs in order for the USFWS to constitute these RMP measures as adequate regulatory mechanisms that conserve the Greater Sage-Grouse, thus contributing to the avoidance of potentially listing the Greater Sage-Grouse.

On November 21, 2014 the U.S. Geological Survey (USGS) published “Conservation Buffer Distance Estimates for Greater Sage-Grouse – A Review” (Open File Report 2014-1239). The USGS review provided a compilation and summary of published scientific studies that evaluated the influence of anthropogenic activities and infrastructure on Greater Sage-Grouse populations. The BLM has reviewed this information and examined how lek buffer-distances were addressed through land use allocations and other management actions in the Draft Buffalo RMP/EIS. The State of Wyoming’s Core Population Area Strategy is designed to protect birds and habitat within core population areas using a suite of tools and mechanisms that work in concert to conserve Greater Sage-Grouse by reducing habitat loss and fragmentation through lek buffers, disturbance limits, excluded activities, and a sophisticated mapping utility to monitor the amount and density of disturbance. The USFWS has informed the BLM that the combined effect of these overlapping and reinforcing mechanisms give USFWS confidence that the lek buffer distances in the Core Population Area Strategy will be protective of breeding Greater Sage-Grouse.

This RMP revision incorporates specific management actions and conservation measures to conserve Greater Sage-Grouse and its habitats on public land.

1.3. Planning Process

The RMP provides basic program direction with the establishment of goals, objectives, and allowable uses. The RMP focuses on what resource conditions, uses, and visitor experiences should be achieved and maintained over time. Since this involves considering natural processes with long-term timeframes, the RMP must take a long-term view.

The planning process is the result of the FLPMA requirement to manage lands under comprehensive plans and the National Environmental Policy Act (NEPA) requirement to analyze alternatives in an EIS and evaluate and disclose impacts for all major federal actions with the potential to result in significant impacts. This EIS analyzes four alternatives, including the NEPA-required No Action Alternative.

1.3.1. BLM Planning Process

Figure 1.2, “BLM Planning Process” (p. 8) illustrates the planning process used to develop and revise RMPs as required by 43 Code of Federal Regulations (CFR) 1600 and planning program guidance in the BLM Handbook H-1601-1, Land Use Planning Handbook (BLM 2005b). The planning process is designed to help the BLM identify the uses of BLM-administered lands desired by the public and to consider these uses to the extent they are consistent with the laws established by Congress and the policies of the executive branch of the federal government.

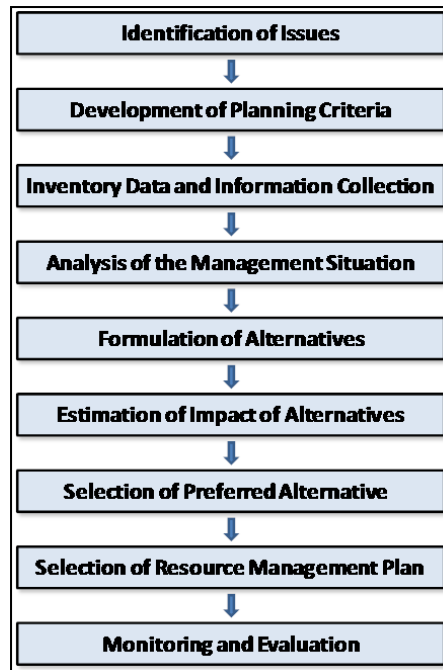

Figure 1.2. BLM Planning Process

The planning process is issue-driven. The BLM utilized the public scoping process to identify planning issues. The scoping process also was used to introduce the public to preliminary planning criteria, and define the scope of the RMP revision.

The BLM collected data to address planning issues and to fill data gaps identified during public scoping. Using this data, the planning issues, and the planning criteria, the BLM conducted an AMS to describe current management and identify management opportunities for addressing the planning issues. Current management reflects management under the existing RMP and management that would continue through selection of the No Action Alternative.

The first steps of the planning process clarified the purpose and need and identified key planning issues to be addressed by the RMP revision. Key planning issues reflect the focus of the RMP revision and are described in more detail in the *Planning Issues* section.

During alternative formulation, the BLM collaborated with cooperating agencies to identify goals and desired outcomes for resources and resource uses in the planning area. These desired outcomes addressed the key planning issues, were constrained by the planning criteria, and incorporated the management opportunities identified by the BLM.

The details of alternatives were filled in through the development of management actions and allowable uses anticipated to achieve the goals and objectives. The alternatives represent a reasonable range for managing resources and resource uses within the planning area. Chapter 2 of this document describes and summarizes the alternatives.

The BLM analyzed the impacts of each alternative in Chapter 4. With input from cooperating agencies and BLM specialists, and consideration of planning issues, planning criteria, and the impacts of alternatives, the BLM selected Alternative D as the Preferred Alternative and published the plan in the Draft RMP and EIS.

The Draft RMP and EIS was published on June 28, 2013, initiating the 90-day public comment period that closed on September 26, 2013. Following receipt and consideration of public comments on the Draft RMP and EIS, the BLM prepared this Proposed RMP and Final EIS.

The publication of the Notice of Availability in the FR for this Proposed RMP and Final EIS initiated a 30-day protest period and 60-day Governor's consistency review period. The BLM will resolve protests and the Governor's recommended changes and prepare a ROD and Approved RMP.

1.3.2. Resource Management Plan Implementation

After issuing the Approved RMP and ROD, an Implementation Strategy will be developed. The Implementation Strategy will include an annual coordination meeting between the BLM and the agencies cooperating in the RMP revision. The annual coordination meeting will include an update on implementation of the plan, foreseeable activities for the upcoming year, and opportunities for continued collaboration with the RMP cooperators. Additional coordination meetings could be held as needed.

Planning and decision making for the management of public lands is a hierarchal process. The hierarchy of documents that BLM decision-makers consider for planning and project implementation is:

- **Land Use Plans.** The highest level of decision-making specific to land use is the resource management plan (RMP). RMPs generally make land allocations and provide goals and objectives for managing specific areas of land. They provide the framework for managing all natural resources under BLM authority for the planning area. Plan decisions are based on a public NEPA disclosure process, usually an EIS.
- **Activity Plans.** Mid-level decisions are provided in activity plans. These plans contain more detailed management decisions than do RMPs. Activity plans address management of specific programs or areas. Examples include allotment management plans, recreation area management plans, and habitat management plans. An activity plan usually selects and applies best management practices to meet land use plan objectives. Decisions that cover major (often geographically widespread) proposals lead to coordinated activity plans that cover all programs in an integrated manner.
- **Project Plans.** The BLM analyzes individual projects proposed in a specific location for localized or site-specific effects. For example, the BLM would evaluate a range improvement proposal with a site-specific environmental analysis including NEPA, Endangered Species Act (ESA) consultation, and National Historic Preservation Act (NHPA) consultation.

1.4. Decision Framework

As described in the previous section, identifying the planning issues and developing planning criteria (discussed in detail below) are the first steps in defining the scope of the RMP revision. The planning issues and planning criteria provide the framework in which RMP decisions are made. RMP decisions refer to what is established or determined by the final RMP. For example, the BLM received nominations (issues) for Areas of Critical Environmental Concern (ACECs). These issues fall within one of the planning criteria (see *Planning Criteria* section), the need to identify and analyze areas potentially suitable for ACEC designation. The RMP revision

will establish (decide) whether any ACEC will be designated within the planning area. In this example, the land use planning decision is referred to as a special designation. The RMP provides guidance for land use planning decisions according to the following categories:

- Physical, biological, and heritage resources
- Resource uses and support
- Special designations

In the context of these categories, the planning team develops management strategies aimed at providing viable options for addressing planning issues. The management strategies provide the building blocks from which general management scenarios and, eventually, the more detailed resource management alternatives, are developed. The resource management alternatives reflect a reasonable range of management options that fall within the planning criteria. The following sections describe the planning issues and planning criteria used to revise the existing plan.

1.4.1. Planning Issues

The BLM conducted public scoping to determine the issues to be addressed in this RMP EIS. As part of the scoping process, the BLM solicited comments and issues from the public, organizations, tribal governments, and federal, state, and local agencies, as well as from BLM specialists. The BLM's Land Use Planning Handbook (BLM 2005b) defines planning issues as "...disputes or controversies about existing and potential land and resource allocations, levels of resource use, production, and related management practices." Issues identified during the scoping and RMP revision process for this EIS comprise two categories:

- Issues within the scope of the EIS and used to develop alternatives or otherwise addressed in the EIS.
- Issues outside the scope of the EIS or that could require policy, regulatory, or administrative actions.

Issues determined to be within the scope of the EIS were used to develop one or more of the alternatives or are addressed in other parts of the EIS. For example, as planning issues were refined, the BLM collaborated with cooperating agencies to develop a reasonable range of alternatives designed to address or resolve key planning issues, such as what areas are suitable for energy and mineral resource development. A reasonable range of alternatives provides various management approaches for how the BLM and cooperating agencies can address this and other key planning issues, including the management of resources and resource uses in the planning area. In other words, key planning issues serve as the rationale for alternative development. The preliminary key planning issues identified from scoping are presented below.

Air Quality and Climate Change

- How can the BLM manage activities occurring on public lands to ensure they do not contribute to air quality-related impacts to human health or resource values?
- How should the BLM incorporate consideration of climate change into its land management practices?

Water Quality and Riparian/Wetlands Areas

- How should the BLM manage the use and development of public lands to ensure surface and groundwater resources are available and of sufficient quality for public, wildlife, and other uses?

- How can BLM-administered lands be managed to protect wetland and riparian areas?

Mineral and Energy Resources

- Which areas should be open to mineral and energy development and how will the BLM address issues related to split estate lands?
- What management and leasing actions are needed for mineral and energy developments to protect natural, biological, and cultural resources?

Biological Resources: Vegetation, Fish, Wildlife, and Special Status Species

- What management actions or development actions are needed to protect, improve, or restore terrestrial and aquatic habitats for fish, wildlife, and special status species?
- How can BLM management sustain ecosystem health while providing for multiple uses?
- In March 2010, the USFWS determined that the Greater Sage-Grouse warranted protection under the ESA, but that listing the species was precluded by the need to address other, higher-priority species first (75 Federal Register [FR] 13910, March 23, 2010). One reason for the USFWS decision was an identified need for “improved regulatory mechanisms” to ensure species conservation. The principal regulatory mechanisms for the BLM are RMPs, therefore, the BLM is using this opportunity to develop long-term and effective management for the species on BLM-administered lands (WO IM No. 2012-044).

Invasive Species and Pest Management

- What development stipulations and management actions are appropriate to control and prevent the spread of noxious weeds, pests, and invasive species?

Cultural and Paleontological Resources and Tribal Concerns

- How can the BLM protect paleontological resources, cultural and heritage sites, and traditional cultural properties?
- How can the BLM effectively involve Native Americans in BLM management and decision making?

Lands and Realty and Rights-Of-Way

- How can land tenure and management adjustments be used for access and development, while also protecting natural, biological, and cultural resource values?
- Which areas should be available for renewable energy development and how should this development be managed to protect other resource values and uses?

Travel and Transportation Management

- How should travel, including OHV use be managed for recreational and commercial access, while also protecting natural, biological, and cultural resources?

Recreation

- How should the BLM manage recreation on public lands to provide a full spectrum of recreational opportunities, while ensuring public safety and the protection of resources values?

Livestock Grazing Management

- How should the BLM manage livestock grazing on public lands to ensure the protection of natural, biological, and cultural resources while maintaining grazing-dependent socioeconomic and heritage values?

Special Designations

- What areas contain sensitive resources requiring special management and what, if any, special designations are appropriate to protect them?

Socioeconomic Resources

- How can the BLM protect natural, biological, and cultural resources while managing BLM-administered lands to support local economies and traditions tied to these lands?

In addition to key planning issues, other issues, themes, and positions were identified during the scoping process. Those issues determined to be outside the scope of the EIS or that would require policy, regulatory, or administrative actions to be addressed were not used to develop alternatives and were not carried forward in this Proposed RMP and EIS.

For a detailed description of all issues identified during scoping, please refer to the Buffalo RMP Revision Project Final Scoping Report (BLM 2009d). This scoping report describes the public involvement process and the issues identified by the public. The report is available on the Buffalo RMP Revision website, <http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo.html>.

1.4.2. Planning Criteria

Planning criteria are the standards, rules, and guidelines that help to guide the RMP planning process. These criteria influence all aspects of the planning process, including inventory and data collection, developing issues to address, formulating alternatives, estimating impacts, and selecting the Preferred Alternative and the Proposed RMP. In conjunction with the planning issues, planning criteria ensure that the planning process is focused and incorporates appropriate analyses. Planning criteria are developed from appropriate laws, regulations, and policies. The criteria also help to guide the final plan selection and are used as a basis for evaluating the responsiveness of the planning options.

The planning criteria for this RMP revision are as follows:

- The proposed RMP will be in compliance with the FLPMA and all other applicable laws, regulations, and policies.
- Impacts from the management alternatives considered in the revised RMP will be analyzed in an EIS developed in accordance with regulations at 43 CFR 1610 and 40 CFR 1500.
- Lands covered in the RMP will be public land including split estate managed by the BLM. No decisions will be made relative to non-BLM-administered lands.

- The planning process will follow 10 stages of an EIS-level planning process: conducting scoping, development of an AMS report, formulation of alternatives, analysis of the alternatives' effects, selection of a preferred alternative, publication of a Draft RMP and EIS, providing a 90-day public comment period for the Draft RMP and EIS, preparation and publication of a Proposed RMP and Final EIS, providing a 30-day public protest period, and preparation of a ROD. For specific information, please see the Land Use Planning Handbook, H-1601-1.
- For program specific guidance of land use planning level decisions, the process will follow the Land Use Planning Manual 1601 and Handbook H-1601-1, Appendix C.
- Broad-based public participation will be an integral part of the planning and EIS process.
- Decisions in the plan will strive to be compatible with the existing plans and policies of adjacent local, state, federal, and tribal agencies to the extent those plans and policies are also consistent with the purposes, policies, and programs of federal law, and regulations applicable to public lands.
- The RMP will recognize the state's responsibility and authority to manage wildlife. The BLM will consult with the Wyoming Game and Fish Department (WGFD).
- The National Greater Sage-Grouse Habitat Conservation Strategy (BLM 2004b) requires that impacts to sagebrush habitat and sagebrush-dependent wildlife species (including Greater Sage-Grouse) be analyzed and considered in BLM land use planning efforts for the public lands with Greater Sage-Grouse sagebrush habitats.
- The BLM will utilize the WAFWA Conservation Assessment of Greater Sage-Grouse and Sagebrush Habitats (Connelly et al. 2004), and any other appropriate resources, to identify Greater Sage-Grouse habitat requirements and best management practices.
- The RMP will comply with WO IM-2012-044 and address public comments received during national scoping related to WO IM-2012-044 implementation.
- The RMP will recognize valid and existing rights.
- The RMP and EIS will incorporate management decisions brought forward from existing planning documents including but not limited to the 2003 Powder River Basin Oil and Gas Project Final EIS and RMP Amendment (BLM 2003c) and the 2011 Fortification Creek Planning Area Final RMP Amendment (BLM 2011c).
- The planning team will work cooperatively and collaboratively with cooperating agencies and all other interested groups, agencies, and individuals.
- The BLM and cooperating agencies will jointly develop alternatives for resolution of resource management issues and management concerns.
- The planning process will incorporate the Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for Public Lands Administered by the BLM in the State of Wyoming as goal statements.
- The BLM will identify lands with wilderness characteristics and analyze a range of management alternatives for this resource, pursuant to BLM Manuals 6310 and 6320.
- Areas with special environmental qualities will be designated as ACECs or other appropriate designations if necessary for their protection.
- Suitable segments of Wild and Scenic Rivers will be managed pursuant to Manual 6400 to protect or enhance the free-flowing condition, water quality, tentative classification, and any outstandingly remarkable values of suitable river segments until Congress designates the river or releases it for other uses. This RMP revision effort will analyze future management options should Congress release the suitable segment to other uses..
- Wilderness Study Areas (WSAs) will be managed pursuant to BLM Manual 6330 – Management of Wilderness Study Areas, which replaces the Interim Management Policy for Lands Under Wilderness Review, until Congress either designates all or portions of the WSA

as wilderness or releases the lands to other uses. This RMP revision effort will analyze future management options should Congress release any WSAs to other uses.

- Forest management strategies will be consistent with the Healthy Forests Restoration Act.
- The Wyoming High Plains District (WHPD) Fire Management Plan (FMP) will be updated to reflect objectives from this RMP, and will be implemented to address fire management on a landscape level.
- Geographic Information System (GIS) and metadata information will meet Federal Geographic Data Committee standards, as required by EO 12906. All other applicable BLM data standards will also be followed.
- The planning process will involve American Indian Tribal governments and will provide strategies for the protection of recognized traditional uses.
- All proposed management actions will be based upon current scientific information, research and technology, as well as existing inventory and monitoring information.
- The RMP will include adaptive management criteria and protocols to deal with future issues.
- The planning process will use the Wyoming BLM Mitigation Guidelines to develop management options and alternatives and analyze their impacts as well as part of the planning criteria for developing the options and alternatives and for determining mitigation requirements.
- A RFD scenario for fluid minerals will be developed.
- Planning and management direction will be focused on the relative values of resources and not the combination of uses that will give the greatest economic return or economic output.
- Coal screening was completed in 2001 for areas within the Buffalo planning area with coal development potential located in Campbell and Sheridan Counties of Wyoming. These coal screening decisions updated the Buffalo RMP and the Thunder Basin National Grasslands Land RMP. Based on the results for of our call for coal resource information, no additional coal planning decisions will be made for the Buffalo RMP, and the 2001 decisions identifying areas acceptable for further consideration for coal leasing, will be moved forward into the revised RMP.
- The RMP and EIS will address *Pennaco v. U.S.*, 377 F.3d 1147 (10th Cir. 2004) requiring analysis of coalbed natural gas development for fluid mineral leasing decisions in the Powder River Basin.

1.4.3. Major Statutes, Policies, and Regulations

Numerous federal and state laws and applicable regulations, policies, and actions affect the alternatives analyzed in this Proposed RMP and Final EIS. The FLPMA is the primary authority for the BLM's management of public lands. This law provides the overarching policy by which public lands are managed and establishes provisions for land use planning, land acquisition, administration, range management, ROW, designated management areas, and the repeal of certain laws and statutes. Sections 201 and 202 of the FLPMA establish the BLM's land use planning requirements. BLM Handbook H-1601-1, Land Use Planning Handbook, provides guidance for implementing the BLM land use planning requirements established by Sections 201 and 202 of the FLPMA and the land use planning regulations found in 43 CFR 1600 (BLM 2005b).

The NEPA stipulates the process through which public officials should make decisions that consider the environmental consequences of their actions and work to protect, restore, and enhance the human environment. NEPA provides for public input regarding issue identification and consideration of the environmental impacts of major federal actions that affect the quality of the human environment.

The NEPA also created the Council on Environmental Quality (CEQ), which has issued regulations (40 CFR 1500-1508) to ensure proper consideration of environmental concerns in federal decision making. The DOI and the BLM have in turn published their own regulations and guidance related to implementation of the NEPA process and CEQ Regulations (43 CFR Part 46, DOI DM Part 516 and BLM Handbook H-1790-1).

Many additional laws, regulations, and policies guide the management of public lands and are therefore relevant to this RMP revision. A list of these laws, regulations, and policies is provided in Appendix A (p. 1771).

1.4.4. Other Related Plans

The BLM is aware that there are specific state laws and local plans relevant to aspects of public land management that are discrete from, and independent of, federal law. However, BLM is bound by federal law. As a consequence, there may be inconsistencies that cannot be reconciled. The FLPMA and its implementing regulations require that BLM's land use plans be consistent with officially-approved state and local plans only if those plans are consistent with the purposes, policies, and programs of federal laws and regulations applicable to public lands. Where officially-approved state and local plans or policies and programs conflict with the purposes, policies, and programs of federal law applicable to public lands, there will be an inconsistency that cannot be resolved. With respect to officially-approved state and local policies and programs (as opposed to plans), this consistency provision only applies to the maximum extent practical. While county and federal planning processes, under FLPMA, are required to as integrated and consistent as practical, the federal agency planning process is not bound by or subject to state or county plans, planning processes, policies, or planning stipulations. Table 1.3, "Related Plans" (p. 16), identifies plans that are related to the management of land and resources considered in this RMP revision.

Table 1.3. Related Plans

Related Plans	
Bighorn National Forest Plan 2005 (USFS 2005)	Powder River Watersheds Water Quality Management Plan (Powder River Conservation District and Powder River Watersheds Steering Committee 2007)

1.5. Collaboration

This section describes specific actions taken by the BLM to consult and coordinate with tribes, government agencies, and interest groups, and to involve the interested public during preparation of the Proposed RMP and Final EIS. A Notice of Intent (NOI) published in the FR on November 14, 2008, formally announced the intent of the BLM to revise the existing plan and prepare the associated EIS. Publication of the NOI initiated the scoping process and invited participation of affected and interested agencies, organizations, and the general public in determining the scope and issues to be addressed by alternatives and analyses in the EIS.

The Notice of Availability announcing the release of the Draft RMP and EIS was published in the FR on June 28, 2013, initiating the 90-day public comment period that ended on September 26, 2013. During the public comment period, the BLM hosted four public meetings in August 2013, in towns and cities throughout the planning area. During this time, the public was encouraged

to review the Draft RMP and EIS and provide comments. The BLM considered all substantive comments received and revised the plan based on certain issues raised in the comments, as presented in this Proposed RMP and Final EIS. The BLM prepared a Comment Analysis Report that summarizes all substantive comments received during the 90-day public comment period and the BLM's responses to those comments, including how the agency revised the RMP and EIS based on comments. The Comment Analysis Report is presented in Appendix Y (p. 2671).

Additional detail regarding actions taken by the BLM to involve the public and consult and coordinate with tribes, government agencies, and interest groups is provided in Appendix C (p. 1843).

1.5.1. Consultation and Coordination

This section documents the consultation and coordination efforts undertaken by the BLM throughout the process of revising the RMP and developing the Proposed RMP and Final EIS. Title II, Section 202, of FLPMA directs the BLM to coordinate inventory, planning, and management efforts with the land use planning and management programs of Native American tribes, other federal departments, and agencies of the state and local governments as part of its land use planning process, to the extent consistent with the laws governing the administration of the public lands. The BLM is also directed to integrate NEPA requirements with other environmental review and consultation requirements to reduce paperwork and delays (40 CFR 1500.4-5). The BLM accomplished coordination with other agencies and consistency with other plans through ongoing communications, meetings, and collaborative efforts with the Interdisciplinary Team, which includes BLM specialists and federal, state, and local agencies. A list of the cooperating agencies that have actively participated in cooperators' meetings leading up to the development of the Proposed RMP and Final EIS include the following:

Counties

- Campbell County Commission
- Crook County Commission
- Johnson County Commission
- Sheridan County Commission

Conservation Districts

- Campbell County Conservation District
- Lake DeSmet Conservation District
- Powder River Conservation District

Wyoming State Agencies

- Office of the Governor
- Department of Agriculture
- Department of Revenue
- State Geological Survey
- Office of State Lands and Investments
- Oil and Gas Conservation Commission
- State Historic Preservation Office
- State Engineer's Office
- State Forestry Division
- State Parks and Cultural Resources

- State Trails Program
- Travel and Tourism
- Water Development Commission
- Department of Environmental Quality
- Department of Transportation
- Game and Fish Department

Federal Agencies

- United States Environmental Protection Agency (EPA), Region 8
- U.S. DOI – Office of Surface Mining
- United States Forest Service – Medicine Bow-Routt National Forest, Thunder Basin National Grasslands

Native American Tribes

- Northern Cheyenne Tribe

The BLM formally invited the cooperating agencies to participate in developing RMP alternatives and providing existing data and other information relative to their agency responsibilities, goals, mandates, and expertise. Cooperating agencies provided input during the initial scoping process on issues of special expertise or legal jurisdiction. In addition, cooperating agencies participated in a series of alternative formulation workshops, reviewed draft information and documents, and periodically met with BLM management and resource specialists throughout the revision process to discuss planning issues and provide input to the process. Table 1.4, “Meetings with Cooperating Agencies” (p. 18) lists these meetings and workshops.

Table 1.4. Meetings with Cooperating Agencies

Date	Location	Type of Meeting
October 22 – 23, 2008	Buffalo, Wyoming	Cooperating Agency Training
October 22, 2008	Buffalo, Wyoming	Socioeconomic Workshop
May 20 – 22, 2009	Buffalo, Wyoming	Goals and Objectives Development Workshop
June 17 – 18, 2009	Buffalo, Wyoming	Range of Alternatives Development Workshop
July 15 – 16, 2009	Buffalo, Wyoming	Range of Alternatives Development Workshop
August 19 – 20, 2009	Buffalo, Wyoming	Range of Alternatives Development Workshop
September 16 – 17, 2009	Buffalo, Wyoming	Range of Alternatives Development Workshop
October 7 – 8, 2009	Buffalo, Wyoming	Range of Alternatives Development Workshop
April 27 – 29, 2010	Buffalo, Wyoming	Preferred Alternative Development Workshop

In addition, the following federal Congressional Offices participated in the meetings with Cooperating Agencies.

- United States Senator Michael Enzi’s Office
- United States Senator John Barrasso’s Office
- United States Representative Cynthia Lummis’ Office

Endangered Species Act Consultation

The USFWS provided the BFO with a list of species on August 15, 2008 to be considered when evaluating actions under the ESA of 1973. The species include: black-footed ferret, blowout penstemon, and Ute ladies'-tresses orchid. Scoping comments provided by the USFWS on January 5, 2009 confirmed the listed species for ESA evaluation and recommended the RMP consider additional species of concern. The USFWS provided an updated ESA species list on August 26, 2010. The August 2010 species list contains the following four species: blowout penstemon, Ute ladies'-tresses orchid, mountain plover and Greater Sage-Grouse. On May 12, 2011, the USFWS withdrew the proposal to list the mountain plover as a Threatened species. On June 30, 2011, the BLM BFO requested that the USFWS remove blowout penstemon from the BFO list after further data and site visits provided clarification that neither the flower nor potential habitat was present. The USFWS agreed that it is unlikely the BFO planning area contains suitable habitat and removed it from the list. Recently (May 2015), the northern long-eared bat was listed as Threatened under the ESA by the USFWS.

The list of species that the USFWS requested to be considered for the BFO planning area now contains three species: Ute ladies'-tresses orchid, a Threatened species, northern long-eared bat, a Threatened species, and Greater Sage-Grouse, a Candidate species.

The USFWS was provided opportunities to comment on the Draft RMP and EIS and Draft Biological Assessment. Consultation letters concerning the Buffalo RMP revision project are located in Appendix C (p. 1843). Consultation will continue through completion of the final biological opinion and final RMP. The Final Biological Assessment is included as Appendix I (p. 2025).

Native American Interests

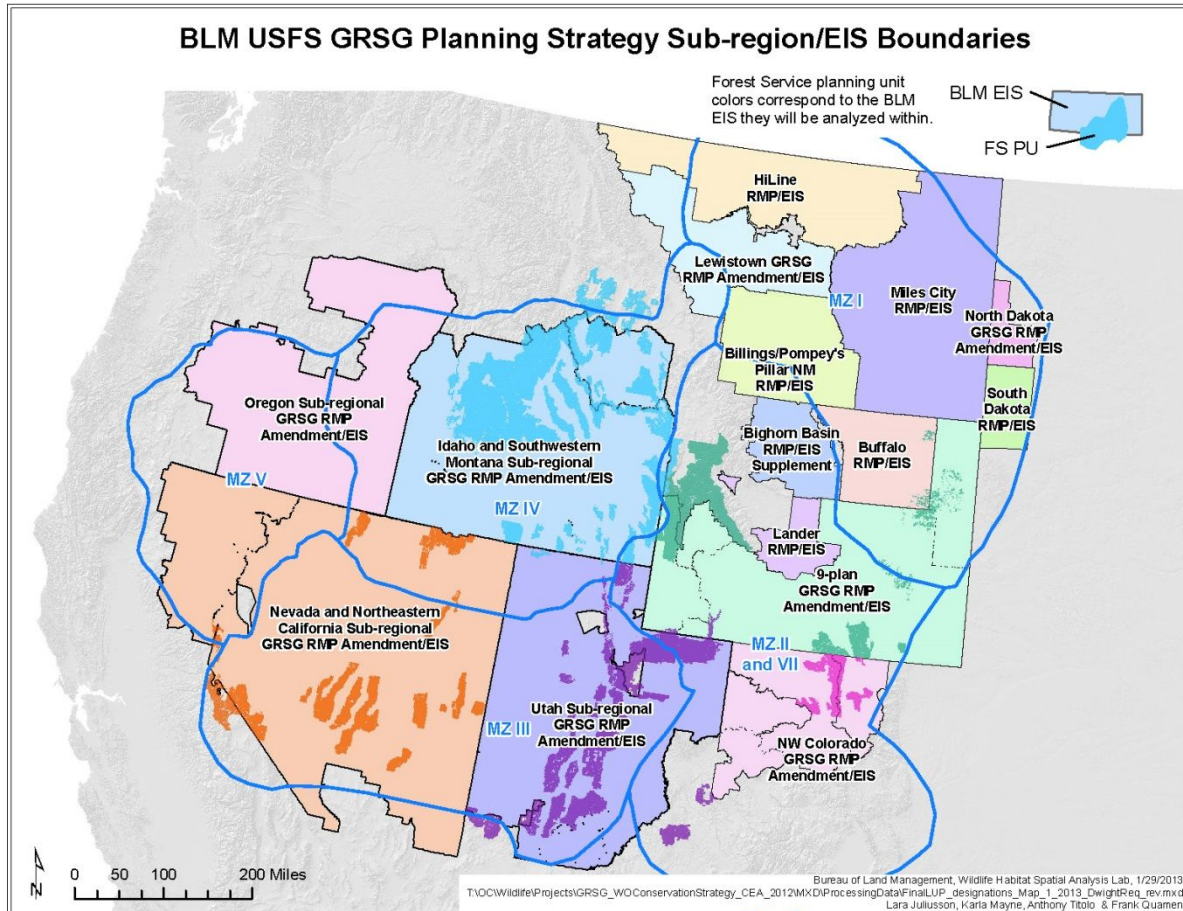

Consultation with Native American tribes is part of the NEPA scoping process and a requirement of FLPMA. The BLM took multiple steps to contact the tribes and include them in the scoping process. On September 19, 2008, the BLM sent letters to the following tribes inviting them to be part of the planning process through consultation and public scoping meetings, as well as requesting information to be considered in the planning process:

- Cheyenne River Sioux
- Crow
- Eastern Shoshone
- Ft. Peck/Assiniboine/Sioux
- Northern Arapahoe
- Northern Cheyenne
- Oglala Sioux
- Three Affiliated Tribes

1.6. National Greater Sage-Grouse Planning Strategy

On December 9, 2011, a Notice of Availability was published in the FR to initiate the BLM Greater Sage-Grouse Planning Strategy across nine western states, including California, Oregon, Nevada, Idaho, Utah, and Southwest Montana in the Great Basin Region and Northwest Colorado, Wyoming, Montana, South Dakota, and North Dakota in the Rocky Mountain Region. This Proposed RMP and Final EIS is one of fourteen separate EISs that are currently being conducted in conjunction with the U.S. Forest Service to analyze and incorporate specific conservation

measures across the range of the Greater Sage-Grouse, consistent with National BLM policy. Figure 1.3, “Greater Sage-Grouse Planning Strategy Subregion/EIS Boundaries” (p. 20) depicts the national Greater Sage-Grouse BLM and U.S. Forest Service planning subregions and EIS boundaries.

Source: BLM 2013m

*These areas will not have plan amendments, but statistics will be generated for them as they contain Preliminary General Habitat.

Note: U.S. Forest Service unit colors correspond to the region they will be analyzed within.

EIS Environmental Impact Statement
FO Field Office
GRSG Greater Sage-Grouse
MZ Management Zone
RMP Resource Management Plan

Figure 1.3. Greater Sage-Grouse Planning Strategy Subregion/EIS Boundaries

On December 27, 2011, the BLM WO released IM No. 2012-044, which directed all of the planning efforts across the Greater Sage-Grouse range to consider all applicable conservation measures when revising or amending its RMPs in Greater Sage-Grouse habitat, including the measures developed by the National Technical Team (NTT) that were presented in their December 2011 document – *A Report on National Greater Sage-Grouse Conservation Measures*.

IM-2012-044 directs all planning efforts associated with the national strategy to consider and analyze (as appropriate) the conservation measures presented in the report.

While energy development has been identified as the primary threat to the Greater Sage-Grouse within its eastern range, this area is not immune to the threat of wildfire. Within the Rocky Mountain Region wildfire was identified by the Conservation Objectives Team Final Report (2013) as a present and widespread threat in seven of thirteen priority areas of conservation and as a present but localized threat in the remaining priority areas of conservation. While fire is a naturally occurring disturbance in the sagebrush steppe, the incursion of non-native annual grasses is facilitating an increase in mean fire frequency which can preclude the opportunity for sagebrush to become re-established. As such the RMP includes requirements (referred to as Greater Sage-Grouse Wildfire and Invasive Species Habitat Assessment in appendices in Draft documents) that landscape scale Fire and Invasives Assessments be completed and updated regularly to more accurately define specific areas to be treated to address threats to sagebrush steppe habitat. Within the Rocky Mountain region, assessments have not yet been completed but will be scheduled based on the need to identify and address potential threats. Additionally, the Secretary of Interior issued Secretarial Order 3336 on January 5, 2015 which establishes the protection, conservation and restoration of “the health of the sagebrush-steppe ecosystem and, in particular, Greater Sage-Grouse habitat, while maintaining safe and efficient operations as a critical fire management priority for the Department”. The Secretarial Order will result in a final report of activities to be implemented prior to the 2016 Western fire season. This will include prioritization and allocation of fire resources and the integration of emerging science, enhancing existing tools to implement the RMP and improve our ability to protect sagebrush-steppe from damaging wildfires.

Along with the applicable measures that were outlined in the NTT Report, planning efforts associated with this National Greater Sage-Grouse Planning Strategy will also analyze applicable conservation measures that were submitted to the BLM from various state governments and from citizens during the public scoping process. It is the goal of the BLM to make a final decision on these plans by the end of 2015, so that adequate regulatory mechanisms are incorporated in place before the USFWS makes a listing decision.

Greater Sage-Grouse Conservation Objectives: Priority Areas for Conservation and How They Correlate with Priority and General Habitat Management Areas

In 2012, the Director of the USFWS asked the Conservation Objectives Team, consisting of state and USFWS representatives, to produce recommendations regarding the degree to which the threats need to be reduced or ameliorated to conserve greater sage-grouse so that it would no longer be in danger of extinction or likely to become in danger of extinction in the foreseeable future. The Conservation Objectives Team Report (USFWS 2013a) provides objectives based upon the best scientific and commercial data available at the time of its release. The BLM and USFS planning decisions analyzed in land use plans/EISs are intended to ameliorate threats identified in the Conservation Objectives Team Report and to reverse the trends in habitat condition. The Conservation Objectives Team Report can be viewed online at the following address: <http://www.fws.gov/mountain-prairie/species/birds/sagegrouse/COT/COT-Report-with-Deer-Interested-Reader-Letter.pdf>

*Chapter 1 Purpose and Need for Action
Greater Sage-Grouse Conservation Objectives:
Priority Areas for Conservation and How
They Correlate with Priority and General
Habitat Management Areas*

The highest level objective in the Conservation Objectives Team Report is identified as meeting the objectives of WAFWA's 2006 Greater Sage-grouse Comprehensive Strategy of "reversing negative population trends and achieving a neutral or positive population trend."

The Conservation Objectives Team Report provides a WAFWA Management Zone and Population Risk Assessment. The report identifies localized threats from sagebrush elimination, fire, conifer encroachment, weed and annual grass invasion, mining, free-roaming wild horses and burros, urbanization, and widespread threats from energy development, infrastructure, grazing, and recreation (USFWS 2013a, p. 18).

Key areas across the landscape that are considered "necessary to maintain redundant, representative, and resilient populations" are identified within the Conservation Objectives Team Report. The USFWS in concert with the respective state wildlife management agencies identified these key areas as priority areas for conservation.

Within the Buffalo RMP Revision Project Planning Area, the priority areas for conservation consist of a total 1,183,244 acres, regardless of ownership. Under the Proposed Plan, the Priority Areas for Conservation are comprised of 137,440 acres of Priority Habitat Management Areas managed by the BLM, 628,162 acres of General Habitat Management Areas managed by the BLM, and 16,500 acres of non-habitat managed by the BLM.

While energy development has been identified as the primary threat to the Greater Sage-Grouse within its eastern range, this area is not immune to the threat of wildfire. Within the Rocky Mountain Region wildfire was identified by the Conservation Objectives Team Final Report (2013) as a present and widespread threat in seven of thirteen priority areas of conservation and as a present but localized threat in the remaining priority areas for conservation. While fire is a naturally occurring disturbance in the sagebrush steppe, the incursion of non-native annual grasses is facilitating an increase in mean fire frequency which can preclude the opportunity for sagebrush to become re-established. As such the RMP includes requirements (referred to as Greater Sage-Grouse Wildfire and Invasive Species Habitat Assessment in appendices in Draft documents) that landscape scale Fire and Invasives Assessments be completed and updated regularly to more accurately define specific areas to be treated to address threats to sagebrush steppe habitat. Within the Rocky Mountain region, assessments have not yet been completed but will be scheduled based on the need to identify and address potential threats. Additionally, the Secretary of Interior issued Secretarial Order 3336 on January 5, 2015 which establishes the protection, conservation and restoration of "the health of the sagebrush-steppe ecosystem and, in particular, greater sage-grouse habitat, while maintaining safe and efficient operations as a critical fire management priority for the Department". The Secretarial Order will result in a final report of activities to be implemented prior to the 2016 Western fire season. This will include prioritization and allocation of fire resources and the integration of emerging science, enhancing existing tools to implement the RMP and improve our ability to protect sagebrush-steppe from damaging wildfires.

Habitat Delineation

The BLM and Forest Service have identified Greater Sage-Grouse habitat in coordination with the State of Wyoming. This habitat falls into one of the following categories:

- **Core Population Areas**—The boundaries of the Greater Sage-Grouse areas that were identified as having the highest conservation value to maintaining sustainable Greater Sage-Grouse populations per version 3 of the State of Wyoming EO Greater Sage-Grouse Core Area of

Protection (WY EO 2010-4) (Wyoming Office of the Governor 2010). These areas include breeding, late brood-rearing, winter concentration areas and migration or connectivity corridors and correspond to WO IM No. WO-2012-043 as Preliminary Priority Habitat.

- **Key Habitat Areas** – The boundaries of the Greater Sage-Grouse areas that were identified as having the highest conservation value to maintaining sustainable Greater Sage-Grouse populations per version 2 of the State of Wyoming EO Greater Sage-Grouse Core Area of Protection (WY EO 2008-2) (Wyoming Office of the Governor 2008). These areas include breeding, late brood-rearing, winter concentration areas and migration or connectivity corridors and correspond to WO IM No. WO-2012-043 as Preliminary Priority Habitat. Key Habitat Areas were replaced by Core Habitat Areas.
- **Connectivity Areas** – Connectivity Areas (as defined in WY EO 2011-5) are state-designated areas identified as - important for Greater Sage-Grouse migration and population connectivity. They correspond to one of two components of Priority Habitat Management Areas as defined in WO IM No. WO-2012-043.
- **Non-Core Sage Grouse Habitat** – Areas of occupied seasonal or year-round habitat not located within Core or Connectivity Habitat. These areas correspond to Preliminary General habitat as defined in WO IM No. WO-2012-043.

The Conservation Objectives Team Report identified priority areas for conservation based upon the data provided by State Fish and Game agencies. The State of Wyoming manages Greater Sage-Grouse and Greater Sage-Grouse habitats consistent with Governor's EO 2011-05, *Greater Sage-Grouse Core Area Protection* (Core Area Strategy), which establishes Core Areas.

In October 2014, the BLM updated the habitat category delineation. In the Proposed Land Use Plan Amendment/Final EIS Greater Sage-Grouse habitat nomenclature has been changed from Core and Connectivity Areas to priority habitat management area and Non-Core Sage Grouse Habitat to general habitat management area.

1.7. Topics Not Addressed in this Resource Management Plan Revision

Laws, regulations, policies, and EOs require specific resource topics be examined during the NEPA process. In some instances, initial evaluation reveals topics that are not relevant to the planning area or do not require further analysis. Examples of these topics are listed below.

- **Prime and Unique Farmlands** – In accordance with the Farmland Protection Policy Act, the BLM determined that no prime or unique farmlands or farmland of statewide or local importance occur on public lands in the planning area. None of the actions proposed in this RMP revision would disturb farmlands; therefore, impacts on prime and unique farmlands were not analyzed further in this RMP revision.
- **Wild Horses and Burros** – Herd areas are limited to areas of public land identified as being habitat used by wild horses and burros at the time of passage of the 1971 Wild Free-Roaming Horse and Burro Act. No wild horses are known to inhabit the planning area, and no herd areas have been identified. Therefore, impacts on wild horses and burros were not analyzed further in this RMP revision.

- **National Trails** – No National Scenic or Historic Trails currently exist within the planning area; therefore, impacts on National Scenic or Historic Trails were not analyzed further in this RMP revision.

Chapter 2. Resource Management Alternatives

This page intentionally
left blank

2.1. Resource Management Alternatives

Chapter 2 presents four alternative Resource Management Plans (RMPs) for managing the Buffalo planning area. The four alternative plans are identified by the letters A, B, C, and D. Alternative A, the No Action Alternative, represents the continuation of current management direction. Alternatives B and C represent the range of alternatives. The Bureau of Land Management (BLM) identified Alternative D as its Preferred Alternative in the Draft RMP and Environmental Impact Statement (EIS). Based on comments received during the public comment period on the Draft RMP and EIS, the BLM revised the Preferred Alternative. As modified, Alternative D is now presented as the Proposed RMP in the Final EIS. Each alternative provides a different emphasis for managing public lands and resources within the planning area, and represents a complete and reasonable land use plan that meets the purpose and need described in Chapter 1.

2.2. Summary of Changes Made Between the Draft RMP/EIS and the Proposed RMP/Final EIS

NEPA requires agencies to prepare a supplement to the draft EIS: 1) if the agency makes substantial changes in the proposed action that are relevant to environmental concerns; or 2) if there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts. A supplement is not necessary if a newly formulated alternative is a minor variation of one of the alternatives and is qualitatively within the spectrum of alternatives analyzed in the Draft EIS.

The Proposed RMP includes components of the alternatives analyzed in the Draft RMP/EIS. Taken together, these components present a suite of management decisions that present a minor variation of alternatives identified in the Draft RMP/EIS and are qualitatively within the spectrum of alternative analyzed. As such, the BLM has determined that the Proposed RMP is a minor variation and that the impacts of the Proposed RMP would not affect the human environment in a substantial manner or to a significant extent not already considered in the EIS. The impacts disclosed in the Proposed RMP and Final EIS are similar or identical to those described in the Draft RMP/EIS such that supplementation of the Buffalo RMP Final Draft EIS is not required. See 40 Code of Federal Regulations (CFR) 1502.9(c)(1).

Since publication of the Buffalo Draft EIS in June 2013, additional reports regarding Greater Sage-Grouse conservation have been published by United States Geological Survey (USGS) and U.S. Fish and Wildlife Service (USFWS); the BLM National Greater-Sage Grouse Land Use Planning Strategy has continued to make progress in the development of cumulative effects analysis based upon Western Association of Fish and Wildlife Agencies (WAFWA) management zones; and the Wyoming 9-Plan Draft RMP Amendment/Draft EIS (December 2013) and the Bighorn Basin Supplemental Draft RMP Revision/Draft EIS (July 2013) have been published. Upon review of each of these subsequent publications which have come out, none constitute “significant new information relevant to environmental concerns and bearing on the proposed action or its impacts” such that supplementation of the Buffalo RMP Final Draft EIS is required. See 40 CFR 1502.9(c)(1).

Greater Sage-Grouse related management changes made to the Proposed RMP/Final EIS from the preferred alternative (D) in Draft RMP/EIS are the following:

- An assessment of the Proposed RMP consistency with USFWS Conservation Objectives Team (COT) Report was completed, and a summary comparison of alleviated threats to Greater Sage-Grouse was also prepared (see Table 2.2).
- Implementation Framework – An implementation framework for Greater Sage-Grouse management (Appendix B (p. 1779)) has been added which includes adaptive management and monitoring strategies developed in cooperation with the USFWS and State of Wyoming. All of the adaptive management hard trigger responses were analyzed within the range of alternatives. For example, if a hard trigger is reached in Priority Habitat Management Area, and Priority Habitat Management Area would be managed as open to saleable minerals in the Proposed Plan, the response would be to manage it as closed to saleable minerals. This closure was analyzed under Alternatives B in the Draft EIS (a 4 mile closure around all occupied or undetermined Greater Sage-Grouse leks). The monitoring framework was further refined in the Final EIS, and further clarification as to how disturbance cap calculations would be measured were developed for the Final EIS.
- WAFWA Management Zone Cumulative Effects Analysis on Greater Sage-Grouse – a quantitative cumulative effects analysis for Greater Sage-Grouse was included in the Final EIS. This analysis was completed to analyze the effects of management actions on Greater Sage-Grouse at a biologically significant scale which as determined to be at the WAFWA Management Zone. The Draft EIS, in Chapter 4, included a qualitative analysis and identified that a quantitative analysis would be completed for the Final EIS at the WAFWA Management Zone.

The Draft RMP and EIS public comment period closed in September 2013. The BLM received approximately 134 individual comment letters and two form emails with approximately 2,143 submissions. The BLM identified 2,142 unique comments from the comment documents received, which touched on a wide range of issues. While many of the comments strongly supported the Preferred Alternative in the Draft RMP and EIS, commenters also identified areas where the document could be improved. The Buffalo Field Office (BFO) carefully evaluated these comments (see Appendix Y (p. 2671)). The Proposed RMP and Final EIS contains a number of changes made in response to comments. Substantive changes are identified in the document with grey shaded text. BLM has reviewed the changes made between the draft and proposed RMPs and has determined that the changes have not triggered the need to prepare a supplemental EIS per 40 CFR 1502.9. A summary of the substantive changes follows.

Physical Resources

Soils: An erosion model was included in the analysis at the request of the U.S. Environmental Protection Agency (EPA). The Revised Universal Soil- Loss Equation (from the Natural Resources Conservation Service [NRCS]) is an erosion model designed to predict the longtime average annual soil loss carried from runoff from specific slopes in specified management conditions.

BLM worked with the Campbell County Conservation District and other cooperators to refine and clarify the information presented within the Affected Environment and Environmental Consequences *Soils* sections. The Soils Exception Criteria appendix was deleted as the information it contained was redundant with other sections such as the Fluid Mineral Lease Stipulation appendix (Appendix H (p. 1959)) and the BFO reclamation policy appendix (Appendix O (p. 2495)).

Water: The EPA and other commenters requested additional background information from the 2003 Powder River Basin (PRB) EIS (BLM 2003c) and whether the assumptions and trend predictions were accurate. The requested information was added to the Proposed RMP and Final EIS. A water management plan appendix (Appendix W (p. 2623)) was added at the request of the EPA, to disclose the process for analyzing water effects and mitigation during the implementation of project level activities.

Mineral Resources

Coal: The BLM edited the Proposed RMP and Final EIS to clarify that no coal leasing allocation decisions are being made through the RMP revision. The coal leasing decisions made in the 2001 RMP update are being carried forward as no substantial new information regarding coal leasing was received during the call for coal information during RMP scoping or through comments on the Draft RMP and EIS. Federal coal lands identified in 2001 as acceptable for further coal leasing consideration are available for Lease by Application, lease modifications, emergency leases, and exchanges. Prior to offering a coal tract for sale, the unsuitability criteria will be reviewed, a tract specific National Environmental Policy Act (NEPA) analysis will be completed, and there will be opportunity for public comment. Federal coal lands acceptable for further leasing consideration do not overlap with Greater Sage-Grouse priority habitat (Maps 11 and 40).

Management action Coal-2001 was revised to clarify that the leasing decisions from 2001 are being carried forward and management action Coal-2003 was deleted from the Proposed RMP and Final EIS. Management action Coal-2002 was revised to clarify coal and fluids management within the areas identified acceptable for further coal leasing consideration.

Fluid Minerals: Management action O&G-2008 was revised to clarify coal and fluids management within the areas identified acceptable for further coal leasing consideration. An oil and gas operations appendix (Appendix V (p. 2599)) was added to summarize the fluid mineral procedures from lease nomination through permitting and development to final abandonment and lease closure for the EPA and other reviewers. There were many comments related to private property rights and split estate. An appendix (Appendix X (p. 2661)) has been added to the Proposed RMP and Final EIS summarizing the BLM's split estate authority and policy.

Several reviewers commented that the fluid mineral constraint maps in the Draft RMP and EIS were difficult to interpret. The Buffalo planning area is complex with multiple overlapping resource values, which makes interpreting the individual resource protections within the constraint maps difficult. To address the concern, BLM added an additional series of maps (Maps 17–22) displaying overlapping fluid mineral lease stipulations by stipulation type (No Surface Occupancy [NSO], Controlled Surface Use [CSU], and Timing Limitation Stipulation [TLS]) for the major resource categories (Physical, Biological, Heritage, and Visual). Reviewers should also consult the individual resource maps (i.e., elk seasonal ranges or raptors).

Fire and Fuels Management

No substantive changes were made to the fire and fuels management sections in the Proposed RMP and Final EIS.

Biological Resources

Grassland and Shrubland Communities and Riparian and Wetland Communities: The analyses in the vegetation sections were reviewed and revised to increase clarity and consistency at the EPA's request.

Wildlife: The USFWS, the Avian Power Line Interaction Committee (APLIC) and others commented on the ineffectiveness of perch inhibitors in preventing raptor perching. Therefore, BLM revised management action WL-2014 by removing the anti-perch requirement and clarifying the intent of the management action to design powerlines (distribution and transmission) to minimize wildlife related impacts and to construct powerlines to the latest APLIC standards. Raptor perch-deterrents will be analyzed within identified wildlife habitats (SS WL-4022, SS WL-4024, SS WL-4025, and Appendix D (p. 1863)), including within Greater Sage-Grouse priority habitat and within 0.5 mile of general habitat leks, and will be required where appropriate.

Some commenters felt the raptor spatial buffer distances and dates were too restrictive while others commented that the protections were not sufficient. Proposed RMP management actions WL-4027 through WL-4030 and SS WL-4029 through SS WL-4032 were revised to fully conform to the distances and dates recommended by the USFWS Wyoming Ecological Services Office. Spatial buffers may be modified for site-specific implementation decisions based on auditory and visual impacts, as well as the topography and other ecological characteristics surrounding the nest site.

A Wildlife Habitat Management Area (WHMA) for the Fortification Creek elk herd (WL-4023) is not being carried forward in the Proposed RMP. A WHMA was not supported by the State of Wyoming, whom has primary management authority over the elk herd, which is above the established population objective. The Fortification Creek RMP Amendment (BLM 2011c) decisions which are sufficient to conserve a viable elk herd are carried forward in the Proposed RMP and Final EIS.

Grazing effects were revised within the wildlife and special status species sections to clarify that while livestock grazing does affect wildlife and their habitat, livestock grazing managed in accordance with the Proposed RMP and Final EIS (*Wyoming Standards for Healthy Rangelands*) is compatible with sustaining suitable wildlife and special status species habitats and that it is improper livestock grazing that can have major adverse effects on wildlife and their habitat.

Special Status Species: The USFWS proposed the northern long-eared bat for listing as an Endangered species after the Draft RMP and EIS was published. The northern long-eared bat's documented range includes eastern Campbell County. The northern long-eared bat has been included in the biological assessment (Appendix I (p. 2025)) and BLM will conference with the USFWS in order to conserve the bat and avoid jeopardizing its existence. BLM waited until the Proposed RMP and Final EIS to include the biological assessment in order to consult on the Proposed RMP.

The text of SS WL-4002 was broadened, including recovery plans and future biological opinions, to be consistent with the companion management actions for special status plants and fish.

BLM further refined Greater Sage-Grouse management within the Proposed RMP at the Governor's request to review the management actions to ensure consistency with Wyoming Executive Orders 2011-5 and 2013-3. Executive Order 2013-3 was released after the Draft RMP and EIS was delivered to the publisher. Text from Executive Order 2013-3 was added to the Greater Sage-Grouse Planning section (Section 2.5, "Greater Sage-Grouse Habitat Management" (p. 36)). Proposed RMP management action SS WL-4021 was revised from

prohibit renewable energy projects within Greater Sage-Grouse Priority Habitat (Core Population Areas and Core Population Connectivity Corridors) to avoid renewable energy projects in Greater Sage-Grouse Core Population Areas unless it can be demonstrated that the activity would not result in declines of core Greater Sage-Grouse populations. SS WL-4022 was revised to clarify when powerlines could be authorized within Core Population Areas and when raptor perch-deterrents could be required. Raptor perch-deterrents remain a required design feature (RDF) within Greater Sage-Grouse priority habitat (Appendix D (p. 1863)). BLM revised the SS WL-4023 requirements of when a fluid mineral lease could be less than the 640 acre minimum in order to be consistent with the Wyoming 9-Plan's *Draft RMP/Draft EIS preferred alternative*. A minimum lease size is also consistent with the proposed management of adjacent Montana field offices, also in WAFWA Greater Sage-Grouse Management Zone I. In management actions SS WL-4024 and SS WL-4025 BLM clarified that the one disturbance per square mile within Core Population Areas is one energy or mining facility; the technical feasibility restriction on facilities was dropped and replaced with the Executive Order 2011-5 noise limitations; and the sagebrush restoration requirement was clarified by replacing the shrub density formula with the formula's source (Wyoming Department of Environmental Quality [DEQ] community-specific full shrub density standard, Chapter 4 Rules and Regulations option III).

Heritage and Visual Resources

Cultural Resources: BLM complied with the Northern Cheyenne's request to combine the requirements for archeological and tribal monitors into one management action, Cultural-5008.

Land Resources

Travel Management: A common to all management action, Trans-6005, was added to respond to commenters concerned that the proposed travel management restricted the operations of authorized/permitted activities. The new management action clarifies that motorized travel under administrative permits and leases will be subject to the terms of the authorization.

Lands with Wilderness Characteristics: Some commenters wanted additional acreage managed to protect wilderness characteristics while others did not want any lands managed to protect wilderness characteristics. BLM continued with the 6,864 acres identified in the Draft RMP and EIS as they are the best suited for management to maintain identified wilderness characteristics. Fluid mineral leasing was changed from closed in the Draft RMP and EIS to leasing with a NSO stipulation in the Proposed RMP and Final EIS. The NSO stipulation enables BLM to protect wilderness characteristics while allowing for potential fluid mineral development (i.e., horizontal drilling).

Special Designations

Some commenters requested additional special designation areas with increased protections and others spoke against any special designation areas.

Areas of Critical Environmental Concern (ACECs): The Fortification Creek ACEC (ACEC-7003) is not being carried forward in the Proposed RMP. The State of Wyoming has primary management authority over the elk herd. State management and the Fortification Creek RMP Amendment (BLM 2011c) decisions, which are carried forward in the Proposed RMP and Final EIS, are sufficient to conserve a viable elk herd and the other ACEC values.

National Byways: Byways did not receive any support from commenters. The management action was to evaluate, not designate, and therefore was not revised.

Socioeconomic Resources

No substantive changes were made to the socioeconomic sections in the Proposed RMP and Final EIS.

2.3. Alternatives Development Process

The BLM complied with NEPA requirements in the development of alternatives for this RMP and EIS by seeking public comment and analyzing a reasonable range of alternatives. Alternative formulation took into consideration existing land use plan decisions, and issues and concerns developed internally and solicited from the public during the scoping process. The process to develop alternatives can be broadly broken down into five steps:

1. Identify Issues (Scoping)
2. Identify Current Management (Alternative A – No Action Alternative)
3. Develop the Range of Alternatives (alternatives B and C)
4. Analyze the Effects of the Alternatives (alternatives A, B, and C)
5. Develop the Preferred Alternative (Alternative D)

Identify Issues

The BLM considered public comments received during the scoping process while developing the alternatives and management actions. The BLM considers public comments received throughout the alternative development process. Chapter 1 and the project Scoping Report (available on the RMP revision website at <http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo/docs.html>) summarize the results of the public scoping process and opportunities for future public involvement.

Identify Current Management

The 1985 Buffalo RMP, as updated in 2001, as amended by the 2003 Record of Decision (ROD) and RMP Amendment for the PRB Oil and Gas Project, and as amended by the 2011 Fortification Creek Planning Area Decision Record and RMP amendment (existing plan), and other current management direction served as the basis for the No Action Alternative (Alternative A). Alternative A, in conjunction with the planning criteria and the key issues identified during the scoping process, set the stage for developing the range of alternatives.

Develop the Range of Alternatives

The BLM conducted a series of seven alternatives development workshops with a team comprised of BLM staff and cooperating agencies. During the initial workshop, the team shared their knowledge and expertise and collaborated to identify goals and objectives (i.e., desired outcomes) for each resource. Each subsequent workshop refined the management actions composing each alternative and narrowed the scope of alternatives to a reasonable range limited by the planning criteria (refer to Chapter 1, Planning Criteria). Table 2.1, “Alternatives Development Workshops” (p. 33) identifies the dates and focus of each workshop. Prior to each workshop, the BLM provided preliminary draft alternatives prepared by BLM specialists to the cooperating

agencies. These preliminary alternatives served as a starting point for alternative formulation and a basis for discussion by team members during the workshops.

Table 2.1. Alternatives Development Workshops

Workshop Number	Dates	Focus
1	May 20 – 22, 2009	Goals and Objectives
2	June 17 – 18, 2009	Range of Alternatives
3	July 15 – 16, 2009	Range of Alternatives
4	August 19 – 20, 2009	Range of Alternatives
5	September 16 – 17, 2009	Range of Alternatives
6	October 7 – 8, 2009	Range of Alternatives
7	April 27 – 29, 2010	Preferred Alternative

The team formulated the range of alternatives (alternatives B and C) to meet the purpose and need of this RMP revision using different approaches to resource use. These alternatives represent the opposite ends of a continuum of resource use from a resource conservation emphasis (Alternative B) to a resource utilization emphasis (Alternative C). Management actions developed under all alternatives are subject to valid existing rights. In addition, management actions may only be implemented when they are consistent with applicable laws, regulations, and policies. The planning area is open to locatable mineral activities unless specifically withdrawn from operation under the mining laws. Alternatives were considered, but not carried forward for detailed analysis in this RMP and EIS if they did not meet the planning criteria or the purpose and need (see Chapter 1), or were already part of an existing plan, policy, requirement, or administrative function that will continue under the revised RMP.

Analyze the Effects of the Alternatives

The fourth step in the process is to analyze the effects of the range of alternatives. This task involved analyzing the impacts of one set of resource management actions on other resources and resource uses. These data were then compiled into Chapter 4 and considered in step five, Develop the Preferred Alternative.

Develop the Preferred Alternative

The BLM developed Alternative D, the Preferred Alternative, by considering the impacts analysis (Chapter 4) of alternatives A through C; knowledge of specific issues raised throughout the planning process; planning criteria; and recommendations from cooperating agencies, BLM specialists, and resource experts.

Refer to Table 2.1, “Alternatives Development Workshops” (p. 33) for the date of the Preferred Alternative workshop. The BLM developed the Preferred Alternative using the following selection criteria:

1. Satisfies statutory requirements (applies to all alternatives).
2. Reflects what the BLM considers to be the best combination of actions to achieve its goals and objectives.
3. Represents the most effective solution to the purpose and need.
4. Provides the most efficient approach to address key planning issues.

5. Best considers cooperating agencies and BLM specialists' recommendations.

The Preferred Alternative was identified as the BLM's preliminary preference in the Draft RMP and EIS. Following publication of the Draft RMP and EIS, the BLM revised the Preferred Alternative based on comments received during the public comment period. As modified, Alternative D is now presented as the Proposed RMP in the Final EIS. Following resolution of protests and the Governor's consistency review, the BLM will prepare a ROD and Approved RMP.

2.4. Alternative Components

Each alternative comprises two categories of land use planning decisions: (1) desired outcomes (goals and objectives) and (2) allowable uses and management actions.

2.4.1. Goals and Objectives

Goals and objectives direct the BLM's actions to most effectively meet legal mandates in statutes and regulations, agency policy, as well as local and regional resource needs. Goals are broad statements of desired outcomes that are usually not quantifiable. Objectives breakdown goals into more specific desired outcomes and typically include a measurable component. The management goals and objectives for each resource are presented in Section 2.9, "Detailed Alternative Descriptions by Resource" (p. 125).

2.4.2. Allowable Uses and Management Actions

Allowable uses and management actions are developed to achieve the goals and objectives defined for each resource.

Allowable Uses

Allowable uses identify uses that are allowed, restricted, or excluded on BLM surface lands and federal mineral estate. Alternatives may include specific land use restrictions or may exclude certain land uses (e.g., mineral leasing, salable mineral development, recreation, forest management, utility corridors, and livestock grazing) in order to meet goals and objectives and conserve resource values. For example, alternatives considered for this RMP revision exclude oil and gas development within certain buffers of occupied Greater Sage-Grouse leks while allowing recreation, livestock grazing, and other land uses. Allowable uses often contain a spatial component because the alternatives identify whether particular land uses are allowed, restricted, or excluded. These spatial components are illustrated on maps to display the geographical extent of the management actions.

Management Actions

Management actions are proactive measures (e.g., measures that will be taken to enhance watershed function and condition), or limitations intended to guide BLM activities in the planning area. An example of this type of management action is to prohibit surface-disturbing activity near riparian/wetland areas in order to achieve proper functioning condition (PFC).

Organization of Allowable Uses and Management Actions in the Alternatives

For simplicity, the term “management action” is inclusive of both allowable uses and management actions. Therefore, when the text refers to management actions, it is referring to both categories. Two types of management actions are included in the alternatives. The first is management actions common to all alternatives, which will apply regardless of the alternative. The second is management actions by alternative, which represent the choice(s) considered across alternatives. Management actions by alternative represents the range of land use management decisions considered. These management actions vary among the alternatives and represent a reasonable range of management options that were considered to meet the stated goals and objectives and purpose and need of the RMP revision. RMPs are strategic in nature, and, while they provide an overarching vision for managing resources in the planning area, they must also be flexible to changing priorities, information, and circumstances.

Conservation Measures and Required Design Features

Appendix D (p. 1863) identifies Greater Sage-Grouse conservation measures many of which have typically been recommended (voluntary) mitigation measures such as best management practices (BMPs) from Washington Office (WO) Instruction Memorandum (IM)-2012-044 (BLM 2012h), BMPs for fire and fuels management from WO IM 2011-138 (BLM 2011d), guidelines from Wyoming Governor’s Executive Order 2011-5, recommended management practices from the Northeast Wyoming Greater Sage-Grouse Local Working Group’s Conservation Plan (NWSGLWG 2006), and suggested management practices from the BLM National Greater Sage-Grouse Habitat Conservation Strategy (BLM 2004b). For the most part, these measures are a restatement of existing management practices, such as co-location of rights-of-way (ROWs) or clustering of development infrastructure.

These conservation measures are treated in the RMP as RDFs for future projects implemented consistent with the direction in the approved plan. Project proponents are encouraged to include all appropriate conservation measures in their proposals. The BLM will require application of all appropriate conservation measures, warranted by site-specific analysis, in order to avoid, minimize, rectify, reduce, or compensate for impacts. Conservation measures not included in project proposals and determined appropriate from the site-specific analysis will be required as Conditions of Approval (COAs). Additional COAs developed through consultation with other federal, state, and local regulatory and resource agencies may be applied when supported by site-specific analysis.

Because of site-specific circumstances, some conservation measures may not apply to all activities (e.g., a resource or conflict is not present on a given site) and/or may require slight variations. Proposed variations in conservation measures will be analyzed and may be applied in the site specific permitting process. All variations in conservation measures will require appropriate analysis and disclosure as part of activity authorization. It is anticipated that variations in the conservation measures will be approved in very limited circumstances and only in coordination with the Wyoming Game and Fish Department (WGFD) and/or the USFWS. Conservation measures and other mitigation selected for implementation will be identified in the project’s decision document. The proponent must implement all identified measures because they are commitments made as part of the BLM decision. Because the decision document creates a clear obligation for the BLM to ensure any proposed mitigation adopted in the environmental analysis is performed, there is the expectation that applied mitigation will lead to a reduction of environmental impacts in the implementation stage and include binding mechanisms for enforcement (CEQ 2011). The determination of adequate application of the mitigation measures and conservation actions for specific projects will remain with the BLM’s authorized officer.

2.5. Greater Sage-Grouse Habitat Management

On December 9, 2011, a Notice of Availability was published in the Federal Register (FR) to initiate the BLM and U.S. Forest Service (USFS) Greater Sage-Grouse Planning Strategy across nine western states, including California, Oregon, Nevada, Idaho, Utah, and Southwest Montana in the Great Basin Region and Northwest Colorado, Wyoming, Montana, South Dakota, and North Dakota in the Rocky Mountain Region. This Proposed RMP and Final EIS is one of fifteen separate EISs that are currently being conducted to analyze and incorporate specific conservation measures across the range of the Greater Sage-Grouse, consistent with BLM policy. The ROD for the first Greater Sage-Grouse related RMP; the Lander, Wyoming RMP revision was signed in June 2014.

The BLM WO issued a National Greater Sage-Grouse Planning Strategy (BLM 2012h) on December 27, 2011. The Wyoming State Office (WYSO) issued a revised Greater Sage-Grouse Habitat Management policy, WYSO IM 2012-019 (BLM 2012g), on February 12, 2012. These policies have been incorporated into the Buffalo Proposed RMP and Final EIS.

In August 2011, the BLM convened the Sage-Grouse National Technical Team (NTT), which brought together resource specialists and scientists from the BLM, state fish and wildlife agencies, the USFWS, the U.S. Department of Agriculture (USDA) NRCS, and the USGS. The NTT developed a series of science-based conservation measures to be considered and analyzed through the land use planning process. /2WO IM 2012-044 provides direction to the BLM on how to consider the NTT conservation measures in the land use planning process.

The WO IM requires that the conservation measures in the NTT report be analyzed in at least one alternative in the land use planning EIS and that a “hard look” be given to the conservation measures, as appropriate and applicable to local ecological site variability. Alternative B incorporates the national strategy (WO IM-2012-044) and Alternative D incorporates the Wyoming strategy (WYSO IM-2012-019).

Wyoming Governor Freudenthal issued the first Executive Order on August 1, 2008, mandating special management for all state lands in Greater Sage-Grouse “Core Population Areas.” Core Population Areas are important breeding areas for Greater Sage-Grouse in Wyoming. In addition to identifying Core Population Areas, the Sage-Grouse Implementation team recommended placing restrictions on development activities to ensure that existing habitat function is maintained within the Core Population Areas. These restrictions would apply to the habitat supporting approximately 80 percent of the total estimated Greater Sage-Grouse breeding population in the state. Wyoming’s Core Population Area strategy has been updated in two subsequent executive orders: Executive Order 2010-4 and Executive Order 2011-5. Governor Mead issued a grazing supplement (Executive Order 2013-3) to Wyoming’s Core Population Area Strategy (Executive Order 2011-5) in 2013. The BLM will implement Executive Order 2013-3 in the following fashion: The BLM will collaborate with appropriate federal agencies, and the State of Wyoming as contemplated under Governor Executive Order 2013-3, to: (1) develop appropriate conservation objectives; (2) define a framework for evaluating situations where Greater Sage-Grouse conservation objectives are not being achieved on federal land, to determine if a causal relationship exists between improper grazing (by wildlife or wild horses or livestock) and Greater Sage-Grouse conservation objectives; and (3) identify appropriate site-based action to achieve Greater Sage-Grouse conservation objectives within the framework. BLM Wyoming adopted the State of Wyoming’s approach for projects under its authority, through a series of IMs; the most recent being Greater Sage-Grouse Habitat Management policy IM 2012-019 (BLM

2012g). WYSO IM 2012-019 applies the State of Wyoming Greater Sage-Grouse management strategy (Wyoming Governor's Executive Order 2011-5) to BLM surface and federal mineral estate. The Protection measures described in the WYSO policy (with the exception of certain interim measures, like the Greater Sage-Grouse leasing screen) and Executive Order 2011-5 are incorporated into Alternative D, the Proposed RMP.

The BLM developed a multi-stage review process to ensure compliance with WO IM 2012-044. The local review (June 21, 2012) demonstrated and confirmed BFO compliance with WO IM 2012-044, Wyoming Executive Order 2011-5, and WYSO IM 2012-019. The WGFD, USFWS, and the BLM WYSO participated in the local review. The USFWS refrained from providing any comments at the local review.

The regional interdisciplinary team reviewed Greater Sage-Grouse management in the Buffalo Preliminary Draft RMP and EIS on July 24, 2012. The Wyoming Governor's office, WGFD, and the NRCS participated; the USFWS was not represented. The regional managers' team performed their review on July 31, 2012; the Wyoming Governor's office, WGFD, NRCS, and USFWS participated. The BLM WO completed their review on September 24, 2012. These reviews have ensured that BFO has complied with WO IM 2012-044 and has adequately incorporated the citizen based recommendations.

2.5.1. BLM Programs for Addressing Greater Sage-Grouse Threats

In 2013, the USFWS released their Conservation Objectives Team Report, which delineates reasonable objectives, based upon the best scientific and commercial data available at the time of its release, for the conservation and survival of Greater Sage-Grouse. The report also identified present and widespread and localized threats facing the Greater Sage-Grouse and their habitat in specific populations across the west. The ranges of management actions for managing Greater Sage-Grouse habitat analyzed in this EIS are directed towards responding to these threats. The USFWS threats do not necessarily align with BLM resource program areas, and are often integrated into several different resource program areas. Table 2.2, "USFWS Threats to Greater Sage-Grouse and Their Habitat, Applicable BLM Resource Program Areas Addressing These Threats" (p. 38) provides a cross-walk between each of the USFWS listing decision and Conservation Objectives Team identified threats and the BLM program areas and shows how those threats were addressed in the BLM's land use plan.

2.5.2. Range of Alternatives for Greater Sage-Grouse Management

The action alternatives (alternatives B, C, and D) in the Proposed RMP and Final EIS offer a range of management approaches to maintain or increase Greater Sage-Grouse abundance and distribution of Greater Sage-Grouse by conserving, enhancing, or restoring the sagebrush ecosystem upon which Greater Sage-Grouse populations depend in collaboration with other conservation partners. The relative emphasis given to particular resources and resource uses differs as well, including allowable uses, restoration measures, and specific direction pertaining to individual resource programs. When resources or resource uses are mandated by law or are not tied to planning issues, there are typically few or no distinctions between alternatives.

The meaningful differences among the alternatives are described in Section 2.8, “Summaries of the Alternatives” (p. 103). Section 2.9, “Detailed Alternative Descriptions by Resource” (p. 125) provides a complete description of the goals, objectives, and management actions for each alternative. In some instances, varying levels of management of Priority and General Habitat Management Areas (Map 36) overlap a single area, or polygon, due to management prescriptions from different resource programs. In instances where varying levels of management prescriptions overlap a single polygon, the stricter of the management prescriptions would apply. For the proposed land use decisions, Table 2.3, “Comparative Summary of Allocation Decisions by Proposed Land Use Decisions in the Buffalo Planning Area: Acres within Priority (PHMA) and General (GHMA) Habitat Management Areas and Percentage of BLM-Administered Estate within the Planning Area” (p. 51) compares the acreage and percentage of Priority and General Habitat Management Areas by alternative.

2.5.3. Development of the BLM Proposed Plan for Greater Sage-Grouse Management

In developing the Proposed Plan for Greater Sage-Grouse management, the BLM made modifications to the Preferred Alternative identified in the Draft Land Use Plan/EIS. The modifications are based on public comments received on the Draft Land Use Plan/EIS, internal BLM review, new information and best available science, the need for clarification in the plans, and ongoing coordination with stakeholders across the range of the Greater Sage-Grouse. As a result, the Proposed Plan provides consistent Greater Sage-Grouse habitat management across the range, prioritizes development outside of Greater Sage-Grouse habitat, and focuses on a landscape-scale approach to conserving Greater Sage-Grouse habitat.

The BLM modified the Preferred Alternative, identified as Alternative D as presented in the Draft Land Use Plan/EIS, which is now considered the proposed plan for managing BLM-administered lands within the Buffalo Planning Area.

Since release of the Draft Land Use Plan/EIS, the BLM have continued to work closely with a broad range of governmental partners, including Governors, State Fish and Game agencies, the USFWS, Indian tribes, county commissioners and many others. Through this coordination, the BLM have developed a Proposed Plan that is consistent with state, Tribal, and local strategies to the maximum extent possible and ensures the long-term conservation of the Greater Sage-Grouse. The BLM also received many substantive public comments on the Draft Land Use Plan (see Appendix Y (p. 2671)), which greatly informed the BLM's development of the Proposed Plan for Greater Sage-Grouse management.

The BLM has refined the Proposed Plan to provide a layered management approach that offers the highest level of protection for Greater Sage-Grouse in the most valuable habitat. Land use allocations in the Proposed Plan would limit or eliminate new surface disturbance in Priority Habitat Management Area, while minimizing disturbance in General Habitat Management Area. In addition to establishing protective land use allocations, the Proposed Plan for Greater Sage-Grouse management would implement a suite of management tools such as disturbance limits, Greater Sage-Grouse habitat objectives and monitoring, mitigation approaches, adaptive management triggers and responses, and lek buffer-distances throughout the range (see Appendix B (p. 1779)). These overlapping and reinforcing conservation measures will work in concert to improve Greater Sage-Grouse habitat condition and provide clarity and consistency on how the BLM will manage activities in Greater Sage-Grouse habitat.

2.5.4. BLM Proposed Plan for Greater Sage-Grouse Habitat Management

Many of the proposed plan goals, objectives, management actions and allowable uses identified in this section originate from the specific BLM resource/program areas (e.g., Physical Resources) and have been determined to be applicable to the proposed management of Greater Sage-Grouse habitat. The management action/goal/objective numbers are the same as those presented in Section 2.9, "Detailed Alternative Descriptions by Resource" (p. 125) of this chapter and have simply been consolidated here to depict how the BLM proposes to manage Greater Sage-Grouse habitat.

Special Status Species

Greater Sage-Grouse

- Goal BR:11 Sustainable sagebrush habitats that provide the quantity, quality, and connectivity that is necessary to maintain sustainable populations of Greater Sage-Grouse and other special status species. (conserves habitat and populations)
 - Objective BR:11.1 Maintain large patches of high quality interconnected sagebrush habitats, with emphasis on patches occupied by Greater Sage-Grouse. (conserves habitat)
 - Objective BR:11.2 Maintain connectivity between and within sagebrush habitats with emphasis on communities occupied by Greater Sage-Grouse. (conserves habitat)
- Goal BR:12 Successful restoration and rehabilitation of potential Greater Sage-Grouse habitat across the planning area. (conserves habitat)
 - Objective BR:12.1 Reestablish sagebrush corridors, where feasible, between Greater Sage-Grouse occupied habitats. (conserves habitat and populations)
 - Objective BR:12.2 Reconnect large patches of sagebrush habitat with emphasis on reconnecting patches occupied by stronghold and isolated populations of Greater Sage-Grouse. (conserves habitat and populations)
- SS WL-4010: The BLM will collaborate with appropriate federal agencies, and the State of Wyoming as contemplated under Governor Executive Order 2013-3, to: (1) develop appropriate conservation objectives; (2) define a framework for evaluating situations where Greater Sage-Grouse conservation objectives are not being achieved on federal land, to determine if a causal relationship exists between improper grazing (by wildlife or livestock) and Greater Sage-Grouse conservation objectives; and (3) identify appropriate site-based action to achieve Greater Sage-Grouse conservation objectives within the framework. (conserves habitat and populations)
- SS WL-4011: Develop avoidance areas restricting the application of broad-spectrum pesticides in areas containing Greater Sage-Grouse nesting and brood-rearing habitats. (conserves habitat and populations)
- SS WL-4012: Restore Greater Sage-Grouse brood-rearing habitats in wetland/riparian areas. Maintain seeps, springs, wet meadows, and riparian vegetation in a functional and diverse condition for young Greater Sage-Grouse and other species that depend on forbs and insects associated with these areas. (conserves habitat and populations)
- SS WL-4013: Manage vegetation composition, diversity and structure, as determined by Ecological Site Description (ESD) and WGFD protocols (WY IM-2012–019 attachment 6), to achieve Greater Sage-Grouse habitat management objectives, in cooperation with stakeholders. (conserves habitat and populations)
- SS WL-4014: Minimize disturbances that would result in alterations to springs and riparian Greater Sage-Grouse habitat. In coordination with stakeholders, develop alternative water sources to replace natural sources that have been affected or destroyed. (conserves habitat)
- SS WL-4015: Manage stored water to control mosquitoes and prevent the spread of West Nile Virus (WNV) to Greater Sage-Grouse. (conserves populations)
- SS WL-4016: Design water facilities with protective features to reduce mortality of Greater Sage-Grouse from drowning or entrapment. (conserves populations)
- SS WL-4017: Design and locate fences to reduce impacts to important Greater Sage-Grouse habitat. (conserves habitat and populations)
- SS WL-4018: Use the Fire Management Plan to incorporate the most current sagebrush habitat information and to guide fire suppression priorities in sagebrush habitats. (conserves habitat)
- SS WL-4019: Remove conifers where they have encroached upon Greater Sage-Grouse habitat in cooperation with stakeholders. Reduce the density of conifers that have encroached into, but do not yet dominate sagebrush plant communities. (conserves habitat)

- SS WL-4020: Inventory, record, and report existing type and condition of BLM fences. Prioritize areas and annually implement modifications to existing fences to reduce hazards to flying Greater Sage-Grouse, in cooperation with stakeholders. All new fences, in priority areas, will be properly designed and located to avoid hazards to flying Greater Sage-Grouse. (conserves populations)
- SS WL-4021: Avoid renewable energy projects in Greater Sage-Grouse Core Population Areas unless it can be demonstrated that the activity would not result in declines of core Greater Sage-Grouse populations. Sufficient demonstration of “no declines” should be coordinated with the WGFD and USFWS. (conserves habitat and populations)
- SS WL-4022: Powerlines (distribution and transmission) will be designed to minimize wildlife related impacts. (conserves populations) This action includes but is not limited to:
 - Avoid areas of high avian use such as water bodies (including ponds, lakes, rivers, streams and wetlands), ridge tops, prairie dog colonies, Greater Sage-Grouse Core Population Areas and Core Population Connectivity Corridors, and sharp-tailed grouse leks. (PRB Final EIS, Executive Order 2011-05)
 - Prohibit within 0.6 mile of Greater Sage-Grouse Core Population Area and Core Population Connectivity Corridor leks unless within an established corridor or it can be demonstrated that the activity will not cause Greater Sage-Grouse population declines. Transmission and collectors lines are not permitted if they are outside designated corridors or at distances greater than 0.5 mile of an existing 115 kilovolt (kV) or greater powerlines, unless there is a demonstration of no declines in Greater Sage-Grouse populations. ROWs for residential and agricultural distribution lines will be evaluated on a project-specific basis. (Executive Order 2011-05)
 - Within general Greater Sage-Grouse habitat (outside Core Population Areas and Core Population Connectivity Corridors) overhead powerlines will be located at least 0.5 mile from Greater Sage-Grouse breeding grounds. (PRB Final EIS)
 - Any new powerlines authorized within the above identified areas will be buried or if overhead then marked to increase visibility and perch-guarded to prevent raptor perching. (PRB Final EIS)
- SS WL-4023: Lease fluid minerals dependent upon lease location and habitat suitability. In order to avoid surface-disturbing activities in Greater Sage-Grouse Priority Habitat (Core Population Areas and Core Population Connectivity Corridors), priority will be given to leasing fluid mineral resources outside of priority habitat. Within Priority Habitat (Core Population Areas and Core Population Connectivity Corridors), leases should be a minimum of 640 contiguous acres of federal mineral estate. Smaller parcels may be leased only when 640 contiguous acres of federal mineral estate is not available and leasing is necessary to remain in compliance with laws, regulations and policy; for example, to protect the federal mineral estate from drainage or to commit the federal mineral estate to unit or communitization agreements. Preliminary parcels reviewed for possible offering in a lease sale should comply with this minimum lease size. Expressions of interest that are less than this minimum lease size would be evaluated and modified by the BLM to meet the minimum lease size, where possible, prior to review for possible offering in a lease sale. (conserves habitat)
- SS WL-4025: In order to avoid surface-disturbing activities in Greater Sage-Grouse Priority Habitat (Core Population Areas and Core Population Connectivity Corridors), priority will be given to development of oil and gas and other mineral resources outside of priority habitat, subject to applicable stipulations. When authorizing development of oil and gas and other mineral resources in priority habitat, subject to applicable stipulations for the conservation of Greater Sage-Grouse, priority will be given to development in non-suitable habitat areas first and then in the least suitable habitat for Greater Sage-Grouse.

Manage Greater Sage-Grouse Core Population Areas as follows (Map 40) (conserves habitat and populations):

- Prohibit surface occupancy and disruptive activities within 0.6 mile of the perimeter of occupied Greater Sage-Grouse leks (independent of habitat suitability). (SS WL-4024: Fluid Mineral leasing NSO)
- Within core population areas, allow on average no more than 1 energy or mining facility per 640 acres. Within all Priority Habitat Management Area, and for all resource uses, allow on average no more than 5 percent total surface disturbance per 640 acres within the Disturbance Density Calculation Tool (DDCT) analysis area. (SS WL-4024: Fluid Mineral leasing CSU)
 - Design and manage facilities to prevent WNV transmission.
 - Prohibit overhead electric transmission lines unless within 0.5 mile either side of existing 115 kV or larger transmission lines creating a corridor no wider than 1.0 mile.
 - Work with proponents to limit project related noise where it would be expected to reduce habitat functionality.
The BLM would evaluate the potential for limitation of new noise sources on a case-by-case basis as appropriate.
BLM's near-term goal would be to limit noise sources that would be expected to negatively impact priority habitat area sage-grouse populations and to continue to support the establishment of ambient baseline noise levels for occupied priority habitat area leks. As additional research and information emerges, specific new limitations appropriate to the type of projects being considered would be evaluated and appropriate limitations would be implemented where necessary to minimize potential for noise impacts on sage-grouse priority population behavioral cycles. As new research is completed, new specific limitations would be coordinated with the WGFD and partners. Noise levels at the perimeter of the lek should not exceed 10 A-weighted decibels (dBA) above ambient noise.
 - Bury electric distribution lines where possible; if not possible, then locate overhead lines at least 0.6 mile from the perimeter of occupied Greater Sage-Grouse leks and install raptor perch guards.
 - Buried utilities constructed in designated utility corridors would not require that a DDCT be conducted.
 - Locate new roads that will have relatively high levels of activity (accessing multiple wells, housing development) greater than 1.9 miles from the perimeter of occupied Greater Sage-Grouse leks. Construct roads to minimum design standards needed.
 - Vegetation treatments in nesting and wintering habitat that would reduce sagebrush canopy cover to less than 15 percent would not be conducted unless it can be shown to be beneficial to sage-grouse habitat and removal of sagebrush canopy cover below 15 percent will be subject to the DDCT.
- Restore disturbed sagebrush communities on BLM surface to meet the Wyoming DEQ community-specific full shrub density standard (Chapter 4 Rules and Regulations, option III) for all predisturbance shrub species and 5 percent minimum canopy cover of sagebrush. A 90 percent confidence interval is required to demonstrate achievement of the standard. The standard must be demonstrated the last year of the responsibility period, and all planted shrubs shall have been in place for at least two years.
- Prohibit surface-disturbing and disruptive activities from March 15 to June 30 (independent of habitat suitability). (SS WL-4024: Fluid Mineral leasing TLS)
- Prohibit surface-disturbing and disruptive activities within Greater Sage-Grouse winter concentration areas, from December 1 to March 14. (SS WL-4024: Fluid Mineral leasing TLS)

To the extent necessary to prevent unnecessary or undue degradation, manage as follows within Greater Sage-Grouse Core Population Connectivity Corridors (conserves habitat and populations):

- Prohibit surface occupancy and disruptive activities within 0.6 mile of the perimeter of occupied Greater Sage-Grouse leks (independent of habitat suitability). (SS WL-4024: Fluid Mineral leasing NSO)
- Allow on average no more than 5 percent total surface disturbance per 640 acres within the DDCT analysis area. (SS WL-4024: Fluid Mineral leasing CSU)
 - Design and manage facilities to prevent WNV transmission.
 - Work with proponents to limit project related noise where it would be expected to reduce habitat functionality.

The BLM would evaluate the potential for limitation of new noise sources on a case-by-case basis as appropriate.

BLM's near-term goal would be to limit noise sources that would be expected to negatively impact priority habitat area sage-grouse populations and to continue to support the establishment of ambient baseline noise levels for occupied priority habitat area leks. As additional research and information emerges, specific new limitations appropriate to the type of projects being considered would be evaluated and appropriate limitations would be implemented where necessary to minimize potential for noise impacts on sage-grouse priority population behavioral cycles. As new research is completed, new specific limitations would be coordinated with the WGFD and partners. Noise levels at the perimeter of the lek should not exceed 10 dBA above ambient noise.
 - Buried utilities constructed in designated utility corridors would not require that a DDCT be conducted.
 - Vegetation treatments in nesting and wintering habitat that would reduce sagebrush canopy cover to less than 15 percent would not be conducted unless it can be shown to be beneficial to sage-grouse habitat and removal of sagebrush canopy cover below 15 percent will be subject to the DDCT. Wildland fire burns will be treated as disturbance if sagebrush is reduced below 5% canopy cover, unless there is an implementation plan outlining restoration efforts and 3 years of data showing a trend back to suitable habitat.
- Restore disturbed sagebrush communities on BLM surface to meet the Wyoming DEQ community-specific full shrub density standard (Chapter 4 Rules and Regulations, option III) for all predisturbance shrub species and 5 percent minimum canopy cover of sagebrush. A 90 percent confidence interval is required to demonstrate achievement of the standard. The standard must be demonstrated the last year of the responsibility period, and all planted shrubs shall have been in place for at least two years.
- Prohibit surface-disturbing and disruptive activities within 4 miles of occupied Greater Sage-Grouse leks from March 15 to June 30 (independent of habitat suitability and restricted to within Core Population Connectivity Corridors). (SS WL-4024: Fluid Mineral leasing TLS)
- Prohibit surface-disturbing and disruptive activities within Greater Sage-Grouse winter concentration areas from December 1 to March 14. (SS WL-4024: Fluid Mineral leasing TLS)

Manage as follows within occupied Greater Sage-Grouse habitat outside of Core Population Areas and Core Population Connectivity Corridors:

- Prohibit or restrict surface occupancy and disruptive activities within 0.25 mile of the perimeter of occupied Greater Sage-Grouse leks. (SS WL-4024: Fluid Mineral leasing NSO)

- Reduce surface disturbance for authorizations within 0.25 mile of occupied Greater Sage-Grouse leks by (SS WL-4024: Fluid Mineral leasing CSU):
 - Design and manage facilities to prevent WNV transmission.
 - Prohibit overhead transmission lines.
- Restore disturbed sagebrush communities on BLM surface to meet the Wyoming DEQ community-specific full shrub density standard (Chapter 4 Rules and Regulations, option III) for all predisturbance shrub species and 5 percent minimum canopy cover of sagebrush. A 90 percent confidence interval is required to demonstrate achievement of the standard. The standard must be demonstrated the last year of the responsibility period, and all planted shrubs shall have been in place for at least two years.

Recommend for all surface-disturbing activities on BLM surface adjacent to Core Population Areas or Core Population Connectivity Corridors, or within or adjacent to lands involved in Greater Sage-Grouse conservation projects.

- Work with proponents to limit project related noise where it would be expected to reduce functionality of habitats that support priority habitat area populations. The BLM would evaluate the potential for limitation of new noise sources on a case-by-case basis as appropriate. BLM's near-term goal would be to limit noise sources that would be expected to negatively impact priority habitat area sage-grouse populations and to continue to support the establishment of ambient baseline noise levels for occupied priority habitat area leks. As additional research and information emerges, specific new limitations appropriate to the type of projects being considered would be evaluated and appropriate limitations would be implemented where necessary to minimize potential for noise impacts on sage-grouse priority population behavioral cycles. As new research is completed, new specific limitations would be coordinated with the WGFD and partners. Noise levels at the perimeter of the lek should not exceed 10 dBA above ambient noise.
- Prohibit surface-disturbing and disruptive activities within 2.0 miles of occupied Greater Sage-Grouse leks, from March 15 to June 30 (independent of habitat suitability). (SS WL-4024: Fluid Mineral leasing TLS)
- Prohibit surface-disturbing and disruptive activities from December 1 to March 14 within mapped Greater Sage-Grouse winter concentration areas that support populations of Greater Sage-Grouse that attend leks within Core Population Areas. (SS WL-4024: Fluid Mineral leasing TLS)

Other Special Status Species

- Goal BR:10 Distribution and abundance of all special status species are optimized. (conserves populations)
 - Objective BR:10.2 Manage BLM-administered lands to maintain or restore populations and habitat consistent with conservation requirements for special status species. (conserves habitat and populations)
 - Objective BR:10.3 Develop effective conservation and cooperative management plans, strategies, and agreements with stakeholders. (conserves habitat and populations)
- SS WL-4001: Utilize current research, management and conservation plans, and similar related documents to guide special status species habitat management. (conserves habitat)
- SS WL-4002: Implement actions set forth in recovery plans, conservation measures, terms and conditions, protection measures, and appropriate BMPs and reasonable and prudent measures within biological opinions for Threatened and/or Endangered wildlife species, including those

specific to this RMP and any future statewide programmatic biological opinions. (conserves habitat and populations)

- SS WL-4003: Maintain (size and quality) or enhance current habitat utilized by special status species. Enlarge/restore habitat on a site-specific basis. (conserves habitat)
- SS WL-4004: Maintain or enhance the integrity of identified special status wildlife species migration corridors. Manage identified special status wildlife species travel corridors consistent with other resource values. (conserves habitat)
- SS WL-4005: Locate and manage facilities to mitigate noise impacts on special status species. (conserves habitat)
- SS WL-4006: Manage surface-disturbing and disruptive activities to mitigate impacts on special status wildlife species and their habitats. (conserves habitat and populations)
- SS WL-4007: Apply a CSU stipulation to fluid mineral leases containing special status species habitat. Surveys required for clearance. (conserves habitat)
- SS WL-4018: Use the Fire Management Plan to incorporate the most current sagebrush habitat information and to guide fire suppression priorities in sagebrush habitats. (conserves habitat)

Vegetation

- Goal BR:1 Vegetation resources sustained in desired ecological conditions. (conserves habitat)
 - Objective BR:1.1 Manage communities for a diversity of native species, habitats, seral stages and distribution. (conserves habitat)
 - Objective BR:1.2 Manage for healthy vegetation communities to ensure their capability to provide sufficient plant composition, cover and litter accumulation to protect soils from wind and water erosion and enhance nutrient cycling and productivity. (conserves habitat)
 - Objective BR:1.3 Reclaim areas affected by surface-disturbing activities to promote healthy functioning native plant communities. (promotes habitat restoration)
 - Objective BR:1.4 Manage habitat to facilitate the conservation, recovery and maintenance of populations of native, desirable non-native, and special status plant species consistent with appropriate local, state, and federal conservation requirements and management plans. (conserves habitat)
 - Objective BR:1.5 Manage for healthy native plant communities by reducing and managing invasive, non-native noxious species. (conserves habitat)

Vegetation – Grassland and Shrubland Communities

- Goal BR:3 A diverse landscape of native grasslands and shrublands sustained in desired ecological conditions. (conserves habitat)
 - Objective BR:3.1 Manage for a full range of sagebrush, shrub, and grassland communities with diverse native species and subspecies, composition, canopies, densities, and age classes across the landscape. (conserves habitat)
- GS-4001: Manage vegetative communities (Map 25) in accordance with Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming. (conserves habitat)
- GS-4002: Use an integrated management approach (e.g., mechanical, chemical, biological treatments, prescribed fire, and grazing management techniques) to maintain, restore, and enhance the health and diversity of plant communities to achieve resource or multi-resource objectives. (conserves habitat)
- GS-4005: Manage grasslands and shrublands to protect, preserve, or enhance plant communities. (conserves habitat)

- GS-4006: Manage the siting of facilities and related infrastructure (utility corridors, roads) to reduce impacts to vegetation resources. (conserves habitat)
- GS-4007: Manage the planning and development of travel routes, recreational uses, mineral exploration and development sites, and ROW to reduce impacts to the vegetation resource. (conserves habitat)
- GS-4008: Develop a contingency plan addressing catastrophic natural events such as drought, wildfires, and large-scale pest infestations, incorporating strategies that best protect vegetation resources. (conserves habitat)
- GS-4009: Work with landowners on split estate lands to reestablish disturbed sites to healthy plant communities in accordance with the ecological site potential. (promotes habitat restoration)

Vegetation – Forest and Woodland Communities

- Forest-4006: Actively manage woodlands to prevent expansion into other communities consistent with multiple resource values, on a project-specific basis. (conserves habitat)

Vegetation – Invasive Species and Pest Management

- Goal BR:5 Healthy native communities with manageable levels of pathogens, undesirable, invasive, non-native, or noxious species. (conserves habitat)
 - Objective BR:5.1 Develop and maintain baseline information regarding the extent, location, and potential impact(s) of pest species. From this baseline information develop and implement an Integrated Pest Management Plan. (conserves habitat)
 - Objective BR:5.2 Facilitate support for an integrated approach for the detection, management or eradication of new and minor infestations. (conserves habitat)
 - Objective BR:5.3 Develop, implement, and maintain a management program for annual bromes and other invasive or undesirable species not listed as noxious, utilizing the best available science and BMPs. (conserves habitat)
 - Objective BR:5.4 Coordinate with Animal and Plant Health Inspection Service (APHIS) to facilitate pest and predator management. (conserves populations)
- Pest-4002: Manage designated pests on public surface lands using an Integrated Pest Management Approach consistent with Department of the Interior (DOI) Manual 517 (BLM 2007f). (conserves habitat)
- Pest-4003: Limit surface disturbance to the minimum needed for safe project completion to limit the spread of noxious weeds. (conserves habitat)
- Pest-4004: Use certified noxious weed seed-free products on all BLM-administered projects and lands. (conserves habitat)
- Pest-4005: Implement and maintain cooperative integrated pest management programs with county weed and pest districts, state agencies, private industry, grazing lessees, and other stakeholders in conjunction with BLM weed and pest control work on public lands adjoining deeded and state lands (Map 27). (conserves habitat)
- Pest-4006: Require surface or vegetation disturbance areas, including areas formerly receiving or holding water, be treated for invasive species and revegetated. (conserves habitat)

- Pest-4009: Treat those plants on the State of Wyoming Designated list, the appropriate county lists, and other species of concern as determined by BLM resource specialists. (conserves habitat)
- Pest-4010: Designate and prioritize areas for the treatment of annual brome species. (conserves habitat)

Vegetation – Riparian and Wetland Communities

- Goal BR:4 Health and functional capabilities in riparian/wetland systems are maintained. (conserves brood-rearing habitat)
 - Objective BR:4.1 Manage lotic and lentic wetland/riparian systems at a minimum to achieve and/or maintain PFC. (conserves brood-rearing habitat)
 - Objective BR:4.2 Improve riparian systems and wetlands in systems operating at less than PFC. (conserves brood-rearing habitat)
 - Objective BR:4.3 Manage contributing watersheds to sustain riparian health and water quality. (conserves brood-rearing habitat)
 - Objective BR:4.4 Manage and enhance riparian and wetland systems for plant, insect, fish and wildlife species that depend on these systems for their health and well being. (conserves brood-rearing habitat)
 - Objective BR:4.5 Coalbed Natural Gas (CBNG) created riparian and wetland systems will be evaluated, retained, or reclaimed to support vegetation and other resource values. (conserves brood-rearing habitat)
- Riparian-4002: Prioritize, and develop activity and implementation plans to manage riparian systems to be at or above, or continue to be improving toward, PFC while achieving the Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming. (conserves brood-rearing habitat)
- Riparian-4003: Manage riparian and wetland systems to enhance forage conditions and improve water quality. Manage all riparian systems with sensitive species concerns to a succession stage appropriate for that system, including vertical as well as horizontal vegetative structure and composition. (conserves brood-rearing habitat)
- Riparian-4004: Expand and enhance riparian/wetland systems and habitat in cooperation with stakeholders. (conserves brood-rearing habitat)
- Riparian-4005: Prevent degradation, loss, or destruction of riparian/wetland habitat. (conserves brood-rearing habitat)
- Riparian-4008: Allow surface disturbance within 500 feet of riparian/wetlands systems and aquatic habitats where riparian/wetland and other resource objectives (including, but not limited to soil, slope, and vegetation) can be met. (Riparian-4009: Fluid Mineral leasing CSU) (conserves brood-rearing habitat)
- Riparian-4010: Identify and manage systems capable of achieving Desired Future Condition (DFC). (conserves brood-rearing habitat)
- Riparian-4011: Restore vegetation in CBNG supported wetland and riparian systems on BLM surface and/or lease in accordance with the ecological site potential. (conserves brood-rearing habitat)

Climate Change

No proposed management actions directly applicable to Greater Sage-Grouse conservation (See Air Quality for proposed air resources management).

Fire and Fuels Management

- Goal FM:1 Life, property, and resource values are protected. (conserves habitat)
 - Objective FM:1.1 Respond to unplanned wildfires based on: (1) ecological, (2) social, and (3) legal consequences while supporting other resource values. (conserves habitat)
 - Objective FM:1.5 Implement appropriate emergency stabilization and rehabilitation actions following wildland fire. (conserves habitat)
- Goal FM:2 Plant community and hazardous fuel objectives are achieved. (conserves habitat)
 - Objective FM:2.1 Improve fire regime condition class and maintain or improve conditions of fire-adapted landscapes by managing fire, planned and unplanned, to accomplish beneficial resource objectives. (conserves habitat)
- Fire-3001: A Fire Management Plan for the Wyoming High Plains District will be maintained that more specifically outlines management response and implementation actions for wildland fire response of public lands. (conserves habitat)
- Fire-3002: A resource advisor appropriate to the potentially affected resource will be consulted, or assigned, to all wildland fires that involve or threaten BLM-administered lands. (conserves habitat)
- Fire-3006: Implement the BLM Emergency Stabilization and Burned Area Rehabilitation standards located in the DOI Interagency Burned Area Emergency Response Guidebook (DOI 2004) and BLM Burned Area Emergency Stabilization and Rehabilitation Handbook (BLM 2007c) as needed. (promotes habitat restoration)
- Fire-3007: Use the District Fire Management Plan to implement the objectives of this RMP; to address fire management on a landscape scale, to maintain or improve conditions in fire-adapted landscapes, and to accomplish resource management objectives. (conserves habitat)
- Fire-3011: Response to wildfire varies from full protection in areas where fire is undesirable to monitoring fire behavior in areas where fire can be managed to accomplish other resource objectives. (conserves habitat)
- Fire-3012: Prohibit heavy equipment use within the following areas, except when human safety is at risk or if the expected fire effects would cause more resource damage than the use of heavy equipment: Identified Greater Sage-Grouse important habitats: Core Population Area, nesting, brood-rearing, Core Population Connectivity Corridor, or winter habitat. (conserves habitat)
- Fire-3013: Use protection strategies in the following areas: Where sensitive or high value resources would be adversely affected by fire (i.e., Greater Sage-Grouse priority habitat). (conserves habitat)
- Fire-3014: Evaluate all fires and rehabilitate fire-damaged lands as needed to meet resource objectives. Repair suppression damages as necessary. (promotes habitat restoration)
- Fire-3015: Use wildland fire and other vegetation treatments to meet desired management objectives. (conserves habitat)

Livestock Grazing Management

- Goal LR:11 Public rangelands provide for a sustainable level of livestock grazing consistent with other resource values and sustained yield. (conserves habitat)
 - Objective LR:11.2 Manage forage to maintain or improve ecological states and achieve and/or maintain Standards for Healthy Rangelands and Guidelines for Livestock Grazing

Management for the Public Lands Administered by the BLM in the State of Wyoming. (conserves habitat)

- Objective LR:11.3 Monitor and evaluate rangeland health and condition in coordination with cooperators, and lessees to determine if, and what additional management is needed to achieve desired ecological state. (conserves habitat)
- Grazing-6001: Develop and implement appropriate livestock grazing management actions to achieve the Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming, to provide watershed protection, to improve forage for livestock, forage and habitat for wildlife, and enhance rangeland health. (conserves habitat)
- Grazing-6004: Continue implementation of existing Allotment Management Plans (AMPs). Develop and implement new AMPs with grazing lessees and other stakeholders to achieve desired resource goals and objectives. (conserves brood-rearing habitat)
- Grazing-6005: Manage livestock grazing to sustain riparian, wetland, mountain mahogany, specials status species, or other special habitats. (conserves habitat)
- Grazing-6009: Implement strategies that best protect rangeland resources during periods of drought. Cooperate with stakeholders for voluntary adjustments in livestock use and/or livestock management. (conserves habitat)
- Grazing-6015: Develop range improvements in accordance with resource needs and livestock management. (conserves habitat)
- Grazing-6016: Conduct baseline inventories. Develop, implement, and monitor AMPs. Base AMP goals/objectives in Category I and M allotments on resource protection and watershed health. (conserves habitat)
- Grazing-6019: Locate livestock salt or mineral supplements a minimum of 500 feet away from water sources, riparian areas, and aspen stands. (conserves brood-rearing habitat)
- Grazing-6021: Provide rest/deferment from livestock grazing following wildfire, prescribed burns, and other vegetative treatments until resource objectives are met. (promotes habitat restoration)

Wild Horses and Burros

Resource not present.

Lands and Realty

Lands and Realty (Land Tenure)

- Goal LR:2 Manage land tenure adjustments and land use authorizations to meet the needs of the customers while protecting other resource values. (conserves habitat)
 - Objective LR:2.1 Develop and maintain a land-ownership pattern that improves access for public use, and improves management and protection of BLM-administered lands. (conserves habitat)
- L&R-6002: Consider land use authorizations (permits, leases, etc.) on a project-specific basis consistent with other resource objectives. (conserves habitat)
- L&R-6003: Consider withdrawals for surface and/or minerals on a project-specific basis. (conserves habitat)
- L&R-6011: Acquire private or state land or interest in land from willing sellers consistent with other resource objectives, on a project-specific basis. (conserves habitat)
- L&R-6012: Acquire and dispose of land based on all resource values, including but not limited to agricultural potential and water. (conserves habitat)

- L&R-6014: Prioritize acquiring land or interests in lands in areas adjacent to large blocks of BLM-administered land or other lands having significant resource or other values before other areas. (conserves habitat)

Renewable Energy (Solar and Wind)

See Special Status Species, Greater Sage-Grouse.

Rights-of-Way and Corridors

- Goal LR:4 Primary infrastructure corridors and subsidiary routes consistent with other resource values. (conserves habitat)
 - Objective LR:4.1 Manage public lands to meet the needs of ROW customers while supporting other resource values. (conserves habitat)
 - Objective LR:4.3 Identify infrastructure corridors consistent with other resource values. (conserves habitat)
 - Objective LR:4.4 Make opportunities available for exploration and development of Carbon Dioxide (CO₂) sequestration research and activities, while avoiding or mitigating impacts of these activities on other resource values. (conserves habitat)
- ROW-6001: Designate corridors for major ROW to minimize surface disturbance and impacts to other resources. (conserves habitat)
- ROW-6004: The preferred location for new ROW will be in or adjacent to existing disturbed areas associated with existing ROW, constructed roads, or highways. (conserves habitat)
- ROW-6005: Maintain a transportation management system in cooperation with appropriate state and local agencies to meet public and resource management needs. (conserves habitat)
- ROW-6009: Designate the following corridors for major ROW transportation and utility use, (Map 58), in cooperation with the State of Wyoming: Echeta Road; Sheridan to Gillette, largely following US 14/16; Highway 59 north of Gillette; Interstate 25; Interstate 90; Gillette to Montana State Line; Powder River; Powder River Breaks (Buffalo to Gillette). Corridor use is required. No above ground lines will be authorized in the Powder River or Powder River Breaks corridors. Lines must be buried within Greater Sage-Grouse Core Population Areas unless within 0.5 mile either side of existing 115 kV or larger transmission lines creating a corridor no wider than 1.0 mile. (conserves habitat)
- ROW-6010: Authorize and place above ground facilities (i.e., compressors, electric distribution powerlines) within ROW and other disturbance areas when resource objectives can be met. (conserves habitat)
- ROW-6012: Evaluate CO₂ sequestration proposals where in accordance with management identified within Alternative D. (conserves habitat)

Withdrawals

Included under the resource for which the withdrawal or closure is recommended.

Mineral Resources

Leasables – Fluid Minerals

- O&G-2001: Continue to require lessees to conduct operations in a manner that minimizes adverse impacts to other resources and other land uses and users. (conserves habitat)

Locatable Minerals

- Objective MR:1.1 Provide opportunities for the exploration and development of locatable minerals, as well as mill and tunnel site operations, while avoiding or mitigating the effects of

these activities on other resource values so that unnecessary or undue degradation is prevented. (conserves habitat)

Salable Minerals (Mineral Materials)

- Objective MR:5.1 Provide opportunities for exploration and development of salable minerals while avoiding or mitigating effects to other resource values. (conserves habitat)

Leasables – Coal

- Objective MR:2.1 Maintain coal leasing and exploration, while minimizing impacts to other resource values. (conserves habitat)

Leasables – Other (Non-energy Leasables)

No proposed management directly related to Greater Sage-Grouse conservation; no foreseeable commercial potential within the planning area.

Travel and Transportation Management

- Goal LR:5 A safe transportation network that supports other resource values. (conserves habitat)
 - Objective LR:5.1 Utilize a comprehensive travel management approach to sustain and enhance access, recreational experiences, and support other resource values. (conserves habitat)
 - Objective LR:5.3 Designate all BLM-administered lands as Open, Limited, or Closed to Off-highway Vehicle (OHV) use, in consideration of other resource values. (conserves habitat)
 - Objective LR:5.4 Provide for acceptable modes of legal public access that supports other resources, reduces conflicts, and provides for diverse recreation opportunities. (conserves habitat)
- Trans-6002: Evaluate roads constructed under other initiatives (e.g., oil and gas exploration) for inclusion in the BLM transportation system. Roads that are no longer needed for their original purposes are assessed for addition to the BLM transportation system prior to reclamation. (conserves habitat)
- Trans-6004: Design, construct, and maintain roads or trails based on the specific objectives for that trail or road in consideration of other resources. Design, construct, and maintain roads to minimize surface disturbance, changes to surface water runoff, and erosion. (conserves habitat)
- Trans-6006: Base road or trail closures and abandonments on resource protection, demand for new roads and accommodation of authorized uses. (conserves habitat)
- Trans-6007: Maintain transportation system roads under BLM jurisdiction in accordance with assigned maintenance levels and in consideration of other resource values. Maintain administrative roads on an as needed basis, dependent on time, funding, and access priorities. (conserves habitat)
- Trans-6008: Within 5 years of the ROD, inventory all routes on public land and develop a Travel Management Plan to classify and designate routes for continued use or decommissioning and reclamation. (conserves habitat)
- Trans-6014: Limit OHV use to designated routes unless compelling reasons exist to classify parcels as Open or Closed, and is consistent with other resource values. (conserves habitat)
- Trans-6019: Limit motorized vehicle use to designated routes within habitat of special status species consistent with travel management designations for that area. Routes will be designated to avoid occupied habitat during travel management planning. (conserves habitat)
- Trans-6020: Evaluate existing routes in the vicinity of any new system roads for closure and reclamation consistent with other resource values. (conserves habitat)

Recreation

- Objective LR:7.2 Manage recreation to protect resources, maintain public health and safety, and to provide a diverse array of benefits to the public. (conserves habitat)
- Goal LR:8 Recreation facilities balance public demand with other resource values. (conserves habitat)
 - Objective LR:8.1 Design and maintain recreation sites to meet acceptable health and safety standards while supporting other resource values. (conserves habitat)
- Rec-6003: Open the planning area to dispersed recreation where consistent with other resource values. (conserves habitat)
- Rec-6010: Avoid riparian habitat or develop and manage recreational sites, recreation facilities, and recreational access in a manner that minimizes impacts to riparian habitats. (conserves brood-rearing habitat)
- Rec-6011: Prohibit dispersed camping and commercial camps within 200 feet of perennial surface water. (conserves brood-rearing habitat)
- Rec-6015: Allow additional recreation facilities in areas where they are supported by recreational use and are consistent with other resource values. (conserves habitat)
- Rec-6018: Designate the following areas as Special Recreation Management Areas (SRMAs) and delineate discrete recreation management zone boundaries (Map 71): Burnt Hollow (17,280 acres); Dry Creek Petrified Tree (2,567 acres); Hole-in-the-Wall (11,952 acres); Middle Fork Powder River (10,083 acres); Mosier Gulch (1,026 acres); Welch Ranch (1,748 acres); Weston Hills (9,504 acres). Strategically emphasize a variety of recreation opportunities along with the protection of natural and cultural resources. Recreation and Visitor Services (R&VS) management will be recognized as the predominant land use focus in SRMAs. (conserves habitat)
- Rec-6019: Do not lease minerals within the boundary of all SRMAs except Weston Hills (CSU). (conserves habitat)
- Rec-6021: Allow surface disturbance within designated SRMAs for administrative use only, where consistent with other resource values. (conserves habitat)
- Rec-6022: Recommend withdrawals from mineral entry under the mining laws in designated SRMAs. (conserves habitat)
- Rec-6023: Allow salable mineral development within designated SRMAs for administrative use only. (conserves habitat)

Special Designations

No proposed Special Designation management directly related to Greater Sage-Grouse conservation.

Other Resources

Soil

- Objective PR:2.1 Achieve and maintain Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming. (conserves habitat)
- Objective PR:2.3 Rehabilitate all surface-disturbing activities consistent with applicable laws, regulations, and policies. (promotes habitat restoration)
- Soil-1002: Authorized surface-disturbing activities will include plans for reclamation; site-specific reclamation actions should reflect the complexity of the project, environmental concerns, and the reclamation potential of the site. (promotes habitat restoration)

Water

- Goal PR:3 Watershed, surface water, and groundwater resources are consistent with applicable state and federal standards and regulations. (conserves habitat)
 - Objective PR:3.1 BLM actions maintain or improve watershed, wetland, and riparian functions to support desired surface-flow regimes and water quality. (conserves habitat)
- Water-1007: Design and manage land use and surface-disturbing activities to reduce channel and bank erosion and the associated loss of riparian habitats. (conserves brood-rearing habitat)
- Water-1013: Allow surface disturbance within 500 feet of springs, non-CBNG reservoirs, water wells, or perennial streams where water and other resource objectives (including, but not limited to soil, slope, and vegetation) can be met. (Water-1014: Fluid Mineral leasing CSU) (conserves brood-rearing habitat)
- Water-1016: Evaluate unneeded reservoirs for removal and reclamation. (promotes habitat restoration)

Fish and Wildlife Resources

- Goal BR:6 Distribution and abundance of all native and desirable non-native species are optimized. (conserves populations)
 - Objective BR:6.1 BLM actions prevent and/or reduce impacts to desirable species. (conserves habitat and populations)
 - Objective BR:6.2 In coordination with cooperating agencies, develop and implement an achievable Wildlife Monitoring and Protection Plan. (conserves habitat and populations)
 - Objective BR:6.3 Maintain, restore, or improve the continuity and productivity of fish and wildlife habitats to support WGFD population objectives. (conserves habitat)
 - Objective BR:6.4 Develop and implement an adaptive conservation and management strategy. (conserves habitat and populations)
- Goal BR:7 Sufficient functional habitat for native and desirable non-native species. (conserves habitat)
 - Objective BR:7.1 Evaluate, update, and revise as necessary existing Wildlife Habitat Management Plans. (conserves habitat)
 - Objective BR:7.2 Develop Wildlife Habitat Management Plans for areas with important habitats. (conserves habitat)
 - Objective BR:7.3 Manage habitat consistent with local, state, and federal management plans, as applicable. (conserves habitat)
 - Objective BR:7.4 Continue to gather habitat and population data while concurrently monitoring human and natural disturbance dynamics to improve habitat management. (conserves habitat and populations)
 - Objective BR:7.5 Provide security habitat, sufficient in amount and distribution, to support WGFD population objectives for fish and wildlife to escape from disruptive activities. (conserves habitat)
 - Objective: BR:7.6 Maintain and provide functioning sagebrush habitat to sustain sagebrush obligates and other sagebrush dependent species. (conserves habitat)
- Goal BR:8 Fish and wildlife are able to move between areas of functionally intact habitat. (conserves habitat and populations)
 - Objective BR:8.1 Develop Travel Management Plans for areas important for fish and wildlife while supporting other resource values. (conserves habitat and populations)
 - Objective BR:8.2 Develop a ROW Management Plan for utility corridors to manage impacts to areas of habitat important to fish and wildlife consistent with other resource values. (conserves habitat)

- Objective BR:8.3 Land acquisitions should support desirable fish and wildlife populations or habitat. (conserves habitat)
- Objective BR:8.4 Restore functionality to areas of degraded habitat important to fish and wildlife populations consistent with other resource values. (conserves habitat and populations)
- Fish-4008: Maintain or enhance streams and riparian areas associated with Class I and II streams (WGFD classifications), Powder River, Tongue River, and other appropriate areas for desired fisheries potential. (conserves brood-rearing habitat)
- Fish-4012: Allow surface-disturbing activities within 0.25 mile of naturally occurring water bodies containing native and desirable non-native fish species where fish resource objectives can be met. (Fish-4013: Fluid Mineral leasing CSU) (conserves brood-rearing habitat)
- WL-4001: Develop appropriate mitigation for surface-disturbing and disruptive activities associated with wildlife habitat management through use of the mitigation guidelines described in Appendix J (p. 2155). (conserves habitat)
- WL-4002: Maintain or improve important wildlife habitats through vegetative manipulations, habitat improvement projects, livestock grazing strategies, and the application of The Wyoming Guidelines for Managing Sagebrush Communities with Emphasis on Fire Management (Wyoming Interagency Vegetation Committee 2002) and Appendix J (p. 2155), WGFD Strategic Habitat Plan (WGFD 2001), State Wildlife Action Plan (SWAP) (WGFD 2010b), and similar guidance updated over time. (conserves habitat)
- WL-4003: Continue to use existing Habitat Management Plans and update as necessary to include management objectives and prescriptions for wildlife: South Big Horns Habitat Management Plan (BLM 1986c), including a portion or all of the Gardner Mountain and North Fork Wilderness Study Areas (WSAs); Wetlands Habitat Management Plan (BLM 1986b); and Middle Fork Powder River Habitat Management Plan (BLM 1980). (conserves habitat)
- WL-4005: Consult with the WGFD and USFWS, in accordance with MOUs, when applying mitigation for wildlife and before waiving, allowing exceptions to, or modifying wildlife-related land use restrictions and mitigation. (conserves habitat and populations)
- WL-4006: Provide, to the extent possible, suitable habitat and forage to support wildlife population objectives as defined by WGFD. BLM will cooperatively consider proposals by the WGFD to change population objective levels based on habitat capability and availability. (conserves habitat and populations)
- WL-4007: Manage access to protect crucial habitats in cooperation with WGFD and other stakeholders. (conserves habitat)
- WL-4008: Utilize current research, management and conservation plans, and similar related documents to guide wildlife habitat management. (conserves habitat)
- WL-4009: Construct new fences to avoid adverse impacts to wildlife and in accordance with BLM Fencing Handbook 1741-1 (BLM 1989) and WO IM 2010-022: Managing Structures for the Safety of Sage-grouse, Sharp-tailed grouse, and Lesser prairie chicken (BLM 2009e). (conserves habitat and populations)
- WL-4012: Inventory, record, and report existing type, condition and location of BLM fences. Prioritize fence projects and annually implement modifications in accordance with appropriate wildlife needs and the BLM Fencing Handbook 1741-1. (conserves habitat and populations)
- WL-4013: Allow surface-disturbing and disruptive activities to occur throughout the entire life of projects during seasons important for wildlife when wildlife resource objectives can be met. (conserves habitat and populations)
- WL-4014: Powerlines (distribution and transmission) will be designed to minimize wildlife related impacts and constructed to the latest APLIC standards. Prohibit above ground

distribution powerlines unless identified in an approved distribution plan. (conserves habitat and populations)

Cultural Resources

- Cultural-5007: Allow surface disturbance and infrastructure within 3.0 miles of the following sites where development is either not visible, or will result in a weak contrast to the setting: Pumpkin Buttes, Cantonment Reno, Dull Knife Battle, Crazy Woman Battle, Contributing and Unevaluated Segments of the Bozeman Trail, All Rock Art Sites, All Native American Burials. (conserves habitat)

Paleontological Resources

- Paleo-5001: Retain public lands with significant paleontological values (Map 47). (conserves habitat)
- Paleo-5006: Avoid areas containing paleontological resources of high quality or importance when developing locatable minerals. (conserves habitat)
- Paleo-5007: Apply an NSO stipulation to mineral leases in areas containing paleontological resources of high quality or importance. (conserves habitat)
- Paleo-5008: Avoid areas containing paleontological resources of high quality or importance when developing salable minerals. (conserves habitat)

Visual Resources

- VRM-5002: Incorporate BMPs for visual resources into project planning for federal actions. (conserves habitat)

RDFs are means, measures, or practices intended to reduce or avoid adverse environmental impacts. The Buffalo RMP proposes a suite of design features that would establish the minimum specifications for water developments, certain mineral development, and fire and fuels management and would mitigate adverse impacts. These design features would be required to provide a greater level of regulatory certainty than through implementing BMPs.

In general, the design features are accepted practices that are known to be effective when implemented properly at the project level. However, their applicability and overall effectiveness cannot be fully assessed except at the project-specific level when the project location and design are known. Because of site-specific circumstances, some features may not apply to some projects (e.g., when a resource is not present on a given site) or may require slight variations from what is described in the RMP/EIS (e.g., a larger or smaller protective area). All variations in design features would require appropriate analysis and disclosure as part of future project authorizations. Additional mitigation measures may be identified and required during individual project development and environmental review. The proposed RDFs are presented in Appendix D (p. 1863).

2.5.5. Adaptive Management Strategy for Greater Sage-Grouse

Management action SS WL-4010 directs that BLM's proposed management will include an adaptive management strategy for Greater Sage-Grouse.

Adaptive Management Plan

Wyoming ADPPs will include an adaptive management plan, as reviewed by the BLM WO, SOL, and USFWS, which includes: Upon determination that a hard trigger is tripped, the BLM will immediately defer issuance of discretionary authorizations for new actions within the Biologically Significant Unit for a period of 90 days. In addition, within 14 days of a determination, the Adaptive Management Working Group will convene to develop an interim response strategy and initiate an assessment to determine the causal factors.

Adaptive management is a decision process that promotes flexible resource management decision making that can be adjusted in the face of uncertainties as outcomes from management actions and other events become better understood. Careful monitoring of these outcomes both advances scientific understanding and helps with adjusting resource management directions as part of an iterative learning process. Adaptive management also recognizes the importance of natural variability in contributing to ecological resilience and productivity. It is not a ‘trial and error’ process, but rather emphasizes learning while doing. Adaptive management does not represent an end in itself, but rather a means to more effective decisions and enhanced benefits.

In relation to the BLM/USFS’ National Greater Sage-grouse Planning Strategy, adaptive management will help identify if Greater Sage-Grouse conservation measures presented in this EIS contain the needed level of certainty for effectiveness. Principles of adaptive management are incorporated into the conservation measures in the plan to ameliorate threats to a species, thereby increasing the likelihood that the conservation measure and plan will be effective in reducing threats to that species. The following provides the BLM adaptive management strategy for the Buffalo RMP.

Adaptive Management and Monitoring

This Proposed RMP contains a monitoring framework plan (Appendix B (p. 1779)) that includes an effectiveness monitoring component. The agencies intend to use the data collected from the effectiveness monitoring to identify any changes in habitat conditions related to the goals and objectives of the plan and other range-wide conservation strategies (DOI 2004; Stiver et al. 2006; USFWS 2013c). The information collected through the Monitoring Framework Plan outlined in Appendix B (p. 1779) will be used by the BLM/USFS to determine when adaptive management hard and soft triggers (discussed below) are met. The Greater Sage-Grouse adaptive management plan provides a means of addressing and responding to unintended negative impacts to Greater Sage-Grouse habitat will be addressed before consequences become severe or irreversible. This adaptive management plan:

- utilizes science based soft and hard adaptive management triggers,
- addresses multiple scales of data, and
- utilizes an adaptive management working group.

Adaptive Management Triggers

Adaptive management triggers are essential for identifying when potential management changes are needed in order to continue meeting Greater Sage-Grouse conservation objectives. With respect to Greater Sage-Grouse, all regulatory entities in Wyoming, including the BLM, use soft and hard triggers. Soft and hard triggers are focused on three metrics: (1) number of active leks, (2) acres of available habitat, and (3) population trends based on annual lek counts.

Soft Triggers:

Soft triggers are indicators that management or specific activities may not be achieving the intended results of conservation action or that unanticipated changes to populations or habitats have occurred that have the potential to place habitats or populations at risk. The soft trigger is

any deviation from normal trends in habitat or population in any given year. Metrics include, but are not limited to, annual lek counts, wing counts, aerial surveys, habitat monitoring, and DDCT evaluations. BLM field offices, with the assistance of their respective land and resource management plan implementation groups, local WGFD offices, and local Greater Sage-Grouse working groups will evaluate the metrics with the Adaptive Management Working Group (AMWG) on an annual basis. The purpose of these strategies is to address localized Greater Sage-Grouse population and habitat changes by providing the framework in which management will change if monitoring identifies negative population and habitat anomalies in order to avoid crossing a hard trigger threshold.

Hard Triggers:

Hard triggers are indicators that management is not achieving desired conservation results. Hard triggers would be considered a indicator that the species is not responding to conservation actions, or that a larger-scale impact or set of impacts is having a negative effect.

Within the range of normal population variables, hard triggers shall be determined to take effect when two of the three metrics exceeds 60 percent of normal variability for the area under management in a single year, or when any of the three metrics exceeds 40 percent of normal variability for a three year time period within a five-year range of analysis. A minimum of three consecutive years in a five-year period is used to determine trends (i.e., Y1-2-3, Y2-3-4, Y3-4-5).

Baseline Greater Sage-Grouse population levels are established by pre-disturbance surveys, reference surveys and accounting for regional and statewide trends in population levels. Population counts in Wyoming are maintained by the WGFD. Estimates of population are determined based upon survey protocols determined by the WGFD, and are implemented consistently throughout the State. Population counts are tracked for individual leks and then calculated for each Core Population Area (PHMA).

Adaptive Management Response**Soft Triggers Response:**

Soft triggers require immediate monitoring and surveillance to determine causal factors and may require curtailment of activities in the short- or long-term, as allowed by law. The project level adaptive management strategies will identify appropriate responses where the project's activities are identified as the causal factor. The management agency (BLM) and the AMWG will implement an appropriate response strategy to address causal factors not attributable to a specific project or to make adjustments at a larger regional or state-wide level.

Hard Trigger Response:

Upon determination that a hard trigger has been tripped, the BLM will immediately defer issuance of discretionary authorizations for new actions within the Biologically Significant Unit for a period of 90 days. In addition, within 14 days of a determination that a hard trigger has been tripped, the AMWG will convene to develop an interim response strategy and initiate an assessment to determine the causal factor or factors (hereafter called the causal factor assessment).

An interim response strategy will be developed, and implemented to the extent permitted by law, within 90 days of determination that a hard trigger has been tripped. The technical team (see Appendix B (p. 1779)) will be consulted to identify the scope and scale of the interim strategy. Based on the recommendation of the AMWG, the BLM will implement an interim response strategy through an Instruction Memorandum or other management mechanisms to direct management until the causal factor(s) and appropriate response(s) can be determined. The interim response strategy will consist of appropriate management measures undertaken at the

project stage, supported by the best available science, to address the specific metric which has been tripped and may include deferral of some activities as appropriate. Measures that were analyzed in this EIS and the COT, NTT reports, and NPT guidance will be reviewed in addition to current science to identify the most appropriate measures to be implemented as part of the interim response strategy. The BLM will comply with all applicable law in implementing such response(s), and, if applicable, will undertake a plan amendment or revision under BLM's planning regulations and policies.

2.5.6. Regional Mitigation for Greater Sage-Grouse Habitat Management

Consistent with the proposed plan's goals outlined in Table 2.7, "1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)" (p. 127) through Table 2.40, "8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY" (p. 275), the intent of the Proposed Plan is to provide a net conservation gain to the species. To do so, in undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation within priority habitat (core population areas and core population connectivity corridors), the BLM will require and ensure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. This is also consistent with BLM Manual 6840 – Special Status Species Management, Section .02B, which states "to initiate proactive conservation measures that reduce or eliminate threats to Bureau sensitive species to minimize the likelihood of the need for listing of these species under the ESA."

Mitigation Standards. In undertaking BLM management actions, and, consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation, the BLM will require and ensure mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. This will be achieved by avoiding, minimizing, and compensating for impacts by applying beneficial mitigation actions. Mitigation will follow the regulations from the White House Council on Environmental Quality (CEQ) (40 CFR 1508.20; e.g., avoid, minimize, and compensate), hereafter referred to as the mitigation hierarchy. If impacts from BLM management actions and authorized third party actions that result in habitat loss and degradation remain after applying avoidance and minimization measures (i.e. residual impacts), then compensatory mitigation projects will be used to provide a net conservation gain to the species. Any compensatory mitigation will be durable, timely, and in addition to that which would have resulted without the compensatory mitigation (see the concepts of durability, timeliness, and additionality as described further in Appendix B (p. 1779)).

Greater Sage-Grouse Conservation Team. The BLM/USFS will establish a WAFWA Management Zone Greater Sage-Grouse Conservation Team (hereafter, Team) to help guide the conservation of Greater Sage-Grouse, within 90 days of the issuance of the ROD. This Team will develop a WAFWA Management Zone Regional Mitigation Strategy (hereafter, Regional Mitigation Strategy). The Team will also compile and report on monitoring data (including data on habitat condition, population trends, and mitigation effectiveness) from States across the WAFWA Management Zone (see Monitoring section). Subsequently, the Team will use these data to either modify the appropriate Regional Mitigation Strategy or recommend adaptive management actions (see Adaptive Management section).

The BLM/USFS will invite governmental and Tribal partners to participate in this Team, including the State Wildlife Agencies and USFWS, in compliance with the exemptions provided for committees defined in the Federal Advisory Committee Act and the regulations that implement that act. The BLM/USFS will strive for a collaborative and unified approach between Federal agencies (e.g., USFWS, BLM, and USFS), Tribal governments, state and local government(s), and other stakeholders for greater sage-grouse conservation. The Team will provide advice, and will not make any decisions that impact Federal lands. The BLM/USFS will remain responsible for making decisions that affect Federal lands.

Developing a Regional Mitigation Strategy. The Team will develop a Regional Mitigation Strategy to inform the mitigation components of NEPA analyses for BLM/USFS management actions and third party actions that result in habitat loss and degradation. The Strategy will be developed within one year of the issuance of the ROD. The BLM's Regional Mitigation Manual MS-1794 will serve as a framework for developing the Regional Mitigation Strategy. The Regional Mitigation Strategy will be applicable to the States/Field Offices/Forests within the WAFWA Management Zone's boundaries.

Regional mitigation is a landscape-scale approach to mitigating impacts to resources. This involves anticipating future mitigation needs and strategically identifying mitigation sites and measures that can provide a net conservation gain to the species. The Regional Mitigation Strategy developed by the Team will elaborate on the components identified above (i.e. avoidance, minimization, and compensation; additionality, timeliness, and durability) and further explained in Appendix B (p. 1779).

In the time period before the Strategy is developed, BLM will consider regional conditions, trends, and sites, to the greatest extent possible, when applying the mitigation hierarchy and will ensure that mitigation is consistent with the standards set forth in the first paragraph of this section.

Incorporating the Regional Mitigation Strategy into NEPA Analyses. The BLM will include the avoidance, minimization, and compensatory recommendations from the Regional Mitigation Strategy in one or more of the NEPA analysis' alternatives for BLM management actions and third party actions that result in habitat loss and degradation and the appropriate mitigation actions will be carried forward into the decision.

Implementing a Compensatory Mitigation Program. Consistent with the principles identified above, the BLM needs to ensure that compensatory mitigation is strategically implemented to provide a net conservation gain to the species, as identified in the Regional Mitigation Strategy. In order to align with existing compensatory mitigation efforts, this compensatory mitigation program will be implemented at a State-level (as opposed to a WAFWA Management Zone, a Field Office, or a Forest), in collaboration with our partners (e.g., Federal, Tribal, and State agencies).

To ensure transparent and effective management of the compensatory mitigation funds, the BLM will enter into a contract or agreement with a third-party to help manage the State-level compensatory mitigation funds, within one year of the issuance of the ROD. The selection of the third-party compensatory mitigation administrator will conform to all relevant laws, regulations, and policies. The BLM will remain responsible for making decisions that affect Federal lands.

2.5.7. Greater Sage-Grouse Habitat Management Objectives

BLM administrated surface will be managed to maintain a minimum of 70% of lands capable of producing sagebrush with 10-30% sagebrush canopy cover. BLM will incorporate Greater Sage-Grouse Seasonal Habitat Objectives (Table 2.4, “Seasonal Habitat Desired Conditions for Greater Sage-Grouse” (p. 82)) into the design of projects or activities, as appropriate, based on ecological site potential unless the NEPA analysis associated with the specific project can demonstrate other appropriate habitat conditions based on other factors such as:

- A specific objective is not applicable to the site-specific conditions of the project or activity;
- An alternative objective is determined to provide equal or better protection for Greater Sage-Grouse or its habitat (based on appropriate scientific findings);
- Analysis concludes that following a specific objective would provide no more protection to Greater Sage-Grouse or its habitat than not following it, for the project being proposed; or
- Achievement of fuels management objectives require additional reduction in sagebrush cover to meet strategic protection of Greater Sage-Grouse habitat and conserve habitat quality for the species.

This information should not be viewed as providing standards by which to judge the overall quality of sagebrush habitats. Instead, these Greater Sage-Grouse habitat characteristics should be used as one tool for assessing habitats and guiding management actions. There is a tendency to review each indicator and its suitability category independently, but site suitability is determined by the relationship among the several indicator values in each matrix and the relative abundance of habitat types across the landscape. It is important to understand that the desired conditions described for these habitat types are based on average plant productivity and structural data and expert opinion relative to Greater Sage-Grouse use of a subset of sagebrush communities and they may not apply to all sagebrush communities in the planning area variation (Davies and Bates 2006). These measures also do not account for inter-annual climate variation (Davies and Bates 2006). Individual indicator values do not define site suitability and overall site suitability descriptions require an interpretation of the relationships between the indicators and other factors. Professional expertise and judgment are required. Measurement of these objectives will follow the steps described in the Habitat Assessment Framework for Fourth Order Habitat Descriptions.

As described in the above paragraphs, the identified habitat objectives are averages and will vary based on the individual ecological sites and their potential. Ecological sites are the basic component of a land-type classification system that describes ecological potential and ecosystem dynamics of land areas. All land/land use types are identified within the ecological site system, including rangeland, pasture, and forest land. An ecological site is defined as a distinctive kind of land with specific soil and physical characteristics that differ from other kinds of land in its ability to produce a distinctive kind and amount of vegetation and its ability to respond similarly to management actions and natural disturbances. Lands are classified considering discrete physical and biotic factors. Physical factors include soils, climate, hydrology, geology, and physiographic features. Biotic factors include plant species occurrence, plant community compositions, annual biomass production, wildlife-vegetation interactions, and other factors. Ecological dynamics, primarily disturbance regimes, such as grazing; fire; drought; management actions; and all resulting interactions are also a primary factor of ecological sites. Information and data pertaining to a particular ecological site is organized into a reference document known as an ESD. ESDs function as a primary repository of ecological knowledge regarding an ecological site. ESDs are maintained on the NRCS Ecological Site Information System,

which is the repository for information associated with ESDs and the collection of all site data (<https://esis.sc.egov.usda.gov/Welcome/pgESDWelcome.aspx>).

The ESD can help interpret if a site's potential is less than or greater than the identified habitat objectives.

These habitat objectives in Table 2.4 summarize the characteristics that research has found represent the seasonal habitat needs for Greater Sage-Grouse. The specific seasonal components identified in the Table were adjusted based on local science and monitoring data to define the range of characteristics used in this subregion. Thus, the habitat objectives provide the broad vegetative conditions we strive to obtain across the landscape that indicate the seasonal habitats used by Greater Sage-Grouse. These habitat indicators are consistent with the rangeland health indicators used by the BLM.

The habitat objectives will be part of the Greater Sage-Grouse habitat assessment to be used during land health evaluations (see Monitoring Framework, Appendix B (p. 1779)). These habitat objectives are not obtainable on every acre within the designated Greater Sage-Grouse habitat management areas. Therefore, the determination on whether the objectives have been met will be based on the specific site's ecological ability to meet the desired condition identified in the table.

All BLM use authorizations will contain terms and conditions regarding the actions needed to meet or progress toward meeting the habitat objectives. If monitoring data show the habitat objectives have not been met nor progress being made towards meeting them, there will be an evaluation and a determination made as to the cause. If it is determined that the authorized use is a cause, the use will be adjusted by the response specified in the instrument that authorized the use.

In addition to the references identified in the following table (Table 2.4, "Seasonal Habitat Desired Conditions for Greater Sage-Grouse" (p. 82)), the Conservation Plans developed for each of the Wyoming Local Sage-Grouse Working Groups will be consulted to identify specific habitat objectives appropriate for site-specific conditions. The Conservation Plans, updated in March 2014, are available on the WGFD website at: <https://wgfd.wyo.gov/web2011/wildlife-1000817.aspx>.

	Sagebrush height above snow	>10 inches (>25 cm)	Connelly, J.W., M.A. Schroeder, A.R. Sands, and C.E. Braun. 2000. Guidelines to manage sage-grouse populations and their habitats. Wildlife Society Bulletin 28:967-985.
¹ Seasonal dates can be adjusted by local unit according to geographic region. ² Absolute cover is the actual recorded cover and can exceed 100% when recorded across all species and all layers. It is not relative cover, which is the proportions of each species, and equals 100%. Note that cover is reported for only those species (e.g., sagebrush, preferred forbs) that are sampled to determine suitability of habitat for sage-grouse. Overall cover at the site will be greater than that sampled for sage-grouse habitat, due to other species present. ³ Arid corresponds to the 10 – 12 inch precipitation zone; <i>Artemisia tridentata wyomingensis</i> is a common big sagebrush sub-species for this type site (Stiver et al. <i>In Press</i>). ⁴ Mesic corresponds to the >12 inch precipitation zone; <i>Artemisia tridentata vaseyana</i> is a common big sagebrush sub-species for this type site (Stiver et al. <i>In Press</i>). ⁵ Collectively the indicators for sagebrush (cover, height, and shape), perennial grass and perennial forb (cover, height and/or availability) represent the desired condition range for nesting/early brood rearing habitat characteristics, consistent with the breeding habitat suitability matrix identified in Stiver et al. <i>In Press</i> . Sagebrush plants that are more tree or columnar-shaped provide less protective cover near the ground than sagebrush plants with a spreading shape (Stiver et al. <i>In Press</i>). Some sagebrush plants are naturally columnar (e.g., Great Basin big sagebrush), and a natural part of the plant community. However, a predominance of columnar shape arising from animal impacts may warrant management investigation or adjustments at site specific scales. ⁶ Preferred forbs are listed in Stiver et al. <i>In press</i> . Overall total forb cover may be greater than that of preferred forb cover since not all forb species are listed as preferred. ⁷ All Desired Conditions will be dependent upon site capability and local variation (e.g., weather patterns, localized drought, ESD state, etc.). ⁸ > greater than ≥ greater than or equal to % percent cm centimeter km kilometer m meter			

2.5.8. Powder River Basin Restoration Program

The PRB Restoration program is a collaborative partnership to restore and enhance Greater Sage-Grouse habitat on a landscape level in the PRB. The PRB encompasses 13,493,840 acres in northeast Wyoming and southeast Montana; surface ownership is approximately 70 percent private, 14 percent BLM (Wyoming 8%, Montana 6%), 8 percent USFS, and 8 percent States of Wyoming/Montana. Mineral ownership is 50-60 percent federal.

This BLM High Plains District Office PRB Restoration program was initiated in 2010 and was developed to form partnerships with local cooperators, federal and state agencies, private landowners, and industry to work collaboratively on Greater Sage-Grouse habitat restoration. PRB Restoration is focusing on areas affected by federal oil and gas development that has occurred over the past decade in the PRB in northeastern Wyoming

The exploration and development of CBNG has to date been the largest mineral development in the PRB. There have been approximately 21,000 CBNG wells drilled over a 12 year period (1998-2010) which has fragmented Greater Sage-Grouse habitat throughout the PRB.

Development included construction of well sites and other facilities (i.e., metering buildings, compressor stations, pumping stations), building of roads to access well sites, construction of pipelines to transport product and wastewater, construction of powerlines to bring electrical power to the wells and other infrastructure, and the construction of water holding impoundments to hold the produced water as the wells must be de-watered to reduce pressure before the natural gas is released. Hundreds of miles of pipelines were constructed to transport CBNG gas from development site to delivery point. Other pipelines include gathering, transportation and distribution pipelines and lines used to transport produced water to discharge points. With a well life of approximately 12 years, many of the CBNG wells that were originally drilled are depleted and ready for the abandonment phase. Most buried pipelines have reclaimed their native vegetative cover and will not be removed. Utility roads and overhead powerlines continue to fragment thousands of acres of Greater Sage-Grouse habitat on private, federal, and state lands.

Goals

- Build partnerships to restore habitat for the Greater Sage-Grouse in large landscape or watershed.
- Integrate habitat improvement programs and projects implemented by partners to leverage funding to enhance Greater Sage-Grouse habitat reclamation.
- Facilitate the sharing of data/data collection methods, monitoring data/methods, and BMPs.

Objectives

- Build partnerships with local governments, federal agencies, and communities to restore large landscape or watershed areas starting with small scale restoration.
- Restore* or enhance disturbed previously suitable habitat to suitable habitat for sagebrush obligate species, primarily Greater Sage-Grouse. This would include multiple sites affected by CBNG abandonment reclamation efforts, wildfires, and/or noxious/invasive plants. Priority will be given to those areas recognized as Priority Habitat (Core Population Areas and Core Population Connectivity Corridors). Habitat objectives include meeting the needs for nesting, brood-rearing, and late brood-rearing.
- Contribute to efforts focused on the management and control of mosquitoes carrying WNV. Contribution would be monetary, manpower, treatment locations, and other needs as determined.
- Reduce fuels in and near Greater Sage-Grouse habitat to enhance sagebrush stands, support restoration efforts, and to reduce future risk of high severity wildfire. Manage conifer forests and woodlands for structural diversity, to reduce encroachment into sagebrush, and to reduce fuels, especially near priority habitat, human developments, and recreation areas.
- Restore health to grassland/shrubland plant communities by managing annual bromes.

*Restoration efforts will include but are not limited to: cheatgrass treatments (herbicide and/or mowing), seeding/interseeding forbs, planting sagebrush, conifer removal in sagebrush plant communities, fence marking, noxious/invasive plant treatments, and solar systems for livestock/wildlife watering.

Partners

Partners contribute technical expertise and/or financial support on three areas of emphasis. The first and primary emphasis is restoration of affected areas by the abandonment of CBNG wells and associated infrastructure, the second is restoration of vegetation communities adversely impacted by wildfires, and third is restoration of areas outside of CBNG development with first priority given to those locations within priority habitat, followed by other habitats of high value.

Current partners in the PRB Restoration include Conservation Districts (Lake DeSmet, Powder River, Campbell County, and Sheridan County), NRCS, WGFD, private landowners, oil and gas companies, Northeast Wyoming Sage-Grouse Local Working Group, BLM Wyoming Resource Advisory Council, University of Wyoming, Sheridan College, State of Wyoming, Thunder Basin Grassland Prairie Ecosystem Association, USFWS, and others.

Healthy Land Initiatives

PRB Restoration is one of three Healthy Land Initiative focal areas for BLM Wyoming. The Healthy Land Initiative is a major vegetation resources enhancement initiative to restore and improve the health and productivity of western public lands. The Healthy Land Initiative strategy increases the effectiveness and efficiencies of vegetation enhancement treatments by focusing on treatments on a substantial percentage of lands (focal areas) – both federal and non-federal – rather than focusing on the local project level. The strategy increases opportunities to leverage cooperative solutions across ownerships and jurisdictions.

The lands in Utah, Wyoming, New Mexico, Oregon, Idaho, Nevada, and Colorado were selected because they encompass Greater Sage-Grouse habitat or other important wildlife habitat in the wildlife - energy interface. Restoring Greater Sage-Grouse habitat is crucial because the Greater Sage-Grouse habitat ranges across 10 states covering more than 100 million acres, with 64 percent of the acreage under federal management.

Treating wildlife habitat in the wildlife-energy interface is important because BLM is clearly at a national crossroads for restoring habitats for a variety of species in a manner that keeps pace with the country's energy needs and demands. Energy production on BLM-administered lands provides 5 percent of our nation's oil, 18 percent of our nation's gas, and 44 percent of our nation's coal. Smaller scale, project-by-project approaches are unlikely to be sufficient.

The Healthy Land Initiative of 2008 is a dramatic change from current practices because of the larger scope and faster pace of the habitat improvement efforts and the more intensive involvement of partners and other landowners. Increased funding and work with partners allows the BLM to:

- Concentrate a large number of treatments in each emphasis area, resulting in a substantial amount of improved habitat in an entire watershed or landscape-wide area in three to five years, rather than the typical 10 to 15 years based on standard funding levels.
- Leverage partnership funding at unprecedented levels.
- Establish or enhance existing partnerships with adjoining landowners, so that a large percent of landowners in the area (federal or non-federal) treat their lands.
- Reduce BLM's overall unit cost due to lower costs per acre from large scale projects.

Accomplishments

To date and in partnership, the PRB Restoration effort has:

On-the-ground projects

- applied herbicide treatment on about 1,250 acres of cheatgrass in priority habitat.
- applied herbicide treatment on about 22,700 acres of annual bromes in plant communities adversely impacted by wildfires located in priority habitat.
- planted about 440 acres of sagebrush – planting plugs and locally collected seeds.
- removed more than 1,500 conifer tress from upland sagebrush habitat to remove the vertical structures of avoidance and perches for raptors.

- collected native seed on 14 forb species, 14 shrub species, and 11 grass species through the work of volunteers and interns funded through the Seeds of Success program. Over 2 million viable sagebrush seeds were collected in 2012.

Educational events

- co-hosted tours for federal, state, and local agencies, elected officials, interested publics, National Public Radio.
- co-hosted workshops (1) for landowners affected by CBNG stressing the importance of the removal of CBNG wells and related infrastructure as it relates to restoring habitat, and (2) for landowners affected by recent wildfires emphasizing the importance of restoring habitats.
- supported graduate student research including (1) the collection of shed feathers at leks to help determine if there is genetic transfer occurring between populations and the distances of the genetic transfer, and (2) the ability of fathead minnows to overwinter in livestock reservoirs. Fathead minnows are being used to control mosquito larvae potentially carrying WNV.

Future

Over the next 10 to 15 years these types of projects will continue as the reclamation effort in the PRB continues. Partnerships, funding, monitoring, and adaptive management will help drive the future of the PRB Restoration effort.

Overall, the initiative allows BLM to do more in substantially less time due to the substantial funding increase. Focusing funds in each of these six areas to a watershed or large landscape area will:

- prevent weeds from spreading;
- prevent the spread of insect infestations that harm native habitat;
- keep habitat suitable so that wide-ranging species can flourish; and
- prevent rare species from being listed.

2.5.9. Monitoring Framework for Greater Sage-Grouse Habitat Management

The BLM's planning regulations, specifically 43 CFR 1610.4-9, require that land use plans establish intervals and standards for monitoring based on the sensitivity of the resource decisions. Land use plan monitoring is the process of tracking the implementation of land use plan decisions (implementation monitoring) and collecting data/information necessary to evaluate the effectiveness of land use plan decisions (effectiveness monitoring). For Greater Sage-Grouse, these types of monitoring are also described in the criteria found in the Policy for Evaluation of Conservation Efforts When Making Listing Decisions (50 CFR Vol. 68, No. 60). One of the Policy for Evaluation of Conservation Efforts When Making Listing Decisions criteria evaluates whether provisions for monitoring and reporting progress on implementation (based on compliance with the implementation schedule) and effectiveness (based on evaluation of quantifiable parameters) of the conservation effort are provided.

A guiding principle in the BLM National Sage-grouse Conservation Strategy (DOI 2004) is that "the Bureau is committed to sage-grouse and sagebrush conservation and will continue to adjust and adapt our National Sage-grouse Strategy as new information, science, and monitoring results evaluate effectiveness over time." In keeping with the WAFWA Sage-grouse Comprehensive Conservation Strategy (Stiver et al. 2006) and the Greater Sage-grouse Conservation Objectives:

Final Report (USFWS 2013c), the BLM will monitor implementation and effectiveness of conservation measures in Greater Sage-Grouse habitats.

On March 5, 2010, USFWS' 12-Month Findings for Petitions to List the Greater Sage-Grouse (*Centrocercus urophasianus*) as Threatened or Endangered were posted as a FR notice (75 FR 13910-14014, March 23, 2010). This notice stated:

“...the information collected by BLM could not be used to make broad generalizations about the status of rangelands and management actions. There was a lack of consistency across the range in how questions were interpreted and answered for the data call, which limited our ability to use the results to understand habitat conditions for sage-grouse on BLM lands.”

Standardization of monitoring methods and implementation of a defensible monitoring approach (within and across jurisdictions) will resolve this situation. The BLM, USFS, and other conservation partners use the resulting information to guide implementation of conservation activities.

Monitoring strategies for Greater Sage-Grouse habitat and populations must be collaborative, as habitat occurs across jurisdictional boundaries (52 percent on BLM-administered lands, 31 percent on private lands, 8 percent on National Forest System lands, 5 percent on state lands, 4 percent on tribal and other federal lands) (75 FR 13910, March 23, 2010), and state fish and wildlife agencies have primary responsibility for population level wildlife management, including population monitoring. Therefore, population efforts will continue to be conducted in partnership with state fish and wildlife agencies. The BLM and USFS have finalized a monitoring framework, which can be found in Appendix B (p. 1779). This framework describes the process that the BLM will use to monitor implementation and effectiveness of RMP decisions. The monitoring framework includes methods, data standards, and intervals of monitoring at broad and mid scales; consistent indicators to measure and metric descriptions for each of the scales; analysis and reporting methods; and the incorporation of monitoring results into adaptive management. The need for fine-scale and site-specific habitat monitoring may vary by area depending on existing conditions, habitat variability, threats, and land health. Indicators at the fine and site scales will be consistent with the Habitat Assessment Framework; however, the values for the indicators could be adjusted for regional conditions.

More specifically, the framework discusses how the BLM and USFS will monitor and track implementation and effectiveness of planning decisions (e.g., tracking of waivers, modifications, site-level actions). The two agencies will monitor the effectiveness of RMP decisions in meeting management and conservation objectives. Effectiveness monitoring will include monitoring disturbance in habitats, as well as landscape habitat attributes. To monitor habitats, the BLM and USFS will measure and track attributes of occupied habitat, priority habitat, and general habitat at the broad scale, and attributes of habitat availability, patch size, connectivity, linkage/connectivity habitat, edge effect, and anthropogenic disturbances at the mid-scale. Disturbance monitoring will measure and track changes in the amount of sagebrush in the landscape and changes in the anthropogenic footprint, including change energy development density. The framework also includes methodology for analysis and reporting for field offices, states, ranger districts, BLM districts, National Forests, and Forest regions, including geospatial and tabular data for disturbance mapping (e.g., geospatial footprint of new permitted disturbances) and management actions effectiveness.

2.6. Alternatives Considered, but not Carried Forward for Detailed Analysis

Several alternatives and management options were considered as possible methods of resolving resource management issues and conflicts, but after further review and consideration were not carried forward for detailed analysis. The alternatives listed below were not carried forward for detailed analysis because (1) they would not fulfill requirements of the Federal Land Policy and Management Act (FLPMA) or other existing laws or regulations, (2) they did not meet the purpose and need, (3) they were already part of an existing plan, policy, or administrative function, or (4) they did not fall within the limits of the planning criteria. These alternatives considered, but not carried forward have been grouped by resource topic, although several may apply to more than one resource.

2.6.1. Physical Resources

Preserve Minimum Instream Flows

The BLM considered, but eliminated from detailed analysis, alternatives to preserve minimum instream flows in the planning area. This alternative is outside the regulatory authority of the BLM as water management is under the jurisdiction of the Wyoming State Engineer's Office. Further, the State of Wyoming and private parties own much of the surface land and mineral estate within the planning area, and the BLM has no legal authority to direct water management on non-federally managed lands or in the development of non-federal mineral leases. BLM WYSO IM WY-2005-14 addresses water disposal and land application (BLM 2005e).

2.6.2. Mineral Resources

Recommend Mineral Withdrawal Across the Planning Area

The BLM considered, but eliminated from detailed analysis alternatives to recommend a withdrawal for the remainder of the planning area under the mining laws, even in the absence of an identified resource conflict. Recommending withdrawal of the entire planning area, even in the absence of a currently-identified resource conflict, would be inconsistent with the goals and objectives for mineral resources. Moreover, the BLM lacks the authority to close lands to the Mining Law in the planning process – its authority is limited to making recommendations for future withdrawals. Alternative B analyzes the impacts of recommending mineral withdrawal for resource conflicts on 467,897 acres of BLM surface (60%), and 618,256 acres of federal mineral estate (13%).

Suspend or Eliminate All Existing Federal Fluid Mineral Leasing

The BLM considered, but eliminated from detailed analysis suspending or eliminating all existing federal oil and gas leasing and development operations and canceling existing oil and gas leases. By law, the BLM must recognize all valid existing rights. The BLM's authority to suspend or cancel existing oil and gas leases is limited by regulation. The BLM can impose reasonable limits on the manner and pace of development, and limits of this type are evaluated in the alternatives analyzed in detail. Individual locations within the planning area which the BLM would close to fluid mineral leasing are also evaluated in the alternatives analyzed in detail.

Closure to Fluid Mineral Leasing

Closing the planning area to new leasing of federal fluid minerals, even where there are no identified resource conflicts, was considered but eliminated from further analysis. Closing the entire planning area to new fluid mineral leasing would not meet BLM's purpose and need. Oil and gas development is an authorized use of public lands and meets BLM's multiple use objectives. In addition, the federal fluid mineral estate in much of the planning area has already been leased (2,570,703 acres; 65%), and the majority of the leases are developed. Therefore, mineral development will continue as leases are subject to valid existing rights and much of the unleased acreage is intermingled with leased acreage.

Public scoping comments indicate a growing level of concern with the rate and scale of oil and gas leasing and development in the planning area. Making portions of the planning area unavailable for oil and gas leasing in response to other identified resource needs is addressed in the alternatives analyzed in detail.

Remove All Stipulations and Restrictions from Oil and Gas Leases

The BLM considered removing all stipulations and restrictions from existing oil and gas leases. The BLM can authorize waivers, modifications, and exceptions to stipulations on existing leases when appropriate given site-specific resource conditions. This alternative was eliminated from detailed analysis as BLM's authority to waive existing oil and gas lease stipulations is limited by regulation.

Phase Fluid Mineral Development

The BLM considered an alternative that would regulate the rate at which oil and gas development in the planning area occurred.

The State of Wyoming and private parties own much of the surface land and mineral estate within the planning area. The BLM is required to ensure that leased federal minerals are fully developed and that production on non-federal leases does not drain federal minerals. Given the extent of non-federal mineral ownership within the planning area, a phased development alternative would not allow compliance with any of the above requirements and therefore it was eliminated from detailed analysis. Limiting development rate can be analyzed in implementation-level NEPA documents that take into consideration existing development on adjacent leases.

Prohibit Surface Water Disposal of Produced Water

The BLM considered, but eliminated an alternative to prohibit surface water disposal of produced water. Discharge of produced water is regulated by the Wyoming DEQ, Wyoming State Engineer's Office, and/or the Wyoming Oil and Gas Conservation Commission. BLM IM WY-2005-14 addresses water disposal and land application.

Require Produced Water to be Returned to Aquifers

BLM's ability to implement this alternative is limited. Much of the planning area involves non-federal minerals and non-federal surface where BLM has limited to no jurisdiction. Discharge of produced water is regulated by the Wyoming DEQ, Wyoming State Engineer's Office, and/or the Wyoming Oil and Gas Conservation Commission. The BLM considered, but eliminated this alternative from detailed analysis. Requiring produced water to be returned to

aquifers is not typically addressed in a land use plan but addressed at the project level with the appropriate state agencies.

Require Produced Water to be Put to Beneficial Use

Under this alternative, produced waters would be used for beneficial uses such as stock watering, wildlife habitat, recreational opportunities, and irrigation. The BLM's ability to implement this alternative is limited since produced water disposal is under the jurisdiction of the Wyoming DEQ, Wyoming State Engineer's Office, and/or the Wyoming Oil and Gas Conservation Commission. The BLM considered, but eliminated this alternative from detailed analysis because of the limited short-term benefit and because it is outside of the BLM's jurisdiction.

2.6.3. Fire and Fuels Management

There were no alternatives considered but eliminated from detailed analysis for this resource category.

2.6.4. Biological Resources

Emphasize the Protection of Resources by Removing Human Uses

The BLM considered, but eliminated from detailed analysis an alternative that removed human uses from the planning area. The FLPMA requires the BLM to manage public lands and resources according to the principles of multiple use and sustained yield. Included in this requirement are human uses, such as mineral development or livestock grazing, that must be managed in consideration of other resource values, such as wilderness or wildlife resources. Management actions, including closure or prohibition of various resource uses over portions of the planning area, are included in the alternatives considered in detail.

Applying the National Technical Team Conservation Measures to Priority Habitat

The BLM National Greater Sage-Grouse Strategy (WO IM-2012-044) directed field offices to consider all applicable conservation measures recommended by the NTT when revising or amending RMPs in Greater Sage-Grouse habitat. Most of the NTT conservation measures are recommended to be applied to priority habitats. However, the designated priority habitat may not be sufficient to conserve Greater Sage-Grouse within the Buffalo planning area (Taylor et al. 2012). Taylor et al. (2012) stated:

“core areas in northeast Wyoming were delineated after widespread development has already occurred, leaving few options for conserving populations. In northeast Wyoming, the far reaching influence of development has already negatively impacted the 103 active leks inside core areas...Despite the impacts, the potential may still exist to maintain populations inside core areas, but further drilling in and around the cores will compromise their remaining value.”

Because of the concern over adequacy of the BFO designated Core Population Areas to meet the planning goal for Greater Sage-Grouse conservation, an alternative applying the NTT conservation measures only to the designated priority habitat was eliminated from detailed analysis.

Instead, in Alternative B, the BFO analyzed the recommended NTT occupancy restrictions and prohibitions within 4.0 miles of lek sites and winter concentration areas to encompass the most

utilized nesting and winter habitats. Four miles is also the NTT recommended prohibition within leased mineral estate (NTT Measure 62) and a multi-state ad-hoc Greater Sage-Grouse committee suggested that within at least 4.0 miles of leks be considered nesting and brood-rearing habitat (Christiansen and Bohne 2008). Sixty percent of the BLM surface and 66 percent of the BLM-administered fluid mineral estate are within 4.0 miles of lek sites and winter concentration areas whereas designated BFO priority habitat encompasses 21 percent of the BLM surface and 22 percent of the BLM-administered fluid mineral estate. Within 4.0 miles of leks is close to the Core Population Area strategy's goal of conserving 66 percent of the population.

No Development Within Occupied Greater Sage-Grouse Habitat

The BLM considered, but eliminated from detailed analysis an alternative that prohibited development within occupied Greater Sage-Grouse habitat. The FLPMA requires the BLM to manage public lands and resources according to the principles of multiple use and sustained yield. Included in this requirement are human uses which must be managed in consideration of other resource values, including wildlife resources such as Greater Sage-Grouse. The BLM worked with cooperators such as the WGFD and the USFWS to develop alternatives protective of Greater Sage-Grouse while allowing for development. Prohibiting development within occupied habitat would eliminate multiple use opportunities within all but the non-habitat areas of the planning area such as forested, mountainous (Big Horn Mountains), or urban areas. This alternative would preclude the BLM from achieving a balance among resources and resource uses. BLM Wyoming Greater Sage-Grouse policy restricts development within Core Population Areas subject to site-specific criteria. The alternatives consider a range of prohibitions on surface occupancy ranging from areas within 0.25 mile from leks (3,594 acres or 0.45% of BLM surface) to areas within 4.0 miles of leks or winter concentration areas (467,897 acres or 60% of BLM surface).

2.6.5. Heritage and Visual Resources

There were no alternatives considered but eliminated from detailed analysis for this resource category.

2.6.6. Land Resources

Boundaries of Public Lands Should be Clearly Marked

The BLM considered, but eliminated from detailed analysis an alternative that institutes clearly marking all boundaries of public lands in the planning area. An RMP is a broad level planning document that defines allocations and levels of land uses. The marking of public land boundaries is more appropriately analyzed in implementation level NEPA documents.

Closing All Public Lands to Motorized Vehicles or Limiting Travel to Existing Roads and Trails Only

Alternatives prohibiting motorized vehicle travel and limiting travel to existing roads and trails on all BLM-administered surface were considered, but eliminated from detailed analysis. The BLM's Travel and Transportation Manual (1626) states "the planning process should consider and address the full range of various modes of travel on public lands." The BLM's travel management program is guided by resource values and user needs. A broad travel designation for the entire planning area would not allow BLM to balance resource values and user needs when considering

travel designations within the planning area. The BLM analyzes a range of travel management designations in the alternatives considered in detail.

No Livestock Grazing

The elimination of livestock grazing from all BLM-administered lands in the planning area as a method for resolving range, watershed, and wildlife habitat-related planning issues was considered, but eliminated from detailed analysis. The BLM recognizes conflicts exist between resources and resource uses. However, BLM determined that resource conditions on BLM-administered lands in the planning area do not warrant such a blanket elimination of livestock grazing because 97 percent of allotments (122 out of 125) assessed to date meet the *Wyoming Standards for Healthy Rangelands*. The non-attainment areas are confined to small portions on each of the three allotments (9,601 acres total). All three allotments are progressing towards the standards. The BLM does not have data showing that resource conflicts in these areas can be resolved by closing them to public land grazing.

The BFO administers 427 grazing leases on 477 allotments; approximately 370 of these are Category C (custodial) allotments where BLM is the minority surface owner (Appendix E (p. 1899)). With the intermingling of private and public lands, each allotment would need to be evaluated to determine the extent to which additional fencing would be required in order to enforce a grazing closure. Fencing custodial allotments to keep cattle off public lands would require hundreds of miles of new fences to prevent unauthorized grazing. In addition, the potential impacts of such extensive fencing on, for example big game movement and Greater Sage-Grouse mortality from raptor predation and collisions are better analyzed on an allotment-by-allotment basis, taking into account distribution of wildlife habitat and other resources as well as site-specific land ownership patterns.

Reduction or elimination of livestock grazing could become necessary on specific allotments where livestock grazing is causing or contributing to conflicts with the protection and/or management of other resource values or uses. Such determinations would be made during site-specific activity planning and associated environmental analysis, and would be based on several sources of information. These sources include: monitoring studies, reviewing current range management science, obtaining input from livestock operators and stakeholders, and assessments of ability to meet the *Wyoming Standards for Healthy Rangelands*.

Alternative B analyzes closing 467,897 acres or 60 percent of BLM surface to livestock grazing for resource conflict including Greater Sage-Grouse habitat and SRMAs.

No Net Loss of Grazing Animal Unit Months

The BLM considered an alternative for no net loss of grazing animal unit months (AUMs), but eliminated it from detailed analysis. The commitment to manage for no net loss of AUMs would be in conflict with 43 CFR § 4110.3 which requires the BLM to periodically review permitted use specified in grazing permits or leases and make changes in the permitted use as needed to manage, maintain, or improve rangeland productivity; to assist in restoring ecosystems to PFC; to conform with land use plans; or to comply with the provisions of 43 CFR § 4100, Subpart 4180 - Fundamentals of Rangeland Health and Standards and Guidelines for Grazing Administration. Alternative B analyzes closing 467,897 acres or 60 percent of BLM surface to livestock grazing which would result in an associated AUM reduction.

2.6.7. Special Designations

New Wilderness Study Areas

The BLM acknowledges that FLPMA Section 603 (43 United States Code [U.S.C.] § 1782) requiring a one-time wilderness review and recommendations has expired. A current inventory of public lands, including wilderness characteristics resources, is required by FLPMA Section 201 (43 U.S.C. § 1711). The BLM periodically, and on a continuing basis, monitors existing WSAs in accordance with the BLM Manual 6330 – Management of Wilderness Study Areas; however, the BLM has no authority to designate new WSAs and considered alternatives for management of those areas, including management to protect their wilderness characteristics. Using existing resource information, the BLM evaluated all public surface in the planning area, including proposals by the public, to determine those areas that contained wilderness characteristics (naturalness and opportunities for solitude or primitive or unconfined recreation). Non WSA lands with wilderness characteristics in the planning area are identified in Chapter 3 of this document.

2.6.8. Socioeconomic Resources

There were no alternatives considered but eliminated from detailed analysis for this resource category.

2.7. Management Actions Common to All Alternatives

This section describes management actions that apply to all alternatives. Management actions common to all alternatives can result because of specific management limitations defined in the laws and regulations that govern BLM management decisions. For the most part, nondiscretionary laws and regulations are not identified here but rather are set forth through the planning criteria to ensure that management actions within all alternatives are compliant with nondiscretionary laws and regulations. Appendix A (p. 1771) contains a list of the laws and regulations guiding BLM management. This section primarily includes management actions not established by such laws or policies. For example, many resource programs require the use of BMPs to reduce impacts. Collaboration with stakeholders and the development of resource specific plans are also a common requirement for many resource programs.

This section provides some of the typical actions captured by management actions that are common to all alternatives. Not all management actions are listed below; instead, actions were selected and summarized to provide an overview. The complete list of management actions common to all alternatives is provided in Table 2.7, “1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)” (p. 127) through Table 2.40, “8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY” (p. 275) under each resource heading. Management action summaries are organized into eight broad resource topics, including: Physical Resources, Mineral Resources, Fire and Fuels Management, Biological Resources, Heritage and Visual Resources, Land Resources, Special Designations, and Socioeconomic Resources.

2.7.1. Physical Resources

Management actions for physical resources are designed to conserve air, soil, cave and karst, and water resources. Certain management actions specify conformance with various laws and

regulations such as Wyoming DEQ smoke-management rules for air quality. Other actions designed to minimize impacts on air quality include implementing appropriate mitigation measures to reduce emissions from current levels and establishing a cooperative monitoring network for criteria pollutants and Air Quality Related Values.

Soil is protected by requiring site-specific reclamation plans for authorized surface-disturbing activities. The BLM manages water resources to meet the *Wyoming Standards for Healthy Rangelands* and to achieve PFC. Under all alternatives, the BLM limits the degradation of water quality by designing and managing surface-disturbing activities to reduce channel and bank erosion, and the associated loss of riparian habitats. Appropriate management for cave and karst resources in the planning area is determined by mapping, inventorying, and evaluating identified resources for significance.

2.7.2. Mineral Resources

Mineral resources management defines the scope of mineral development, applies measures to conserve other resources, and manages lands in the planning area for mineral exploration and development. Under all alternatives, the BLM manages land not formally withdrawn or segregated from mineral entry for exploration and development of locatable minerals (mining claim minerals). The 2001 Buffalo RMP update coal management decisions remain the basis for current coal management in the planning area. Those areas determined to be available for future coal leasing consideration will be carried forward in this RMP revision (Map 11). All federal oil and gas mineral estate is open to leasing of fluid mineral resources, unless otherwise noted. All federal salable minerals (also called mineral materials) estate is available for exploration and development, unless otherwise noted.

2.7.3. Fire and Fuels Management

Fire and fuels management in the planning area follows guidance from the National Wildland Fire Management Policy (DOI and USDA 1995), the Interagency Standards for Fire and Fire Aviation Operations, the BLM Emergency Stabilization and Burned Area Rehabilitation standards located in the DOI Interagency Burned Area Emergency Response Guidebook (DOI 2004), and the BLM Burned Area Emergency Stabilization and Rehabilitation Handbook (BLM 2007c). The Wyoming High Plains District Fire Management Plan (BLM 2004c) outlines management response and implementation actions for wildland fire response on public lands in the BFO. Management prescriptions include consulting appropriate resource advisors for all resources potentially affected by wildland fire; rehabilitation of firelines on steep slopes or constructed by heavy equipment; prohibiting the use of retardant and foam within 300 feet of surface water sources; and cooperating with other agencies and landowners to implement landscape treatments to achieve fuels management objectives and to maintain or improve the condition of fire-adapted ecosystems. Prescribed burns must comply with Wyoming DEQ air quality standards and smoke management rules.

2.7.4. Biological Resources

Management actions common to all alternatives for biological resources include laws, regulations, and BLM policies that govern management of biological resources as well as actions that set management to meet thresholds, minimize resource conflict and damage, and require stakeholder

coordination. Examples of these types of management actions include: a requirement that surface or vegetation disturbance areas be treated for invasive species and revegetated; that riparian/wetland areas be managed to enhance forage conditions and improve water quality; and that the BLM work cooperatively to complete vegetation inventories with appropriate stakeholders. Vegetative communities are managed in accordance with the *Wyoming Standards for Healthy Rangelands* and are maintained to provide sustainable forage levels for livestock and wildlife. Management prescriptions for invasive species include implementing cooperative integrated pest management programs with appropriate stakeholders; using certified noxious weed seed-free products on all BLM-administered projects and lands; and limiting surface disturbance to the minimum needed for safe project completion to limit the spread of noxious weeds.

Fish and wildlife management includes actions to appropriately mitigate surface-disturbing activities and maintain or improve fish and wildlife habitat. Management calls for collaboration with the WGFD and other stakeholders to manage barriers to fish passage, activities potentially affecting native and desirable non-native fish species, and harmful non-native riparian vegetation in important fish habitats. Wildlife habitats are maintained or improved through vegetative manipulations, habitat improvement projects, and livestock grazing strategies, in accordance with appropriate planning and guidance documents. Existing habitat management plans are used and updated as necessary to reflect current wildlife management objectives and prescriptions.

In consultation with stakeholders, projects that may affect special status species are to be modified in order to protect these species. The BLM implements actions set forth in recovery plans, conservation measures, terms and conditions, and reasonable and prudent measures within biological opinions for Threatened and/or Endangered plant and wildlife species. Management actions specific to special status fish species include supporting the WGFD in obtaining water rights for the benefit of special status fish species and prioritizing special status fish species over other fish species in planning and management actions. Management actions specific to special status plant and wildlife species include utilizing current research and management and conservation plans to guide special status species habitat management, and establishing a year-round disturbance-free buffer zone of at least 0.5 mile for known active bald eagle nests. For Greater Sage-Grouse, the BLM would collaborate with appropriate federal agencies and the State of Wyoming to develop and monitor conservation objectives and identify site-based actions to achieve the objectives. Additional management actions specific to Greater Sage-Grouse include managing habitat and reduce resource conflicts, and include specific restrictions on the application of pesticides in nesting and brood-rearing habitats; specifications on the design and location of water facilities and fences; and the maintenance of seeps, springs, wet meadows, riparian vegetation, and sagebrush habitat.

2.7.5. Heritage and Visual Resources

Cultural resources management includes cooperation with Native American tribes to protect land and artifacts important to them as well as preservation of all cultural resources by limiting exposure to incompatible uses. Specific actions include ensuring areas important to Native American tribes are not transferred from federal ownership and stabilizing and providing long-term protection for significant cultural sites that are experiencing adverse impacts.

The primary emphasis of paleontological resources management is the protection of land containing significant paleontological resources. To that end, the BLM retains all public lands with significant paleontological values.

Visual resource management (VRM) involves managing each VRM class according to the definitions and objectives in the VRM manual (H-8410-1). The BLM would manage WSAs and the Middle Fork Powder River, if designated by Congress as a Wild and Scenic River (WSR), under VRM Class I objectives. Measures designed to protect visual resources (i.e., screening, painting, and designing to blend with the surrounding landscape) are required for non-temporary facilities and structures.

2.7.6. Land Resources

Lands and realty management, including cadastral survey, seeks to improve access to public land and enable better overall management of BLM-administered land. Withdrawals, Recreation and Public Purpose applications, and land use authorizations (permits, leases, etc.) are all considered on a project-specific basis. Lands meeting the identified disposal criteria have priority consideration for disposal. In order to reduce inadvertent trespass potential, the BLM uses appropriate signage and access authorizations. Management of renewable energy and ROWs include cooperating with stakeholders to coordinate renewable energy opportunities and scientific research in accordance with other resource values; providing reasonable access across public land to private land; designating ROW corridors to minimize surface disturbance; developing communication site management plans for all existing and newly identified communication site concentration areas; and maintaining a transportation management system to meet public and resource management needs.

Travel and transportation management in the planning area involves maintaining a transportation system across public lands, improving access to public lands, and designating areas as Open, Closed, or Limited to designated routes or seasons for OHV use. Unless otherwise specified, OHV use is Limited to designated routes on BLM-administered land. Areas within the planning area will no longer be classified as Limited to existing routes. Specific management actions include negotiating access across non-BLM-administered lands to isolated public lands, evaluating roads constructed under other initiatives (e.g., oil and gas exploration) for inclusion in the BLM transportation system, and improving access for people with disabilities.

The BLM manages recreational use to provide recreational opportunities for public land users while protecting public safety and other resource values. Management actions include managing recreation sites, facilities, and access to minimize impacts to riparian habitat and opening the planning area to dispersed recreation where consistent with other resource values. Newly acquired lands, and other parcels meeting the size and naturalness requirements, are evaluated for wilderness characteristics.

The BLM manages livestock grazing to achieve the *Wyoming Standards for Healthy Rangelands*, improve forage for livestock, improve forage and habitat for wildlife, and enhance rangeland health. Forage allocations in grazing permits or leases can be adjusted when supported by monitoring, field observations, rangeland (land) health assessments/evaluations, or other data acceptable to the authorized officer.

2.7.7. Special Designations

The BLM evaluates authorized activities and develops mitigation to protect the integrity of the characteristics for which ACECs were designated. The BLM manages Scenic or National Back Country Byways with the objective of encouraging responsible motorized recreational

use of the proposed byway, while protecting and displaying the scenic, cultural, geological, multiple use, and crucial wildlife habitat values that occur in the area. The Middle Fork Powder River is managed in accordance with the Middle Fork Interim Management Plan (available on the BFO website, <http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo/docs.html>) until Congress designates it as a WSR or releases the river for other uses. Similarly, WSAs within the planning area including Fortification Creek, Gardner Mountain, and North Fork are managed in accordance with BLM Manual 6330 – Management of Wilderness Study Areas until Congress acts upon the proposals.

2.7.8. Socioeconomic Resources

Socioeconomic impacts are largely derived from actions for management of other resources. These management actions are described under the resource headings they belong to. Management of socioeconomic resources includes quantifying socioeconomic impacts associated with site-specific and programmatic BLM actions, referring to available indicators for the economic and social health of an affected area, and, generally, managing in a way that considers the fact that BLM actions are integrally connected with both socioeconomics and the cultural health of the planning area. Indicators of economic activity on BLM-administered lands include leases and permits, visitation estimates, grazing allotment AUMs, among others. Management prescriptions for health and safety in the planning area generally seek to reduce human and environmental risk. Some of the actions designed to reduce these risks include prioritizing abandoned mine sites that most affect human health, safety, and the environment; using public awareness techniques to prevent exposure by the public to hydrogen sulfide gas; reducing waste produced by BLM activities through waste minimization practices; and mitigating hazards from coalbed fires.

2.8. Summaries of the Alternatives

This section summarizes the four alternatives (A through D) considered in detail in the Proposed RMP and Final EIS. Due to the breadth of management prescriptions in the alternatives, only key elements of the alternatives (those with the most potential to affect resources) are summarized in this section. The summary descriptions of each alternative in this section provide a general overview of the alternative, the management emphasis associated with each alternative, and key management actions for each alternative.

Table 2.5, “Comparative Summary of Acreage Affected (and associated fluid mineral lease stipulation) by Proposed Land Use Decisions in the Buffalo Planning Area” (p. 104) identifies acreage allocations for resources and resource uses by alternative. Table 2.6, “Comparative Summary of Proposed Areas of Critical Environmental Concern” (p. 110) identifies acreage allocations and the emphasis for management in proposed ACECs. These tables provide a comparative summary of acreage allocations in the four alternatives. Detailed descriptions of the alternatives can be found in Table 2.7, “1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)” (p. 127) through Table 2.40, “8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY” (p. 275) in this chapter. The maps in Appendix F (p. 1931) further illustrate differences in acreage allocations and management prescriptions by alternative.

Restrictions on resource uses (e.g., closed to mineral leasing) apply throughout the life of the RMP, unless changed through an RMP amendment. Management actions developed under all alternatives are subject to valid existing rights. In addition, management actions may only be implemented when consistent with applicable laws, regulations, and policies. The planning area is open to locatable mineral activities unless specifically withdrawn from operation of the mining laws. NSO, CSU, and TLS stipulations apply only to fluid mineral leasing and not to other mineral resources. Changes in resource use restrictions that require an RMP amendment can result due to public demand, statewide or national policy and guidance, or other factors. The timing and degree of implementation for management prescriptions in this document depend on available budget, staffing, and agency priorities. Actions taken or authorized by the BLM during RMP implementation would comply with standard practices, guidelines for surface-disturbing activities, and other BLM guidance and policy. Therefore, these practices and guidelines are considered part of each alternative. Implementation of new BLM policy and guidance during the life of this RMP will be incorporated into the land use planning process consistent with the management prescriptions in the plan.

The planning process does not include detailed, implementation-level decisions. During the implementation stage, additional environmental analyses will be conducted, as appropriate, for site-specific actions and the BLM will determine on a project-specific basis what, if any, mitigation is required.

2.8.1. Alternative A – Current Management (No Action)

Overview of the Alternative

Alternative A represents the current management of resources on BLM surface and federal mineral estate within the planning area under the existing plan. Alternative A represents the No Action Alternative required by NEPA.

Physical Resources

Physical resources are managed under Alternative A to conserve air, water, soil, and cave and karst resources, and to support resources and resource uses. Under Alternative A, activities with expected effects to air resources are analyzed and monitoring may be performed on a project-specific basis. Alternative A places limitations on surface-disturbing activities to protect soil resources including prohibiting surface disturbance within areas of severe erosion hazard from March 1 through June 15, prohibiting surface disturbance on slopes of more than 25 percent, and restricting activity on soils having poor reclamation suitability on a project-specific basis. Water resources management under Alternative A includes prohibiting surface disturbance within 500 feet of any spring, reservoir, water well, or perennial stream. No previous management actions were defined for cave and karst management and, as such, management is considered on a project-specific basis under Alternative A.

Mineral Resources

Mineral resource uses are managed by identifying BLM-administered lands and federal mineral estate within the planning area suitable for exploration and/or development of leasable, locatable, and/or salable minerals. Management actions also seek to conserve other resource values where they are incompatible with mineral resources activity. For example, the Amsden Creek, Middle Fork Canyon, and Kerns Game Ranges are closed to mineral entry (11,373 acres), while the

WSAs (28,931 acres) remain open to mineral entry (locatable mineral activities). The WSAs, however, come under the purview of 43 CFR 3802, which includes stringent requirements for non-impairment of these areas. No new withdrawals are recommended under Alternative A. All federal coal lands are open to exploration. A portion of the federal coal lands have been reviewed against the coal screening criteria and have been determined to be acceptable for further consideration for coal leasing. Leasing of other minerals (i.e., phosphates or sodium) is considered on a project-specific basis.

Approximately 2,346,307 acres of federal mineral estate are closed to fluid mineral leasing. The remaining federal mineral estate is open for leasing subject to the following constraints: 146,126 acres are subject to standard stipulations only, 26,048 acres are subject to minor constraints, 782,501 acres are subject to moderate constraints, and 85,548 acres are subject to major constraints. Salable mineral exploration and development are prohibited on approximately 28,873 acres in the Fortification Creek, Gardner Mountain, and North Fork WSAs.

Fire and Fuels Management

For unplanned ignitions in Alternative A, fire management seeks to balance variable suppression strategies with resource values. Priority response is given to wildfires where there are high value resources, or where fires may spread to non-BLM-administered lands. No portion of the planning area is available to manage fires for other multiple resource objectives. Alternative A restricts the use of some types of suppression equipment in sensitive areas, and rehabilitates suppression damage.

Fuels management in Alternative A would treat about 14,000 acres with prescribed fire during the life of the plan (Appendix G (p. 1937)). These acres are based on treatments completed in the planning area from the years 1984 to 2007. Wildland fire and other vegetation treatments would be used to support vegetation and wildlife habitat objectives.

Biological Resources

Alternative A identifies few management actions to address vegetation and invasive species management and, as such, management is typically considered on a project-specific basis for these resources. Under Alternative A, vegetation treatments, including forest management and sagebrush spraying or burning, are designed to meet overall resource management objectives consistent with the policy to protect or improve biodiversity and water quality. Diseased old growth and overstocked forests are managed in accordance with the Healthy Forest Restoration Act. Control of noxious weeds under Alternative A is managed in cooperation with county weed and pest districts.

Alternative A management actions attempt to provide habitat for fish and wildlife and comply with the Endangered Species Act and BLM policy for special status species. For example, Alternative A management includes cooperation with the WGFD in introducing native and desirable non-native fish and maintaining reservoirs and riparian areas to improve or enhance potential fisheries. Wildlife management under Alternative A includes seasonal restrictions such as prohibiting surface disturbance in crucial elk winter range between November 15 and April 30, in elk calving areas from May 1 to June 30, and within 0.5 mile of raptor nests from February 1 to July 31. In addition, surface disturbance is prohibited in the Ed O. Taylor, Kerns, Bud Love, and Amsden Creek winter ranges for big game, within 750 feet of sharp-tailed grouse leks, and within biologic buffer zones around active raptor nests.

No previous decisions were identified under current management for special status plant and fish species, and, as such, management is considered on a project-specific basis for these resources. The BLM manages vegetation resources to comply with the Endangered Species Act and BLM policy associated with management of habitat for special status species. Management prescriptions to protect Greater Sage-Grouse include requiring anti-perching devices on new powerlines with 0.5 mile of occupied Greater Sage-Grouse leks and nesting habitat, and restricting surface disturbance and occupancy within a 0.25-mile radius of the perimeter of occupied or undetermined Greater Sage-Grouse leks. Management actions that limit surface-disturbing activity for the benefit of other special status wildlife species include a year-round disturbance-free buffer zone of 0.5 mile for bald eagle winter roosts, TLS for bald eagle winter roosts of 1.0 mile from November 1 to April 1, and prohibition of surface disturbance within a biologic buffer zone around active nests of special status raptor species.

Heritage and Visual Resources

Alternative A primarily considers cultural and paleontological resource management on a project-specific basis. Specific actions include applying a NSO stipulation to fluid mineral leases where potentially eligible or significant segments of the Bozeman Trail and Crazy Woman Battle Site exist, and developing Cultural RMPs for Cantonment Reno, Dull Knife Battlefield, and the Outlaw Cave Archeological District. VRM includes managing visual resources in accordance with objectives for VRM classes that have been assigned in the planning area.

Land Resources

Forest products management under Alternative A balances forest and woodland health with other resource uses such as commercial timber production. For example, forest products management under Alternative A allows the sale of minor forest products from woodlands and/or noncommercial forestlands on BLM-administered lands throughout the planning area, offers approximately 9 million board feet of sawtimber and 1 million board feet of minor green forest products from BLM-administered forestlands over a 10 year period, and limits individual clear-cuts to less than 20 acres.

Land resource program actions under Alternative A identify approximately 108,243 acres within the planning area as available for disposal. Lands having agricultural potential and water may be considered for disposal. Priority is given to acquiring land or interests in lands in areas adjacent to large blocks of BLM-administered land, especially in areas of high recreational potential. Other land resource program actions under Alternative A include requiring approval of renewable energy development projects on a project-specific basis. Under the existing plan, no specific management actions are identified for renewable energy resources. Alternative D recommends the use of designated corridors for ROWs and requires lines to be buried within Greater Sage-Grouse Core Population Areas unless they are within 0.5 mile of existing 115 kV or larger transmission lines. Surface disturbance and occupancy associated with ROW corridors is not allowed on slopes of 25 percent or more.

Transportation management designations under Alternative A include 3,650 acres Closed to OHV use and 737,166 acres Limited to designated roads and trails for OHV use. In addition, a seasonal closure (November 15 to April 30) for motorized vehicle use is instituted on several areas (37,646 acres) in the planning area. As noted in the *Management Actions Common to All Alternatives* section above, areas will no longer be classified as Limited to existing routes.

Recreation management under Alternative A balances protection of the recreational experience with other resource uses. For example, surface disturbance and fluid mineral leasing are prohibited near the Dry Creek Petrified Tree Environmental Education Area and the Mosier Gulch Recreation Area to protect the recreational experience and other resource values. However, salable mineral development and withdrawals from appropriation under the mining laws in Recreation Areas and SRMAs are considered on a project-specific basis under Alternative A. Alternative A manages the planning area as one Extensive Recreation Management Area (ERMA) with several developed recreation sites.

No previous decisions were identified under current management for areas with wilderness characteristics, and, as such, management is considered on a project-specific basis for this resource.

Under Alternative A, the BLM does not allow livestock grazing on about 4,000 acres of BLM-administered land located in the southern Big Horn Mountains due to the area's rough terrain and steep slopes and does not allow livestock grazing on about 6,000 acres where it is incompatible with other resource values. Management stipulates that any permanent increases in forage produced are considered for wildlife and watershed protection before additional livestock use is authorized. Several livestock grazing management decisions prescribed under the other alternatives are not included under Alternative A, and, therefore, management is typically conducted on a project-specific basis. For example, Alternative A does not specify the distance salt or mineral supplements should be placed away from water sources and placement is instead managed on a project-specific basis.

Special Designations

Alternative A does not designate any ACECs and no management actions are identified regarding Scenic or National Back Country Byways and WSRs. If Congress decides not to designate the WSAs in the planning area as Wilderness, the Gardner Mountain, North Fork, and Fortification Creek WSAs will be available for oil and gas leasing. The Middle Fork Powder River segments suitable for WSR designation are managed under an interim management plan (BLM 2003d) to protect the free-flowing condition, tentative "wild" classification, and identified outstandingly remarkable values. Alternative A does not address management for the release of WSRs for other uses, nor does it consider designation of Scenic and Back Country Byways, therefore, such management is considered on a project-specific basis.

Socioeconomic Resources

BLM's management recognizes and considers local and regional economic development and land use plans.

2.8.2. Alternative B – Resource Conservation

Overview of the Alternative

Alternative B emphasizes conservation of physical, biological, heritage and visual resources, and areas with wilderness characteristics with constraints on resource uses. Relative to all alternatives, Alternative B conserves the most land area for physical, biological, and heritage resources; designates the highest number of ACECs; and is the most restrictive to motorized vehicle use and mineral development.

Physical Resources

Under Alternative B, the BLM manages physical resources (air, water, soil, and cave and karst resources) with an emphasis on conserving these resources. This alternative is less focused on supporting resource uses than the other alternatives. Alternative B requires quantitative air quality modeling of industrial activities in order to determine the potential impacts of proposed emission sources and subsequently of potential mitigation strategies. Management of soil resources is similar to Alternative A although more limitations are placed on surface-disturbing activities to protect soils. For example, soils with severe erosion hazard are protected from surface disturbance year-round instead of from March 1 through June 15. In addition, Alternative B prohibits surface disturbance and applies an NSO stipulation on all slopes 25 percent and greater, soils with poor reclamation suitability, badlands, rock outcrops, and slopes susceptible to mass movement. Management under Alternative B includes more protections for water resources through prohibitions of on-channel reservoirs, restrictions on activities resulting in surface discharge of produced water, and prohibiting the conversion of oil and gas wells to water supply wells. Similar to Alternative A, Alternative B prohibits surface-disturbing activities within 500 feet of springs, water wells, and perennial streams and associated riparian habitat. In addition, Alternative B also prohibits surface-disturbing activities within 500 feet of non-CBNG reservoirs. Cave and karst management actions under Alternative B apply restrictions to incompatible resource uses and enable greater overall management of cave and karst resources through cave specific Cave Management Plans.

Mineral Resources

Mineral resource uses are subject to more extensive constraints under Alternative B than under the other alternatives. The BLM would recommend withdrawals to locatable mineral entry on 618,256 acres (2,686,776 acres open to locatable mineral entry, should these withdrawals occur).

Approximately 2,612,920 acres of federal fluid mineral estate are closed to fluid mineral leasing. The remaining federal mineral estate is open for leasing subject to the following constraints: 1,225 acres are subject to standard stipulations only, 5,685 acres are subject to minor constraints, 124,467 acres are subject to moderate constraints, and 642,232 acres are subject to major constraints (Map 14). Approximately 1,239,723 acres are open to leasing of other minerals (i.e., phosphates, sodium, etc.) Alternative B would result in 129,431 acres open to salable mineral exploration and development and 3,218,690 acres closed to or restricted from salable mineral exploration and development.

Fire and Fuels Management

Fire and fuels management under Alternative B places more emphasis on natural processes and less emphasis on planned vegetation treatments.

Response to unplanned ignitions in this alternative would vary from full protection in areas where fire is undesirable, to managing wildfire for other resource objectives. The entire planning area would be available to manage fires to meet resource objectives. This alternative utilizes protection strategies in the wildland urban interface, wildland industrial interface, developed recreation sites, commercial timber areas, and other sensitive resource areas. The BLM would limit heavy suppression equipment to existing roads and trails or immediately adjacent to them. This alternative rehabilitates all fire related damage including suppression activity and fire severity.

Fuels management in Alternative B would treat about 3,500 acres with prescribed fire during the life of the plan. Wildland fire and other vegetation treatments would be applied to restore fire-adapted ecosystems and to reduce hazardous fuels.

Biological Resources

Vegetation management under Alternative B emphasizes natural processes and ecosystem protection. For example, Alternative B minimizes silvicultural treatments; allows insect, disease, and wildland fire to run their natural course; and manages aspen communities as a seral stage and natural component of the forest. In addition, Alternative B authorizes only native plant species for reclamation activities and restores vegetation in all CBNG supported wetland and riparian systems. Alternative B provides the most protection for riparian/wetland resources by applying an NSO stipulation within 500 feet of riparian/wetland systems, aquatic habitat, and floodplains. Invasive species and pest management under Alternative B places no limitations on the aerial application of pesticides and requires the development of pest management areas, prioritizes noxious weed treatments where infestations on private land are threatening public lands, and requires the treatment of annual brome species throughout the planning area.

Alternative B emphasizes the conservation of habitat for fish and wildlife and places more constraints on resource uses that affect biological resources compared to Alternative A. For example, fish resources management under Alternative B prohibits surface-disturbing and disruptive activities within 0.25 mile of naturally occurring water bodies containing native and desirable non-native fish species. Proactive fish management includes designing crossings of water bodies to allow fish passage and performing restoration of important instream segments for fish habitat. Alternative B applies more constraints on resource uses to protect wildlife habitat than Alternative A including applying a seasonal restriction on surface disturbance in elk crucial winter range and prohibiting surface disturbance and disruptive activities within 0.5 mile of a big game migration corridor. Under Alternative B, raptor management is species based with varying protective distances and timing by species.

Compared to other alternatives, special status species receive increased protection under Alternative B. To protect special status plant species, Alternative B prohibits surface disturbance, mineral exploration, motor vehicle use, and the use of explosives and blasting within special status plant habitat. Under Alternative B, surface disturbance is prohibited within 0.25 mile of any waters containing special status fish species. Management actions to protect Greater Sage-Grouse are greater than Alternative A and include increased controlled management distances, winter timing limitation and winter habitat restrictions, and protection of brood-rearing habitat. Management actions to protect other special status wildlife include more constraints than Alternative A and list specific areas and species that will be impacted by these actions. For example, Alternative B institutes a disturbance free zone and applies an NSO stipulation to mineral leases within 0.5 mile of bald and golden eagle roosting sites and the following riparian corridors consistently used by wintering eagles: Clear Creek, Crazy Woman Creek, Piney Creek, Powder River, and Tongue River.

Heritage and Visual Resources

Alternative B emphasizes the protection of cultural and paleontological resources and places restrictions on resource uses that may adversely impact them. Around sites containing historical properties, the BLM prohibits surface disturbance and initiates mineral withdrawals in areas containing sensitive cultural sites such as traditional cultural properties (TCPs). Under this alternative, the BLM prohibits salable mineral exploration, recommends withdrawals to locatable

mineral entry, and closes mineral leasing in areas containing paleontological resources of high quality or importance. Proactive management designed to protect and enhance cultural and paleontological resources include establishing site stewardship opportunities in coordination with stakeholders and initiating paleontological field surveys on all Potential Fossil Yield Classification (PFYC) Class 3, 4, and 5 formations potentially affected by proposed activities.

Under Alternative B, the BLM manages all visual resource inventory (VRI) Class II areas and special emphasis areas as VRM Class II and all VRI Class III areas outside special emphasis areas as VRM Class III.

Land Resources

Forest products management under Alternative B places a greater emphasis on the role of natural processes. For example, Alternative B offers sawtimber only from specified forest areas, manages forest product sales to remain within ecologically sustainable limits, and limits forest management to five acres per select group harvest.

Land resource program actions under Alternative B retain BLM-administered lands identified for disposal that have agricultural potential, water, or other natural resource value. Alternative B considers all lands within the planning area for acquisition without prioritizing major blocks of public land and areas of high recreation potential. Renewable energy development is excluded in all areas where surface disturbance is prohibited and is avoided in mineral leasing NSO and CSU areas, ROW avoidance areas, and all other areas with surface disturbance restrictions. The BLM authorizes transmission lines only within identified corridors and requires co-location of new communication sites within designated areas. Fewer ROW corridors are designated under Alternative B than under other alternatives and no above ground high-voltage transmission lines would be authorized in the planning area. As under Alternative A, ROWs are excluded on slopes 25 percent or greater, but Alternative B additionally stipulates that placement of above ground facilities should be avoided along major transportation routes to protect visual resources. Alternative B also prohibits CO₂ sequestration research and projects. Transportation management designations under Alternative B include 625,854 acres Closed to motorized vehicle use, and 137,126 acres Limited to designated roads and trails for motorized vehicle use. In addition, Alternative B seasonally closes 18,259 acres to motorized vehicle use within big game crucial winter range.

Under Alternative B, recreation management emphasizes protection of resources and recreational experiences, and includes more restrictions on resource uses than the other alternatives. For example, the BLM limits development of additional recreational facilities to SRMAs and other high-use areas. Alternative B expands the constraints on resource uses applied under Alternative A by not leasing minerals within designated SRMAs, instituting a 0.5 mile buffer from mineral leasing surrounding SRMAs, and recommending withdrawals from appropriation under the mining law in designated SRMAs. However, Alternative B would allow salable mineral development within designated SRMAs for administrative use. Under Alternative B, the planning area would be managed under two ERMAs (Southern Big Horns and Buffalo ERMAs), totaling 726,573 acres. The BLM would also designate a total of 55,529 acres in eight SRMAs: Burnt Hollow, Dry Creek Petrified Tree, Middle Fork Powder River, Mosier Gulch, Welch Ranch, Weston Hills, Hole-in-the-Wall, and Cabin Canyon.

Alternative B manages areas with wilderness characteristics to emphasize primitive recreational opportunities and natural values. In order to protect these characteristics, Alternative B limits incompatible uses within these areas such as mineral development and motorized vehicle use.

Alternative B limits or prohibits livestock grazing where it has been determined to be incompatible with other uses, including areas within 4 miles of the perimeter of occupied or undetermined sage-grouse leks and winter concentrations areas (467,897 acres) as proposed under this alternative. Similar to Alternative A, Alternative B authorizes permanent increases in forage allocations to wildlife habitat and watershed protection as the first priority, livestock grazing second. Alternative B prohibits increases in livestock stocking rates as a result of vegetation treatment and locates livestock salt or mineral supplements a minimum of 0.5 mile away from water sources.

Special Designations

Alternative B designates eight ACECs including Cantonment Reno, Burnt Hollow, Dry Creek Petrified Tree, Fortification Creek Elk Area, Hole-in-the-Wall, Pumpkin Buttes, Sagebrush Ecosystem, and Welch Ranch. Refer to Table 2.6, “Comparative Summary of Proposed Areas of Critical Environmental Concern” (p. 110) for the management emphasis and acreages of each ACEC.

Alternative B would evaluate roads within the planning area for designation as National Back Country or Scenic Byways. If Congress does not designate the Middle Fork Powder River as a WSR, and releases the river for other uses, management will continue in accordance with the Middle Fork Interim Management Plan to protect and/or enhance its free-flowing condition and outstandingly remarkable values. The Middle Fork Interim Management Plan is available on the BFO website, <http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo/docs.html>. If Congress decides not to designate the three WSAs in the planning area as Wilderness, and releases an area for other uses, the Gardner Mountain, North Fork, and Fortification Creek WSAs would not be available for oil and gas leasing until a plan amendment is completed. WSAs released from Congressional designation would then be subject to consideration for lands with wilderness characteristics.

Socioeconomic Resources

BLM management under Alternative B develops mitigation strategies to resolve conflicts that have detrimental effects on multiple resource use. Similar to Alternative A, BLM management under Alternative B considers local and regional economic development land use plans.

2.8.3. Alternative C – Resource Development

Overview of the Alternative

Alternative C emphasizes resource uses by limiting conservation measures afforded to physical, biological, heritage and visual resources. Relative to all other alternatives, Alternative C conserves the least land area for physical, biological, and heritage resources and is the least restrictive to motorized vehicle use and mineral development.

Physical Resources

Physical resources under Alternative C are generally managed with fewer management requirements and more allowance for the project-specific applications of management actions than the other alternatives. For example, quantitative air quality monitoring is not required for industrial activities and surface-disturbing activities and surface occupancy can be allowed on soils with severe erosion hazard, slopes 25 percent and greater, soils with poor reclamation

suitability, and on badlands and rock outcrops consistent with other resource values and subject to standard lease terms. Water resources management is more flexible in Alternative C than in other alternatives. For example, suitable abandoned oil and gas wells could be converted to water wells for livestock, recreation, and wildlife use, and on-channel reservoirs could be allowed in consideration of other resource uses. In addition, surface-disturbing activities can be allowed within 500 feet of springs, reservoirs, water wells, and perennial streams and riparian habitat. Cave and karst management under Alternative C is similar to Alternative B although fewer restrictions are placed on resource uses in proximity to cave and karst resources. For example, Alternative C applies a CSU stipulation within cave and karst areas whereas Alternative B applies an NSO stipulation. In addition, Alternative C would manage human activity in caves with significant resources by developing and implementing a Cave Management Plan for the entire planning area versus individual cave management plans.

Mineral Resources

Under Alternative C, mineral resource uses are subject to fewer constraints than under the other alternatives. No withdrawals from locatable mineral entry are recommended under Alternative C – all 3,319,535 acres currently open would remain open to locatable mineral entry within the planning area. Under Alternative C, the BLM would open all coal lands to coal exploration and leasing, resulting in zero acres closed to coal exploration and leasing and 4,775,136 acres open to coal exploration and leasing.

The entire federal fluid mineral estate is open for leasing subject to the following constraints: 539,499 acres are subject to standard stipulations only, 40,437 acres are subject to minor constraints, 2,472,472 acres are subject to moderate constraints, and 303,601 acres are subject to major constraints. Approximately 4,707,436 acres are open to leasing of other minerals (i.e., phosphates, sodium, etc.). Alternative C would also result in 3,290,908 acres open to salable mineral exploration and development and 57,213 acres closed to or restricted from salable mineral exploration and development.

Fire and Fuels Management

Fire and fuels management under Alternative C places more emphasis on suppression of unplanned ignitions, and uses planned ignitions to meet vegetation management objectives.

Response to unplanned ignitions in this alternative would use full protection strategies throughout the planning area. The BLM could use heavy equipment with few constraints for suppression efforts. This alternative rehabilitates suppression-related damage only.

Fuels management in Alternative C would treat about 42,000 acres with prescribed fire during the life of the plan. Wildland fire and other vegetation treatments would be used to restore fire-adapted ecosystems, enhance forage for commodity production, and to reduce hazardous fuels.

Biological Resources

Vegetation management under Alternative C emphasizes more resource use and greater intensive management practices compared to the other alternatives. For example, Alternative C implements silvicultural treatments to maximize forest health; utilizes intensive management tactics to manage for desired forest/woodland health; and manages forest/woodland to emphasize the forest resource. Reclamation under Alternative C could include using desirable non-native plant species for initial reclamation activities and would address vegetation restoration only on direct CBNG

disturbance areas. In addition, Alternative C would only apply standard lease terms to mineral leases within 500 feet of riparian/wetland systems, aquatic habitats, and floodplains. Alternative C prioritizes noxious weed treatments where infestations on public land are threatening private lands, and restricts noxious weed treatments to only those plants on the State of Wyoming Designated list. In addition, Alternative C limits aerial application to insecticides and treats annual brome species only in designated areas.

Alternative C generally applies less stringent management restrictions for surface-disturbing activities within fish and wildlife habitat than the other alternatives. For example, fish resource management under Alternative C allows surface-disturbing activities within 0.25 mile of naturally occurring water bodies consistent with other resource values while Alternative B restricts activity within that buffer. Proactive fish management makes more allowances for project-specific management decisions than the other alternatives. Alternative C also places few constraints on resource uses to protect wildlife habitat. For example, surface-disturbing activities are not prohibited in the Ed O. Taylor, Kerns, Bud Love, and Amsden Creek winter ranges as they are under the other alternatives.

Special status species receive limited protection from incompatible resource uses under Alternative C. Management of special status plant species under Alternative C is similar to Alternative B although restrictions on uses are typically limited to known special status plant populations versus within special status plant species habitat. Under Alternative C, surface disturbance is allowed to within 500 feet of any waters containing special status fish species when their impacts can be mitigated. Alternative C applies similar, but less stringent restrictions on surface-disturbing activities to protect special status wildlife species than Alternative B. For example, this alternative prohibits surface-disturbing activities within 0.25 mile of a special status species raptor nest whereas Alternative B prohibits surface disturbance within 1.5 miles. Similarly, Alternative C restricts surface-disturbing activities, disruptive activities, and occupancy within 0.25 mile of the perimeter of occupied or undetermined Greater Sage-Grouse leks, while Alternative B prohibits these activities within 4.0 miles of occupied or undetermined leks and winter concentration areas.

Heritage and Visual Resources

Alternative C provides for mineral development near historic and other cultural properties protecting them through NSO stipulations and other appropriate mitigation. The BLM applies stipulations such as NSO and CSU to protect culturally sensitive sites such as TCPs and/or sacred sites. In contrast to Alternative B, Alternative C does not prohibit salable mineral exploration, or initiate locatable mineral withdrawals in areas containing paleontological resources of high quality or importance. However, Alternative C does require paleontological field surveys on all PFYC Class 4 and 5 formations potentially affected by proposed activities.

Under Alternative C, the BLM manages all VRI Class II areas as VRM Class III and all VRI Class III areas as VRM Class IV.

Land Resources

Forest products management under Alternative C places a greater emphasis on forest products commodity production. The BLM manages forest products sales to maximize economic return and does not limit the size and design/shape of forest management in order to maximize the removal of harvestable products within the limits of Wyoming Forestry BMPs and other guidance.

All lands identified for disposal are available for disposal under Alternative C. In contrast to alternatives A and B, Alternative C lands and realty actions do not include land acquisition. Renewable energy development is allowed within the planning area as long as development is consistent with other resource values. Alternative C offers additional acreage for ROW development in comparison to Alternative B, and allows the authorization of above ground transmission lines in any designated corridor. Alternative C also does not require co-location of new communication sites nor does it exclude ROW on slopes of 25 percent or greater. CO₂ sequestration research and projects are allowed where consistent with other resource values. Transportation management under Alternative C closes 28,931 acres to motorized vehicle use and limits motorized vehicle use to designated roads and trails on 723,497 acres. In addition, Alternative C closes 6,839 acres of big game crucial winter range to motorized vehicle use from November 15 to April 30. As under all alternatives, motorized vehicle use is limited to designated routes on BLM-administered land throughout the planning area unless otherwise designated.

Alternative C allows additional recreation facilities in areas where they are supported by recreational use and are consistent with other resource values. Generally, Alternative C does not apply specific limitations on surface disturbance or mineral development and manages recreational areas consistent with other resource values. Under Alternative C, the BLM would designate six SRMAs: Burnt Hollow, Dry Creek Petrified Tree, Middle Fork Powder River, Mosier Gulch, Welch Ranch, and Weston Hills. The rest of the planning area would be managed as the Buffalo ERMA.

Lands with wilderness characteristics are managed to follow the management within the surrounding areas and are not managed to emphasize primitive recreational opportunities and natural values.

Livestock grazing under Alternative C is limited or prohibited only in those areas where it is currently prohibited under Alternative A. Livestock grazing is generally managed with less emphasis on providing for other resource values than the other alternatives. For example, Alternative C authorizes permanent increases in forage allocations to livestock grazing as the first priority, wildlife habitat and watershed protection as the second priority. Alternative C requires livestock salt or mineral supplements to be placed a minimum of 500 feet away from water sources, riparian areas, and aspen stands.

Special Designations

Alternative C does not designate any ACECs. If Congress does not designate the Middle Fork Powder River as a WSR, and releases the river for other uses, management will follow the management within the surrounding areas as outlined in this RMP. Like Alternative B, if Congress decides not to designate the three WSAs in the planning area as wilderness, the Gardner Mountain, North Fork, and Fortification Creek WSAs would not be available for oil and gas leasing until a plan amendment is completed. WSAs released from Congressional designation would then be subject to consideration for lands with wilderness characteristics.

Socioeconomic Resources

BLM management under Alternative C develops management strategies designed to recognize and point out conflicts that are expected to impact multiple resource use. Alternative C also incorporates, to the extent possible, local and regional economic development and land use plans.

2.8.4. Alternative D – Proposed RMP

Overview of the Alternative

Alternative D generally allows resource use if the activity can be conducted in a manner that conserves physical, biological, and heritage and visual resources. Alternative D designates the second most land as SRMAs and ACECs and emphasizes moderate constraints on resource uses to reduce impacts to resource values.

Physical Resources

Physical resources management under Alternative D places few universal constraints on resource uses and instead allows activities if they meet certain requirements designed to mitigate impacts to air, soil, water, and cave and karst resources. For example, the BLM allows activities on highly erosive soils and on slopes 25 percent and greater if the actions meet certain criteria including having an approved stabilization and reclamation plan. Similar to Alternative B, this alternative would require quantitative air quality modeling of proposed activities to determine potential emission impacts and identify mitigation strategies. Water resources management generally seeks to support other resource uses while protecting water quality and quantity by allowing activities such as converting abandoned oil and gas wells to water supply wells (with proper permitting and regulation by the Wyoming DEQ) if a beneficial use can be demonstrated and allowing surface disturbance within 500 feet of springs, reservoirs, water wells, and perennial streams where water and other resource objectives can be met. In order to protect cave and karst resources, Alternative D applies site-specific buffers to restrict resource uses such as forest management around significant caves. In addition, Alternative D would manage human activity in caves with significant resources by developing and implementing a Cave Management Plan for the entire planning area with potential cave specific components.

Mineral Resources

Under Alternative D, mineral resource uses are subject to less extensive constraints than under Alternative B, but more than either alternatives A or C. The BLM recommends withdrawals from mineral entry for an additional 82,691 acres (totaling 94,288 acres potentially closed to mineral entry; closure of these acres would leave 4,720,586 acres open to mineral entry within the planning area). All coal lands are open to exploration, subject to multiple use constraints, resulting in zero acres closed to coal exploration and 4,775,136 acres open to coal leasing, subject to application of the coal planning screens in 43 CFR 3420.1-4.

Approximately 72,276 acres of federal fluid mineral estate are closed to fluid mineral leasing. The remaining federal fluid mineral estate is open for leasing subject to the following constraints: 135,909 acres are subject to standard stipulations only, 104,927 acres are subject to minor constraints, 2,516,826 acres are subject to moderate constraints, and 556,592 acres are subject to major constraints. In addition, approximately 3,801,889 acres are open to leasing of other minerals (i.e., phosphates, sodium, etc.). Alternative D would result in 2,725,060 acres remaining open to salable mineral exploration and development, and 623,061 acres closed to or restricted from salable mineral exploration and development.

Fire and Fuels Management

Fire management under Alternative D balances suppression strategies with resource values and desired conditions. Unplanned ignitions in this alternative may be managed to enhance other

resources such as wildlife habitat and forest health. Response to wildfires could vary from full protection in areas where fire is undesirable, to monitoring fire behavior in areas where fire can be used as a management tool. The entire planning area would be available to manage fires to meet resource objectives. Heavy equipment is prohibited in certain areas with sensitive resources such as riparian/wetland habitat, except where human safety is at risk or if the effects of the fire are anticipated to cause more resource damage than the use of heavy equipment.

Fuels management in Alternative D would treat about 14,000 acres with prescribed fire during the life of the plan. Wildland fire and other vegetation treatments would be used to meet desired management objectives.

Biological Resources

Vegetation management under Alternative D allows for resource uses where activities can be conducted that conserve vegetation and other resource values. For example, Alternative D manages forests and woodlands to emphasize multiple resource values and not just the forest resource as under Alternative C. Alternative D also implements silvicultural treatments to maximize forest health and manages forests and woodlands to emphasize multiple resource values including recreation, wildlife, soils, water, and forest products. Alternative D allows desirable non-native plant species for short-term reclamation activities as a component of an authorized reclamation plan. In addition, Alternative D would apply a CSU stipulation to any mineral lease within 500 feet of riparian/wetland systems and aquatic habitats. Invasive species and pest management under Alternative D includes the development of long-range pest management plans, treatment areas, and priorities in cooperation with stakeholders.

Alternative D emphasizes protection of fish and wildlife resources through the application of moderate resource constraints and defining resource objectives. For fish species, the BLM allows surface-disturbing activity within 0.25 mile of naturally occurring water bodies containing fish if fish resource objectives can be met. Proactive fish management includes performing restoration of important instream segments for fish habitat in accordance with WGFD priorities and designing crossings to allow fish passage. Alternative D would continue to prohibit surface disturbance in sensitive wildlife areas such as big game crucial winter range, but would allow other resource uses in certain habitat if the activities met specific criteria such as following an approved resource protection plan.

Special status species generally receive greater protection under Alternative D than under Alternative A. To protect special status plant species, Alternative D prohibits surface disturbance, mineral exploration, motor vehicle use, explosives, and the placement of water developments within known special status plant species populations. Alternative D prohibits new surface-disturbing activities within 0.25 mile of any waters containing special status fish species, although certain exceptions are allowed. For Greater Sage-Grouse, constraints on resource uses are greater within Core Population Areas than outside Core Population Areas. For example, the BLM would apply an NSO stipulation within 0.6 mile of Greater Sage-Grouse leks within priority habitat (Core Population Areas and Connectivity Corridors) and within 0.25 mile of occupied Greater Sage-Grouse leks outside of priority habitat. Alternative D applies similar, but less stringent restrictions on surface-disturbing activities to protect other special status wildlife species than Alternative B. For example, Alternative D institutes a disturbance free zone and applies a CSU stipulation to mineral leases within 0.5 mile of eagle roost sites and consistently used riparian corridors.

Heritage and Visual Resources

Cultural and paleontological resources generally receive more protection under Alternative D than under Alternative A. Alternative D applies an NSO stipulation to specific historic properties and a CSU stipulation to protect the setting of the same sites, subject to certain exceptions. Alternative D also avoids areas containing important paleontological resources when developing locatable and salable minerals and applies an NSO stipulation to mineral leases in the same areas. Paleontological field surveys are required on PFYC Class 4 and 5 formations potentially affected by proposed activities and on Class 3 formations as needed.

VRM under Alternative D includes managing VRI Class II areas (except Powder River Breaks and Fortification Creek) and special emphasis areas (i.e., SRMAs, ACECs, and wilderness characteristic areas) as VRM Class II.

Land Resources

Forest products management under Alternative D emphasizes commodity production while still managing for long-term ecological health of forestland. For example, sales of forest products are managed to remain within ecologically sustainable limits while maximizing economic return. The designing/shaping of forest management areas is conducted in accordance with other resource values and within the limits of the Wyoming Forestry BMPs.

The BLM actively pursues a program to dispose of BLM surface lands identified for disposal including other lands not identified but meeting appropriate disposal criteria. Land acquisition and disposal is based on all resources values, including but not limited to agricultural potential and water. Renewable energy development is excluded on 352,068 acres. Alternative D requires co-location of communication sites within identified communication site areas and avoids ROW on slopes 25 percent or greater and highly erodible soils. Alternative D requires corridor use and authorizes above ground and below ground structures in designated corridors when resource objectives can be met. Designated ROW corridors would be utilized as transportation and utility corridors. CO₂ sequestration proposals are evaluated in accordance with other management objectives. Transportation management under Alternative D closes 37,389 acres to motorized vehicle use and limits motorized vehicle use to designated roads and trails on 661,726 acres. In addition, Alternative D seasonally closes 18,259 acres to motorized vehicle use to protect wintering big game.

Recreation management under Alternative D generally increases constraints on resource uses within recreation management areas and places a greater emphasis on recreational facility development compared to current management. Surface disturbance and salable mineral development are allowed in SRMAs for administrative use only, while SRMAs are recommended for withdrawal from locatable mineral entry. Seven SRMAs totaling 54,160 acres and eight ERMAs totaling 349,663 acres would be designated under Alternative D. Cabin Canyon, proposed as an SRMA under Alternative B, would not be designated as an SRMA in Alternative D.

Non WSA lands with wilderness characteristics are managed to emphasize ecosystem health, natural values, and primitive recreational opportunities.

Livestock grazing is allowed on all public lands in the planning area except where an evaluation has determined it to be incompatible with other resource uses or values. Permanent forage allocations would consider watershed protection, livestock grazing, wildlife habitat, and other resource values. Similar to Alternative C, Alternative D allows increases in livestock stocking rates as a result of vegetation treatments and requires livestock salt or mineral supplements to be placed a minimum of 500 feet away from water sources.

Special Designations

Alternative D designates two ACECs including Fortification Creek Elk Area, Pumpkin Buttes, and Welch Ranch. Refer to Table 2.6, “Comparative Summary of Proposed Areas of Critical Environmental Concern” (p. 110) for the management emphasis and acreages of each ACEC.

Alternative D would evaluate roads in coordination with the counties and other stakeholders for designation as National Back Country or Scenic Byways. If Congress does not designate the Middle Fork Powder River as a WSR, and releases the river for other uses, management will continue to retain its free-flowing condition and outstandingly remarkable values. As under alternatives B and C, if Congress decides not to designate the three WSAs in the planning area as Wilderness, the Gardner Mountain, North Fork, and Fortification Creek WSAs will not be available for oil and gas leasing until a plan amendment is completed. WSAs released by Congressional for uses other than wilderness would then be considered pursuant to Manuals 6310 and 6320 to maintain wilderness characteristics.

Socioeconomic Resources

BLM management under Alternative D emphasizes collaboration with local, state, federal, and private entities to promote a healthy and sustainable social and economic environment. Similar to the other alternatives, Alternative D considers local and regional land use and economic development plans.

2.9. Detailed Alternative Descriptions by Resource

This section is comprised of multiple tables. Table 2.7, “1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)” (p. 127) through Table 2.40, “8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY” (p. 275) identify goals and objectives, management actions common to all alternatives, and management actions by alternative. Table 2.7, “1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)” (p. 127) through Table 2.40, “8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY” (p. 275) are arranged according to the following resource topics:

Number	Resource Topic
1000	Physical Resources (PR)
2000	Mineral Resources (MR)
3000	Fire and Fuels Management (FM)
4000	Biological Resources (BR)
5000	Heritage and Visual Resources (HR)
6000	Land Resources (LR)
7000	Special Designations (SD)
8000	Socioeconomic Resources (SR)

The above numbering system and abbreviations for each of the eight resource topics appear as headings and serve to organize Table 2.7, “1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)” (p. 127) through Table 2.40, “8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY” (p. 275). Following the headings are the applicable goals and objectives for each resource topic. These goals and objectives apply to all four alternatives under consideration for the entire planning area and would apply for the life of the RMP.

Management actions are anticipated to achieve the goals and objectives identified for each resource topic. Some management actions are constant across all alternatives and are listed

for each resource topic under the Management Actions Common to All Alternatives sections. Other management actions vary by alternative and are identified in the Management Actions by Alternative sections.

Actions apply for the life of the RMP, but can be changed by amending the RMP. For example, areas identified as closed to mineral leasing refer to federal mineral estate closed from leasing for the life of the RMP unless changed through an RMP amendment. Moreover, where seasonal or other restrictions or limitations are placed on development, exception, waiver, or modification of these limitations may be approved in writing (Appendix H (p. 1959)), including documented supporting analysis, by the authorized officer. This applies to all restrictions and limitations.

2.9.1. 1000 PHYSICAL RESOURCES

Table 2.7. 1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)

GOAL PR:1 Maintain existing air quality and air quality related values such as visibility by requiring that all BLM actions minimize impacts on air quality and comply with all applicable air quality laws, rules, and regulations.					
Objectives:					
PR:1.1 Reduce the impacts of criteria pollutants and greenhouse gases associated with BLM actions in compliance with applicable state and federal AAQS.					
PR:1.2 Work cooperatively with Wyoming DEQ to reduce visibility-impairing pollutants in accordance with the State of Wyoming’s Regional Haze SIP.					
PR:1.3 Reduce atmospheric deposition of pollutants to levels below accepted and LAC.					
PR:1.4 Manage fugitive dust to reduce impacts associated with BLM actions.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
AQ-1001	PR:1	Manage prescribed burns to comply with Wyoming DEQ AQD smoke-management rules and regulations.			
AQ-1002	PR:1	Define a criteria pollutant and AQRV monitoring strategy and cooperatively establish a monitoring network by creating a method for siting AQ monitors in order to provide additional data for describing background concentrations.			
AQ-1003	PR:1	Implement mitigation measures within BLM’s authority (BMPs – for example, dust suppression) to reduce emissions from current levels in the planning area and work cooperatively to encourage industry and other permittees to adopt measures to reduce emissions.			
AQ-1004	PR:1	Enhance the existing cooperative process that shares air quality information with agencies, stakeholders, and the public.			
AQ-1005	PR:1	Work cooperatively with stakeholders to reduce cumulative dust emissions (i.e., Campbell County Dust Coalition) and address other air quality concerns.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
AQ-1006	PR:1	Perform analysis of activities with expected effects to air resources. Modeling may be performed on a project-specific basis.	Require quantitative AQ modeling of industrial activities (e.g., oil and gas field development or mining activities) in order to determine the potential impacts of proposed emission sources and subsequently of potential mitigation strategies for projects expected to approach or exceed emission standards at the project level.	Do not require quantitative AQ modeling of industrial activities.	Require quantitative AQ modeling of industrial activities (i.e., oil and gas or mining) expected to result in emissions where ambient conditions may approach or exceed ambient air quality standards, in consultation with the Wyoming DEQ Air Quality Division and other stakeholder, in order to determine the potential impacts of proposed emission sources and potential mitigation strategies

Table 2.8. 1000 PHYSICAL RESOURCES (PR) – SOIL

GOAL PR:2 Soil quality is maintained, improved, or restored while supporting other resource values. Objectives: PR:2.1 Achieve and maintain Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming. PR:2.2 Incorporate soil protection consistent with soil resource capabilities for all BLM actions. PR:2.3 Rehabilitate all surface-disturbing activities consistent with applicable laws, regulations, and policies.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Soil-1001	PR:2.1 PR:2.2	Evaluate the effects of a proposed surface-disturbing activity to the soil resource using NRCS Soil Survey data and/or onsite investigation. Apply mitigation measures if necessary, relocate the activity to a more suitable soil type, or deny the authorization.			
Soil-1002	PR:2.1 PR:2.2 PR:2.3	Authorized surface-disturbing activities will include plans for reclamation; site-specific reclamation actions should reflect the complexity of the project, environmental concerns, and the reclamation potential of the site.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Soil-1003	PR:2.2	Prohibit surface-disturbing activities within areas of severe erosion hazard (Map 3) from March 1 through June 15, unless the prohibition is waived by the authorized officer.	Prohibit surface-disturbing activities on soils with a severe erosion hazard (Map 3).	Allow surface-disturbing activities on soils with a severe erosion hazard consistent with other resource values.	Allow surface-disturbing activities on soils without a severe erosion hazard. Activities on highly erosive soils would be allowed with approved site-specific construction, stabilization, and reclamation plans to conserve the soil resource and meet reclamation (Appendix O (p. 2495)) and resource objectives.
Soil-1004	PR:2.1 PR:2.2	NSO on areas of severe erosion hazard from March 1 through June 15, unless waived by the authorized officer.	Apply an NSO stipulation on soils with a severe erosion hazard.	Allow surface occupancy on soils with a severe erosion hazard subject to standard lease terms.	Apply a CSU stipulation on soils with a severe erosion hazard with approved site-specific construction, stabilization, and reclamation plans.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Soil-1005	PR:2.2	Prohibit surface-disturbing activities on slopes of more than 25% (Map 4), unless the prohibition is waived by the authorized officer.	Prohibit surface-disturbing activities on slopes 25% and greater (Map 4).	Allow surface-disturbing activities on slopes 25% and greater consistent with other resource values (Map 4).	Allow surface-disturbing activities on slopes less than 25%. Activities on slopes 25% and greater would be allowed with approved site-specific construction, stabilization, and reclamation plans to conserve the soil resource and meet reclamation (Appendix O (p. 2495)) and resource objectives (Map 4).
Soil-1006	PR:2.2	NSO for fluid mineral leases on slopes of more than 25% unless waived by the authorized officer (Map 4).	Apply an NSO stipulation on all slopes 25% and greater (Map 4).	Allow surface occupancy on slopes 25% and greater subject to standard lease terms (Map 4).	Apply a CSU stipulation on all slopes 25% and greater with approved site-specific construction, stabilization, and reclamation plans (Map 4).
Soil-1007	PR:2.2 PR:2.3	Surface-disturbing activities are restricted on soils having poor reclamation suitability on a project-specific basis (Map 5).	Prohibit surface-disturbing activities on soils with poor reclamation suitability (Map 5).	Allow surface-disturbing activities on soils with poor reclamation suitability consistent with other resource values (Map 5).	Allow surface-disturbing activities on soils with poor reclamation suitability recognizing that reclamation may be challenging and that construction, stabilization, and reclamation plans are required to conserve the soil resource (Map 5) (Appendix O (p. 2495)).
Soil-1008	PR:2.2 PR:2.3	Surface-disturbing activities are restricted on soils having poor reclamation suitability on a project-specific basis (Map 5).	Apply an NSO stipulation on soils having poor reclamation suitability (Map 5).	Allow surface occupancy on soils having poor reclamation suitability subject to standard lease terms (Map 5).	Apply a lease notice on soils with poor reclamation suitability identifying that reclamation may be challenging and that construction, stabilization, and reclamation plans are required to conserve the soil resource (Map 5).

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Soil-1009	PR:2.2	No previous decision; considered on a project-specific basis.	Prohibit surface-disturbing activities on badlands, rock outcrops, biologic crusts, and slopes susceptible to mass movement (Map 6).	Allow surface-disturbing activities on badlands, rock outcrops, biologic crusts, and slopes susceptible to mass movement consistent with other resource values (Map 6).	Avoid surface-disturbing activities on limited reclamation potential areas such as badlands, rock outcrops, biologic crusts, and slopes susceptible to mass movement (Map 6). Activities may be allowed in limited cases with approved site-specific construction, stabilization, and reclamation plans to conserve the soil resource and meet reclamation (Appendix O (p. 2495)) and resource objectives.
Soil-1010	PR:2.2	No previous decision; considered on a project-specific basis.	Apply an NSO stipulation on badlands, rock outcrops, biologic crusts, and slopes susceptible to mass movement (Map 6).	Allow surface occupancy on badlands, rock outcrops, biologic crusts, and slopes susceptible to mass movement subject to standard lease terms (Map 6).	Apply a CSU stipulation on limited reclamation potential areas such as badlands, rock outcrops, biologic crusts, and slopes susceptible to mass movement with approved site-specific construction, stabilization, and reclamation plans (Map 6).

Table 2.9. 1000 PHYSICAL RESOURCES (PR) – WATER

GOAL PR:3 Watershed, surface water, and groundwater resources are consistent with applicable state and federal standards and regulations.		
Objectives:		
PR:3.1 BLM actions maintain or improve watershed, wetland, and riparian functions to support desired surface-flow regimes and water quality.		
PR:3.2 Mitigate accelerated channel erosion and instability as a result of BLM actions.		
PR:3.3 Ensure adequate reclamation of reservoir structures and affected downstream channels associated with BLM actions.		
PR:3.4 Cooperatively develop monitoring, rehabilitation and restoration plans for degraded water bodies and riparian zones.		
PR:3.5 Reclaim or remove unneeded, nonfunctional or poorly-sited reservoirs on BLM-administered lands.		
PR:3.6 Continue monitoring groundwater potentially impacted as a result of BLM actions and expand the monitoring network as needed.		
PR:3.7 Minimize impacts to aquifers and groundwater quality.		
GOAL PR:4 Water availability to facilitate authorized uses while providing for the conservation of those waters.		
Objectives:		
PR:4.1 Develop new water-supply sources where appropriate during BLM actions.		
PR:4.2 Identify abandoned oil and gas wells that are desirable for conversion to livestock and wildlife water supply use.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Water-1001	PR:3.1 PR:3.4	Provide an alternative or “off-source” water supply (e.g., piping water to troughs, tanks, or ponds) in locations where BLM-authorized uses are fenced out of water sources.
Water-1002	PR:4.1	Install flow-control devices on new and existing BLM-authorized water wells and spring developments and evaluate the need for additional flow-control devices on a project-specific basis.
Water-1003	PR:3.1 PR:3.7	File for water rights on BLM water projects.
Water-1004	PR:3.1 PR:3.2	Manage surface-disturbing activities to prevent degradation of water quality for all waters.
Water-1005	PR:3.6 PR:3.7	Minimize impacts to water quality and quantity during BLM-authorized actions. BLM will work with Wyoming DEQ to assess impacts and develop mitigation.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Water-1006	PR:3.1 PR:3.2 PR:3.4	Manage water resources to meet the Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming, achieve PFC, and meet Wyoming water quality standards. Take appropriate actions to improve the biological, chemical, and geomorphic conditions of streams adversely impacted by BLM-authorized actions and permitted activities.			
Water-1007	PR:3.1 PR:3.2 PR:3.4	Design and manage land use and surface-disturbing activities to reduce channel and bank erosion and the associated loss of riparian habitats.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Water-1008	PR:3.1 PR:3.3 PR:3.5	No previous decision; considered on a project-specific basis.	Prohibit on-channel reservoirs to minimize effects to natural stream flow regimes.	Allow for on-channel reservoirs effecting natural stream flow regimes in consideration of other resource values.	Allow for on-channel reservoirs effecting natural stream flow regimes in consideration of other resource values.
Water-1009	PR:3.1 PR:3.2	No previous decision; considered on a project-specific basis.	Do not authorize activities resulting in the surface discharge of produced water from development of federal minerals.	Authorize activities associated with the surface discharge of produced water from development of federal minerals, when permitted by the State of Wyoming.	Authorize activities associated with the surface discharge of water produced during federal activities if erosive conditions, channel stability, soil characteristics, and other resource values warrant. Coordinate permitting process with the State of Wyoming.
Water-1010	PR:3.1 PR:3.2	No previous decision; considered on a project-specific basis.	Maintain existing water supply sources to meet current demand and need.	Maintain existing water supply sources and drill new water supply wells, develop new seeps and springs, and construct new reservoirs to meet demand and need.	Maintain existing water supply sources where possible, otherwise supply new water sources to meet demand and need, consistent with other resources.
Water-1011	PR:3.7 PR:4.1 PR:4.2	No previous decision; considered on a project-specific basis.	Do not convert abandoned oil and gas wells to water supply wells.	Convert suitable abandoned oil and gas development wells to water supply wells for livestock, recreation, and wildlife use.	Allow abandoned oil and gas wells to be converted to water supply wells if a beneficial use (livestock, recreation, and wildlife) can be demonstrated.
Water-1012	PR:4	No previous decision; considered on a project-specific basis.	Require alternative energy (e.g., solar and wind) to power all new and existing water resource developments.	Do not require alternative energy (e.g., solar and wind) to power new and existing water resource developments.	Encourage alternative energy (e.g., solar and wind) to power new water resource developments versus overhead power or petroleum based.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Water-1013	PR:3.1 PR:3.2	Prohibit surface disturbance within 500 feet of any spring, reservoir, water well, or perennial stream, unless the prohibition is waived by the authorized officer.	Prohibit surface-disturbing activities within 500 feet of springs, non-CBNG reservoirs, water wells, or perennial streams and associated riparian habitat.	Allow surface-disturbing activities within 500 feet of springs, non-CBNG reservoirs, water wells, or perennial streams and associated riparian habitat.	Allow surface disturbance within 500 feet of springs, non-CBNG reservoirs, water wells, or perennial streams where water and other resource objectives (including, but not limited to soil, slope, and vegetation) can be met.
Water-1014	PR:3.1 PR:3.2	No previous decision; considered on a project-specific basis.	Apply an NSO stipulation to any fluid mineral lease within 500 feet of springs, non-CBNG reservoirs, water wells, or perennial streams and associated riparian habitat.	Do not apply an NSO stipulation to any fluid mineral lease within 500 feet of springs, non-CBNG reservoirs, water wells, or perennial streams and associated riparian habitat.	Apply a CSU stipulation to any fluid mineral lease within 500 feet of any spring, non-CBNG reservoir, water well, or perennial stream, based on other resource values, including, but not limited to soil, slope, and vegetation.
Water-1015	PR:3.1 PR:3.2 PR:3.4	No previous decision; considered on a project-specific basis.	Manage riparian and uplands in historically perennial systems to restore perennial flows or standing water.	Manage riparian and uplands in historically perennial systems on a project-specific basis.	Manage riparian and uplands to restore perennial flows or standing water.
Water-1016	PR:3.1 PR:3.3 PR:3.5	No previous decision; considered on a project-specific basis.	Require removal and reclamation of unneeded CBNG reservoirs for removal and reclamation.	Require removal and reclamation of unneeded CBNG reservoirs on BLM surface and where requested on private surface.	Evaluate unneeded reservoirs for removal and reclamation.

Table 2.10. 1000 PHYSICAL RESOURCES (PR) – CAVE AND KARST

GOAL PR:5 Significant cave and karst resources are conserved.					
Objectives:					
PR:5.1 Identify and determine cave and karst resources that meet significance criteria of 43 CFR 37.11(c).					
PR:5.2 Manage significant cave and karst resources while supporting other resource values.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Cave-1001	PR:5.1	Conduct cave inventories and significance determinations.			
Cave-1002	PR:5.1	Inventory and map cave and karst areas.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Cave-1003	PR:5.2	No previous decision; considered on a project-specific basis.	Manage human activity in caves with significant resources through cave specific Cave Management Plans.	Manage human activity in caves with significant resources by developing and implementing a Cave Management Plan for the planning area.	Manage human activity in caves with significant resources by developing and implementing a Cave Management Plan for the planning area, with potential cave specific components.
Cave-1004	PR:5.2	No previous decision; considered on a project-specific basis.	Apply an NSO stipulation within cave and karst areas. Close these areas to surface and sub-surface-disturbing activities.	Apply a CSU stipulation within cave and karst areas. Mineral resource activities would likely be required to maintain a buffer around significant cave entrances and passages.	Apply a CSU stipulation within cave and karst areas. Note: Mineral resource activities would likely be required to maintain a site-specific buffer around significant cave entrances and passages.
Cave-1005	PR:5.2	No previous decision; considered on a project-specific basis.	Prohibit surface-disturbing activities in areas containing cave and karst resources (Map 7).	Require a buffer from significant cave entrances for surface-disturbing activities (Map 7).	Require a site-specific buffer from significant cave entrances for surface-disturbing activities.
Cave-1006	PR:5.2	No previous decision; considered on a project-specific basis.	Prohibit forest management in areas containing cave and karst resources.	Require forest management to maintain a buffer from significant cave entrances.	Require forest management to maintain a site-specific buffer from significant cave entrances.
Cave-1007	PR:5.2	No previous decision; considered on a project-specific basis.	Restrict livestock from entrances to significant caves.	Do not restrict livestock grazing in areas containing cave and karst resources.	Restrict livestock from entrances to significant caves.

2.9.2. 2000 MINERAL RESOURCES

Table 2.11. 2000 MINERAL RESOURCES (MR) – LOCATABLE MINERALS

GOAL MR:1 Federal mineral lands are open to mineral entry to support short-term and long-term domestic needs.					
Objectives:					
MR:1.1 Provide opportunities for the exploration and development of locatable minerals, as well as mill and tunnel site operations, while avoiding or mitigating the effects of these activities on other resource values so that unnecessary or undue degradation is prevented.					
MR:1.2 Provide opportunities for the exploration, development, and reclamation of locatable minerals (including uranium), as well as mill and tunnel site operations, in coordination with other governmental agencies.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Locatable-2001	MR:1.1	Lands not formally withdrawn or segregated from mineral entry are open for the exploration and development of locatable minerals.			
Locatable-2002	MR:1.2	Implement the MOUs between BLM and Wyoming DEQ, and BLM and NRC, addressing locatable mineral exploration, development, and reclamation activities.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Locatable-2003	MR:1.1	Amsden Creek (523 acres), Middle Fork Canyon (about 10,695 acres), and Kerns (155 acres) Game Ranges are withdrawn from mineral entry; these withdrawals total 11,373 acres (Map 8). Although Fortification Creek, Gardner Mountain, and North Fork WSAs (28,931 acres) (Map 8) remain open to mineral entry, locatable mineral exploration and development activities on active claims or sites in these areas would be regulated pursuant to restrictions under 43 CFR 3802 to prevent impairment of the suitability of these areas for inclusion in the wilderness system.	Recommend withdrawals from mineral entry for areas identified within Alternative B to conserve other resource values (Map 8). This results in: <ul style="list-style-type: none"> • 159,054 acres remain open to mineral entry, if all acres recommended for withdrawal are withdrawn. • 687,813 acres recommended for withdrawal from mineral entry. • 11,373 acres remain withdrawn from mineral entry. 	Do not recommend any new withdrawals from mineral entry. Manage lands open to mineral entry in accordance with Alternative C, as consistent with other resource values. This results in: <ul style="list-style-type: none"> • 777,310 acres remain open to mineral entry. • 0 acres recommended for withdrawal from mineral entry. • 11,373 acres remain withdrawn from mineral entry. 	Recommend withdrawals from mineral entry for areas identified within Alternative D to conserve other resource values (Map 8). This results in: <ul style="list-style-type: none"> • 694,619 acres remain open to mineral entry, if all acres recommended for withdrawal are withdrawn. • 115,614 acres recommended for withdrawal from mineral entry. • 11,373 acres remain withdrawn from mineral entry.

Table 2.12. 2000 MINERAL RESOURCES (MR) – LEASABLE – COAL

GOAL MR:2 Leasable coal resources are available to support domestic and export needs.					
Objectives:					
MR:2.1 Maintain coal leasing and exploration, while minimizing impacts to other resource values.					
MR:2.2 Manage opportunities for exploration and development of coal resources.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Coal-2001	MR:2.1 MR:2.2	<p>Coal planning was completed as part of the April 2001 BFO RMP update. At that time the four coal planning screens (i.e., coal development potential, unsuitability, multiple use and surface owner consultation) were applied to certain federal coal lands within the BFO planning area. The result of this planning effort was a decision identifying lands acceptable for further coal leasing consideration. The coal management decisions made in the BFO RMP update will be carried forward in this RMP revision (Map 11). Federal coal lands identified acceptable for further coal leasing consideration are available for Lease By Applications, lease modifications, emergency leases, and exchanges. Prior to offering a coal tract for sale, the need to reapply the unsuitability criteria will be reviewed, a tract specific NEPA analysis will be completed, and there will be opportunity for public comment.</p> <p>At the time an application for a new coal lease or lease modification is submitted to the BLM, the BLM will determine whether the lease application area is "unsuitable" for all or certain coal mining methods pursuant to 43 CFR 3461.5. Priority habitat (core population areas and core population connectivity corridors) is essential habitat for maintaining Greater Sage-Grouse for purposes of the suitability criteria set forth at 43 CFR 3461.5(o)(1).</p>			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Coal-2002	MR:2.1 MR:2.2	On coal leases for which mining and reclamation plans have been approved, stipulate oil and gas leases to regulate oil and gas operations that would interfere with approved coal mining.	When a coal lease-by-application is filed over existing oil and gas leases, the coal lease applicant will be required to develop a mitigation plan acceptable to the oil and gas lessee allowing maximum recovery of both resources. Implementation of this mitigation plan must be accepted by any successful lease-by-application bidder and will become a stipulation on the coal lease. If a mitigation plan cannot be agreed upon prior to offering the coal lease sale, then BLM will delineate coal tracts to avoid oil and gas operations or will delay leasing of the coal tract.	Stipulate fluid mineral leases when nominated within the areas identified acceptable for further consideration for coal leasing (BLM 2001a) to require a mitigation plan allowing for maximization of both coal and oil and gas resources.	Stipulate fluid mineral leases when nominated over existing coal leases to allow maximum recover of the coal resources. When an oil and gas parcel is nominated over a coal lease application or coal lease modification application, the parcel will be pulled from the oil and gas sale list and deferred until such time a coal lease is issued. Once a coal leased is issued or the sale cancelled and the case closed, the deferred parcel nomination may be added to the oil and gas lease sale list with stipulations.

Table 2.13. 2000 MINERAL RESOURCES (MR) – LEASABLE – FLUID (Oil/Gas and Geothermal)

<p>GOAL MR:3 Leasable fluid mineral resources are available to support domestic needs.</p> <p>Objectives:</p> <p>MR:3.1 Provide opportunities for exploration, leasing, and development of fluid mineral resources.</p> <p>MR:3.2 Facilitate the evaluation of BLM-administered lands for fluid mineral potential.</p> <p>MR:3.3 Manage BLM-administered lands for collection of subsurface geological (geophysical) data to aid in the exploration of fluid mineral resources.</p> <p>MR:3.4 Priority will be given to leasing and development of fluid mineral resources, including geothermal, outside of Greater Sage-Grouse habitat. When analyzing leasing and authorizing development of fluid mineral resources, including geothermal, in priority habitat (core population areas and core population connectivity corridors) and general habitat, and subject to applicable stipulations for the conservation of Greater Sage-Grouse, priority will be given to development in non-habitat areas first and then in the least suitable habitat for Greater Sage-Grouse. The implementation of these priorities will be subject to valid existing rights and any applicable law or regulation, including, but not limited to, 30 U.S.C. 226(p) and 43 CFR 3162.3-1(h). Where a proposed fluid mineral development project on an existing lease could adversely affect Greater Sage-Grouse populations or habitat, the BLM will work with the lessees, operators, or other project proponents to avoid, reduce and mitigate adverse impacts to the extent compatible with lessees' rights to drill and produce fluid mineral resources. The BLM will work with the lessee, operator, or project proponent in developing an APD for the lease to avoid and minimize impacts to Greater Sage-Grouse or its habitat and will ensure that the best information about the Greater Sage-Grouse and its habitat informs and helps to guide development of such Federal leases.</p>		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
O&G-2001	MR:3.1	<p>Continue to require lessees to conduct operations in a manner that minimizes adverse impacts to other resources and other land uses and users.</p> <p>Where the federal government owns the mineral estate in Greater Sage-Grouse habitat and the surface is in non-federal ownership, apply to BLM authorizations regulating the Federal lessee the same stipulations, COAs, and/or conservation measures and RDFs applied if the mineral estate is developed on BLM-administered surface lands in that management area, to the maximum extent permissible under existing authorities, and in coordination with the landowner.</p> <p>Where the federal government owns the surface and the mineral estate is in non-federal ownership in Greater Sage-Grouse habitat, apply appropriate surface use COAs, stipulations, and mineral RDFs through ROW grants or other surface management instruments, to the maximum extent permissible under existing authorities, in coordination with the mineral estate owner/lessee.</p>
O&G-2002	MR:3.1 MR:3.2 MR:3.3	<p>Open all oil and gas mineral estate to leasing (Map 12), unless specifically identified as closed to mineral leasing. These open areas will be managed on a project-specific basis.</p> <p>Areas closed due to regulation, legislation, policy, or similar action:</p> <ul style="list-style-type: none"> • Incorporated municipalities and proximity to commercial airports • WSAs and WSRs • Withdrawals

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
O&G-2003	MR:3.1 MR:3.2 MR:3.3	Manage any acquired mineral estate, obtained during land tenure adjustments, in accordance with the management of the surrounding areas.
O&G-2004	MR:3.1 MR:3.2 MR:3.3	Defer fluid mineral leasing in areas where coal is already leased until fluid mineral development would not interfere with the economic recovery of the coal resources. This is determined on a project-specific basis during fluid mineral lease review.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
O&G-2005	MR:3.1	Make geothermal resources available for leasing in areas that are open to oil and gas leasing. Areas closed to oil and gas leasing are also closed to geothermal leasing.			
O&G-2006	MR:3.3	Areas that are open to oil and gas leasing are open to geophysical exploration subject to appropriate mitigation developed through use of the mitigation guidelines described in Appendix J (p. 2155). Areas closed to oil and gas leasing are closed to geophysical exploration. Geophysical exploration is subject to motorized travel limitations and restrictions on surface-disturbing and disruptive activities.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
N/A	N/A	<p>Note: The following definitions apply only to fluid mineral management within the BFO planning area.</p> <p>Fluid Mineral Constraints Definitions:</p> <p>Closed:</p> <ul style="list-style-type: none"> • Closed, withdrawn, or otherwise closed <p>Major:</p> <ul style="list-style-type: none"> • NSO more than 40 acres in size or more than 0.25 mile in width • TLS lasting 6 months or longer • Prohibition on surface disturbance more than 40 acres in size or more than 0.25 mile in width • VRM Class I <p>Moderate:</p> <ul style="list-style-type: none"> • CSU more than 40 acres in size or more than 0.25 mile in width • NSO less than 40 acres in size or less than 0.25 mile in width • TLS lasting more than 60 days but less than 6 months • Avoidance of 200 meters or more • VRM Class II <p>Minor:</p> <ul style="list-style-type: none"> • CSU less than 40 acres in size or less than 0.25 mile in width • TLS lasting less than 60 days • Avoidance of less than 200 meters • VRM Class III <p>Open (standard):</p> <ul style="list-style-type: none"> • Subject to standard lease terms and conditions, existing laws, regulations and formal orders 			
O&G-2007	MR:3.1 MR:3.2 MR:3.3	Continue to lease and allow development of federal oil and gas (Map 13). This results in: <ul style="list-style-type: none"> • 2,346,307 acres closed to fluid mineral leasing. • 146,126 acres subject to the standard lease terms and conditions. 	Make lands available for fluid mineral leasing and exploration in accordance with management identified within Alternative B to conserve other resources (Map 14). This results in: <ul style="list-style-type: none"> • 2,612,920 acres closed to fluid mineral leasing. 	Make lands available for fluid mineral leasing and exploration in accordance with management identified within Alternative C consistent with other resource values (Map 15). This results in: <ul style="list-style-type: none"> • 30,520 acres closed to fluid mineral leasing. 	Make lands available for fluid mineral leasing and exploration in accordance with management identified within Alternative D to conserve other resources (Map 16). This results in: <ul style="list-style-type: none"> • 72,276 acres closed to fluid mineral leasing.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
		<ul style="list-style-type: none"> • 26,048 acres subject to minor constraints. • 782,501 acres subject to moderate constraints. • 85,548 acres subject to major constraints. <p>Within the boundary of the Wyodak-Anderson coal seam is closed to leasing [Pennaco v. U.S., 377 F.3d 1147 (10th Cir. 2004)].</p> <p>30,520 acres closed from present RMP.</p>	<ul style="list-style-type: none"> • 1,225 acres subject to the standard lease terms and conditions. • 5,685 acres subject to minor constraints. • 124,467 acres subject to moderate constraints. • 642,232 acres subject to major constraints. <p>Adopt a minimum lease size of 640 contiguous acres where feasible.</p> <p>Greater Sage-Grouse Priority Habitat Area (Core Population Area and Connectivity Corridors) are closed to leasing.</p>	<ul style="list-style-type: none"> • 539,499 acres subject to the standard lease terms and conditions. • 40,437 acres subject to minor constraints. • 2,472,472 acres subject to moderate constraints. • 303,601 acres subject to major constraints. 	<ul style="list-style-type: none"> • 135,909 acres subject to the standard lease terms and conditions. • 104,927 acres subject to minor constraints. • 2,516,826 acres subject to moderate constraints. • 556,592 acres subject to major constraints.
O&G-2008	MR:3.1 MR:3.2	Stipulate oil and gas leases to regulate any oil and gas operations that would interfere with ongoing coal operations.	When a coal lease-by-application is filed over existing oil and gas leases, the coal lease applicant will be required to develop a mitigation plan acceptable to the oil and gas lessee allowing maximum recovery of both resources. Implementation of this mitigation plan must be accepted by any successful lease-by-application bidder and will become a stipulation on the coal lease. If a mitigation plan cannot be agreed upon prior to offering the coal lease sale, then BLM will delineate coal tracts to avoid oil and gas operations or will delay leasing of the coal tract.	Stipulate fluid mineral leases when nominated within the areas identified acceptable for further consideration for coal leasing (BLM 2001a) to require a mitigation plan allowing for maximization of both coal and oil and gas resources.	Stipulate fluid mineral leases when nominated over existing coal leases to allow maximum recover of the coal resources. When an oil and gas parcel is nominated over a coal lease application or coal lease modification application, the parcel will be pulled from the oil and gas sale list and deferred until such time a coal lease is issued. Once a coal leased is issued or the sale cancelled and the case closed, the deferred parcel nomination may be added to the oil and gas lease sale list with stipulations.

Table 2.14. 2000 MINERAL RESOURCES (MR) – LEASABLES – OTHER LEASABLE MINERALS

GOAL MR:4 Manage leasable minerals other than oil, gas, coal, and geothermal energy based on demand, while avoiding or mitigating impacts to other resource values.					
Objective:					
MR:4.1 Make opportunities available for exploration and development of leasable minerals other than oil, gas, coal, and geothermal energy, while avoiding or mitigating impacts of these activities on other resource values.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
OL-2001	MR:4.1	All lands in the planning area are available to exploration and development of other leasable minerals unless closed to mineral leasing.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
OL-2002	MR:4.1	Consider leasing other minerals (i.e., phosphates, sodium, etc.) on a project-specific basis.	<p>Close to leasing of other leasable minerals in accordance with management identified within Alternative B, to conserve other resource values. This results in:</p> <ul style="list-style-type: none"> • 1,239,723 acres open to leasing of other leasable minerals. • 3,547,781 acres closed to leasing of other leasable minerals. 	<p>Allow leasing of other leasable minerals in accordance with management identified within Alternative C, as consistent with other resource values. This results in:</p> <ul style="list-style-type: none"> • 4,707,436 acres open to leasing of other leasable minerals. • 80,068 acres closed to leasing of other leasable minerals. 	<p>Allow leasing of other leasable minerals in accordance with management identified within Alternative D, as consistent with other resource values. This results in:</p> <ul style="list-style-type: none"> • 3,801,889 acres open to leasing of other leasable minerals. • 4,699,229 acres closed to leasing of other leasable minerals.

Table 2.15. 2000 MINERAL RESOURCES (MR) – SALABLE MINERALS

GOAL MR:5 Salable mineral resources (also called mineral materials) are available to support short-term and long-term local and regional demand.					
Objective:					
MR:5.1 Provide opportunities for exploration and development of salable minerals while avoiding or mitigating effects to other resource values.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Salable-2001	MR:5.1	The majority of lands in the planning area, including federally administered surface/minerals and split estate, are available for mineral material exploration and development.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Salable-2002	MR:5.1	Mineral materials activities are prohibited in the Fortification Creek, Gardner Mountain, and North Fork WSAs (28,931 acres).	<p>Close to or restrict from salable mineral exploration and development in accordance with management identified within Alternative B, to conserve other resource values. This results in:</p> <ul style="list-style-type: none"> • 129,431 acres remain open to salable mineral exploration and development. • 3,218,690 acres closed to or restricted from salable mineral exploration and development. • 28,931 acres remain closed to salable minerals activities in the three current WSAs. 	<p>Allow salable mineral exploration and development in accordance with management identified within Alternative C, as consistent with other resource values. This results in:</p> <ul style="list-style-type: none"> • 3,290,908 acres remain open to salable mineral exploration and development. • 57,213 acres closed to or restricted from salable mineral exploration and development. • 28,931 acres remain closed to salable minerals activities in the three current WSAs. 	<p>Allow salable mineral exploration and development in accordance with management identified within Alternative D, as consistent with other resource values. This results in:</p> <ul style="list-style-type: none"> • 2,725,060 acres remain open to salable mineral exploration and development. • 623,061 acres closed to or restricted from salable mineral exploration and development. • 28,931 acres remain closed to salable minerals activities in the three current WSAs.

2.9.3. 3000 FIRE AND FUELS MANAGEMENT

Table 2.16. 3000 FIRE AND FUELS MANAGEMENT (FM)

GOAL FM:1 Life, property, and resource values are protected.		
Objectives:		
FM:1.1 Respond to unplanned wildfires based on: (1) ecological, (2) social, and (3) legal consequences while supporting other resource values.		
FM:1.2 Maintain partnerships with interagency cooperators and the public to strengthen coordination of all fire suppression activities.		
FM:1.3 Manage fuels in WUI areas to reduce potential losses due to fire consistent with the BLM's 10-year comprehensive strategy.		
FM:1.4 Cooperate with stakeholders to enhance the local fire prevention, defensible space protection, and public education programs.		
FM:1.5 Implement appropriate emergency stabilization and rehabilitation actions following wildland fire.		
FM:1.6 Pursue wildland fire management agreements to achieve resource objectives while protecting life and property.		
GOAL FM:2 Plant community and hazardous fuel objectives are achieved.		
Objectives:		
FM:2.1 Improve fire regime condition class and maintain or improve conditions of fire-adapted landscapes by managing fire, planned and unplanned, to accomplish beneficial resource objectives.		
FM:2.2 Cooperate with stakeholders to plan and implement fire and other vegetation treatments.		
FM:2.3 In collaboration with stakeholders, manage and coordinate fire and fuel treatments consistent with approved local fire plans (CWPP).		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Fire-3001	FM:1.1	A Fire Management Plan for the Wyoming High Plains District will be maintained that more specifically outlines management response and implementation actions for wildland fire response of public lands.
Fire-3002	FM:1.1	A resource advisor appropriate to the potentially affected resource will be consulted, or assigned, to all wildland fires that involve or threaten BLM-administered lands.
Fire-3003	FM:1.1	Restrict or prohibit fire retardant chemicals as appropriate to protect rock art.
Fire-3004	FM:1.1	Prohibit use of retardant or foam within 300 feet of surface water sources consistent with guidelines described in the <i>Interagency Standards for Fire and Fire Aviation Operations</i> (BLM 2011e).
Fire-3005	FM:1.3 FM:1.4	Reduce hazardous fuels in the WUI.
Fire-3006	FM:1.5	Implement the BLM Emergency Stabilization and Burned Area Rehabilitation standards located in the DOI Interagency Burned Area Emergency Response Guidebook (DOI 2004) and BLM Burned Area Emergency Stabilization and Rehabilitation Handbook (BLM 2007c) as needed.
Fire-3007	FM:2.1	Use the District Fire Management Plan to implement the objectives of this RMP; to address fire management on a landscape scale, to maintain or improve conditions in fire-adapted landscapes, and to accomplish resource management objectives.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Fire-3008	FM:2.2	<p>Ensure all prescribed burning activities comply with Wyoming DEQ air quality standards and smoke management rules.</p> <p>If prescribed fire is used in Greater Sage-Grouse habitat, the NEPA analysis for the Burn Plan will address:</p> <ul style="list-style-type: none"> • why alternative techniques were not selected as a viable options; • how Greater Sage-Grouse goals and objectives would be met by its use; • how the Conservation Objectives Team Report objectives would be addressed and met; • a risk assessment to address how potential threats to Greater Sage-Grouse habitat would be minimized. <p>Prescribed fire as a vegetation or fuels treatment shall only be considered after the NEPA analysis for the Burn Plan has addressed the four bullets outlined above. Prescribed fire could be used to meet specific fuels objectives that would protect Greater Sage-Grouse habitat (e.g., creation of fuel breaks that would disrupt the fuel continuity across the landscape in stands where annual invasive grasses are a minor component in the understory, burning slash piles from conifer reduction treatments, used as a component with other treatment methods to combat annual grasses and restore native plant communities).</p> <p>Prescribed fire in known Greater Sage-Grouse winter range shall only be considered after the NEPA analysis for the Burn Plan has addressed the four bullets outlined above. Any prescribed fire in winter habitat would need to be designed to strategically reduce wildfire risk around and/or in the winter range and designed to protect winter range habitat quality.</p>

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Fire-3009	FM:2.2 FM:2.3	Cooperate with and pursue agreements with other agencies and landowners to conduct landscape treatments to achieve enhanced fuels management and/or restoration of fire-adapted ecosystems.			
Fire-3010	FM:1.5	Rehabilitate firelines constructed by heavy equipment, or on steep slopes, to prevent or control erosion. Rehabilitation includes, but is not limited to, water barring and reseeded.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Fire-3011	FM:1.1 FM:1.2	All fires are suppressed, though variable strategies are used. Priority response is given to wildfires where there are high value resources or where fires may spread to other land ownerships. Full protection is used in high value areas such as developed areas or where sensitive resources would be adversely affected by fire. Appropriate suppression actions are used in low value areas or where fire control is very difficult or extremely hazardous to firefighting personnel. No portion of the planning area is available to manage fires for multiple objectives.	Response to wildland fires varies from full protection in areas where fire is undesirable to monitoring fire behavior in areas where fire can be managed to accomplish other resource objectives. The entire planning area is available to manage wildfire for multiple objectives.	Use full protection strategies and tactics across the entire planning area. No portion of the planning area is available to manage fires for multiple objectives.	Response to wildfire varies from full protection in areas where fire is undesirable to monitoring fire behavior in areas where fire can be managed to accomplish other resource objectives. The entire planning area is available to manage wildfire for multiple objectives.
Fire-3012	FM:1.1 FM:1.2	Restrict the use of some types of suppression equipment in some areas.	Limit heavy equipment usage to existing roads and trails, or immediately adjacent to them, in areas not identified as full protection.	Utilize heavy equipment with few constraints and consistent with other resource values.	Prohibit heavy equipment use within the following areas, except when human safety is at risk or if the expected fire effects would cause more resource damage than the use of heavy equipment: <ul style="list-style-type: none"> • Areas of cultural resource sensitivity • Riparian/wetland habitats

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
					<ul style="list-style-type: none"> • Identified Greater Sage-Grouse important habitats: Core Population Area, nesting, brood-rearing, Connectivity Corridor, or winter habitat • Areas of highly erosive soils • Lands with wilderness characteristics <p>Limit heavy equipment usage to existing roads and trails, or immediately adjacent to them, in areas not identified as full protection.</p>
Fire-3013	FM:1.1 FM:1.2	Give priority to suppressing fires in or threatening higher value resources (commercial timber areas, developed recreation sites, and WUI areas) and keeping fires from spreading onto private, state, or other federal lands.	<p>Use protection strategies in the following areas:</p> <ul style="list-style-type: none"> • WUI • Wildland Industrial Interface • Developed recreation sites • Commercial timber areas • Where sensitive resources would be adversely affected by fire (i.e., within 4.0 miles of Greater Sage-Grouse leks or winter concentration areas) 	Use full protection strategies across the entire planning area.	<p>Use protection strategies in the following areas:</p> <ul style="list-style-type: none"> • WUI • Wildland Industrial Interface • Developed recreation • Developed electronic/communication sites of all types • Where sensitive or high value resources would be adversely affected by fire (i.e., Greater Sage-Grouse Core Population Area and Connectivity Corridor)

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Fire-3014	FM:1.5	Rehabilitate fire-damaged lands to meet resource objectives; repair suppression damages as necessary.	Rehabilitate all fire-damaged lands; repair all suppression damages.	Repair suppression related damages only.	Evaluate all fires and rehabilitate fire-damaged lands as needed to meet resource objectives. Repair suppression damages as necessary.
Fire-3015	FM:1.6	Use wildland fire and other vegetation treatments to support vegetation and wildlife habitat objectives.	Use wildland fire and other vegetation treatments to restore fire-adapted ecosystems and to reduce hazardous fuels.	Use wildland fire and other vegetation treatments to restore fire-adapted ecosystems, enhance forage for commodity production, and to reduce hazardous fuels.	Use wildland fire and other vegetation treatments to meet desired management objectives.

2.9.4. 4000 BIOLOGICAL RESOURCES

Table 2.17. 4000 BIOLOGICAL RESOURCES (BR) – VEGETATION

<p>GOAL BR:1 Vegetation resources sustained in desired ecological conditions.</p> <p>Objectives:</p> <p>BR:1.1 Manage communities for a diversity of native species, habitats, seral stages and distribution.</p> <p>BR:1.2 Manage for healthy vegetation communities to ensure their capability to provide sufficient plant composition, cover and litter accumulation to protect soils from wind and water erosion and enhance nutrient cycling and productivity.</p> <p>BR:1.3 Reclaim areas affected by surface-disturbing activities to promote healthy functioning native plant communities.</p> <p>BR:1.4 Manage habitat to facilitate the conservation, recovery and maintenance of populations of native, desirable non-native, and special status plant species consistent with appropriate local, state, and federal conservation requirements and management plans.</p> <p>BR:1.5 Manage for healthy native plant communities by reducing and managing invasive, nonnative noxious species.</p> <p>BR:1.6 Identify and manage Native American traditional plant gathering areas.</p>
--

Table 2.18. 4000 BIOLOGICAL RESOURCES (BR) – VEGETATION – FORESTS AND WOODLANDS

GOAL BR:2 Healthy forests and woodlands are sustained in desired ecological conditions.					
Objective:					
BR:2.1 Manage forests and woodlands to benefit multiple resource values.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
		None identified.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Forest-4001	BR:2.1	Design vegetation treatments, including forest management and sagebrush spraying or burning, to meet overall resource management objectives consistent with the policy to protect or improve biodiversity and water quality.	Keep silvicultural treatments to a minimum, and only utilize them when catastrophic events, such as wildland fire, present hazardous conditions to the public and surrounding lands.	Design and implement silvicultural treatments to maximize forest health.	Design and implement silvicultural treatments to maximize forest health.
Forest-4002	BR:2.1	Diseased old growth and over stocked forests are managed in accordance with the HFRA.	Allow insect and disease, wildland fire, and other natural forces to run their natural course within forests and woodlands, without intervention.	Utilize intensive management tactics, such as large clear-cuts, to manage for desired forest/woodland health (HFRA) and to reduce or circumvent events such as insects, disease, and wildfire.	Utilize intensive management tactics to manage for desired forest/woodland health (HFRA) and to reduce or circumvent events such as insects, disease, and wildfire.
Forest-4003	BR:2.1	No previous decision; old growth considered on a project-specific basis.	Manage old growth forest stands to emphasize old growth characteristics.	Manage old growth forest stands to emphasize other stand characteristics.	Manage old growth forest stands to emphasize old growth characteristics.
Forest-4004	BR:2.1	No previous decision; recreation, wildlife, and other resource values considered on a project-specific basis.	Manage forests/woodlands to emphasize recreation, wildlife, and other resource values.	Manage forests/woodlands to emphasize the forest resource.	Manage forests/woodlands to emphasize multiple resource values (recreation, wildlife, soils, water, forest products).

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Forest-4005	BR:2.1	No previous decision; aspen management considered on a project-specific basis.	Manage aspen communities as a seral stage and natural component of the forest. Allow decadent and non-reproductive stands to be naturally replaced in the ecosystem by climax forest.	Manage aspen communities to maintain aspen stands and strive for the DFC of all aspen forest.	Manage aspen communities to maintain aspen stands and strive for DFC in all aspen forests.
Forest-4006	BR:2.1	No previous decision; woodland encroachment evaluated on a project-specific basis.	Allow woodlands to expand into other communities.	Actively manage woodlands to prevent expansion into other communities.	Actively manage woodlands to prevent expansion into other communities consistent with multiple resource values, on a project-specific basis.

Table 2.19. 4000 BIOLOGICAL RESOURCES (BR) – VEGETATION – GRASSLAND AND SHRUBLAND COMMUNITIES

GOAL BR:3 A diverse landscape of native grasslands and shrublands sustained in desired ecological conditions.					
Objective:					
BR:3.1 Manage for a full range of sagebrush, shrub, and grassland communities with diverse native species and subspecies, composition, canopies, densities, and age classes across the landscape.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
GS-4001	BR:3.1	Manage vegetative communities (Map 25) in accordance with Wyoming Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming.			
GS-4002	BR:3.1	Complete vegetation inventories. When applicable do so in coordination with stakeholders.			
GS-4003	BR:3.1	Use an integrated management approach (e.g., mechanical, chemical, biological treatments, prescribed fire, and grazing management techniques) to maintain, restore, and enhance the health and diversity of plant communities to achieve resource or multi-resource objectives.			
GS-4004	BR:3.1	Maintain sustainable forage levels for livestock and wildlife habitats.			
GS-4005	BR:3.1	Manage grasslands and shrublands to protect, preserve, or enhance plant communities.			
GS-4006	BR:3.1	Manage the siting of facilities and related infrastructure (utility corridors, roads) to reduce impacts to vegetation resources.			
GS-4007	BR:3.1	Manage the planning and development of travel routes, recreational uses, mineral exploration and development sites, and ROW to reduce impacts to the vegetation resource.			
GS-4008	BR:3.1	Develop a contingency plan addressing catastrophic natural events such as drought, wildfires, and large-scale pest infestations, incorporating strategies that best protect vegetation resources.			
GS-4009	BR:3.1	Work with landowners on split estate lands to reestablish disturbed sites to healthy plant communities in accordance with the ecological site potential.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
GS-4010	BR:3.1	No previous decision; considered on a project-specific basis.	Authorize only native plant species for all reclamation activities.	Allow desirable non-native plant species for initial reclamation activities.	Allow desirable non-native plant species for short-term reclamation activities as a component in an authorized reclamation plan (followed up with planting of native species).

Table 2.20. 4000 BIOLOGICAL RESOURCES (BR) – VEGETATION – RIPARIAN/WETLAND RESOURCES

GOAL BR:4 Health and functional capabilities in riparian/wetland systems.		
Objectives:		
BR:4.1 Manage lotic and lentic wetland/riparian systems at a minimum to achieve and/or maintain PFC.		
BR:4.2 Improve riparian systems and wetlands in systems operating at less than PFC.		
BR:4.3 Manage contributing watersheds to sustain riparian health and water quality.		
BR:4.4 Manage and enhance riparian and wetland systems for plant, insect, fish and wildlife species that depend on these systems for their health and well being.		
BR:4.5 CBNG created riparian and wetland systems will be evaluated, retained, or reclaimed to support vegetation and other resource values.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Riparian-4001	BR:4.1 BR:4.2 BR:4.3 BR:4.4	Inventory lotic and lentic riparian/wetland systems.
Riparian-4002	BR:4.1 BR:4.2 BR:4.4	Prioritize, and develop activity and implementation plans to manage riparian systems to be at or above, or continue to be improving toward, PFC while achieving the Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming.
Riparian-4003	BR:4.1 BR:4.2 BR:4.3 BR:4.4 BR:4.5	Manage riparian and wetland systems to enhance forage conditions and improve water quality. Manage all riparian systems with sensitive species concerns to a succession stage appropriate for that system, including vertical as well as horizontal vegetative structure and composition.
Riparian-4004	BR:4.1 BR:4.2 BR:4.3 BR:4.4 BR:4.5	Expand and enhance riparian/wetland systems and habitat in cooperation with stakeholders.
Riparian-4005	BR:4.1 BR:4.2 BR:4.3 BR:4.4 BR:4.5	Prevent degradation, loss, or destruction of riparian/wetland habitat.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Riparian-4006	BR:4.4 BR:4.5	Prohibit conflicting uses within riparian research areas and special exclosures, such as waterfowl reservoirs and wetland systems on springs and streams.			
Riparian-4007	BR:4.5	Evaluate CBNG created riparian and wetland systems for retention or reclamation.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Riparian-4008	BR:4.1 BR:4.2 BR:4.3 BR:4.4 BR:4.5	Prohibit surface-disturbing activities within 500 feet of springs, reservoirs, water wells, or perennial streams unless the prohibition is waived by the authorized officer.	Prohibit surface-disturbing and disruptive activities within 500 feet of riparian/wetlands systems, aquatic habitats, and floodplains.	Allow surface-disturbing and disruptive activities within 500 feet of riparian/wetlands systems, aquatic habitats, and floodplains consistent with other resource values.	Allow surface disturbance within 500 feet of riparian/wetlands systems and aquatic habitats where riparian/wetland and other resource objectives (including, but not limited to soil, slope, and vegetation) can be met.
Riparian-4009	BR:4.1 BR:4.2 BR:4.3 BR:4.4 BR:4.5	No previous decision; considered on a project-specific basis.	Apply an NSO stipulation for fluid mineral leasing within 500 feet of riparian/wetlands systems, aquatic habitats, and floodplains.	Apply standard lease terms to fluid mineral leases within 500 feet of riparian/wetlands systems, aquatic habitats, and floodplains consistent with other resource values.	Apply a CSU stipulation to any fluid mineral lease within 500 feet of riparian/wetlands systems, and aquatic habitats (based on other resource values - soil, slope).
Riparian-4010	BR:4.1 BR:4.3 BR:4.4	No previous decision; considered on a project-specific basis.	Identify and manage systems capable of achieving DFC.	Do not identify and manage systems capable of achieving DFC.	Identify and manage systems capable of achieving DFC.
Riparian-4011	BR:4.5	No previous decision; considered on a project-specific basis.	Restore vegetation in all CBNG supported wetland and riparian systems.	Restore vegetation only on direct CBNG disturbance areas (e.g., dams, reservoirs, etc.).	Restore vegetation in CBNG supported wetland and riparian systems on BLM surface and/or lease in accordance with the ecological site potential.

Table 2.21. 4000 BIOLOGICAL RESOURCES (BR) – INVASIVE SPECIES AND PEST MANAGEMENT

GOAL BR:5 Healthy native communities with manageable levels of pathogens, undesirable, invasive, non-native, or noxious species.					
Objectives:					
BR:5.1 Develop and maintain baseline information regarding the extent, location and potential impact(s) of pest species. From this baseline information develop and implement an Integrated Pest Management Plan. Integrated management would be used to control, suppress, and eradicate, where possible, noxious and invasive species per BLM Handbook H-1740-2. Manage noxious or invasive species treatments to maintain or improve Greater Sage-Grouse habitat. Apply Required Design Features as Conditions of Approval, such as those in Appendix B. Encourage the use of voluntary BMPs.					
BR:5.2 Facilitate support for an integrated approach for the detection, management, or eradication of new and minor infestations.					
BR:5.3 Develop, implement, and maintain a management program for annual bromes and other invasive or undesirable species not listed as noxious, utilizing the best available science and BMPs.					
BR:5.4 Coordinate with APHIS to facilitate pest and predator management.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Pest-4001	BR:5.1 BR:5.2 BR:5.4	Cooperate with APHIS to control grasshoppers and Mormon crickets on public lands in conjunction with the control efforts initiated on adjoining non-federal lands.			
Pest-4002	BR:5.1 BR:5.2 BR:5.3 BR:5.4	Manage designated pests on public surface lands using an Integrated Pest Management Approach consistent with DOI Manual 517 (BLM 2007f).			
Pest-4003	BR:5.1 BR:5.2 BR:5.3 BR:5.4	Limit surface disturbance to the minimum needed for safe project completion to limit the spread of noxious weeds.			
Pest-4004	BR:5.1 BR:5.2 BR:5.3	Use certified noxious weed seed-free products on all BLM-administered projects and lands.			
Pest-4005	BR:5.1 BR:5.2 BR:5.3	Implement and maintain cooperative integrated pest management programs with county weed and pest districts, state agencies, private industry, grazing lessees, and other stakeholders in conjunction with BLM weed and pest control work on public lands adjoining deeded and state lands (Map 27).			
Pest-4006	BR:5.2	Require surface or vegetation disturbance areas, including areas formerly receiving or holding water, be treated for invasive species and revegetated.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Pest-4007	BR:5.2	No previous decision; aerial application decided on a project-specific basis.	Do not limit aerial application of pesticides.	Limit aerial application to insecticides only.	Authorize aerial application in areas where topography, extent of infestation, target species, and timing limit other application methods.
Pest-4008	BR:5.1	No previous decision; treatment areas decided annually.	Develop pest management areas within 5 years of the signing of the ROD.	Determine area to be treated with pesticides on an annual basis.	Develop long range pest management plans, treatment areas, priorities, etc. in cooperation with stakeholders.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Pest-4009	BR:5.1 BR:5.2 BR:5.3	Control noxious weeds on public lands in cooperation with county weed and pest districts.	Treat those plants on the State of Wyoming Designated list, the appropriate county lists, and other species of concern as determined by BLM resource specialists. Priority treatments are those areas where infestations on private land are threatening public lands.	Treat only those plants on the State of Wyoming Designated list. Priority treatments are those areas where infestations on public land are threatening private lands.	Treat those plants on the State of Wyoming Designated list, the appropriate county lists, and other species of concern as determined by BLM resource specialists. Note: Priority treatments are those areas where infestations on private land are threatening public lands.
Pest-4010	BR:5.3	No previous decision; determine whether to treat annual brome species on a project-specific basis.	Treat annual brome species throughout the planning area.	Designate and prioritize areas for the treatment of annual brome species.	Designate and prioritize areas for the treatment of annual brome species.

Table 2.22. 4000 BIOLOGICAL RESOURCES (BR) – FISH & WILDLIFE RESOURCES

GOAL BR:6 Distribution and abundance of all native and desirable non-native species are optimized.

Objectives:

BR:6.1 BLM actions prevent and/or reduce impacts to desirable species.

BR:6.2 In coordination with cooperating agencies, develop and implement an achievable Wildlife Monitoring and Protection Plan.

BR:6.3 Maintain, restore, or improve the continuity and productivity of fish and wildlife habitats to support WGFD population objectives.

BR:6.4 Develop and implement an adaptive conservation and management strategy.

GOAL BR:7 Sufficient functional habitat for native and desirable non-native species.

Objectives:

BR:7.1 Evaluate, update, and revise as necessary existing Wildlife Habitat Management Plans.

BR:7.2 Develop Wildlife Habitat Management Plans for areas with important habitats.

BR:7.3 Manage habitat consistent with local, state, and federal management plans, as applicable.

BR:7.4 Continue to gather habitat and population data while concurrently monitoring human and natural disturbance dynamics to improve habitat management.

BR:7.5 Provide security habitat, sufficient in amount and distribution, to support WGFD population objectives for fish and wildlife to escape from disruptive activities.

BR:7.6 Maintain and provide functioning sagebrush habitat to sustain sagebrush obligates and other sagebrush dependent species.

GOAL BR:8 Fish and wildlife are able to move between areas of functionally intact habitat.

Objectives:

BR:8.1 Develop Travel Management Plans for areas important for fish and wildlife while supporting other resource values.

BR:8.2 Develop a ROW Management Plan for utility corridors to manage impacts to areas of habitat important to fish and wildlife consistent with other resource values.

BR:8.3 Land acquisitions should support desirable fish and wildlife populations or habitat.

BR:8.4 Restore functionality to areas of degraded habitat important to fish and wildlife populations consistent with other resource values.

GOAL BR:9 Terrestrial and aquatic ecosystems that provide recreational and educational benefits.

Objectives:

BR:9.1 Manage for a broad range of wildlife and fisheries based experiences.

BR:9.2 Improve public awareness, understanding, and support for resolving issues surrounding species conservation, management, and ecology.

BR:9.3 Identify, develop, and maximize distribution of natural resource interpretation media.

BR:9.4 Provide for research to support the management of fish and wildlife resources administered by the BLM.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES – Upland Game Birds			
SS WL-4010	BR:10.1 BR:10.2 BR:10.3	<p>The BLM will collaborate with appropriate federal agencies and the State of Wyoming, as contemplated under the Wyoming Governor’s Executive Order 2013-3, to: 1) develop appropriate conservation objectives; 2) define a framework for evaluating situations where Greater Sage-Grouse conservation objectives are not being achieved on federal land, to determine if a significant causal relationship exists between improper grazing (by wildlife or wild horses or livestock) and Greater Sage-Grouse conservation objectives; and 3) identify appropriate site-based actions to achieve Greater Sage-Grouse conservation objectives within the framework. Absent substantial and compelling information that adjustments are necessary to the core population area strategy, these core population areas, connectivity areas, identified and mapped winter concentration areas, and protective stipulations shall not be altered for a minimum of 7 years. Any changes shall involve a transparent process that provides an opportunity for public input and proper consideration of any proposal consistent with the provisions contemplated under Wyoming’s core population area strategy.</p> <p>The BLM will coordinate new recommendations, mitigation, and sage-grouse habitat objectives and management considerations with the WGFD and other appropriate agencies, local government cooperators, and the Wyoming SGIT. These measures will be analyzed in site-specific NEPA documents, as necessary.</p> <p>The Greater Sage-Grouse adaptive management plan (Appendix B (p. 1779)) provides regulatory assurance that unintended negative impacts to Greater Sage-Grouse habitat will be addressed before consequences become severe or irreversible. Projects requiring an EIS shall develop adaptive management strategies in support of the population management objectives for Greater Sage-Grouse set by the State of Wyoming (State of WY EO 2011-05).</p> <p>Adaptive management triggers are essential for identifying when potential management changes are needed in order to continue meeting Greater Sage-Grouse conservation objectives. With respect to sage-grouse, all regulatory entities in Wyoming, including the BLM, use soft and hard triggers. Soft and hard triggers are focused on three metrics: 1) number of active leks, 2) acres of available habitat, and 3) population trends based on annual lek counts.</p>			

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES – Upland Game Birds
		<p>Soft Triggers Response: Soft triggers require immediate monitoring and surveillance to determine causal factors and may require curtailment of activities in the short- or long-term, as allowed by law. The project level adaptive management strategies will identify appropriate responses where the project's activities are identified as the causal factor. The management agency (BLM) and the Adaptive Management Working Group will implement an appropriate response strategy to address causal factors not attributable to a specific project or to make adjustments at a larger regional or state-wide level.</p> <p>Hard Trigger Response: Upon determination that a hard trigger has been tripped, the BLM will immediately defer issuance of discretionary authorizations for new actions within the Biologically Significant Unit for a period of 90 days. In addition, within 14 days of a determination that a hard trigger has been tripped, the Adaptive Management Working Group will convene to develop an interim response strategy and initiate an assessment to determine the causal factor or factors (hereafter called the causal factor assessment).</p>
SS WL-4011	BR:10.1 BR:10.2 BR:10.3 BR:11.1 BR:11.2	Develop avoidance areas restricting the application of broad-spectrum pesticides in areas containing Greater Sage-Grouse nesting and brood-rearing habitats.

2.9.5. 5000 HERITAGE AND VISUAL RESOURCES

Table 2.24. 5000 HERITAGE AND VISUAL RESOURCES (HR) – CULTURAL RESOURCES

GOAL HR:1 Stewardship and appreciation of cultural resources is promoted.

Objectives:

HR:1.1 In compliance with NAGPRA, maintain and enhance programs that provide opportunities for scientific research of cultural resources.

HR:1.2 Develop a public outreach and education program to instill a preservation ethic in the public regarding archeological and historic resources.

HR:1.3 Develop and maintain interpretation of cultural resources in areas of high public interest.

HR:1.4 Enhance public experience through interpretive facilities and support of heritage tourism.

GOAL HR:2 Native American sacred sites are preserved and protected.

Objectives:

HR:2.1 In coordination with tribes, identify Native American sacred sites.

HR:2.2 In coordination with tribes and other stakeholders, provide for tribal access to known sacred sites.

HR:2.3 Consult with Native Americans to identify resource types or places that may be impacted by BLM actions.

HR:2.4 Maximize opportunities for cooperation with tribal governments for managing cultural resources and public education.

GOAL HR:3 National Register eligible and unevaluated cultural resources are protected.

Objectives:

HR:3.1 Identify cultural resources by defining priority geographic areas for new field inventory, based on the probability for unrecorded significant cultural resources.

HR:3.2 In cooperation with stakeholders, develop and implement activity plans for significant cultural resources.

GOAL HR:4 Cultural resources are identified, preserved, and protected, while remaining available for appropriate uses by present and future generations.					
Objectives:					
HR:4.1 Manage each type of cultural resource according to their proper use allocation, and monitor their condition and use.					
HR:4.2 Develop activity plans for special areas or historic properties identified as high risk for adverse impacts.					
HR:4.3 Recruit site stewards to assist with monitoring the condition of sites important to national heritage.					
GOAL HR:5 Select historic properties are managed for long-term heritage and educational values and to enhance the public experience.					
Objectives:					
HR:5.1 Maintain compatible recreational use with the historic values of these historic properties.					
HR:5.2 Maintain the setting for those contributing trail segments, battlefield sites, forts, and other historic properties for which setting is an important aspect of site integrity, by utilizing viewshed management tools.					
HR:5.3 Maximize partnership and cooperative management opportunities.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Cultural-5001	HR:3.2 HR:4.2 HR:4.3	Complete site stabilization and long-term protection for significant sites that are experiencing adverse impacts.			
Cultural-5002	HR:1.1 HR:2.1 HR:2.2 HR:2.3 HR:2.4	Maintain existing relationships and develop new relationships with Native American tribes to identify sites, areas, and resources important to them. Document and keep confidential sites, areas, and resources that necessitate protection. Incorporate the information obtained from the tribes into planning decisions. Manage identified areas of tribal importance to minimize disturbance.			
Cultural-5003	HR:2.1 HR:2.2 HR:2.3 HR:2.4	Ensure areas of importance to Native American tribes are not transferred from federal ownership.

Initiate mineral withdrawals in areas containing sensitive sites such as TCPs and/or sacred sites to protect the setting. Close to mineral leasing areas containing sensitive sites such as TCPs and/or sacred sites to protect the setting.	Do not initiate mineral withdrawals in areas containing sensitive sites such as TCPs and/or sacred sites. Mitigate through appropriate stipulation such as NSO or CSU to protect the setting. Allow mineral leasing in areas containing sensitive sites such as TCPs and/or sacred sites. Mitigate through appropriate stipulations such as NSO or CSU to protect the setting.	Mitigate adverse effects to sensitive sites such as TCPs and/or sacred sites through appropriate prohibitions and measures to protect setting. Allow mineral leasing in areas containing sensitive sites such as TCPs and/or sacred sites. Mitigate through appropriate stipulations such as NSO, CSU, surface occupancy prohibitions or measures to protect setting.

Table 2.25. 5000 HERITAGE AND VISUAL RESOURCES (HR) – PALEONTOLOGICAL RESOURCES

GOAL HR:6 Paleontological resources are preserved and protected. Objectives: HR:6.1 Reduce threats to paleontological resources from natural or human-caused deterioration. HR:6.2 Implement proper assessment procedures for all surface-disturbing activities on public lands, split estate, and under all federal actions. GOAL HR:7 Paleontological resources are appreciated and scientific knowledge of paleontological resources promoted. Objectives: HR:7.1 Provide paleontological research opportunities for qualified scientists/academia. HR:7.2 Manage select paleontological sites for their educational value and to enhance the public experience.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Paleo-5001	HR:6.1 HR:6.2	Retain public lands with significant paleontological values (Map 47).			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Paleo-5002	HR:6.1 HR:6.2	No previous decision; considered on a project-specific basis.	Require paleontological field surveys on all PFYC Class 3, 4, and 5 formations potentially affected by proposed activities. Require monitoring of surface-disturbing activities on all Class 4 and 5 formations and as needed for Class 3 formations.	Require paleontological field surveys on all PFYC Class 4 and 5 formations potentially affected by proposed activities. Monitoring may be required on a project-specific basis.	Require paleontological field surveys on PFYC Class 4 and 5 formations potentially affected by proposed activities and Class 3 formations as needed. Require monitoring of surface-disturbing activities based on survey results.
Paleo-5003	HR:6.1 HR:6.2	No previous decision; considered on a project-specific basis.	Do not identify specific casual collection areas.	Identify and designate casual collection areas for common invertebrate, plant, and petrified wood fossil collection by the public.	Do not identify specific casual collection areas.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Paleo-5004	HR:7.1	No previous decision; cooperative agreements and partnerships with researchers, museums, or other institutions are established as requested by proponents.	Actively solicit research efforts throughout the planning area to identify, monitor, and gather research data on paleontological resources. Proactively develop supporting cooperative agreements and partnerships with researchers, museums or other institutions.	Evaluate and establish cooperative agreements and partnerships with researchers, museums or other institutions as requested by proponents.	Evaluate and establish cooperative agreements and partnerships with researchers, museums or other institutions where appropriate; BLM initiated or as requested by proponents.
Paleo-5005	HR:6.1 HR:6.2 HR:7.2	No previous decision; considered on a project-specific basis.	Designate areas containing paleontological resources of high quality or importance for special management, as they are identified.	Do not designate areas containing paleontological resources of high quality or importance for special management.	Designate areas containing paleontological resources of high quality or importance for special management, as they are identified.
Paleo-5006	HR:6.1 HR:6.2	No previous decision; considered on a project-specific basis.	Initiate locatable mineral withdrawals in areas containing paleontological resources of high quality or importance.	Do not initiate locatable mineral withdrawals in areas containing paleontological resources of high quality or importance.	Avoid areas containing paleontological resources of high quality or importance when developing locatable minerals.
Paleo-5007	HR:6.1 HR:6.2	No previous decision; considered on a project-specific basis.	Close to mineral leasing areas containing paleontological resources of high quality or importance.	Allow mineral leasing in areas containing paleontological resources of high quality or importance.	Apply an NSO stipulation to mineral leases in areas containing paleontological resources of high quality or importance.
Paleo-5008	HR:6.1 HR:6.2	No previous decision; considered on a project-specific basis.	Prohibit salable mineral exploration and development in areas containing paleontological resources of high quality or importance.	Allow salable mineral exploration and development in areas containing paleontological resources of high quality or importance.	Avoid areas containing paleontological resources of high quality or importance when developing salable minerals.

Table 2.26. 5000 HERITAGE AND VISUAL RESOURCES (HR) – VISUAL RESOURCES

GOAL HR:8 The scenic (visual) quality of BLM-administered lands are maintained.		
Objectives:		
HR:8.1 Perform VRI and update VRM management classes.		
HR:8.2 Manage each VRM class according to the definitions in the VRM manual (H-8410-1).		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
VRM-5001	HR:8.2	Manage WSAs under VRM Class I objectives. Any facilities or structures proposed in WSAs will be designed so as not to impair wilderness suitability. If the Middle Fork Powder River is designated by Congress as a Wild and Scenic River, the river will be managed as VRM Class I.
VRM-5002	HR:8.2	Incorporate BMPs for visual resources into project planning for federal actions.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
VRM-5003	HR:8.1 HR:8.2	Manage areas rated as VRI Class IV that do not contain special emphasis areas as VRM Class IV. Manage areas that were not rated during the VRI that contain BLM-administered surface to match the surrounding VRM classification.			
VRM-5004	HR:8.2	Require non-temporary facilities and structures to be screened, painted, and designed to blend with the surrounding landscape except where safety indicates otherwise.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
VRM-5005	HR:8.1 HR:8.2	Manage visual resources in accordance with objectives for VRM classes that have been assigned to the planning area (Map 48).	Manage all VRI Class II areas and special emphasis areas as VRM Class II (Map 49).	Manage all VRI Class II areas as VRM Class III (Map 50).	Manage VRI Class II areas (except the Powder River Breaks, Fortification Creek and northwestern portion of the Main Powder River VRI rating units) and special emphasis areas as VRM Class II (Map 51). Special emphasis areas will include: SRMAs, designated ACECs, and lands with wilderness characteristics units.
VRM-5006	HR:8.1 HR:8.2	Manage visual resources in accordance with objectives for VRM classes that have been assigned to the planning area (Map 48).	Manage all VRI Class III areas outside special emphasis areas as VRM Class III (Map 49).	Manage all VRI Class III areas as VRM Class IV (Map 50).	Manage all VRI Class III areas, plus the Powder River Breaks, Fortification Creek and northwestern portion of the Main Powder River VRI rating units (outside of special emphasis areas) as VRM Class III (Map 51).
VRM-5007	HR:8.2	No previous decision; utilize visual simulations on a project-specific basis.	Complete a visual simulation and mitigation design for all proposed actions within or viewable from VRM Classes I to III.	Utilize visual simulations on a project-specific basis.	Complete a visual simulation and mitigation design for all proposed actions within VRM Classes I and II. Visual simulation and mitigation design may be required on a project-specific basis within VRM Class III areas with high visual sensitivity.

2.9.6. 6000 LAND RESOURCES

Table 2.27. 6000 LAND RESOURCES (LR) – FOREST PRODUCTS

GOAL LR:1 Healthy forests and woodlands are available to provide a variety of products for consumptive use.					
Objectives:					
LR:1.1 Provide for diverse social and economic outputs in a fair, balanced, efficient, and ecologically sustainable manner.					
LR:1.2 Manage forests and woodlands to provide a diversity of forest products.					
LR:1.3 Cooperation with stakeholders in the utilization of silviculture and land management while implementing Wyoming Forestry BMPs.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
FP-6001	LR:1.1	Prohibit forest management activities within 200 feet of surface waters.			
FP-6002	LR:1.1 LR:1.2	Allow the sale of permits to meet the public demand for personal use of forest products consistent with wildlife habitat requirements and other resource values.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
FP-6003	LR:1.1 LR:1.2	Allow the sale of minor forest products (posts, poles, and fuelwood) from woodlands and/or noncommercial forestlands throughout the planning area on BLM-administered lands (Map 52).	Offer sawtimber only from specified forest areas (Map 52).	Offer an array of forest products from forest and woodlands throughout the planning area (Map 52).	Offer an array of forest products from forest and woodlands throughout the planning area in accordance with other resource values (Map 52).
FP-6004	LR:1.1 LR:1.2	Offer approximately 9 MMBF of sawtimber for sale from BLM-administered forestlands over the next ten years. In addition, offer approximately 1 MMBF of minor green forest products for sale over the next ten years from BLM-administered forestlands.	Manage forest product sales to remain within ecologically sustainable limits.	Manage forest product sales to maximize economic return.	Manage forest product sales to remain within ecologically sustainable limits while maximizing economic return.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
FP-6005	LR:1.3	No previous decision; access dealt with on a project-specific basis.	Require the contractor and/or partner involved in commercial sales to take responsibility for acquiring access when needed for forest management purposes.	Do not require the contractor and/or partner involved in commercial sales to take responsibility for acquiring access. BLM will negotiate and procure access when needed for forest management purposes.	Require the contractor and/or partner involved in commercial sales to take responsibility for acquiring access when needed for forest management purposes. BLM will negotiate and procure access when needed. (BLM driven project or commercial sale.)
FP-6006	LR:1.1	Limit individual clear-cuts to less than 20 acres.	Limit forest management to 5 acres per select group harvest; with the exception being the harvest and removal after catastrophic events that require removal for safety. Design all forest management and/or silvicultural practices to have meandering boundaries that follow topographic lines and natural obstacles.	Do not limit the acres and design/shape of forest management. Design select group harvests and all other methods of forest management practices to maximize the removal of harvestable products within the limits of the Wyoming Forestry BMPs and other guidance.	Design/shape forest management areas to have meandering boundaries, follow topography, avoid natural barriers, and in accordance with other resource values and within the limits of the Wyoming Forestry BMPs and other guidance without limiting the harvest area size.
FP-6007	LR:1.1 LR:1.2	Consider fencing of regeneration areas to prevent livestock from damaging seedlings.	Require fencing of regeneration areas to prevent damage to seedlings.	Do not require fencing of regeneration areas to prevent damage to seedlings.	Protect forest regeneration areas that are being damaged or in an area where damage is probable.
FP-6008	LR:1.1 LR:1.2	Plant trees on forest management areas that fail to regenerate naturally to minimum stocking levels within five years of harvest completion and rehabilitation activities.	Allow forest management areas to regenerate naturally.	Plant and maintain trees following forest management to minimum stocking levels.	Evaluate forest management areas and their successional dynamics, and where necessary implement tactics to assure regeneration (forest sustainability).
FP-6009	LR:1.1 LR:1.2	Initiate pre-commercial tree thinning on overstocked re-leasable seedling and sapling size stands.	Do not utilize pre-commercial thinning or other non-harvest silvicultural operations.	Utilize pre-commercial thinning and other silvicultural practices to create healthy and economically sustainable forest stands.	Utilize pre-commercial thinning and other silvicultural practices to create healthy and economically sustainable forest stands consistent with other resource values.

Table 2.28. 6000 LAND RESOURCES (LR) – LANDS AND REALTY

GOAL LR:2 Manage land tenure adjustments and land use authorizations to meet the needs of the customers while protecting other resource values.		
Objectives:		
LR:2.1 Develop and maintain a land-ownership pattern that improves access for public use, and improves management and protection of BLM-administered lands by:		
<ol style="list-style-type: none"> 1. Acquiring legal easements to BLM-administered lands for recreational opportunities and administrative use. 2. Responding to requests for land authorizations for access needs. 3. Responding to requests for land transfers. 4. Giving priority to land exchanges and/or sales on custodial grazing allotments while supporting other resource values. 		
LR:2.2 Through consolidation and disposal, the overall result should be no net acreage gain during the life of the RMP.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
L&R-6001	LR:2.1	Consider R&PP applications on a project-specific basis. Prohibit subsequent uses on these lands unless they are compatible with each R&PP authorization.
L&R-6002	LR:2.1	Consider land use authorizations (permits, leases, etc.) on a project-specific basis consistent with other resource objectives.
L&R-6003	LR:2.1	Consider withdrawals for surface and/or minerals on a project-specific basis.
L&R-6004	LR:2.1	Review withdrawal proposals from other agencies on a project-specific basis.
L&R-6005	LR:2.1 LR:2.2	Lands meeting the identified disposal criteria will have priority consideration for disposal.
L&R-6006	LR:2.1	Avoid the potential of inadvertent trespass by people accessing public lands through the use of appropriate signage and access authorizations.
L&R-6007	LR:2.1	Review existing withdrawals on a case-by-case basis. Determine whether the use is consistent with the intent of the withdrawal and whether the withdrawal should be continued, modified, revoked or terminated.
L&R-6008	LR:2.1	Any land becoming unencumbered by withdrawals will be managed in a manner consistent with adjacent or comparable public land within the planning area.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
L&R-6009	LR:2.1	Review existing classification and segregations on a case-by-case basis to determine whether classification and segregation is appropriate and should be continued, modified or terminated.			
L&R-6010	LR:2.1	Land on which a classification or segregation has been terminated will be managed in a manner consistent with adjacent or comparable public land within the planning area.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
L&R-6011	LR:2.1	Acquire private or state land or interest in land from willing sellers in coordination with other resource objective, on a project-specific basis.	Acquire private or state land or interest in land from willing sellers in coordination with other resource objectives (i.e., Greater Sage-Grouse habitat).	Do not acquire private or state lands or interest in land.	Acquire private or state land or interest in land from willing sellers consistent with other resource objectives, on a project-specific basis.
L&R-6012	LR:2.1	Consider disposal of lands having agricultural potential and water by sale, exchange, or desert land entry.	Retain lands having agricultural potential, water, or other natural resource value (i.e., Greater Sage-Grouse habitat).	Dispose of lands having agricultural potential or water.	Acquire and dispose of land based on all resource values, including but not limited to agricultural potential and water. Do not classify, open, or make available any BLM-administered public lands within the planning area for agricultural leasing or agricultural entry under either Desert Land Entry or Indian Allotment for one or more of the following reasons: rugged topography, presence of sensitive resources, lack of water or access, small parcel size, and/or unsuitable soils. Greater Sage-Grouse habitat will be retained in federal management unless: (1) the agency can demonstrate that disposal of the lands will provide a net conservation benefit to the Greater Sage-Grouse or (2) the agency can demonstrate that the lands will have no direct or indirect adverse impact on conservation of the Greater Sage-Grouse.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
L&R-6013	LR:2.2	Approximately 108,243 acres of BLM-administered lands are identified for disposal (Map 53). These areas have priority consideration for exchange, public sale, or transfer of jurisdiction to another agency, subject to disposal criteria.	Retain lands identified for disposal, but having important natural resource values (i.e., Greater Sage-Grouse habitat).	Do not retain lands identified for disposal, but having important natural resource values, until all other lands identified for disposal are disposed of (Map 54).	Actively pursue a program to dispose of BLM surface lands identified for disposal including other lands not identified but meeting appropriate disposal criteria (Map 54). These areas have priority consideration for exchange, public sale, or transfer of jurisdiction to another agency, subject to disposal criteria.
L&R-6014	LR:2.2	Priority is given to acquiring land or interests in lands in areas adjacent to large blocks of BLM-administered land, especially in areas of high recreational potential like the south Big Horn Mountains.	Consider all lands within the planning area for acquisition from interested parties without giving priority to major blocks of public land, and areas of high recreational potential.	Do not acquire land in areas adjacent to major blocks of public land or areas of high recreational potential.	Prioritize acquiring land or interests in lands in areas adjacent to large blocks of BLM-administered land or other lands having significant resource or other values before other areas.
L&R-6015	LR:2.2	Pursue easements that will provide access to BLM-administered lands for recreation and administrative purposes.	Pursue easements accessing public lands that would benefit BLM management for any resource value.	Do not pursue easements to facilitate BLM management.	Pursue easements accessing public lands that would benefit any resource value.
L&R-6016	LR:2.2	No previous decision; considered on a project-specific basis.	Pursue land tenure adjustments on lands holding custodial grazing allotments and/or sales, in accordance with other resource values.	Allow land tenure adjustments for lands holding custodial grazing allotments and/or sales independent of other resource values.	Pursue land tenure adjustments on lands holding custodial grazing allotments and/or sales, in accordance with other resource values.

Table 2.29. 6000 LAND RESOURCES (LR) – RENEWABLE ENERGY

GOAL LR:3 Renewable energy development consistent with other resource values.					
Objectives:					
LR:3.1 Identify BLM-administered lands that are suitable and not suitable for renewable energy development while supporting other resource values.					
LR:3.2 In cooperation with stakeholders, provide opportunities for scientific research of renewable energy and affected resources.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
RE-6001	LR:3.2	Cooperate with stakeholders to promote opportunities for scientific research for renewable energy in accordance with other resource values.			
RE-6002	LR:3.2	Cooperate with stakeholders to coordinate renewable energy opportunities in accordance with other resource values.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
RE-6003	LR:3.1	No previous decision; considered on a project-specific basis.	Exclude renewable energy development in the following areas (730,530 acres) (Map 55): <ul style="list-style-type: none"> • Areas closed to mineral leasing (fluid and solid) • Areas closed to mineral entry (locatable and salable) • ROW exclusion areas • All other areas where surface disturbance is prohibited 	Exclude renewable energy development on 28,551 acres in accordance with management outlined in Alternative C.	Exclude renewable energy development on 352,068 acres in accordance with management outlined in Alternative D. <ul style="list-style-type: none"> • Southern Big Horn Mountains • Areas closed to mineral leasing (fluid and solid) • Areas recommended for withdrawal to mineral entry (locatable) • Areas closed to mineral material entry (salable) • ROW exclusion areas • Areas within 3.0 miles and visible from historic properties that retain an intact setting • All other areas where surface disturbance is prohibited

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
RE-6004	LR:3.1	No previous decision; considered on a project-specific basis.	<p>Avoid renewable energy development in the following areas (45,441 acres) (Map 55):</p> <ul style="list-style-type: none"> • Mineral leasing (fluid and solid), NSO, and CSU areas • ROW avoidance areas • All other areas with surface disturbance restrictions <p>Allow renewable energy development on 6,131 acres.</p>	<p>Avoid renewable energy development on 618,676 acres where inconsistent with other resource values.</p> <p>Allow renewable energy development on 134,875 acres.</p>	<p>Avoid renewable energy development on 374,518 acres in the following areas (Map 56):</p> <ul style="list-style-type: none"> • Mineral leasing (fluid and solid), NSO, and CSU areas • ROW avoidance areas • Areas greater than 3.0 miles and visible from historic properties that retain an intact setting • All other areas with surface disturbance restrictions <p>Renewable energy development would be avoided in Greater Sage-Grouse priority habitat (Core Population Areas and Core Population Connectivity Corridors), unless it can be sufficiently demonstrated that the development activity would not result in declines of Greater Sage-Grouse priority populations. Sufficient demonstration of “no declines” should be coordinated with the WGFD and USFWS.</p>

Table 2.30. 6000 LAND RESOURCES (LR) – RIGHTS-OF-WAY AND CORRIDORS

GOAL LR:4 Primary infrastructure corridors and subsidiary routes consistent with other resource values.		
Objectives:		
LR:4.1 Manage public lands to meet the needs of ROW customers while supporting other resource values.		
LR:4.2 Maintain and acquire access routes across non public lands to meet resource management and use objectives.		
LR:4.3 Identify infrastructure corridors consistent with other resource values.		
LR:4.4 Make opportunities available for exploration and development of CO ₂ sequestration research and activities, while avoiding or mitigating impacts of these activities on other resource values.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
ROW-6001	LR:4.3	Designate corridors for major ROW to minimize surface disturbance and impacts to other resources.
ROW-6002	LR:4.2	Provide reasonable access across public land to private land, subject to other resource values.
ROW-6003	LR:4.1	Develop communication site management plans for all existing and newly identified communication site concentration areas.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
ROW-6004	LR:4.3	The preferred location for new ROW will be in or adjacent to existing disturbed areas associated with existing ROW, constructed roads, or highways.			
ROW-6005	LR:4.2	Maintain a transportation management system in cooperation with appropriate state and local agencies to meet public and resource management needs.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
ROW-6006	LR:4.1	Continue to authorize ROW grants.	<p>Make lands available for ROW in accordance with management identified within Alternative B to conserve other resources. This results in:</p> <ul style="list-style-type: none"> • 706,556 acres excluded from ROW. • 56,857 acres identified for ROW avoidance. • 18,869 acres are open for ROW development. 	<p>Make lands available for ROW in accordance with management identified within Alternative C to conserve other resources. This results in:</p> <ul style="list-style-type: none"> • 28,554 acres excluded from ROW. • 27,706 acres identified for ROW avoidance. • 725,842 acres are open for ROW development. 	<p>Make lands available for ROW in accordance with management identified within Alternative D to conserve other resources (Map 59). This results in:</p> <ul style="list-style-type: none"> • 79,777 acres excluded from ROW. • 321,149 acres identified for ROW avoidance. <p>Greater Sage-Grouse priority habitat (core population areas and core population connectivity corridors) are designated as avoidance areas for ROWs.</p> <ul style="list-style-type: none"> • 381,176 acres are open for ROW development.
ROW-6007	LR:4.1	<p>Authorize communication sites only in the Pumpkin Buttes area on South Middle Butte until that area has been fully utilized, unless the decision is waived by the authorized officer.</p> <p>Prohibit communication sites on North Middle Butte unless it becomes absolutely necessary to use that butte for the line-of-sight needs (such as microwave transmission).</p>	Prohibit new communication authorizations in the Pumpkin Buttes area. Maintain existing land use authorizations until they expire.	<p>Allow authorizations for communication sites in the Pumpkin Buttes area without first fully utilizing the South Middle Butte.</p> <p>Authorize communication sites on North Middle Butte regardless of line-of-sight needs.</p>	<p>Manage authorizations for communication sites in the Pumpkin Buttes area for the protection of cultural and visual resources.</p> <p>New authorizations would be limited to existing towers. Prohibit communication sites on North Middle Butte.</p>

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
ROW-6008	LR:4.1	No previous decision; considered on a project-specific basis.	Require new communication proposals to co-locate within existing communication sites (portable stations excluded).	Preference is to use designated communication concentration areas. Proposals outside concentration areas are not required to be co-located.	Identify and designate communication concentration areas. Evaluate proposals outside designated concentration areas and co-locate sites where feasible.
ROW-6009	LR:4.1	<p>Designate the following corridors for major ROW (Map 57):</p> <ul style="list-style-type: none"> • Echeta Road • Sheridan to Gillette, largely following US 14/16 • Highway 59 north of Gillette • Interstate 25 • Interstate 90, Gillette to Montana State Line • Powder River • Powder River Breaks (Buffalo to Gillette) <p>Corridor use is recommended, but not required. There are no restrictions on above ground lines except that lines must be buried within Greater Sage-Grouse Core Population Areas unless within 0.5 mile either side of existing 115 kV or larger transmission lines creating a corridor no wider than 1.0 mile.</p>	<p>Designate the following corridors for major ROW transportation and utility corridor (Map 58):</p> <ul style="list-style-type: none"> • Echeta Road • Sheridan to Gillette, largely following US 14/16 • Highway 59 north of Gillette • Interstate 25 • Interstate 90, Gillette to Montana State Line • Powder River <p>Corridor use is required. No above ground lines will be authorized.</p>	<p>Designate the following corridors for major ROW transportation and utility corridor (Map 57):</p> <ul style="list-style-type: none"> • Echeta Road • Sheridan to Gillette, largely following US 14/16 • Highway 59 north of Gillette • Interstate 25 • Interstate 90, Gillette to Montana State Line • Powder River • Powder River Breaks (Buffalo to Gillette) <p>Corridor use is required. Above ground lines can be authorized in any corridor.</p>	<p>Designate the following corridors for major ROW transportation and utility use, (Map 58) in cooperation with the State of Wyoming:</p> <ul style="list-style-type: none"> • Echeta Road • Sheridan to Gillette, largely following US 14/16 • Highway 59 north of Gillette • Interstate 25 • Interstate 90, Gillette to Montana State Line • Powder River • Powder River Breaks (Buffalo to Gillette) <p>Corridor use is required. No above ground lines will be authorized in the Powder River or Powder River Breaks corridors. Lines must be buried within Greater Sage-Grouse Core Population Areas unless within 0.5 mile either side of existing 115 kV or larger transmission lines creating a corridor no wider than 1.0 mile.</p>

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
ROW-6010	LR:4.1	No previous decision; considered on a project-specific basis.	Avoid placement of above ground facilities such as powerlines along major transportation routes to protect visual resources.	Place above ground facilities such as powerlines along major transportation routes.	Authorize and place above ground facilities (i.e., compressors, electric distribution powerlines) within ROW and other disturbance areas when resource objectives can be met.
ROW-6011	LR:4.1	Surface disturbance and occupancy will not be allowed on slopes of 25% or more.	Exclude ROW on slopes 25% or greater and highly erodible soils.	Do not exclude ROW on slopes 25% or greater and highly erodible soils.	Avoid ROW on slopes 25% or greater and highly erodible soils.
ROW-6012	LR:4.4	No previous decision.	Prohibit CO ₂ sequestration research and projects.	Allow CO ₂ sequestration research and projects where consistent with other resource values.	Evaluate CO ₂ sequestration proposals where in accordance with management identified within Alternative D.

Table 2.31. 6000 LAND RESOURCES (LR) – TRAVEL AND TRANSPORTATION MANAGEMENT

GOAL LR:5 A safe transportation network that supports other resource values.		
Objectives:		
LR:5.1 Utilize a comprehensive travel management approach to sustain and enhance access, recreational experiences, and support other resource values.		
LR:5.2 Maintain an inventory of the road and trail system.		
LR:5.3 Designate all BLM-administered lands as Open, Limited, or Closed to OHV use, in consideration of other resource values.		
LR:5.4 Provide for acceptable modes of legal public access that supports other resources, reduces conflicts, and provides for diverse recreation opportunities.		
GOAL LR:6 Opportunities for safe and enjoyable OHV use are provided while supporting other resource values.		
Objectives:		
LR:6.1 Assess OHV demand and plan for and balance the demand for OHV use with other uses.		
LR:6.2 Manage OHV use to conserve soil functionality, vegetative cover, watershed health, and other resource values.		
LR:6.3 Manage OHV use in partnership with stakeholders.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Trans-6001	LR:5.4	Negotiate access across non-BLM-administered lands to isolated public land parcels from willing landowners.
Trans-6002	LR:5.1 LR:5.4	Evaluate roads constructed under other initiatives (e.g., oil and gas exploration) for inclusion in the BLM transportation system. Roads that are no longer needed for their original purposes are assessed for addition to the BLM transportation system prior to reclamation.
Trans-6003	LR:5.1	Require maintenance of all designated routes to meet or exceed BLM standards according to the road classification (i.e. road, primitive road, trail) assigned in FAMS.
Trans-6004	LR:5.1	Design, construct, and maintain roads or trails based on the specific objectives for that trail or road in consideration of other resources. Design, construct, and maintain roads to minimize surface disturbance, changes to surface water runoff, and erosion.
Trans-6005	LR:5.1 LR:5.4	All motorized use, except emergency response, will be subject to the Open, Closed and Limited OHV area designations, unless specifically addressed in an authorization or otherwise approved by the authorized officer.
Trans-6006	LR:5.1 LR:5.4	Base road or trail closures and abandonments on resource protection, demand for new roads and accommodation of authorized uses.
Trans-6007	LR:5.4 LR:6.1 LR:6.2 LR:6.3	Maintain transportation system roads under BLM jurisdiction in accordance with assigned maintenance levels and in consideration of other resource values. Maintain administrative roads on an as needed basis, dependent on time, funding, and access priorities.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Trans-6008	LR:5.2	Within 5 years of the ROD, inventory all routes on public land and develop a travel management plan to classify and designate routes for continued use or decommissioning and reclamation. Include maintenance standards for routes to be retained for public use, as well as specific measures to accomplish road closure in the travel management plan. Inventory, designate, number, and sign all routes as appropriate. Posted signs will include allowed uses and activities. Restrictions to existing roads and trails remains in effect until travel management planning is completed and designated routes are identified.
Trans-6009	LR:5.1 LR:6.3	Establish TMAs for locations receiving intensive use or areas where resource damage is imminent.
Trans-6010	LR:5.3	Restrict OHV use to signed roads in areas limited to designated roads and trails.
Trans-6011	LR:5.1 LR:5.4	Consider ways to allow motorized access for people with disabilities under section 504 of the Rehabilitation Act of 1973.
Trans-6012	LR:5.4	Identify areas appropriate for providing access for people with disabilities for recreational activities. Prioritize trails appropriate for upgrades that make them ADA compliant.
Trans-6013	LR:5.1 LR:5.3	<p>Allow temporary closures to motorized vehicle use in areas that pose public health and safety risks, and/or where resource damage is imminent.</p> <p>In Greater Sage-Grouse priority habitat (core population areas and core population connectivity corridors) and general habitat, temporary closures will be considered in accordance with 43 CFR subpart 8364 (Closures and Restrictions); 43 CFR subpart 8351 (Designated National Area); 43 CFR subpart 6302 (Use of Wilderness Areas, Prohibited Acts, and Penalties); 43 CFR subpart 8341 (Conditions of Use).</p> <p>Temporary closure or restriction orders under these authorities are enacted at the discretion of the authorized officer to resolve management conflicts and protect persons, property, and public lands and resources. Where an authorized officer determines that off-highway vehicles are causing or will cause considerable adverse effects upon soil, vegetation, wildlife, wildlife habitat, cultural resources, historical resources, threatened or endangered species, wilderness suitability, other authorized uses, or other resources, the affected areas shall be immediately closed to the type(s) of vehicle causing the adverse effect until the adverse effects are eliminated and measures implemented to prevent recurrence. (43 CFR 8341.2) A closure or restriction order should be considered only after other management strategies and alternatives have been explored. The duration of temporary closure or restriction orders should be limited to 24 months or less; however, certain situations may require longer closures and/or iterative temporary closures. This may include closure of routes or areas.”</p>
Trans-6014	LR:5.3	Limit OHV use to designated routes unless compelling reasons exist to classify parcels as Open or Closed, and is consistent with other resource values. Until individual routes are designated, areas subject to route designation will be classified as Limited to existing routes (Map 60). Once route designation is completed, areas will no longer be classified as Limited to existing routes.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Trans-6015	LR:5.1 LR:5.2 LR:5.4 LR:6.1	Consider nominations from the public for appropriate OHV use areas, consistent with other resource values.			
Trans-6016	LR:5.1 LR:5.3 LR:6.1 LR:6.2	Prohibit motorized travel if damage to vegetation, soils, or water quality would result.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Trans-6017	LR:6.2	Open stock driveways and stock rests to motorized vehicle use.	Limit motorized vehicle use to designated routes within stock driveways.	Open stock driveways and stock rests to motorized vehicle use.	Allow OHV use only on designated routes within stock driveways for the general public and in additional areas within stock driveways and rests under a trailing permit.
Trans-6018	LR:6.2	No previous decision; considered on a project-specific basis.	Allow over-the-snow vehicle use consistent with motorized use designations when snow cover is sufficient to prevent resource damage.	Allow over-the-snow vehicle use when snow cover is sufficient to prevent resource damage.	Allow over-the-snow vehicle use consistent with OHV use designations when snow cover is sufficient to prevent resource damage.
Trans-6019	LR:6.2	No previous decision; considered on a project-specific basis.	Close areas within habitat of special status species to motorized vehicle use..	Allow motorized vehicle use within habitat of special status species consistent with travel management designations for that area.	Limit motorized vehicle use to designated routes within habitat of special status species consistent with travel management designations for that area. Routes will be designated to avoid occupied habitat during travel management planning.
Trans-6020	LR:5.1 LR:5.4	No previous decision; considered on a project-specific basis.	Evaluate existing routes in the vicinity of any new system roads for closure and reclamation consistent with other resource values.	Do not close and reclaim existing routes in the vicinity of any new system roads.	Evaluate existing routes in the vicinity of any new system roads for closure and reclamation consistent with other resource values.

Trans-6023	LR:5.3	<p>Areas where motorized vehicle use is Closed (approximately 37,646 acres) from November 15 to April 30 include (Map 65):</p> <ul style="list-style-type: none"> • North Fork Powder River area 10 miles northwest of Barnum • Barnum Mountain 6.0 miles west of Barnum • A portion of the Middle Fork Management Area 12 miles southwest of Barnum • Fortification Creek Area, including portions of WSA <p>Note: The Ed O. Taylor is Closed for winter, following the hunting season.</p>	<p>Prohibit motorized vehicle use from November 15 to April 30 within the following areas (Map 66):</p> <ul style="list-style-type: none"> • Big game crucial winter ranges 	<p>Prohibit motorized vehicle use from November 15 to April 30 within the following areas (Map 67):</p> <ul style="list-style-type: none"> • Big game crucial winter ranges in the Southern Big Horns 	<p>Protect wintering big game by seasonally prohibiting motorized vehicle use within big game crucial winter ranges in accordance with WGFD recommendations (presently November 15 or December 1 to April 30) (Map 68).</p>
Trans-6024	LR:5.3	No previous decision; considered on a project-specific basis.	Prohibit motorized vehicle use from May 1 to June 30 within big game calving areas.	Do not prohibit motorized vehicle use seasonally within big game calving areas.	Protect big game by seasonally prohibiting motorized vehicle use within big game calving areas in accordance with WGFD recommendations (presently May 1 to June 30).
Trans-6025	LR:5.1 LR:5.3 LR:6.2	No previous decision; considered on a project-specific basis.	Allow motorized travel off designated routes only under a special use permit (grazing lessee, administrative use, etc.).	Allow motorized travel not causing resource damage, to go up to 300 feet off designated routes, for necessary tasks.	Allow motorized travel not causing resource damage to go up to 300 feet off designated routes for dispersed camping and game retrieval, where consistent with travel management designations in defined areas (activities under administrative permits excluded) (Map 60).

Table 2.32. 6000 LAND RESOURCES (LR) – RECREATION

GOAL LR:7 Diverse recreational opportunities are provided.		
Objectives:		
LR:7.1 Manage SRMAs and ERMA's in partnership with stakeholders.		
LR:7.2 Manage recreation to protect resources, maintain public health and safety, and to provide a diverse array of benefits to the public.		
LR:7.3 Manage recreation opportunities to maintain a minimal level of user conflict.		
GOAL LR:8 Recreation facilities balance public demand with other resource values.		
Objective:		
LR:8.1 Design and maintain recreation sites to meet acceptable health and safety standards while supporting other resource values.		
GOAL LR:9 Awareness, education, and support for BFO recreation programs and opportunities.		
Objective:		
LR:9.1 Emphasize and support collaborative public outreach.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Rec-6001	LR:7.1 LR:7.2	Develop or revise RAMPs for the SRMAs and ERMA's as public demand and management needs dictate.
Rec-6002	LR:7.2	Allow casual use of the public land for hiking, bicycling, hunting, fishing, camping and similar uses.
Rec-6003	LR:7.2 LR:8.1 LR:9.1	Open the planning area to dispersed recreation where consistent with other resource values.
Rec-6004	LR:9.1	Provide general and interpretive information as well as information designed to prevent trespass to visitors of SRMAs and other high-use recreation areas.
Rec-6005	LR:8.1	Maintain existing facilities consistent with the recreational setting.
Rec-6006	LR:7.2	Provide diverse recreational opportunities in cooperation with a variety of user groups.
Rec-6007	LR:9.1	Work with state, local groups, and adjacent landowners to identify and develop recreational facilities and trails and to improve public access to public lands.
Rec-6008	LR:7.2 LR:8.1	Design any new recreation facilities within a SRMA to be ADA compliant. Upgrade existing recreation facilities to be ADA compliant as time and funding allow.
Rec-6009	LR:7.2	Pursue access to public lands for recreational purposes.
Rec-6010	LR:7.2	Avoid riparian habitat or develop and manage recreational sites, recreation facilities, and recreational access in a manner that minimizes impacts to riparian habitats.
Rec-6011	LR:7.2	Prohibit dispersed camping and commercial camps within 200 feet of perennial surface water.
Rec-6012	LR:7.2	Manage access to caves for recreationists under a Cave Management Plan.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Rec-6013	LR:7.2	Use the best available technology to minimize noise and light pollution potentially affecting recreation facilities and sites.			
Rec-6014	LR:7.2	Close developed recreation sites such as picnic areas, campgrounds, and environmental education areas to livestock grazing.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Rec-6015	LR:7.3 LR:8.1	No previous decision; considered on a project-specific basis.	Limit development of additional recreation facilities to SRMAs and other high-use areas.	Allow additional recreation facilities in areas where they are supported by recreational use and are consistent with other resource values.	Allow additional recreation facilities in areas where they are supported by recreational use and are consistent with other resource values. In Greater Sage-Grouse priority habitat (core population areas and core population connectivity corridors), do not construct new recreation facilities (e.g., campgrounds, trails, trailheads, staging areas) unless the development would have a net conservation gain to Greater Sage-Grouse habitat (such as concentrating recreation, diverting use away from important areas, etc.), or unless the development is required for visitor health and safety or resource protection.
Rec-6016	LR:7.2 LR:7.3	Camping is limited to 14 days at any one spot.	Allow camping, unless otherwise posted, for no more than 14 days within any period of 28 consecutive days. After this period, the visitor must relocate to another site at least 5.0 miles away.	Allow camping, unless otherwise posted, for no more than a period of 14 days within any period of 28 consecutive days. After this period, the visitor must relocate to another site at least 1.0 mile away.	Allow camping for no more than 14 days within any 28 consecutive days. After reaching this time limit, the visitor must relocate to another site at least 1.0 mile away.

Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Rec-6017	LR:7.1	No previous decision; the planning area has been managed as one ERMA with several developed recreation sites and trails.	<p>Divide the planning area into the following ERMA (Map 69):</p> <ul style="list-style-type: none"> • Southern Big Horns ERMA (128,761 acres): Lands south of the Bighorn National Forest and west of I-25 in southwestern Johnson County (excludes Middle Fork and Hole-in-the-Wall SRMAs) • Buffalo ERMA (597,812 acres): This ERMA includes the remainder of the planning area not included in the Southern Big Horns ERMA or the designated SRMAs. <p>Recreation opportunities in ERMA's will be allowed that are in concert with protecting cultural and visual resources and sustaining the biological integrity of habitats for plant, wildlife, and fish species. In sensitive areas, recreation use could be limited.</p>	Do not designate any ERMA's. Address recreation issues outside of SRMAs on a case-by-case basis through site-specific analysis.	<p>Divide the planning area into the following ERMA (Map 71):</p> <ul style="list-style-type: none"> • Cabin Canyon (1,369 acres): Includes lands adjacent to State of Wyoming lands north of Bishop Road. • Face of the Bighorns/North Fork ERMA (34,477 acres): Includes lands from the Poison Creek Trail area south along the Face of the Bighorns, the Horn, and the North Fork WSA. • Gardner Mountain ERMA (55,181 acres): Includes lands along and south of the Mayoworth-Slip Road and north of Barnum Mountain Road. • Kaycee Stockrest ERMA (2,685 acres) • North Bighorns ERMA (2,926 acres): Includes parcels in Sheridan County adjacent to the Bighorn National Forest. • Powder River Basin ERMA (224,483 acres): This ERMA includes the public lands in the planning area with reasonable public access of sufficient size to support recreation that are not included in the other ERMA's or SRMAs.

Prohibiting all other surface-disturbing activities not compatible with retaining or enhancing the area's natural values.

Table 2.34. 6000 LAND RESOURCES (LR) – LIVESTOCK GRAZING MANAGEMENT

GOAL LR:11 Public rangelands provide for a sustainable level of livestock grazing consistent with other resource values and sustained yield.		
Objectives:		
LR:11.1 Continue livestock grazing on available BLM-administered lands.		
LR:11.2 Manage forage to maintain or improve ecological states and achieve and/or maintain Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming.		
LR:11.3 Monitor and evaluate rangeland health and condition in coordination with cooperators, and lessees to determine if, and what additional management is needed to achieve desired ecological state.		
LR:11.4 Emphasize the use of mechanical, chemical, and biological methods, as well as fire and livestock grazing to achieve desired ecological state.		
LR:11.5 Continue the existence and use of stock driveways and other stock driveway withdrawals.		
LR:11.6 Identify and implement opportunities for vegetation improvements to increase the number of AUMs available for livestock grazing to support and sustain the economies of local communities.		
LR:11.7 Create and maintain reserve common allotments or pastures for temporary grazing purposes to facilitate another allotment in attaining management objectives.		
LR:11.8 In coordination with cooperators and lessees develop and implement allotment management plans, where feasible. Emphasis to be placed on Category I allotments.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Grazing-6001	LR:11.1 LR:11.2 LR:11.3 LR:11.4 LR:11.6 LR:11.7 LR:11.8	Develop and implement appropriate livestock grazing management actions to achieve the Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming, to provide watershed protection, to improve forage for livestock, forage and habitat for wildlife, and enhance rangeland health.
Grazing-6002	LR:11.1 LR:11.2 LR:11.3 LR:11.4 LR:11.6 LR:11.8	Continue to authorize appropriate amounts, kinds, and seasons of use. Forage allocations in grazing leases can be adjusted when supported by monitoring, field observations, rangeland health standards assessment/evaluation results, or other data acceptable to the authorized officer. Category C allotments have a low priority, Category M allotments have a medium priority, and Category I allotments have a high priority for monitoring and funding of range improvement projects.
Grazing-6003	LR:11.1 LR:11.3 LR:11.8	Continue the M, C, and I allotment categorization designations (Map 72).
Grazing-6004	LR:11.1 LR:11.2 LR:11.3 LR:11.4 LR:11.6 LR:11.8	Continue implementation of existing AMPs. Develop and implement new AMPs with grazing lessees and other stakeholders to achieve desired resource goals and objectives.
Grazing-6005	LR:11.1 LR:11.2 LR:11.3 LR:11.8	Manage livestock grazing to sustain riparian, wetland, mountain mahogany, specials status species, or other special habitats.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Grazing-6006	LR:11.1 LR:11.2 LR:11.3	Manage Category C allotments to continue authorized livestock use.			
Grazing-6007	LR:11.1 LR:11.2 LR:11.3 LR:11.4 LR:11.6 LR:11.7 LR:11.8	Construct reservoirs, wells, troughs and pipelines to provide water to disperse grazing use. The grazing lessee or other cooperator will be required to maintain water in troughs located on public land during the frost-free period (April through October) for wildlife.			
Grazing-6008	LR:11.1 LR:11.5	Retain designated stock driveways and livestock trails. Consider any stock driveway designation change on a project-specific basis and analyze through an environmental assessment.			
Grazing-6009	LR:11.1 LR:11.2 LR:11.3 LR:11.7 LR:11.8	Implement strategies that best protect rangeland resources during periods of drought. Cooperate with stakeholders for voluntary adjustments in livestock use and/or livestock management.			
Grazing-6010	LR:11.2 LR:11.4	Rest prescribed burn areas from livestock grazing prior to treatment when necessary to increase or maintain fuels for burning.			
Grazing-6011	LR:11.2 LR:11.3 LR:11.4	Authorize OHV travel for maintaining range improvements and animal husbandry activities by the grazing lessee and his/her agent, consistent with other management actions, as long as resource damage does not occur or new routes created.			
Grazing-6012	LR:11.2 LR:11.4	Avoid creating concentrations of livestock in areas of known eligible and unevaluated cultural sites. (salt blocks, water source)			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Grazing-6013	LR:11.1 LR:11.3	Suspend or adjust livestock grazing use in areas where forest management has occurred whenever grazing would impair forest regeneration.	Restoration treatments may include actions to reduce or eliminate potential grazing impacts to meet regeneration objectives following forest management.	Restoration treatments will not include actions to reduce or eliminate potential grazing impacts to meet regeneration objectives following forest management.	Restoration treatments may include actions to reduce or eliminate potential grazing impacts to meet regeneration objectives following forest management.
Grazing-6014	LR:11.1 LR:11.2 LR:11.3 LR:11.4 LR:11.6	Manage Category M allotments to continue the current authorized livestock use on 98 "M" allotments at 43,573 AUMs.	Manage Category M allotments to achieve multiple resource health and objectives.	Manage Category M allotments to achieve livestock management objectives only.	Manage Category M allotments to achieve multiple resource health and objectives.
Grazing-6015	LR:11.1 LR:11.2 LR:11.6	Allow development of range improvements. Establish resource monitoring studies as necessary to detect undesirable changes in the current satisfactory resource conditions.	Develop range improvements for Category M allotments in accordance with resource needs and livestock management.	Develop range improvements for Category M allotments that are lessee proposed and funded only.	Develop range improvements in accordance with resource needs and livestock management.

ACEC-7004	SD:1.2	Continue with no ACECs designated in the planning area.	<p>Manage designated ACECs through the following actions:</p> <ul style="list-style-type: none"> • Closing or limiting motorized vehicles to designated roads and trails • Managing for visual resources as Class II • Closing the area to mineral leasing (fluid and solid) • Recommending withdrawal to locatable mineral entry • Closing the area to salable minerals • Excluding ROW • Prohibiting all other surface-disturbing activities not compatible with retaining or enhancing the area's values for which the ACEC was designated 	Continue with no ACECs designated in the planning area.	Manage ACECs under site specific management plans. Site specific management plans will be consistent with and implement the provisions specified for ACECs in Appendix S (p. 2531)..

Table 2.36. 7000 SPECIAL DESIGNATIONS (SD) – SCENIC OR NATIONAL BACK COUNTRY BYWAYS

GOAL SD:2 Potential National Byways are evaluated to enhance opportunities for the public to see and enjoy public lands.					
Objectives:					
SD:2.1 Where appropriate, identify scenic or national back country byways and develop management prescriptions to maintain resource values.					
SD:2.2 Promote the increased awareness of historical and cultural values and facilitate a sense of stewardship within proposed national back country byways.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
BCB-7001	SD:2.1	Manage national back country byways with the objective of encouraging responsible use of the proposed byway, while protecting and displaying the scenic, cultural, geological, multiple use, and crucial wildlife habitat values that occur in the area.			
BCB-7002	SD:2.2	Coordinate with local residents in the area of any designated national back country byway to develop information and interpretive materials for visitors that highlight multiple uses of public lands and land stewardship in the area.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
BCB-7003	SD:2.1	No previous decision; considered on a project-specific basis.	<p>Evaluate roads within the planning area for designation as National Back Country or Scenic Byways. Eligible routes may be proposed for National Back Country or Scenic Byway designation (Map 73).</p> <p>Potential routes include:</p> <ul style="list-style-type: none"> ● Hazelton Road ● Slip Road ● Trabing/Sussex ● Powder River ● Rome Hill ● Tipperary/Thompson Road 	Do not evaluate roads within the planning area for National Back Country or Scenic Byway inclusion.	<p>Evaluate roads in coordination with the counties and other stakeholders for designation as National Back Country or Scenic Byways. Eligible routes may be proposed for National Back Country or Scenic Byway designation (Map 74).</p> <p>Potential routes include:</p> <ul style="list-style-type: none"> ● Hazelton Road ● Slip Road ● Trabing/Sussex ● Powder River ● Rome Hill ● Tipperary/Thompson Road

Table 2.37. 7000 SPECIAL DESIGNATIONS (SD) – WILD AND SCENIC RIVERS

GOAL SD:3 Suitable waterway segments' free-flowing condition, water quality, outstandingly remarkable values and tentative classification would be protected and/or enhanced until such time that Congress designates the Middle Fork Powder River as a WSR or releases the river for other uses.					
Objectives:					
SD:3.1 Manage suitable segments to protect and enhance their free-flowing condition, water quality, outstandingly remarkable values and tentative classification.					
SD:3.2 Develop partnerships for managing and promoting suitable waterways to enhance their public enjoyment.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
WSR-7001	SD:3.1	Manage the Middle Fork Powder River (Map 75) in accordance with the Middle Fork Interim Management Plan until Congress acts upon the nomination. (The interim management plan and eligibility review report are available on the BFO website, http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo/docs.html .)			
WSR-7002	SD:3.2	Work with stakeholders to manage the Middle Fork Powder River corridor.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
WSR-7003	SD:3.1 SD:3.2	No previous decision.	If Congress does not designate the Middle Fork Powder River as a WSR, and releases the river for other uses, management will continue in accordance with the Middle Fork Interim Management Plan to protect and enhance its free-flowing condition and outstandingly remarkable values.	If Congress does not designate the Middle Fork Powder River as a WSR, and releases the river for other uses, do not apply special provisions related to protection of free-flowing characteristics and outstanding resource values. Manage the Middle Fork Powder River to follow the management outlined in Alternative C of this RMP.	If Congress does not designate the Middle Fork Powder River as a WSR, and releases the river for other uses, management will continue to retain the free-flowing characteristics and outstanding remarkable values.

Table 2.38. 7000 SPECIAL DESIGNATIONS (SD) – WILDERNESS STUDY AREAS

GOAL SD:4 Existing WSAs will meet the “non-impairment standard” under BLM Manual 6330 – Management of Wilderness Study Areas.					
Objectives:					
SD:4.1 Monitor and document condition and use of each WSA at least once per year.					
SD:4.2 Manage and protect the characteristics of each WSA so as to maintain their existing size, naturalness, unique values, and outstanding opportunities.					
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
WSA-7001	SD:4.2	If Congress acts to either designate as Wilderness or release WSAs from further consideration (Fortification Creek, Gardner Mountain, North Fork) (Map 75), the RMP will be amended as necessary.			
WSA-7002	SD:4.2	Manage WSAs for the preservation of natural conditions and processes, and to provide opportunities for solitude or a primitive and unconfined type of recreation. Under the guidance of BLM Manual 6330 – Management of Wilderness Study Areas, manage WSAs to emphasize primitive, nonmotorized activities to maintain the current natural values.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
WSA-7003	SD:4.2	If Congress decides not to designate the WSAs as wilderness, lease for oil and gas development in the following WSAs: <ul style="list-style-type: none"> • Gardner Mountain WSA (6,423 acres) • North Fork WSA (10,089 acres) • Fortification Creek WSA (12,419 acres) 	If Congress decides not to designate a WSA as wilderness, do not lease mineral rights until a plan amendment is completed. Additionally, motorized travel, surface-disturbing activities and any other activities (except valid existing rights) that may impair wilderness characteristics will be prohibited until a plan amendment is completed. WSAs released by Congressional for uses other than wilderness would then be considered pursuant to Manuals 6310 and 6320 to maintain wilderness characteristics.	If Congress decides not to designate a WSA as wilderness, do not lease mineral rights until a plan amendment is completed. Additionally, motorized travel, surface-disturbing activities and any other activities (except valid existing rights) that may impair wilderness characteristics will be prohibited until a plan amendment is completed. WSAs released by Congressional for uses other than wilderness would then be considered pursuant to Manuals 6310 and 6320 to maintain wilderness characteristics.	If Congress decides not to designate a WSA as wilderness, do not lease mineral rights until a plan amendment is completed. Additionally, motorized travel, surface-disturbing activities and any other activities (except valid existing rights) that may impair wilderness characteristics will be prohibited until a plan amendment is completed. WSAs released by Congressional for uses other than wilderness would then be considered pursuant to Manuals 6310 and 6320 to maintain wilderness characteristics.
WSA-7004	SD:4.2	No previous decision; considered on a project-specific basis. All WSAs are currently Closed to motorized use or use is Limited to designated routes, though no routes have been designated in any of the WSAs.	Prohibit all motorized and mechanized equipment within WSAs.	Prohibit motorized equipment within WSAs.	Prohibit all motorized and mechanized equipment within WSAs.

2.9.8. 8000 SOCIOECONOMIC RESOURCES

Table 2.39. 8000 SOCIOECONOMIC RESOURCES (SR) – SOCIAL AND ECONOMIC

GOAL SR:1 Opportunities for economic and social sustainability are provided at the national, regional, and local levels.		
Objectives:		
SR:1.1 Ensure local and regional economic development and local land use plans are considered in BLM actions.		
SR:1.2 Consider and address economic impact of BLM actions.		
SR:1.3 Coordinate and address impacts to the social structure to the extent BLM actions are expected to affect the social structure.		
SR:1.4 Recognize city and county infrastructure needs associated with BLM actions.		
GOAL SR:2 Sustainable consumptive economic development opportunities are provided for and are balanced against non-consumptive uses.		
Objectives:		
SR:2.1 Identify options to utilize resources consistent with a multiple resource management philosophy that provides a balance between local, regional, and national views.		
SR:2.2 Maintain a balance between consumptive and nonconsumptive uses.		
GOAL SR:3 Use conflicts are managed through public education and outreach.		
Objective:		
SR:3.1 Work cooperatively with local agencies to foster public awareness.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Socio-8001	SR:2	Remain sensitive to the economic and social health of the impacted area.
Socio-8002	SR:1	Refer to available socioeconomic monitoring plans that provide indicators for the economic and social health of an affected area.
Socio-8003	SR:1	Manage in a way that considers the fact that BLM actions are integrally connected with both socioeconomics and the cultural health of the planning area.

Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES			
Socio-8004	SR:1	Quantify socioeconomic impacts associated with site-specific and programmatic BLM actions to the extent possible.			
Socio-8005	SR:3	Share the results with state and local governmental officials for the purpose of promoting collaborative management, where possible, to ensure the affected parties and overlapping jurisdictions are provided that information as required by law.			
Record #	Goal/Obj.	Alternative A (Current Management)	Alternative B (Resource Conservation)	Alternative C (Resource Utilization)	Alternative D (Proposed RMP)
Socio-8006	SR:2	No previous decision.	Develop mitigation strategies designed to resolve conflicts that have detrimental effects on multiple resource use.	Develop management strategies designed to recognize and point out conflicts that are expected to have an impact on multiple resource use.	Work with local, state, federal, and private entities with the intention of developing mitigation strategies designed to promote a healthy and sustainable social and economic environment.
Socio-8007	SR:1 SR:3	BLM's management recognizes and considers local and regional economic development and land use plans.	Consider local and regional economic development and land use plans.	Incorporate, to the extent possible, local and regional economic development and land use plans.	In consideration of local and regional economic development and land use plans, work cooperatively with all stakeholders to identify the socioeconomic impacts of BLM actions and develop strategies that would mitigate those impacts where possible with the overriding goal of promoting sustainability in a multiple resource use environment.

Table 2.40. 8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY

GOAL SR:4 Public health and safety are protected.		
Objectives:		
SR:4.1 Reduce or eliminate hazards to human health and safety and the environment by reporting, cleanup, and reclamation of contaminated sites.		
SR:4.2 Integrate environmental protection and hazard management into all BLM actions.		
SR:4.3 Collaborate with Wyoming DEQ to identify, mitigate, or remediate Abandoned Mine Land sites and coalbed fires.		
SR:4.4 Avoid public exposure to H ₂ S.		
SR:4.5 Reduce or eliminate physical hazards through appropriate mitigation.		
Record #	Goal/Obj.	MANAGEMENT ACTIONS COMMON TO ALL ALTERNATIVES
Health-8001	SR:4.1 SR:4.2	Identify, report, control, and mitigate imminent and potential hazards or threats to human health and/or the environment from hazardous substance releases and physical hazards.
Health-8002	SR:4.1	Manage the cleanup of hazardous substance and other contaminant spills and releases to reduce human health and/or environmental risk, reclaim and monitor contaminated lands, and carry out emergency response activities.
Health-8003	SR:4.3	Identify and prioritize abandoned mine sites for reclamation that most affect human health or safety, and the environment.
Health-8004	SR:4.4	Require, as appropriate, warning signs, sirens, and public education to prevent exposure by the public to hydrogen sulfide gas associated with oil and gas development and production. Develop and maintain a field office hydrogen sulfide gas safety plan to identify areas of potential hydrogen sulfide gas, appropriate safety distances, and access restrictions, if necessary.
Health-8005	SR:4.5	Ensure appropriate review of BLM-authorized activities and the application of effective management controls to minimize hazardous substance and other contaminant spills, releases, and physical hazards.
Health-8006	SR:4.1 SR:4.5	Reduce waste produced by BLM activities and from authorized uses of public lands through waste minimization practices that promote reducing, reusing, recycling, substituting, and other innovative methods of pollution prevention.
Health-8007	SR:4.3	Identify, monitor, and mitigate hazards to public health and safety from coal seamfires.

Note: NSO, CSU, and TSU stipulations identified in the management actions in Table 2.7, “1000 PHYSICAL RESOURCES (PR) – AIR QUALITY (AQ)” (p. 127) through Table 2.40, “8000 SOCIOECONOMIC RESOURCES (SR) – HEALTH AND SAFETY” (p. 275), apply only to fluid mineral leasing.

2.10. Summary of Environmental Consequences by Alternative

Table 2.41, “Summary of Environmental Consequences by Alternative” (p. 277) summarizes potential impacts under alternatives A through D. Where appropriate, the table quantifies potential impacts anticipated from BLM-authorized actions. Table 2.41, “Summary of Environmental Consequences by Alternative” (p. 277) summarizes impacts under the four alternatives in acres (e.g., more acreage implies more impact, either beneficial or adverse) or qualitative descriptions comparing the anticipated impacts among the alternatives (i.e., negligible, minor, moderate, or major). See the Scale of Impacts section in the Chapter 4 Introduction, for the definition of each of these terms as applied to the extent of anticipated impact. The *Summary of Impacts* section for each resource in Chapter 4 provides a more detailed comparison of impacts between alternatives. Chapter 4 describes cumulative impacts from non-BLM actions; Table 2.41, “Summary of Environmental Consequences by Alternative” (p. 277) does not include cumulative impacts.

The environmental consequences of alternatives are not anticipated to exceed known legal thresholds or standards over the life of this RMP, with the exception of air quality. Standard practices, RDFs, BMPs, and guidelines for surface-disturbing activities are built into each alternative to avoid and minimize potential impacts. The BLM would consider mitigation of residual impacts during subsequent implementation-level projects and any associated environmental analyses performed at that time. All alternatives include reclamation of surface disturbance to reduce long-term impacts.

Chapter 3. Affected Environment

This page intentionally
left blank

This chapter describes existing conditions for the resources in the Buffalo Field Office (BFO) planning area and serves as the baseline against which Chapter 4 analyzes and compares impacts under alternatives A, B, C, and D. A variety of laws, regulations, policies, and other requirements direct public land management, as summarized in Chapter 1. The BFO operates under these requirements and guidance. In addition to describing existing conditions, this chapter describes management challenges as identified through the Bureau of Land Management (BLM) Analysis of the Management Situation (AMS) and issues identified during the public scoping process.

3.1. Physical Resources

3.1.1. Air Quality

This section describes the air resources in the region that would be potentially affected by BLM activities and decisions in the Buffalo planning area. The discussion of air resources includes a description of the topography, climate, climate change, and existing air quality of the planning area. Air pollutants addressed include criteria air pollutants, hazardous air pollutants (HAPs), and sulfur and nitrogen compounds that could contribute to Air Quality Related Values (AQRV), including visibility, atmospheric deposition, and acid rain.

3.1.1.1. Regional Context

For this analysis, air quality data were examined from monitors located within the planning area (Campbell, Johnson, and Sheridan counties) and in nearby areas (Weston and Converse counties). Air quality data from these locations provides an overall summary of current air quality conditions within the planning area and in the surrounding regions.

3.1.1.2. Regulatory and Policy Framework

The Clean Air Act (CAA) and its amendments mandate the control of air pollutants throughout the United States. The CAA imposes an obligation on all state and federal agencies, including the BLM, to comply with all state and local air pollution requirements. The CAA addresses criteria air pollutants, state and National Ambient Air Quality Standards (NAAQS) for criteria air pollutants, AQRVs such as visibility and deposition, and the Prevention of Significant Deterioration (PSD) program.

Further, the National Environmental Policy Act ([NEPA] Public Law 91-190, January 1, 1970) requires federal agencies to "... promote efforts which will prevent or eliminate damage to the environment ..." and to "... attain the widest range of beneficial uses ... without degradation, risk to health and safety, or other undesirable and unintended consequences ..."

Air quality protection is also a part of the Federal Land Policy and Management Act ([FLPMA] Public Law 94-579, October 21, 1976), which states that "... it is the policy of the United States that ... the public lands be managed in a manner that will protect ... air and atmospheric ... values ..."

In 2011 BLM and other federal land managers including the Environmental Protection Agency (EPA), signed an Memorandum of Understanding (MOU) entitled "Regarding Air Quality Analyses and Mitigation for Federal O&G Decisions Through the National Environmental Policy Act Process".

3.1.1.3. Indicators

This analysis addresses criteria pollutants (carbon monoxide [CO], nitrogen oxide [NO_x], particulate matter less than 2.5 microns in diameter [PM_{2.5}, particulate matter less than 10 microns in diameter [PM₁₀], sulfur dioxide [SO₂], organics and toxics (HAPs and volatile organic compounds [VOCs]), and sulfur and nitrogen compounds, which could contribute to visibility impairment and atmospheric deposition, including acid rain. The analysis also addresses greenhouse gases (GHG) including carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O). The NAAQS set the maximum standards for criteria air pollutants. The CAA provides special protection for air quality and visibility in designated classified areas of the country. National parks larger than 6,000 acres and wilderness areas larger than 5,000 acres that existed or were authorized as of August 7, 1977 receive the highest degree of air quality protection under the CAA. The CAA originally designated the 158 Class I areas, but in 1980 Bradwell Bay, Florida, and Rainbow Lake, Wisconsin were excluded for purposes of visibility protection. In addition to the 156 remaining Class I areas, five Tribal areas have been designated Class I areas, including the Northern Cheyenne area, which is located in Montana just north of the Buffalo planning area. All other wilderness areas (and areas such as national monuments and seashores) are designated Class II. For air quality impact analyses as part of Environmental Impact Statement (EIS) development, the Class II wilderness area may be referred to as a sensitive Class II wilderness area because potential air pollutants could impair air quality concentrations, visibility, or lake acidification in these areas. The CAA's PSD program establishes allowable increases of a given pollutant for a particular area from specific sources. For the purposes of the Resource Management Plan (RMP), no formal PSD increment consumption analysis will be performed since this is handled through the permit process for a particular new source by state or other Federal agencies.

Criteria Air Pollutants

The EPA has established air quality standards for criteria pollutants and identifies them as the NAAQS. Concentrations of air pollutants greater than the national standards represent a risk to human health. Criteria pollutants include CO, nitrogen dioxide (NO₂), ozone (O₃), PM₁₀ and PM_{2.5}, SO₂, and lead.

Wyoming and National Ambient Air Quality Standards

Wyoming Ambient Air Quality Standards (WAAQS) and NAAQS identify maximum limits for criteria air pollutant concentrations at all locations to which the public has access. The WAAQS and NAAQS are legally enforceable standards. Concentrations above the WAAQS and NAAQS represent a risk to human health that by law, require public safeguards be implemented. State standards must be at least as protective of human health as federal standards, and may be more restrictive than the federal standards.

Volatile Organic Compounds and Hazardous Air Pollutants

There are numerous organic compounds in the atmosphere, referred to as VOC, that are emitted from anthropogenic sources, such as petroleum products, paints, stains, etc., and from biogenic sources, such as trees and crops, that act as precursors to O₃ production and secondary aerosol formation. Because of their toxic effects, a subset of these compounds has been designated as HAPs, including benzene, toluene, ethylbenzene, xylene (also referred to as BTEX), N-hexane, and formaldehyde. Although HAPs do not have federal ambient air quality standards (AAQS) (there are exposure thresholds), some states have established "significance thresholds" to

evaluate human exposure for potential chronic inhalation illness and cancer risks. The State of Wyoming has not established AAQS or significance thresholds for HAPs. The EPA regulates the emissions of HAPs from major stationary sources and some minor area sources through the National Emissions Standards for HAPs.

Visibility

Visibility can be expressed in terms of deciviews, a measure for describing perceived changes in visibility. One deciview is defined as a change in visibility that is just perceptible to an average person, which is approximately a 10 percent change in light extinction. To estimate potential visibility impairment, monitored aerosol concentrations are used to reconstruct visibility conditions for each day monitored. These daily values are then ranked from clearest to haziest and divided into three categories to indicate the mean visibility for all days (average), the 20 percent of days with the clearest visibility (20% clearest), and the 20 percent of days with the worst visibility (20% haziest). Visibility can also be defined by standard visual range (SVR) measured in miles, and is the farthest distance at which an observer can see a black object viewed against the sky above the horizon; the larger the SVR, the cleaner the air.

Since 1980 the Interagency Monitoring of Protected Visual Environments (IMPROVE) network has measured visibility in national parks and wilderness areas. There are six IMPROVE stations in Wyoming, including two in the Buffalo planning area — one in the Thunder Basin National Grasslands and one in the Cloud Peak Wilderness.

Atmospheric Deposition

Atmospheric deposition refers to processes by which air pollutants are removed from the atmosphere and deposited into terrestrial and aquatic ecosystems. Air pollutants can be deposited by either wet (precipitation via rain or snow) or dry (gravitational) settling of particles and adherence of gaseous pollutants to soil, water, and vegetation. Much of the concern about deposition is due to secondary formation of acids and other compounds from emitted nitrogen and sulfur species such as NO_x and SO_2 , which can contribute to acidification of lakes, streams, and soils, and affect other ecosystem characteristics, including nutrient cycling and biological diversity.

Substances deposited include:

- Acids, such as sulfuric and nitric, sometimes referred to as acid rain
- Air toxics, such as pesticides, herbicides, and VOCs
- Heavy metals, such as mercury
- Nutrients, such as nitrates and ammonium (NH_4)

The accurate measurement of atmospheric deposition is complicated by contributions to deposition from several components – rain, snow, cloud water, particle settling, and gaseous pollutants. Deposition varies with precipitation and other meteorological variables (e.g., temperature, humidity, winds, and atmospheric stability), which in turn, vary with elevation and time.

Federal land managers, including the United States Forest Service (USFS) and National Park Service, have established guidelines or Levels of Concern (LOC) for total deposition of nitrogen and sulfur compounds in Class 1 Wilderness Areas. Total nitrogen deposition, which includes both wet and dry deposition, of 2.2 kilograms (kg) per hectare (ha) per year or less is considered to be unlikely to harm terrestrial or aquatic ecosystems. For total sulfur deposition, the LOC is 3 kg per ha per year.

Monitoring of Air Quality, Visibility, and Deposition in the Buffalo Planning Area

Various state and federal agencies continuously monitor air pollutant concentrations, visibility, and atmospheric deposition in and near the Buffalo planning area. Table 3.1, “Air Quality Monitoring Sites in and Near the Buffalo Planning Area” (p. 286) lists the air quality monitoring sites in the Buffalo planning area (Sheridan, Johnson, and Campbell counties), as well as sites in adjacent counties (Weston and Converse counties). The Wyoming Department of Environmental Quality (DEQ) operates monitors as part of the State and Local Monitoring Site (SLAMS) network and the Special Purpose Monitoring (SPM) network.

There are two monitors in the IMPROVE network located in the Buffalo planning area – one in the Cloud Peak Wilderness in Johnson County and one in the Thunder Basin National Grasslands in Campbell County. The BLM operates monitors in Johnson County as part of the Wyoming Air Resource Monitoring System (WARMS), including one at the Buffalo site. The Clean Air Status and Trends Network (CASTNet) measures concentrations of nitrogen and sulfur compounds and O₃ at multiple sites in Wyoming. The closest CASTNet sites to the Buffalo planning area are the BLM WARMS monitoring sites at Basin and Newcastle. The Basin site is located north of Worland, and the Newcastle site is co-located with the National Acid Deposition Program (NADP) monitoring site near Newcastle. Data from these sites might not be representative of concentrations in the Buffalo planning area. Atmospheric deposition (wet) measurements of NH₄, sulfate (SO₄), and various metals are taken at the Newcastle monitor, which the BLM operates as part of the NADP. Figure 3.1, “Location of Meteorological and Air Quality Monitoring Sites and Class I and II Areas in Northeast Wyoming” (p. 289) presents a map of northwestern Wyoming and parts of Montana, South Dakota, and Nebraska that includes an outline of the Buffalo planning area, the locations of Class I and II areas, and the locations of the various air quality and meteorological monitors discussed in this analysis.

3.1.1.4. Current Condition

Climate

The climate in the planning area is temperate; it is a semi-arid region with long cold winters and short summers. The major factors controlling climate in the planning area are elevation, strong westerly winds, moisture flow, and mountainous barriers to the west. Elevations in the planning area are both variable and relatively flat, ranging from 3,400 feet along the Powder River at the Montana state line to 6,000 feet at the top of the Pumpkin Buttes; the elevation is 4,544 feet near Gillette and 4,645 feet near Buffalo. The Big Horn Mountains along the western edge of the planning area rise to more than 13,000 feet. In Gillette, monthly average temperatures range from 21.6 degrees Fahrenheit (°F) in the winter to 70.8°F in the summer. Wind speed and direction are highly variable because of the effect of local topography in the planning area. Wind speeds are generally strong and gusts above 40 miles per hour are not unusual. Table 3.2, “Climate Information for the Buffalo Planning Area” (p. 290) lists temperature, precipitation, and wind speed data for the planning area.

Table 3.2. Climate Information for the Buffalo Planning Area

Climate Component	Description
Temperature	Mean maximum summer temperature ¹ : 80.1 °F and 83.0 °F Mean minimum winter temperature ¹ : 14.1 °F and 14.6 °F Mean annual temperature ¹ : 45.3 °F and 46.2 °F
Precipitation	Mean annual precipitation: 13 to 17 inches Mean annual snowfall: 34 and 58 inches
Winds	Mean annual wind speed ² : 9.5 miles per hour Prevailing wind direction ² : north/northwest
Source: Western Regional Climate Center 2013 ¹ Buffalo (site 481165) and Gillette (site 483855) respectively (1981–2010) ² Buffalo (2000–2012) °F degrees Fahrenheit	

Air Quality

Table 3.3, “Applicable National and State Primary Air Quality Standards for Criteria Pollutants and Recent Representative Concentrations for the Planning Area” (p. 290) is an overview of the applicable primary WAAQS and NAAQS and recent representative maximum pollutant concentrations measured in or near the planning area. Figure 3.2, “Representative Maximum Pollutant Concentrations in the Buffalo Planning Area as a Percentage of the NAAQS” (p. 291) shows that the planning area is currently in compliance with all applicable national air quality standards, with the exception of existing PM₁₀ nonattainment area in Sheridan (due primarily to PM emissions from wood stove use in the winter months).

Summary of Air Quality Modeling Studies of the Powder River Basin

During the last decade, a number of studies have been conducted to evaluate the potential effects of emissions from natural resource development sources and activities in the Buffalo planning area, primarily associated with coal and coalbed natural gas (CBNG) development in the Powder River Basin (PRB). Several of these air quality impact assessment studies for the PRB have included air quality modeling and related activities such as the development of comprehensive emission inventories. The studies summarized below exemplify the types of analyses that have

been conducted or are ongoing in the Buffalo planning area that not only include estimates of the expected increases in criteria pollutant emissions from these activities, but also examine their potential future year impacts on air quality concentrations using air quality modeling tools.

PRB-I

In 2002, Argonne National Laboratory conducted an air quality impact assessment for the PRB, referred to as PRB-I (Argonne National Laboratory 2002). The geographic area of interest included the Montana and Wyoming portions of the PRB. The primary focus of the study was to examine potential air quality impacts from CBNG and conventional oil and gas (O&G) development sources in the Wyoming and Montana portions of the PRB. Prior studies focused on Wyoming only and Montana only, but this study was conducted for the two areas combined. At the time of the assessment, development was expected to occur over a 20-year period for the Montana portion of the PRB and over a 10-year period for the Wyoming portion.

The assessment included the application of the CALPUFF air quality model (version 5) using MM5/CALMET-derived meteorological inputs for 1996 and emission inputs for a base year of 2000. The modeling domain included most of Wyoming and Montana and portions of North Dakota, South Dakota, and Nebraska. The assessment focused on criteria pollutants (NO₂, SO₂, CO, PM₁₀ and PM_{2.5}), HAPs, visibility, and atmospheric deposition to lakes (lake chemistry). O₃ was not addressed due to limitations of the CALPUFF modeling system.

CALPUFF was used to estimate direct, indirect, and cumulative near-field and far-field air quality impacts for comparison with air quality standards and PSD increments. The study considered four development alternatives for Wyoming project sources. Near-field modeling focused on project sources located in Wyoming found that:

- For all four alternatives, the concentration increases due to the emissions from the Wyoming project sources are expected to be less than the maximum allowable PSD increments for Class II areas, representing percentages equal to or less than about 32, 3, and 67 percent of the maximum allowable Class II PSD increments for NO₂, SO₂, and PM₁₀, respectively.
- HAPs impacts are expected to be small, except for formaldehyde.

Far-field modeling results indicated that:

- The maximum far-field impacts of criteria air pollutants due to the Wyoming project source emissions were shown to occur at the Northern Cheyenne Indian Reservation, the closest Class I sensitive receptor area.
- The concentration increases in NO₂, SO₂, and PM₁₀ due to the Wyoming project emissions are expected to be less than the maximum allowable PSD increments for all mandatory Class I areas and all alternatives. The concentration increases attributable to the emissions from Wyoming project sources are lower than those attributed to non-Wyoming project source emissions for all criteria pollutants examined.
- The number of days per year with visibility degradation equal to or greater than 1 deciview due to emissions from the Wyoming project sources was estimated to be on average approximately 4 days for the Preferred Alternative (at the sensitive receptors). The highest value (20 days) was modeled at the Crow Indian Reservation under the Preferred Alternative.
- For Florence Lake, the estimated potential change in acid neutralizing capacity (ANC) due to emissions from all sources under the Preferred Alternative is slightly above 10 percent, which is the limit of acceptable change (LAC) threshold for lakes with background ANC values greater than 25 microequivalents per liter (µeq/L), as used for this study. For Upper Frozen Lake, the estimated potential change in ANC is greater than 1 µeq/L, which is the LAC threshold for

lakes with background ANC values less than 25 µeq/L. In both cases, the impact is mostly due to non-Wyoming sources, likely because the lakes are generally upwind of the PRB.

- For other sensitive lakes, the estimated potential changes in ANC due to Wyoming project sources and cumulative sources for all alternative combinations evaluated are less than 10 percent (the applicable LAC threshold for lakes with background ANC values greater than 25 µeq/L).

Finally, the assessment report indicated that mitigation options for NO₂ and fugitive dust were to be considered.

PRB Coal Review

Four studies comprise the PRB Coal Review (ENSR 2005a). These focused on current conditions (for 2002), and cumulative effects for three (at the time) future years including 2010, 2015, and 2020.

Current Conditions

To establish the current conditions, ENSR (ENSR 2005a) prepared a summary of 2002 air quality in the PRB area. The Wyoming portion of the study area included Campbell, Sheridan, and Johnson counties excepting the Bighorn National Forest lands to the west of the PRB, and the northern portion of Converse County. The Montana portion of the PRB study area included portions of Rosebud, Custer, Powder River, Big Horn, and Treasure counties (where coal mines are located).

This assessment of current conditions included the application of the CALPUFF air quality model (version 5) using MM5/CALMET-derived meteorological inputs for 1996 and emission inputs for a base year of 2002. The modeling domain included most of Wyoming, southeastern Montana, southwestern North Dakota, western South Dakota, and western Nebraska. The assessment focused on criteria pollutants (NO₂, SO₂, CO, PM₁₀ and PM_{2.5}), HAPS, visibility, and acid deposition. Impacts from different source groups were evaluated, including CBNG sources, coal-related sources, coal mines, non-coal sources, power plants, Wyoming sources, Montana sources, and all sources.

Modeled impacts of the cumulative sources showed predicted values that were greater than the 24-hour PM₁₀ standards at near-field receptors, both in Wyoming and Montana. These impacts are primarily attributable to nearby sources and result in concentrations that exceed the NAAQS by approximately 15 percent for the Montana receptors and by more than a factor of two for the Wyoming receptors. These impacts only affect the near-field receptors. Modeled impacts of other criteria air pollutants were shown to be well below the NAAQS as well as the individual state AAQS for all receptors. Visibility in Class I and in sensitive Class II areas was affected with impacts above 1 deciview for several modeled days. Impacts on acid deposition were shown to be well below established guidelines.

The CALPUFF results were used to quantify the relative impacts from sources/source categories for each receptor. Results vary by receptor, pollutant and AQRV. Coal-related (and CBNG) sources were shown to have their greatest impacts at the near field receptors. Coal-related sources were estimated to comprise 50 percent or more of the overall (all sources) impact at numerous Class I and Class II receptors. CBNG was associated with up to 30 percent of the coal-related impact – this varied by receptor, pollutant and AQRV.

Cumulative Effects 2010

ENSR (ENSR 2006) conducted additional modeling to examine the effects of Reasonably Foreseeable Development (RFD) for 2010. The modeling approach was the same as that used to establish the current conditions, except that emissions from existing sources were adjusted to represent 2010 levels in accordance with RFD. The types of sources considered included power plants, coal mines, conventional O&G, CBNG, and other coal-related energy development sources.

This study examined two scenarios, a lower production (or development) scenario and a higher production scenario. The study evaluates impacts on air quality and air quality-related values resulting from projected development of RFD activities in the study area. For Wyoming, these include coal mine development as well as coal-related activities (i.e., railroads, coal-fired power plants, major transmission lines, and coal technology projects) and non-coal-related activities (i.e., other mines, CBNG, conventional O&G, major transportation pipelines, and key water storage reservoirs) in the Wyoming PRB study area. For Montana, these include coal mine development and coal-related activities in the Montana PRB study area.

For both development scenarios, the modeled near-field concentrations for all criteria pollutants were shown to increase in accordance with the increase in emissions. Maximum 24-hour $PM_{2.5}$ concentrations for the Wyoming receptors were estimated to be 13 percent higher (compared to current conditions) for the lower development scenario and 31 percent higher for the upper development scenario. Annual $PM_{2.5}$ concentrations for the Wyoming receptors were estimated to be 15 percent higher for the lower development scenario and 35 percent higher for the upper development scenario. The results are similar for the Montana receptors. For both receptor groups (Wyoming and Montana), modeled impacts above the ambient standard occurred at a small number of near-field receptors, and impacts decrease dramatically away from these locations.

Modeled visibility impacts at the identified Class I areas indicated an increase in the number of days with impacts above 1 deciview. The greatest visibility impacts were modeled at Badlands, Theodore Roosevelt, and Wind Cave National Parks, with an increase in the number of days exceeding 1 deciview of less than or equal to 26 days per year. The modeling results indicated a greater increase in the number of days with degraded visibility at certain of the Class II areas, including Agate Fossil Beds National Monument (30 days), Fort Laramie National Historic Site (30 days), and Soldier Creek Wilderness Area (29 days).

For acid deposition of nitrogen and sulfur compounds, the modeling results indicated substantial percentage increases in deposition under the lower and upper development scenarios. Impacts were estimated to be below the threshold values (with the exception of Florence Lake and Upper Frozen Lake). In this study, the modeled impacts were primarily attributable to coal-related sources and power plants, including sources from both Montana and Wyoming.

Model results selected HAPs emissions (benzene, ethyl benzene, formaldehyde, n-hexane, toluene, and xylene) for the 2010 upper development scenario estimated impacts to be above the acute Reference Exposure Level (REL) for formaldehyde at two receptors in Wyoming. The modeled impacts for the 2010 lower development scenario reflected the same patterns as the 2002 base year.

Cumulative Effects 2015

ENSR (ENSR 2008) conducted additional modeling to examine the effects of RFD for 2015. The modeling approach was the same as that used for the current conditions and 2010 analyses, but an updated version of the CALPUFF model (version 5.8) was used and the model inputs were also updated. MM5/CALMET-derived meteorological inputs for 2003 were used. The emissions inputs were derived using 2004 base-year emissions projected to 2015. The types of sources considered included power plants, coal mines, conventional O&G, CBNG, and other coal-related energy development sources.

For the Wyoming near-field receptors, the 24-hour PM_{10} and $PM_{2.5}$ concentrations included localized values that were greater than the NAAQS for the base year (2004), as well as for both development scenarios for 2015. The modeling results for the 2015 development scenarios indicated an increase in concentration of about a factor of two, relative to the base year for these parameters, primarily due to CBNG operations and coal mining activities. Additionally, a 30 to 50 percent increase of annual PM_{10} and $PM_{2.5}$ concentrations at the Wyoming near-field receptors was also predicted. This level of increase would lead to values greater than the annual standards for both PM_{10} and $PM_{2.5}$. Impacts of NO_2 and SO_2 emissions are predicted to be below the NAAQS and WAAQS at the Wyoming near-field receptors.

Modeled impacts at Montana near-field receptors indicated compliance with the NAAQS and the Montana AAQS for all pollutants and averaging periods except the 1-hour NO_2 .

Modeled visibility impacts at Class I and Class II areas showed an increase in the number of days with impacts above 1 deciview, compared to the 2004 base year, by as much as 36 days for the lower development scenario 47 days for the upper development scenario.

For acid deposition of nitrogen and sulfur compounds, the modeling results indicated substantial percentage increases in deposition under the lower and upper development scenarios. Impacts were estimated to be below the threshold values (with the exception of Florence Lake and Upper Frozen Lake). As for 2010, the modeled impacts were primarily attributable to coal-related sources and power plants, including sources from both Montana and Wyoming.

Model results for the base year (2004) and 2015 development scenarios predicted impacts to be well below the acute RELs, Reference Concentrations for Chronic Inhalation, and carcinogenic risk threshold for HAPs. Benzene exposure was predicted to increase by 50 percent as a result of projected PRB development, but even with this increase the risk is below carcinogenic risk thresholds.

Cumulative Effects 2020

AECOM (ENSR 2009b) conducted additional modeling to examine the effects of RFD for 2020. The modeling approach was the same as that used for the 2015 analyses.

For the Wyoming near-field receptors, the modeled impact of the 24-hour PM_{10} and $PM_{2.5}$ concentrations showed localized values greater than the NAAQS for the base year (2004), as well as for both development scenarios for 2020. For the 2020 development scenarios, concentrations of these parameters were shown to increase by a factor of 2.5 relative to the base year, primarily due to CBNG operations and coal mining activities. Annual PM_{10} and $PM_{2.5}$ concentrations at peak Wyoming near-field receptors were shown to increase by about 20 percent, commensurate with modeled values greater than the annual standards for $PM_{2.5}$. Impacts of NO_2 and SO_2 emissions were predicted to be below the NAAQS and Wyoming AAQS at the Wyoming near-field receptors.

Modeling results for the Montana near-field receptors showed compliance with the NAAQS and the Montana AAQS for all pollutants and averaging periods. The 1-hour NO₂ concentrations at Montana near-field receptors were predicted to exceed the AAQS for 2015, but not for 2020. The authors suggest that this is due to a southward relocation of CBNG wells.

Modeled visibility impacts at Class I and Class II areas were shown to increase in the number of days with impacts above 1 deciview, compared to the 2004 base year, by up to 59 days for the lower development scenario and up to 60 days for the upper development scenario.

The model results indicated that the increased deposition, especially from SO₂ emissions from power plants, contributed to modeled values greater than the ANC thresholds at Florence Lake and Upper Frozen Lake. The authors suggest that increased growth in power plant operations (presumably especially upwind of the sensitive lakes) would further reduce the ANC of the sensitive lakes and that this issue should be carefully examined for each proposed future development project.

PRB-II

The modeling and air analysis completed for the 2009 PRB I report were based on a projected level of development that ultimately never came to fruition. As a result, the PRB I analysis is not representative of the current state of air quality or for the future of coal or O&G development in the planning area. The BLM recently completed a subsequent report, PRB II (released February 2014), which included a modeling analysis to characterize future development and air quality impacts in the planning area.

The geographic area of interest for the PRB II study is the Montana and Wyoming portions of the PRB. Types of sources to be considered include CBNG, conventional O&G development sources, and coal in the Wyoming and Montana portions of the PRB. Pollutants of interest are: criteria pollutants (O₃, NO₂, SO₂, CO, PM₁₀, PM_{2.5}), HAPS, visibility, deposition (lake chemistry).

The proposed modeling approach included the use of the Weather Research and Forecasting meteorological model and the Comprehensive Air Quality Model, with Extensions photochemical air quality model. The proposed modeling domain included a high resolution (4-kilometer) grid over the PRB study area. The analysis examined a 2008 base-year and cumulative impacts for future-years of 2020 and 2030. Due to revised O&G development plans within the Buffalo planning area and adjacent areas that were not accounted for in the PRB II air quality analysis, the BLM will not be using the PRB II air analysis to inform planning decisions for the Buffalo RMP or for future O&G projects in the planning area. Air quality modeling analyses that are currently underway for the Converse County EIS (AECOM) and the 2011 base case model being prepared as part of the Three State Data Warehouse Project will include updated RFD and emissions for the planning area. These current modeling efforts will be used to assess current and future air quality within the planning area.

WRAP-III

To support future modeling studies of the area, Environ (2011) conducted an analysis of the criteria pollutant emissions for O&G exploration and production operations in the PRB. This study did not perform modeling. The study focused on emission inventory development only for the year 2006. The emissions totals for the PRB for 2006 are 21,086 tons of NO_x and 14,367 tons of VOC. Overall, compressor engines accounted for approximately 44 percent and drilling rigs accounted for approximately 27 percent of basin-wide NO_x emissions. Pneumatic devices, well

fugitive devices, and compressor engines accounted for approximately 61 percent of basin-wide VOC emissions.

Summary

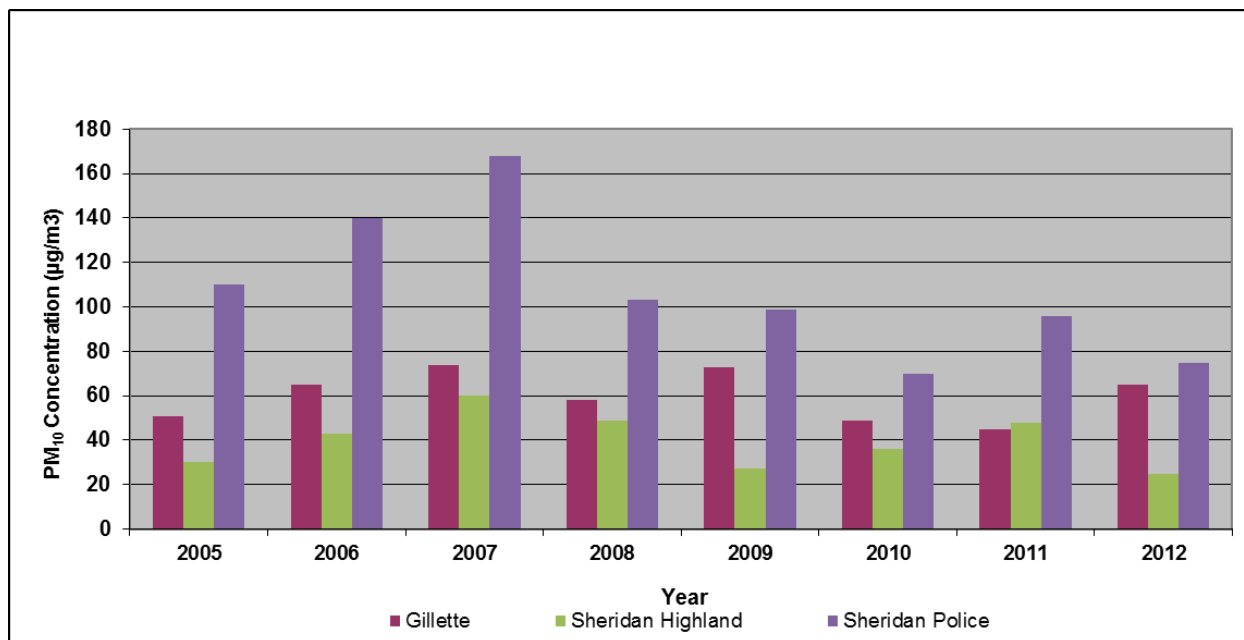

In summary, recent modeling and modeling-related studies of the PRB have provided quantitative information on the potential effects of various development scenarios on air quality and deposition throughout the region as well as the relative contribution of various sources/source categories to air quality impacts. The PRB-I modeling (using CALPUFF) showed that planned development would result in air quality impacts, including some localized values greater than the air quality standards for PM₁₀ and PM_{2.5}, and degraded visibility at nearby Class I and Class II areas. Additional modeling conducted in support of a multi-year coal review study (also using CALPUFF) found that coal-related (and CBNG) sources were shown to have their greatest impacts at the near field receptors. For a base-year of 2002, coal-related sources were estimated to comprise 50 percent or more of the overall impact at numerous Class I and Class II receptors. CBNG was associated with up to 30 percent of the coal-related impact – this varied by receptor, pollutant, and AQRV. Additional modeling for 2010, 2015 and 2020 indicated that RFD would result in air quality impacts, including some localized values greater than the air quality standards for PM₁₀ and PM_{2.5}, degraded visibility at nearby Class I and Class II areas, and increased deposition to sensitive lakes. An additional modeling study (PRB-II) examined impacts for future years of 2020 and 2030. However, due to revised development plans in the planning area and adjacent areas that were not factored into the PRB II air analysis, the BLM does not intend to use the PRB II air analysis to inform the Buffalo RMP or future O&G development in the planning area. Air resources will be managed in accordance with the Buffalo RMP Air Resource Plan, which was developed collaboratively with EPA Region 8 and the Wyoming DEQ-Air Quality Division (AQD).

3.1.1.5. Trends

This section evaluates the recent trends in air quality in the Buffalo planning area by examining criteria pollutant, visibility, and deposition data collected at various monitoring sites in and near the planning area. It should be noted that no statistics were computed to quantify the actual trends or their significance attributes. Rather, all discussions below related to the various trends are derived from simple visual inspection of the data.

Air Pollutant Concentrations

Air quality data collected at a number of monitors in the Buffalo planning area (see Table 3.1, “Air Quality Monitoring Sites in and Near the Buffalo Planning Area” (p. 286)) are presented graphically for PM₁₀, PM_{2.5}, O₃ and SO₂. Figure 3.3, “Peak 24-Hour Average Particulate Matter Concentrations at Selected Sites in the Buffalo Planning Area” (p. 298) shows annual peak 24-hour average PM₁₀ concentrations at the Gillette, Sheridan Highland, and Sheridan Police Station sites for the period 2005 to 2012. Although the peak concentration for 2007 was over the standard at the Sheridan Police Station Site, recent measurements of 24-hour PM₁₀ at this site and other sites shown are well below the standard.

Figure 3.4, “Three-year Average of Annual Mean PM_{2.5} Concentrations for the Buffalo Planning Area” (p. 299) presents the annual mean averaged over three years of PM_{2.5} data collected at the Black Thunder, Belle Ayr, Buckskin, Sheridan Highland Park, and Sheridan Police Station monitors for the period 2005 to 2012. For some of the sites, complete data records were not available until more recent years. Except for the Police Station site, the concentrations measured at the other sites are well below the annual average NAAQS.

Figure 3.5, “8–Hour Ozone Design Value” (p. 300) presents recent design values calculated using monitoring data for the period 2005 to 2012. The O₃ design value is calculated as the 3-year average of the fourth highest observed concentration. The data indicate a slight downward trend for the period 2008 through 2011, with a slight increase in design value calculated for 2012 at both sites.

Monitoring sites at Buffalo and Sheridan as part of the BLM WARMS network provide a summary of observed concentrations of sulfur and nitrogen compounds in the planning area. Figure 3.6, “Weekly SO₂ Concentrations (μg/m³) – Buffalo WARMS Monitor” (p. 301) through Figure 3.9, “Weekly NH₄ Concentrations (μg/m³) – Buffalo WARMS Monitor” (p. 304) present weekly average concentrations of SO₂, SO₄, NO₃, and NH₄, respectively, for the Buffalo site for the period 2003 to 2011. Figure 3.10, “Weekly SO₂ Concentrations (μg/m³) – Sheridan WARMS Monitor” (p. 305) through Figure 3.13, “Weekly NH₄ Concentrations (μg/m³) – Sheridan WARMS Monitor” (p. 308) present similar measures for the Sheridan site for this same period. There are data missing for a number of weeks throughout this period, especially in 2008. The data show weekly and seasonal variations in these compounds at both sites, with no real discernible long-term trends over this period. Observed concentrations of SO₂, SO₄, and NO₃, are consistently higher at the Sheridan site in the northwest portion of the planning area compared to the Buffalo site. Observations of NH₄ are comparable at both sites during this period.

Visibility

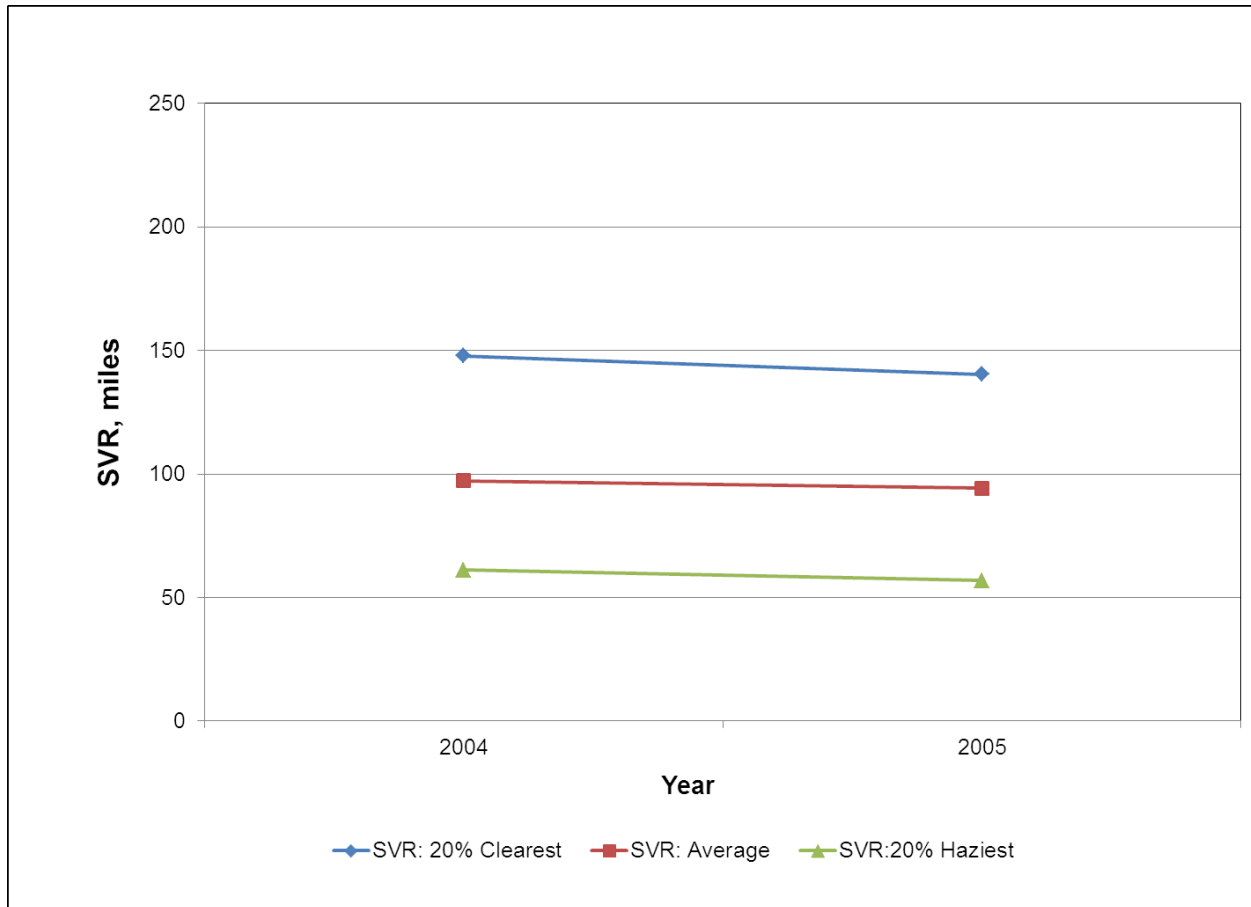

An assessment of the general trends in visibility was conducted by examining weekly and annual average SVR estimates for the Thunder Basin, Cloud Peak, and Badlands IMPROVE monitors. There are several national parks, wilderness areas, national monuments, national memorials, Tribal Areas and national trails in or near the Buffalo planning area. Table 3.4, “Class I and Class II Areas in or near the Buffalo Planning Area” (p. 309) lists these areas, which are designated Class I or Class II areas in accordance with the CAA. Although there are a number of Class II areas in and near the Buffalo planning area, there are no Class I areas in the planning area. The nearest Class I areas are the Northern Cheyenne Indian Reservation, located in southern Montana, and the Wind Cave National Park and Badlands Wilderness Area, both in located South Dakota.

Table 3.4. Class I and Class II Areas in or near the Buffalo Planning Area

Area Type	Area Name	Closest Distance to the Buffalo Planning Area (miles)	Direction from the Buffalo Planning Area	Clean Air Act Designation of the Area
National Park	Wind Cave National Park	110	East	Class I
Recreation Area	Missouri National Recreational River	275	North and East	Class II

Area Type	Area Name	Closest Distance to the Buffalo Planning Area (miles)	Direction from the Buffalo Planning Area	Clean Air Act Designation of the Area
Tribal Area	Northern Cheyenne Indian Reservation	25	North	Class I
Wilderness Areas	Cloud Peak Wilderness Area	In	Western edge of planning area	Class II
	Badlands Wilderness Area	150	East	Class I
National Forests	Bighorn National Forest	In	Near western edge of planning area	Class II
	Black Hills National Forest	20	East	Class II

Historic Trail	Lewis and Clark National Historic Trail	140	North	Class II
National Memorial	Mount Rushmore National Memorial	100	East	Class II
Source: NPS 2006				

As noted above, data collected at the Thunder Basin National Grasslands and Cloud Peak Wilderness IMPROVE monitoring sites have been used indirectly to measure visibility in the planning area. Figure 3.14, “Annual Visibility (SVR) for the Thunder Basin IMPROVE Site” (p. 310) presents visibility data for the Thunder Basin IMPROVE site for the period 2004 to 2005, and Figure 3.15, “Annual Visibility (SVR) for the Cloud Peak IMPROVE Site” (p. 311) presents visibility data for the Cloud Peak IMPROVE site for the period 2003 to 2010. Figure 3.16, “Weekly Visibility (SVR) for the Thunder Basin IMPROVE Site” (p. 312) presents weekly visibility data for the Thunder Basin IMPROVE site for the period 2003 to 2012, and Figure 3.17, “Weekly Visibility (SVR) for the Cloud Peak IMPROVE Site” (p. 313) presents week visibility data for the Cloud Peak IMPROVE site for the period 2003 through 2012. According to the EPA, “In our nation’s scenic areas, the visual range has been substantially reduced by air pollution. In eastern parks, average visual range has decreased from 90 miles to 15-25 miles. In the West, visual range has decreased from 140 miles to 35-90 miles.” A comparison of these numbers and data from the two sites indicates that they are consistent and show very good to excellent visibility ranges in the planning area, even for the 20 percent haziest days. Although there are not enough data to discern trends at the Thunder Basin site, the 8-year record for the Cloud Peak site does show a very slight improvement in visibility during the last four years of this period. These data also show that visibility is consistently better at the Cloud Peak Wilderness site compared to the Thunder Basin site.

In addition to visibility measurements in the Buffalo planning area, Figure 3.18, “Annual Visibility (SVR) for the Badlands National Park IMPROVE Site” (p. 314) presents SVR visibility estimates for the Badlands National Park site located east of the planning area for the period 2003 to 2010, and Figure 3.19, “Weekly Visibility (SVR) for the Badlands IMPROVE Site” (p. 315) presents weekly visibility estimates for the Badlands National Park site east of the planning area for this same period. The visibility estimates for the Badlands site are lower than those for the Thunder Basin and Cloud Peak sites, but there is no discernible trend in visibility during this period at the Badlands monitor.

Atmospheric Deposition

There are no NADP or CASTNet/WARMS stations in the planning area, but wet deposition measurements are available for the Newcastle NADP monitor located just east of the area. Figure 3.20, “Mean Annual Wet Deposition (kilogram per hectare per year) – Newcastle, Wyoming NADP Site” (p. 316) presents mean annual wet deposition for NH_4 , NO_3 , and SO_4 , for the period 2003 to 2012. There are no discernible long-term trends in these measurements over this period. Wet nitrogen deposition (of NH_4 and NO_3) is exceeding the current LOCs at the Newcastle monitor for this period, and wet sulfur deposition does not exceed the LOC at this site during this period.

Hazardous Air Pollutants

Existing sources of HAPs, criteria pollutants, and GHGs in the planning area include fossil fuel combustion that emits HAPs, and oil, gas, and coal development operations that emit VOCs, NO_x, and hydrogen sulfide (H₂S). In addition, large fires are a source of HAPs emissions. The growth in resource development and accompanying increases in emissions from these types of sources will depend on a number of external factors that make it difficult to estimate actual trends in these pollutants in the planning area.

Summary of Air Quality Trends

Available air quality data for recent years for a number of criteria pollutants examined for various monitors in and near the Buffalo planning area do not show any major upward or downward trends over the period of record. Concentrations of PM_{2.5} and the calculated 8-hour average O₃ design values are consistent year to year, without any discernible trends. Although trends were not explicitly calculated for SO₂, SO₄, NO₃, and NH₄, the data do not indicate any major trends for the 10-year period examined for the Buffalo and Sheridan sites. The visibility data collected at the Cloud Peak and Thunder Basin sites show very good to excellent visibility, even for the 20 percent haziest days, with a very slight degradation observed at the Cloud Peak monitor during the last few years of the 10-year period of record. The data collected at the Badlands National Park IMPROVE

site show generally lower estimates of visibility range compared to Cloud Peak and Thunder Basin, with no distinct trend in visibility range during the period 2003 to 2012. Wet-deposition data for NH_4 , NO_3 , and SO_4 , for the Newcastle NADP site east of the planning area also show no distinct trend in deposition over the 2003 to 2012 period examined in this analysis.

3.1.1.6. Climate Change

A growing body of evidence indicates that Earth's atmosphere is warming. Records show that surface temperatures in the Wyoming region have risen approximately 1.5°F since the 1960 to 1979 baseline years (Global Change Research Program 2009). The largest increase in average temperature has occurred in the winter months in the northern portions of the region. Relatively cold days in the region are becoming less frequent and relatively hot days are becoming more frequent (Global Change Research Program 2009). Observed changes in oceans, ecosystems, and ice cover are consistent with this warming trend (National Academy of Sciences 2006). Ongoing scientific research has identified the potential impacts of GHG emissions, including CO_2 , CH_4 , N_2O , water vapor and several trace gases, on global climate change. Through complex interactions at regional and global scales, these GHG emissions cause a net warming of the atmosphere (which makes surface temperatures suitable for life on Earth), primarily by decreasing the amount of heat energy Earth radiates back into space. Although GHG concentrations in the atmosphere and climatic conditions have varied throughout Earth's history, recent industrialization and burning of fossil fuels has caused global atmospheric CO_2 concentration to increase dramatically; this most recent CO_2 increase is likely to contribute to overall climatic changes (National Academy of Sciences 2006).

Global atmospheric concentrations of CO_2 , CH_4 , and N_2O have increased markedly as a result of human activities since 1750 and now far exceed pre-industrial values (as determined from ice cores spanning many thousands of years). The global increase in CO_2 concentrations is due primarily to fossil fuel use and land use change, while those of CH_4 and N_2O are due to agricultural soil management, animal manure management, sewage treatment, and mobile and stationary combustion of fossil fuels (Intergovernmental Panel on Climate Change 2007; EPA 2013a).

According to climate change researchers, the effects of climate change are expected to vary by region, season, and time of day (National Academy of Sciences 2006, Global Change Research Program 2009). Computer model forecasts indicate that increases in temperature will not be evenly or equally distributed, but are likely to be accentuated at higher latitudes. Warming during winter is expected to be greater than during the summer, and increases in daily minimum temperatures are more likely than increases in daily maximum temperatures (National Academy of Sciences 2006). Within a given region, increasing temperatures also could affect the amount of water vapor in the atmosphere, the timing and amount of precipitation, the intensity of storm systems, snow melt, and soil moisture. All of these factors can affect climate, day-to-day weather conditions, plant physiology, and air quality in the planning area.

Based on research compiled for the International Panel on Climate Change Fourth Assessment Report, 2007, (Intergovernmental Panel on Climate Change 2007) potential effects of climate change on resources in the affected environment are likely to be varied. Within North America, the report specifically forecasts that: warming in western mountains is projected to cause decreased snowpack, more winter flooding and reduced summer flows, exacerbating competition for over-allocated water resources; in the early decades of the century, moderate climate change is projected to increase aggregate yields of rain-fed agriculture by 5 to 20 percent, but with important variability among regions; major challenges are projected for crops that are near the warm end

of their suitable range or which depend on highly utilized water resources; cities that currently experience heat waves are expected to be further challenged by an increased number, intensity and duration of heat waves during the course of the century, with potential for adverse health impacts; and coastal communities and habitats will be increasingly stressed by climate change impacts interacting with development and pollution. Specific modeling and/or assessments of the potential effects for the Buffalo planning area and for the State of Wyoming currently do not exist; however, there are downscaled models that can be applied, such as the Northwestern Plains Rapid Ecoregional Assessment (REA) and the 2014 National Climate Assessment (NCA) (<http://nca2014.globalchange.gov/report/regions/great-plains>).

In 2014, the Northwestern Plains REA presented the results of the climate change analysis for this ecoregion. The current or baseline period of 1980 to 1999 was analyzed. The general annual average precipitation pattern for the Northwestern Plains ecoregion is a trend of increasing precipitation from the northwest to the southeast. This trend is not present in the November to February period and is less apparent during the warm rainy season in May and June. The PRB southwest of the Black Hills is another exception as it is relatively drier than the southeastern area of the ecoregion. Figure 3.21, “Current (1980–1999) Total Annual Precipitation (mm)” (p. 320) shows the current total annual precipitation in the Northwestern Plains.

The mean annual temperature pattern in the Northwestern Plains indicates that the southeastern corner of the Northwestern Plains is generally warmer than the rest of the ecoregion. The model shows an exception as an area in south central Montana that is slightly warmer than the surrounding areas during the November to February season.

The NCA released on May 5, 2014 updates the baseline period (1981–2010) for precipitation and temperature. The NCA portrays similar baseline conditions that the REA shows.

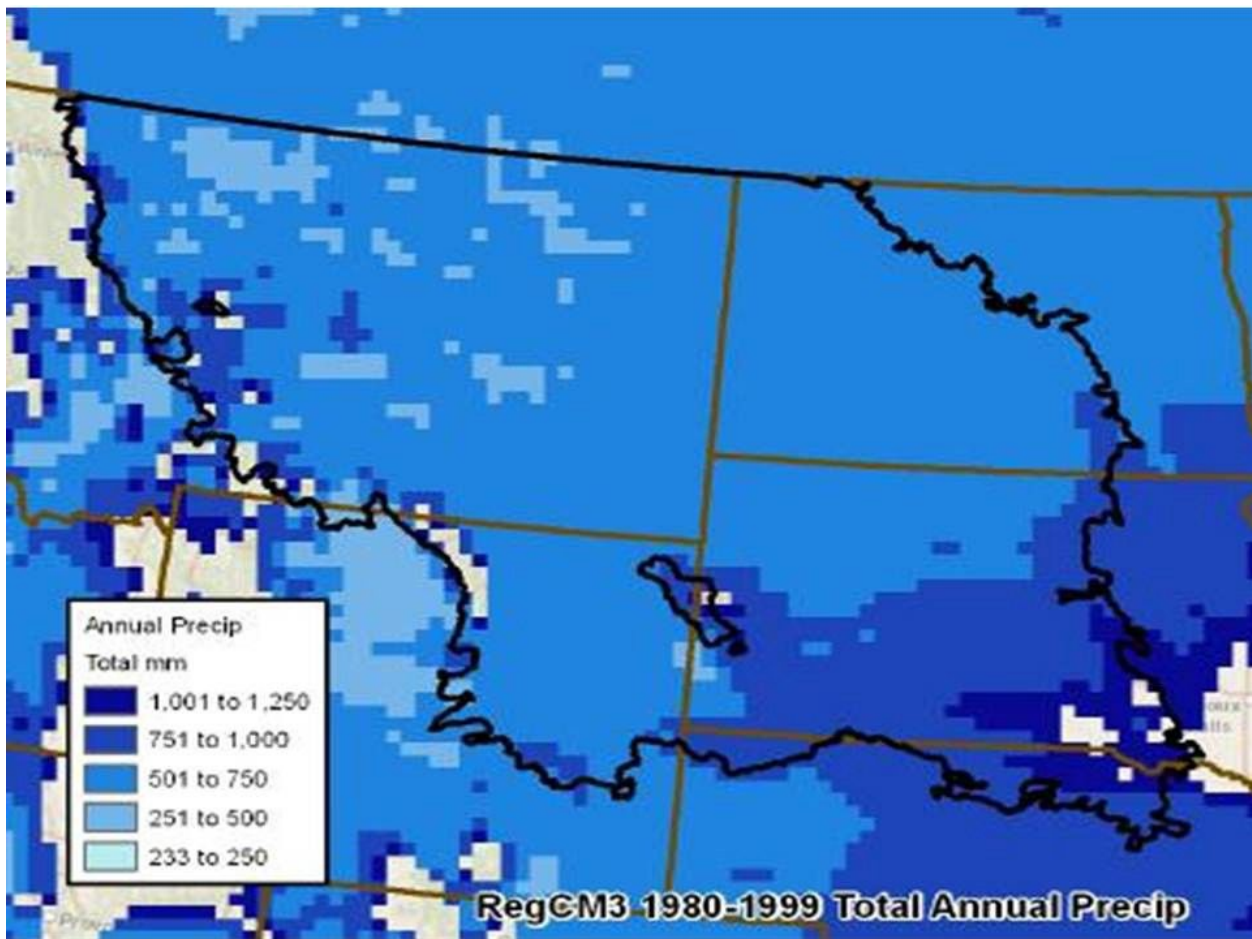

Figure 3.21. Current (1980–1999) Total Annual Precipitation (mm)

The mean annual temperature for existing climate pattern in the Northwestern Plains is presented on Figure 3.22, “Current (1980 - 1999) Mean Annual Temperature (°C)” (p. 321). The climate change model indicates that the southeastern corner of the Northwestern Plains is generally warmer than the rest of the ecoregion. The model shows an exception as an area in south central Montana that is slightly warmer than the surrounding areas during the November to February season.

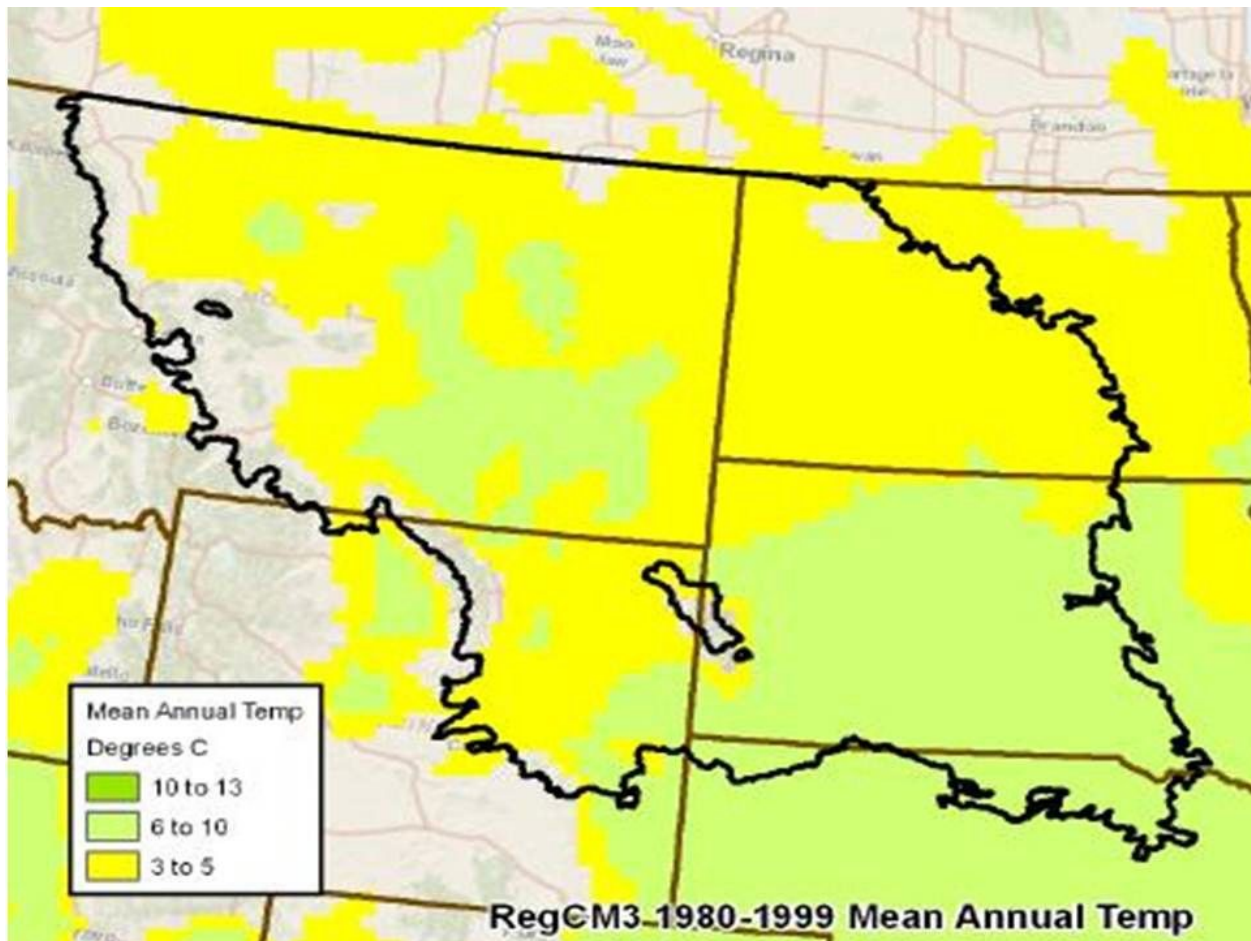

Figure 3.22. Current (1980 - 1999) Mean Annual Temperature (°C)

All of North America is likely to experience an increase in average temperature during the next 100 years, and annual mean warming is likely to exceed global mean warming in most areas (Intergovernmental Panel on Climate Change 2007). Temperatures in the planning area are projected to increase substantially by the end of this century (Global Change Research Program 2009). Summer temperatures in the planning area are expected to increase between approximately 7°F and 10+°F by 2080 to 2099. Overall, temperature in the region that includes the planning area is projected to increase between 2.5°F to more than 13°F compared to the 1960 to 1979 baseline, depending on future GHG emissions (Global Change Research Program 2009). This range of temperature increase reflects the current uncertainty in climate change modeling and represents the likely range of model projections, although lower or higher outcomes are possible.

Increasing temperatures in the planning area are likely to contribute to increased evaporation, drought frequencies, and declining water quantity. The warming of lakes and rivers will adversely affect the thermal structure and water quality of hydrological systems, which will add additional stress to water resources in the region (Intergovernmental Panel on Climate Change 2007). The planning area depends on temperature-sensitive springtime snowpack to meet demand for water from municipal, industrial, agricultural, recreational uses and BLM-authorized activities. The USGS notes that mountain ecosystems in the western United States are particularly sensitive to climate change, especially in the higher elevations, where much of the snowpack occurs, which have experienced three times the global average temperature increase over the past century

(USGS 2010). Higher temperatures are causing more winter precipitation to fall as rain rather than snow, which contributes to earlier snowmelt. Additional declines in snowmelt associated with climate change are projected, which would reduce the amount of water available during summer (Global Change Research Program 2009). Rapid spring snowmelt due to sudden and unseasonal temperature increases can also lead to greater erosive events and unstable soil conditions.

Increases in average summer temperatures and earlier spring snowmelt in the planning area are expected to increase the risk of wildfires by increasing summer moisture deficits (Global Change Research Program 2009). Studies have shown that earlier snowmelts can lead to a longer dry season, which increases the incidence of catastrophic fire (Westerling et al. 2006). Together with historic changes in land use, climate change is anticipated to increase the occurrence of wildfire throughout the western United States.

There is evidence that recent warming is impacting terrestrial and aquatic biological systems (Intergovernmental Panel on Climate Change 2007). Warming temperatures are leading to earlier timing of spring events such as leaf-unfolding, bird migration, and egg-laying (Intergovernmental Panel on Climate Change 2007). The range of many plant and animal species has shifted poleward and to higher elevation, as the climate of these species' traditional habitat changes. As future changes in climate are projected to be even greater than those in the recent past, there will likely be even larger range shifts in the coming decades (Lawler et al. 2009). Warming temperatures are also linked to earlier "greening" of vegetation in the spring and longer thermal growing seasons (Intergovernmental Panel on Climate Change 2007). In aquatic habitats, increases in algal abundance in high-altitude lakes have been linked to warmer temperatures, while range changes and earlier fish migrations in rivers have also been observed (Intergovernmental Panel on Climate Change 2007). Climate change is likely to combine with other human-induced stress to further increase the vulnerability of ecosystems to other pests, invasive species, and loss of native species. Climate change is likely to affect breeding patterns, water and food supply, and habitat availability to some degree. Sensitive species in the planning area, such as the Greater Sage-Grouse, which are already stressed by declining habitat, increased development and other factors, could experience additional pressures as a result of climate change.

More frequent flooding events, erosion, wildfires and hotter temperatures all pose increased threats to cultural and paleontological sites and artifacts. Heat from wildfires, suppression activities and equipment, as well as greater ambient daytime heat can damage sensitive cultural resources. Similarly, flooding and erosion can wash away artifacts and damage cultural and paleontological sites. However, these same events may also uncover and lead to discoveries of new cultural and paleontological localities.

Climate change also poses challenges for many resource uses on BLM-administered land. Increased temperatures, drought and evaporation may reduce seasonal water supplies for livestock and could impact forage availability. However, in non-drought years, longer growing seasons resulting from thermal increases may increase forage availability throughout the year. Shifts in wildlife habitat due to climate change may influence hunting and fishing activities, and early snowmelt may impact winter and water-based recreational activities. Drought and resulting stress on vegetation is likely to increase the frequency and intensity of mountain bark beetle and other insect infestations, which further increases the risk of fire and reduces the potential for sale of forest products on BLM-administered lands.

A variety of activities in the planning area currently generate GHGs. Fuels combustion, industrial processes and any number of other activities on public lands result in direct emissions of GHGs.

Direct emissions in the planning area include those related to current and ongoing O&G and other minerals development, fire events, motorized vehicle use (e.g., OHVs), facilities development, and other fugitive emissions. Contributions to climate change also result from land use changes (conversion of land to less reflective surfaces that absorb heat, such as concrete or pavement), and soil erosion (which can reduce snow's solar reflectivity and contribute to faster snowmelt).

In an effort to address climate change impacts and reduce GHG emissions nationally, the EPA proposed a new rule for existing power plants (Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units) on June 18, 2014. Upon implementation, this rule would achieve CO₂ emission reductions from the power sector of approximately 30 percent from 2005 CO₂ emission levels by 2030. The rule would impact existing power plants within the planning area, the Wyodak and Dry Fork stations, and result in considerable CO₂ reductions.

Climate change science and projections of climate change is a continually growing and emerging science. Additional and recent information on climate change and regional projections of climate change for the planning area can be found through the U.S. Global Change Research Program (<http://www.globalchange.gov/>) and the Intergovernmental Panel on Climate Change (<http://www.ipcc.ch/>).

Several federal initiatives have been launched to improve the ability to understand, predict, and adapt to the challenges of climate change. The Secretary of the Interior signed Secretarial Order 3289 on February 22, 2010, establishing a Department-wide, scientific-based approach to increase understanding of climate change and to coordinate an effective response to impacts on managed resources. The order reiterated the importance of analyzing potential climate change impacts when undertaking long-range planning issues, and also established several initiatives including the development of eight Regional Climate Science Centers. Regional Climate Science Centers would provide scientific information and tools that land and resource managers can apply to monitor and adapt to climate changes at regional and local scales (DOI 2010a). The North Central Climate Science Center, which incorporates the planning area, was established in 2011.

Given the broad spatial influence of climate change which requires response at the landscape-level, the Department of the Interior (DOI) also established Landscape Conservation Cooperatives which are management-science partnerships that help to inform management actions addressing climate change across landscapes. These Cooperatives are formed and directed by land, water, wildlife and cultural resource managers and interested public and private organizations, designed to increase the scope of climate change response beyond federal lands.

REAs are one of the tools the BLM uses to monitor and respond to the effects of climate change. Ecoregional assessments are geospatial landscape evaluations that are designed to identify areas of high ecological value within an ecoregion that may warrant conservation, adaptation, or restoration. These assessments can help to identify resources that are being impacted by climate change and provide information to facilitate the subsequent development of an ecoregional conservation strategy for plants, wildlife and fish communities on public lands. Ecoregional assessments can identify areas, species, and ecological features and services that are sensitive to ecosystem instability and changes in climatic conditions. One of the objectives of the BLM REAs is to provide guidance for adaptation and mitigation planning in response to climate change. The Middle Rockies and Northwest Plains REAs which encompass the planning area, have a tentative release date of April 2014.

In addition to efforts being undertaken to better respond and adapt to climate change, other federal initiatives are being implemented to mitigate climate change. The Carbon Storage Project was implemented to develop carbon sequestration methodologies for geological (i.e., underground) and biological (e.g., forests and rangelands) carbon storage. The project is a collaboration of federal agency and external stakeholders to enhance carbon storage in geologic formations and in plants and soils in an environmentally responsible manner. The Carbon Footprint Project is a project to develop a unified GHG emission reduction program for the DOI, including setting a baseline and reduction goal for the Department's GHG emissions and energy use. More information about DOI's efforts to respond to climate change is available at: www.doi.gov/archive/climatechange/.

In addition to DOI's efforts to address this issue, the EPA has undertaken a number of regulatory initiatives in recent years to reduce GHG emissions. This started in 2009 with a finding under the CAA identifying the key constituent gases that threaten public health and welfare and contribute to climate change. An initiative was developed for mobile sources by setting engine and fuel standards to cut GHGs and fuel use for new motor vehicles, and the implementation of a renewable fuel standard aimed at decreasing oil imports and reducing GHGs. Another initiative addresses stationary sources to limit GHGs for power plants and other large industrial facilities. The EPA also initiated a national GHG emissions reporting program for large emitters. Most recently (2012), EPA finalized regulations to reduce pollution from the oil and natural gas industry which is expected to result in substantial reductions in VOC emissions, air toxics, and CH₄, an important GHG. These actions, initiatives, and regulations will impact activities in the planning area, especially those related to oil and natural gas development, in an overall effort to balance growth in resource development with continued reductions in key GHG emissions.

The Council on Environmental Quality's (CEQ) December 2014 Revised Draft Guidance for Federal Agencies' Consideration of GHG Emissions and Climate Change was proposed while final changes to this Proposed RMP were under way. The CEQ guidance will be considered for conducting analyses of GHGs and climate change impacts. (see: <https://www.whitehouse.gov/administration/eop/ceq/initiatives/nepa/ghg-guidance>).

3.1.2. Geological Resources

3.1.2.1. Regional Context

Most of the Buffalo planning area occurs in the Wyoming portion of the PRB. The PRB is bordered to the west by the Big Horn Mountains, to the south by the Casper Arch, Laramie Range and the Hartville Uplift, and to the east by the Black Hills. The PRB is an asymmetrical syncline with an axis that trends in a general northwesterly direction, and extends from northeastern Wyoming north into southeastern Montana. The PRB formed through a combination of structural deformation and infilling. Thick sedimentary deposits, which include some of the largest known deposits of coal in the world, overlie Precambrian-age crystalline basement rock in the PRB; the deepest sedimentary rocks are found along the basin axis (close and approximately parallel to the Big Horn Mountains) and could be more than 18,000 feet thick (Tryhorn 1987). Numerous areas of geological beauty and interest occur in the planning area, including the Red Wall (tilted red sandstone exposed in the southern Big Horns), cave and karst-formations (areas of limestone and dolomite in the southern Big Horns), the Pumpkin Buttes (several largish relatively-flat butte-like erosional remnants near the Powder River), Dry Creek Petrified Tree Environmental Education Area (EEA) (area containing exposed logs and trunk portions of petrified trees), and numerous scoria hills (small butte-like to ridge-like erosional remnants capped by reddish clinker). Refer

to the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more detailed geological information for the Buffalo planning area.

3.1.2.2. Indicators

None of the geological features occurring on public lands in the Buffalo planning area are considered unique enough to be under special management or conservation measures. However, caves will be managed under cave management plans, as discussed in *Cave and Karst Resources*. The Dry Creek Petrified Tree EEA area is a unique feature, and is under special management due to its special paleontological value, as discussed in *Paleontological Resources*. Coal is not a unique occurrence, however the very large amount of coal present in the PRB is fairly unique (see *Leasable Minerals – Coal* for more information). Crude oil and natural gas are similarly not unique occurrences, but the large volumes of crude oil and natural gas, and especially the volumes of natural gas contained in the coals in the PRB is fairly unique (see *Leasable Minerals – Fluids* for more information).

As there are no key geological features in the planning area, there are no factors that relate their changing condition. However, mass wasting (i.e., rock falls, landslides, slumps, etc.) and other erosional processes can alter external topography and some landforms in the planning area, and coal seam fires often occur in the PRB (see *Health and Safety*). The remaining geological resources in the planning area are minerals (see *Mineral Resources* and the individual mineral resource categories for information regarding indicators for the mineral resources). Mineral resources currently being developed in the planning area include coal, crude oil, natural gas (including CBNG), Wyoming-type bentonite, uranium, aggregate (sand and gravel), clinker (porcellanite; locally called “scoria” due to its sometimes resembling that volcanic rock), moss rock, and stone. Other minerals are known to occur in the planning area (e.g., gypsum, geothermal resources, rare earth elements [REEs], and many others), however these have not been economically feasible to develop. Based on economic forecasts, that situation is not expected to change during the planning period (see *Mineral Resources*).

3.1.2.3. Current Condition

The minerals currently being explored for and developed in the planning area are coal, crude oil, natural gas (including CBNG), Wyoming-type bentonite, uranium, sand, gravel, clinker (porcellanite; locally called “scoria”), and stone. See *Mineral Resources* for more information on these minerals. Coal, oil, and natural gas are extremely important mineral commodities in the PRB; extraction of these minerals and ranching are the biggest income-producing industries in the planning area (see *Social and Economic Resources*). Over 80 percent of all coal mined on federal lands in the United States comes from the Buffalo planning area. See also *Leasable Minerals – Coal* and *Leasable Minerals – Fluids* for more information regarding these resources. Table 3.5, “Some Important Mineral-bearing Formations in the Buffalo Planning Area” (p. 326) lists some of the most important mineral-bearing rock and rock strata in the planning area (generally listed from youngest to oldest, and from least to greatest depth) (Love et al. 1993).

Table 3.5. Some Important Mineral-bearing Formations in the Buffalo Planning Area

Strata Name	Geological Age	Description
Alluvium (sand and gravel deposits)	Quaternary	Sand and gravel eroded from Paleozoic- through Precambrian-aged rocks in the Big Horn Mountains is found in terrace deposits scattered across much of the surface of the planning area. See <i>Salable Minerals</i> .
Clinker (Porcellanite; locally called “Scoria”)		Numerous areas of reddish, relatively resistant clinker (porcellanite; called “scoria” locally) occur across the planning area, often as outcrops capping hills and ridges. Clinker forms when the rock and sediment overlying a burning coal seam become baked by the heat being produced. Clinker's sometimes melted and vesicular (bubbly-looking) texture can make it hard to distinguish from true scoria (a melted-looking and often vesicular volcanic rock), hence its local nickname. See <i>Salable Minerals</i> .
White River Formation	Oligocene	Only a few outcrops of this formation occur in the planning area; these cap the Pumpkin Buttes. Known to contain important fossils and has a high Potential Fossil Yield Classification. See <i>Paleontological Resources</i> .
Wasatch Formation	Eocene	Approximately 45% of the surface outcrops in the planning area.
		Contains numerous coal seams of varying thickness, quality, and areal extent. Natural gas often forms within these coals (coal-bed natural gas, or CBNG), and CBNG can be found almost everywhere in the Powder River Basin where coal is found. See also <i>Leasable Minerals – Coal</i> and <i>Leasable Minerals – Fluids</i> .
		Contains numerous areas of clinker, often as outcrops capping hills and ridges. See <i>Salable Minerals</i> .
		Contains sandstone beds and lenses that can have “roll-front” deposits of uranium; these formed where dissolved uranium carrying along by groundwater solidified, usually where it contacted carbon-rich areas in the sandstones. See <i>Locatable Minerals</i> .
Fort Union Formation	Paleocene	Contains much of the petrified wood found in the Powder River Basin, including that in the Dry Creek Petrified Tree EEA (see <i>Paleontological Resources</i>).
		Approximately 30% of the surface outcrops in the planning area.
Fort Union Formation	Paleocene	Like the Wasatch Formation, also contains numerous coal seams of varying thickness, quality, and areal extent, which also often contain CBNG. Almost 40% of U.S. coal currently mined comes from the Wyodak-Anderson coal zone. See <i>Leasable Minerals – Coal</i> and <i>Leasable Minerals – Fluids</i> .
		Clinker occurs in numerous areas, mostly where coal seams became exposed along the Powder River Basin margins and burned; for example, the Rochelle Hills east of Gillette and Wright formed by natural burning of the Wyodak-Anderson coal zone. See <i>Salable Minerals</i> .
Fox Hills Sandstone	Upper Cretaceous	This sandstone varies in thickness and quality throughout the Powder River Basin, and serves as the major fresh-water aquifer in the planning area. For this reason, it is protected during activities that could adversely affect it, such as oil and gas development. See <i>Water Resources</i> , and <i>Leasable Minerals – Fluids</i> .
Frontier Formation and underlying Mowry Shale	Upper Cretaceous	The Clay Spur Bentonite bed occurring near the contact between these two formations is the main source of Wyoming-type bentonite mined in the planning area; thinner beds in the Frontier Formation are also mined. See <i>Locatable Minerals</i> .
		The lower portion of the Mowry Shale contains crude oil. See <i>Leasable Minerals – Fluids</i> .

Strata Name	Geological Age	Description
Gypsum Spring Formation	Jurassic	Contains numerous gypsum beds of varying thickness, quality, and areal extent. See <i>Locatable Minerals</i> .
Parkman Sandstone	Upper Cretaceous	These formations are the most prolific and most widespread crude oil-producing formations in the Powder River Basin; they can also yield natural gas. However, some of these formations can have “pools” (reservoirs) of crude oil/natural gas that tend to be more localized.
Sussex Sandstone		
Shannon Sandstone		
Muddy Sandstone	Lower Cretaceous	Other formations also yield oil and gas in the Powder River Basin, but the pools within those formations tend to be more localized than in those formations listed.
Dakota and Lakota Sandstones		
Minnelusa/Tensleep Sandstone	Pennsylvanian	See <i>Leasable Minerals – Fluids</i> .

EEA Environmental Education Area		

Although there is some potential for geothermal energy development in the planning area, current knowledge of this resource leads to the belief that it is not, and may never be, economically viable for most current commercial uses due to the relatively low temperatures measured even at relatively great depths (120°F or 49 degrees Celsius [°C] at over 8,000 feet near the western PRB margin, to 185°F or 85°C at over 12,000 feet near the PRB axis [WOGCC 2010]). The relatively great thickness of the sedimentary rocks in the PRB (possibly up to 18,000 feet [Tryhorn 1987]) and the non-volcanic/non-igneous formation history of the Big Horn Mountains, leads to the relatively low bottom-hole temperatures seen in deep oil/gas wells. Although some commercial uses of low-temperature geothermal energy (up to 194°F or 90°C) can be economically viable (BLM 2008e), the depth where the higher temperatures occur are likely too deep to make development economically feasible (BLM 2008d; Williams et al. 2008; DOE 2006; National Oceanic and Atmospheric Administration 1983). No commercial low-temperature geothermal energy projects are known to exist in the planning area, although many of these types of projects could be incompatible with current land uses. Most knowledge of this resource comes from bottom-hole temperatures (the temperature measured at the deepest point in a wellbore) in O&G wells, and very little geothermal exploration has been performed in the planning area (Williams et al. 2008; DOE 2006; National Oceanic and Atmospheric Administration 1983). Only with more exploration will the extent of this resource in the planning area, and the likelihood for its development, become more fully understood. To date, no lands in the planning area have been nominated for competitive geothermal leasing, nor have any leases or nominations for leases for geothermal energy been received for the planning area. See *Leasable Minerals – Fluids*.

There is some potential for REEs in the planning area, although current knowledge of this resource is limited to mostly unconfirmed reports of occurrences and geochemical analyses. The likelihood of REE development in the planning area is very low. See *Locatable Minerals* for more information.

Carbon dioxide sequestration projects, also called Carbon Capture and Storage (CCS) projects, are dedicated solely to sequestering carbon by injecting it subsurface for long-term isolation and storage. This is thought to keep GHGs, such as CO₂, from entering the atmosphere, potentially to slow down the rate and severity of global climate change. These projects involve injecting liquefied CO₂ into the underground pore spaces that exist in rocks subsurface, or into other rocks types or conditions that may accept injection of this substance. None of these projects exist on

public lands in the planning area, nor have any proposals for such projects been received by the BFO. However, due to climate change-related legislation, sequestration (long-term storage) of this GHG is being studied and researched. The geological formations currently identified as being most suitable for CO₂ sequestration are unmineable coal seams, depleted O&G reservoirs, and saline geological formations (Burruss et al. 2009; Intergovernmental Panel on Climate Change 2005). There are numerous O&G reservoirs and unmineable coal seams, and several saline geological formations, in the PRB. Wyoming and several other U.S. states are thought to be ideal for CO₂ sequestration projects: they have relatively high potential CO₂ storage capacity in “suitable” formations (such formations tend to be relatively common formations in these states), and they have relatively “quiet” geological settings (they tend to have fewer earthquakes/earth movements, and of lower magnitudes) (Intergovernmental Panel on Climate Change 2005). The current BLM direction regarding CO₂ sequestration projects on public lands is that they would be handled as Land Use Applications and Permits, which are types of rights-of-way (ROWs) (Washington Office [WO] Instruction Memorandum [IM]-2012-035). See *Lands and Realty*.

Injection of CO₂ for the purpose of enhanced oil recovery (EOR) in oil wells has been, and continues to be, a relatively common practice in the PRB and elsewhere. Several CO₂ pipelines exist in the PRB to supply this gas to a number of areas in the basin for this purpose. However, CO₂ used in EOR is recovered and reused, again and again. Most CO₂ used in EOR is recoverable, and relatively little tends to remain in the formation(s) it was injected into, and therefore is not considered a CCS technique. See *Leasable Minerals – Fluids*.

There are a number of geological and other natural hazards in the planning area, including coal seam fires, ground subsidence, H₂S gas, abandoned mine lands (AMLs), and landslides. See *Health and Safety* for more information.

3.1.2.4. Trends

As discussed above, the geological resources managed in the Buffalo planning area consist of mineral resources. See *Mineral Resources* for information regarding trends for the various individual mineral resources.

As the development of alternative energy sources increases in the United States and worldwide, it could become economically viable to develop the low-temperature geothermal resources in the PRB in the future, even at the relatively great depths at which it occurs. If geothermal resources in the planning area become a development target in the future, the BFO would administer this resource in a manner similar to that of other field offices with existing geothermal energy programs (see *Leasable Minerals – Fluids*).

Almost the entire PRB could be targeted for CO₂ sequestration, or CCS, projects. These projects are intended solely to sequester carbon, keeping it out of the atmosphere, which is thought to reduce GHGs. These types of projects do not include those in which injection of CO₂ occurs for EOR purposes (to enhance the recovery of oil from oil wells). The geological formations currently identified as being most suitable for CO₂ sequestration are abundant throughout the entire PRB. Although no CO₂ sequestration projects have been proposed for public lands in the planning area, it is quite likely that such projects may be proposed in the future. The current guidance is that these types of projects would be handled as Land Use Applications and Permits, a type of ROW – see *Lands and Realty*. See *Leasable Minerals- Fluids* regarding CO₂ injection for the purpose of EOR.

The geological and natural hazards in the Buffalo planning area, and their changing conditions and trends, are addressed in *Health and Safety*.

3.1.2.5. Key Features

As discussed under Regional Context and Indicators, above, key geological features are discussed in other sections such as *Paleontological Resources* (Dry Creek Petrified Tree EEA) and *Cave and Karst* (caves and karst areas). Mineral-related features, such as coal, O&G, Wyoming-type bentonite, uranium, aggregate (sand and gravel), and clinker (porcellanite; locally called “scoria”) are discussed in *Mineral Resources*, and the individual mineral sections under that heading (*Leasable Minerals – Coal*, *Leasable Minerals – Fluids*, *Locatable Minerals*, and *Salable Minerals*).

3.1.3. Soil

Information in the following soils section is based on the best available science which is currently available through the Natural Resources Conservation Service (NRCS) soil survey data (NRCS 2011a). On a regional level, general State Soils Geographic Database (STATSGO2) was reviewed and incorporated as appropriate. Smaller scale information Soil Survey Geographic Database (SSURGO) was also reviewed and incorporated as appropriate into document sections below. Additional pertinent information from NRCS, BLM, academic, and regional expert sources on specific soil management issues may be reviewed, verified and incorporated on a project specific basis as needed, but may not be included or referenced in this document.

BLM soil program guidance is established under BLM Manual Section 7100, Soil Resource Management, which focuses on BLM’s relationship with the National Cooperative Soil Survey and describes program goals and objectives, organization, management roles and responsibilities, and applicable authorities and regulations. BLM Handbook H-7100-1 Soil Inventory, Monitoring, and Management (Final Draft September 21, 2010) provides BLM personnel with information, guidance, and direction related to the inventory, monitoring, assessment, and management of soil resources on public lands. To help implement the many laws, rules, and regulations, the BLM Soil Program relies on various guidance documents developed by BLM and other agencies. Additional BLM soil resource information is available in the soil resources section of the BLM Soil, Water, and Air Program (<http://www.blm.gov/wo/st/en/prog/more/soil2/soil2.html>), and the BLM soil web page (<http://www.blm.gov/nstc/Soil2007/index.html>).

3.1.3.1. Regional Context

The planning area’s soils are grouped geographically by Land Resource Regions (LRRs) and Major Land Resource Areas (MLRAs) for descriptive purposes. LRRs are geographically associated MLRAs which approximate broad agricultural market regions. Identification of these large areas is important in statewide agricultural planning and has value in interstate, regional, and national planning. The MLRA concept guides the development of cooperative soil survey work on BLM-administered lands. The planning area is located predominately in LRR G (Western Great Plains and Irrigated Region) and E (Rocky Mountain Range and Forest Region). The dominant MLRA within LRR G is 58B (Northern Rolling High Plains Southern Part) with soils that formed in alluvium, eolian sediments, colluvium, or residuum on fans, terraces, hills, and plateaus. MLRA 43B (Central Rocky Mountains) is dominant in LRR E and is comprised of soils that formed in colluvium, residuum, and glacial till on mountain sideslopes and ridges.

3.1.3.2. Indicators

Indicators are soil characteristics that are sensitive to change in the environment that reflect changes in soil quality. According to the NRCS, oil quality is the capacity of a specific kind of soil to function within natural or managed ecosystem boundaries to do the following: sustain plant and animal productivity; maintain or enhance water and air quality; and support human health and habitation. Soil quality is measured quantitatively and/or qualitatively. The biological, physical, and chemical properties, processes and characteristics as well as plant features are evaluated to determine soil quality.

Soil quality reflects both inherent and dynamic properties. The NRCS defines the inherent soil quality property as the natural ability of the soil to function. Inherent soil properties form over thousands of years with soil-forming processes and change very little as a result of management practices. Many inherent properties are described by soil surveys and can be used to develop local interpretations for suitable uses and limitations. Dynamic soil properties are readily affected by management practices and natural disturbances, including drought, over relatively short time scales. By linking biological, physical, and chemical properties of soil, all of the components and interactions of a soil system are viewed together. The selection of method(s) to assess soil quality will depend on the intended use of the information, the time and resources available, the ease with which the information can be obtained, and any regional, local, or site-specific considerations.

The primary attributes for assessing soil quality currently used in the BFO are soil/site stability, hydrologic function, and biotic integrity described in “Interpreting Indicators of Rangeland Health” (see TR 1734-6). Observed indicator ratings are used to help determine the degree of departure from the Reference Sheet for each attribute. Qualitative and quantitative soil indicators are used to determine if rangeland conditions are achieving the land use plan objectives and Wyoming’s Rangeland Health Standards and Guidelines. Reclamation success is evaluated on a site specific case-by-case basis. BLM’s Wyoming Reclamation Policy also provides guidance to help maintain healthy productive soils, while maintaining an effective multiple-use land management program.

3.1.3.3. Current Condition

Soils in the planning area are diverse; great differences in soil properties can occur within short distances. The distribution and occurrence of soils is dependent on a number of factors including the interaction of relief (slope), parent material, living organisms, climate, and time. These variables create complex and diverse soil patterns that influence the use and management of the soil resource.

Generally, there is not a direct demand for soil resources from public lands in the planning area. Primarily demands placed on soil resources are surface-disturbing activities associated with the development of other resources. The most important regional or national demand placed on soils in the planning area results from the development of mineral resources. Locally other actions that affect soils include a variety of surface uses that loosen topsoil and remove vegetation or other ground cover, such as overgrazing and over browsing by animals, off-highway vehicle (OHV) use, development of trails and campgrounds, ROW, fire-suppression activities, and the use of prescribed fire.

General soils information for the planning area was obtained from the United States General Soils Map (NRCS 2006) which is designed primarily for regional, multi-state, river basin, state,

and multi-county resource planning, management and monitoring. STATSGO2 data provides a general overview of soils distribution and occurrence in the planning area, and is not suitable for site-specific evaluations. Detailed information is available from the SSURGO Database for the individual soil surveys within the planning area. These individual soil surveys include, Soil Survey of Southern Campbell County (WY605), Soil Survey of Northern Campbell County (WY705), Soil Survey of Southern Johnson County (WY619), Soil Survey of Northern Johnson County (WY719) (preliminary data), Soil Survey of Sheridan County (WY 633) and the Soil Survey of Bighorn National Forest (WY 650). These soil surveys were performed by the NRCS according to National Cooperative Soil Survey standards, policies and procedures, and were conducted at the second and third order of detail. For site-specific analysis, onsite soil investigations and detailed soils information should be considered in all resource management decisions.

According to the NRCS (Code of Federal Regulations [CFR] Chapter VI - NRCS, USDA, Subchapter F - Support Activities, Part 657 - Prime and Unique Farmlands Subpart A - Important Farmlands Inventory), prime farmland is land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops and that is available for these uses. It has the combination of soil properties, growing season, and moisture supply needed to produce sustained high yields of crops in an economic manner if it is treated and managed according to acceptable farming methods. In general, prime farmland has an adequate and dependable water supply from precipitation or irrigation, a favorable temperature and growing season, an acceptable level of acidity or alkalinity, an acceptable content of salt or sodium, and few or no rocks. Its soils are permeable to water and air. Prime farmland is not excessively eroded or saturated with water for long periods of time, and it either does not flood frequently during the growing season or is protected from flooding. By definition, no prime farmlands currently occur on BLM-administered lands within the planning area. However, some areas could qualify as prime farmland if there is a dependable water supply. Dependable irrigation water is usually lacking on BLM-administered lands. Areas identified as "prime farmland if irrigated" on BLM-administered surface are generally along major drainage in the South Johnson and Sheridan County Soil Survey areas. The BLM Welch Management Area has adjudicated water rights and has the potential to be irrigated. This property will have a management plan developed which may include irrigation as a management option. There are potentially 546 acres, less than 1 percent of the planning area that is described as being "prime farmland if irrigated."

Unique farmland is land other than prime farmland that is used for the production of specific high value food and fiber crops. It has the special combination of soil quality, location, growing season, and moisture supply needed to economically produce sustained high quality and/or high yields of a specific crop when treated and managed according to acceptable farming methods. Examples of such crops are citrus, tree nuts, olives, cranberries, fruit, and vegetables. By definition according to the CFR above, no unique farmlands occur within the planning area.

The storm water discharge requirements under the Wyoming Pollutant Discharge Elimination System (WYPDES) have been imposed for most surface-disturbing activities that would affect one acre or more. Storm water discharge permit requirements have reduced erosional impacts caused by major surface-disturbing activities. (http://deq.state.wy.us/wqd/WYPDES_Permitting/WYPDES_Storm_Water/stormwater.asp)

3.1.3.4. Trends

As stated above, the primary attributes for assessing soil quality are soil/site stability, hydrologic function, and biotic integrity. Most soils in the area are capable of producing forage for

wildlife and livestock, maintaining infiltration and runoff protective of watershed condition, and recovering from impacts associated with surface-disturbing activities. Major soil resource concerns in this region are surface disturbance associated with the development of other resources. Any surface-disturbing activity has a potential to increase annual soil loss beyond a level to which it would be productive for plant growth. The amount of impact to the soil resource is site specific. The anticipated trend for impacts to the soil resources can be inferred with the predicted reasonable foreseeable development discussed in this document. The reasonable foreseeable development for the planning area is shown in Table G.1, “RFA-1A Reasonable Foreseeable Development Assumptions: Oil and Gas” (p. 1938) and Table G.2, “RFA-1B Reasonable Foreseeable Development Assumptions: Other Resource Uses” (p. 1942). Site-specific Best Management Practices (BMPs) and successful reclamation will lessen adverse impacts to the soil resources from the predicted actions.

3.1.3.5. Key Features

Key features are areas that require special management practices to prevent adverse impacts to soil quality. Water and air quality can be impacted by soil quality. For instance, wind-blown soil particles degrade air quality, while excessive sediment in water bodies impairs water quality (BLM 2010a). Key features identified in the planning area include soils with poor reclamation suitability, highly erodible soils, Limited Reclamation Potential (LRP) areas, and soils on steep slopes.

Successful reclamation efforts are critical in maintaining a multiple use land management program. Reclamation suitability is based, in part, on the inherent ability of the soil to recover from impacts; often referred to as soil resilience. Suitability factors include physical and chemical properties to consider for successful reclamation. These limiting features include clayey and sandy textures, drought conditions, shallow depth to bedrock, stones and cobbles, erosion potential, low organic matter content, alkalinity and pH, salinity, and sodium content. (Poor Reclamation Suitability) Sometimes the soil limitations may require additional mitigation to meet reclamation goals and objectives. According to existing NRCS Order 3 soil mapping, 58 percent of the BLM surface (40% of the federal mineral estate) contain some portion of areas having poor reclamation suitability (See Map 5).

There are areas in the planning area that are identified as having highly erodible soils. Highly erodible soils are those soils which are susceptible to wind or water erosion in either their natural or disturbed state (See Map 3.) For purposes of this analysis, elements used to determine highly erodible soils are slope, surface soil K factor, and wind erodibility group (WEG). However, it should be noted that K factors are also assigned to soil horizons deeper in the profile; at the project specific level, it may be useful to evaluate these deeper K factors. Potentially 28 percent of BLM surface and 17.5 percent of the federal mineral estate have surface properties identified as being highly erodible (wind or water).

The K factor (K_f for fine earth fraction or K_w for whole soil) indicates the susceptibility of a soil to sheet and rill erosion by water. This is based on percentage of silt, sand, organic matter, surface soil structure and saturated hydraulic conductivity (K_{sat}). Values of K range from 0.02 to 0.69. Other factors being equal, the higher the value, the more susceptible the soil is to sheet and rill erosion by water. Severe water erosion hazards for each Soil Mapping Unit (SMU) were identified using the k-factor and representative slope percentage (Rv Slope) assigned to each SMU. These values are available in the soil characteristic tables in the soil surveys, published by the NRCS. Based on regional experts, SMUs with an erosion index ($k_w \times R_v \text{ Slope}$) greater than or equal to 7.0, are considered to be susceptible to water erosion.

Severe wind erosion hazards for each SMU were identified by using the WEG assigned to each SMU. WEG, is a numerical value indicating the susceptibility of soil to wind erosion. There is a close correlation between wind erosion and the texture of the surface layer, the size and durability of surface clods, rock fragments, organic matter, and a calcareous reaction. Soil moisture, frozen soil layers, slope and other factors may also influence erosion. There are nine WEG groupings: 1, 2, 3, 4, 4L, 5, 6, 7, and 8. The lower the number, the greater the risk of wind erosion. These groupings are also available in the soil characteristic tables in the Soil Surveys, published by the NRCS. SMUs with a WEG of 2 and less are considered susceptible to wind erosion.

LRP areas, according to the BLM statewide reclamation policy, are defined as areas possessing unique landscape characteristics (e.g., sensitive geologic formations, extremely limiting soil conditions, biological soil crusts, badlands, rock-outcrops, etc.) that often make reclamation success impractical and/or unrealistic due to physical, biological, and/or chemical challenges. In the BFO LRP areas are identified through analysis of NRCS SSURGO data, and onsite investigation. LRP areas are displayed thematically in the NRCS soil survey SSURGO data as “miscellaneous areas.” The NRCS SSURGO thematic data display includes, but is not limited to, badlands, gullied lands, and rock outcrop. Other potential LRP’s include areas susceptible to mass movement, areas with biologic soil crusts, very shallow ecological sites or other areas identified through onsite investigation as having properties that make meeting all the requirements of reclamation unrealistic or impossible. Areas that have additive key features, described in this section, that make successful reclamation impractical or impossible may also be considered LRP areas. Current analysis indicates potentially 8 percent of BLM surface and 4 percent federal mineral estate contain LRP areas. Map 6 shows areas that potentially contain a component of LRP areas.

Soils on steep slopes are another key feature in the planning area (Map 4). Slope gradient is the difference in elevation between two points, expressed as a percentage of the difference between those points. Slope is a component in determining water erosion potential, slumping, mass wasting, and landslide potential. Slope impacts total disturbance calculations and potential cut and fill depths for surface-disturbing activities. Current analysis indicates 22% of BLM surface and 10% federal mineral estate have slopes equal to or greater than 25%.

Key features will be identified using NRCS soil survey SSURGO data and onsite evaluations. Criteria used to determine soil sensitivity to surface uses would continually be adapted as conditions change or new information or technology becomes available that enhances the understanding of the above susceptible soils.

3.1.4. Water Resources

3.1.4.1. Regional Context

The planning area is comprised of six major watersheds that collect and convey surface water out of the region. These are the Belle Fourche River, Little Bighorn River, Cheyenne River, Little Missouri River, Powder River, and Tongue River. These rivers are fed by numerous smaller drainages, most of which are ephemeral or intermittent. Groundwater also plays an important role in the planning area. Numerous groundwater aquifers are present in the planning area at a wide range of depths, in varying geologic conditions, and water quality levels. Regulatory issues regarding water in the planning area are largely handled by the Wyoming DEQ and the Wyoming State Engineers Office (WSEO).

3.1.4.2. Indicators

This section identifies indicators of the condition of water resources in the planning area and the sources of those indicators.

Natural processes and human actions influence the chemical, physical, and biological characteristics of water. Water quality varies from place to place, seasonally, and according to the kind of substrate through which the water moves. Indicators of water quality include, but are not limited to:

- Chemical characteristics (e.g., pH, conductivity, dissolved oxygen)
- Physical characteristics (e.g., sediment, temperature, color)
- Biological characteristics (e.g., macro- and micro-invertebrates, fecal coliform/e-coli, and plant and animal species)

Indicators of watershed health include:

- Channel morphology characteristics (e.g., aggradation, degradation, and bank failure)
- Watershed conditions (e.g., soil erosion and vegetation condition)

Water resource monitoring in the planning area is designed and managed to provide the BLM with baseline information on the conditions of water quantity and quality, and changes to those conditions that could be attributable to natural processes or BLM management activities. Monitoring activities include the collection of surface and subsurface hydrological data, and climatological data. As part of the hydrologic assessments, the BLM collects data on water quality, stream channel morphology, streamflow, and groundwater elevation at a variety of locations. Climatological data that is collected includes precipitation, temperature, wind intensity and direction, solar radiation, barometric pressure, relative humidity, and soil moisture.

Additionally, the BLM monitors some stream channels and riparian areas for Proper Functioning Condition (PFC) (see the *Vegetation – Riparian/Wetland Resources* section of this chapter), which are indirect indicators of water quality and watershed health. The BLM uses other survey methodologies, such as Multiple Indicator Monitoring (MIM) (Burton et al. 2008), to provide further detail for the assessment of stream corridor conditions.

3.1.4.3. Current Condition

This section characterizes surface water and groundwater resources and describes water use and current water management practices in the planning area.

Administration of water rights and beneficial use determinations within the planning area are primarily the responsibility of the WSEO, and the Wyoming DEQ, which regulates water quality of groundwater and surface water under the Clean Water Act (CWA) as delegated by the EPA. The BLM is responsible for the management of federal lands and minerals in a manner that maintains or enhances water quality and quantity for other uses. Data collection, resource monitoring, and analysis is performed to evaluate impacts or investigate special concerns related to water resources. Other agencies involved in managing and regulating the water resources of the area are the U.S. Army Corps of Engineers, the EPA, the U.S. Fish and Wildlife Service (USFWS), and Wyoming Game and Fish Department (WGFD).

Surface Water

Information in this section includes:

- Watersheds within the planning area, and a map showing the major streams and lakes in the planning area
- The major tributary waterways in the planning area and their flow conditions
- A description of surface water quality and quantity and a reference to the Wyoming DEQ requirements for water quality in Class 1 and 2 waterway segments
- Identification of watersheds in the planning area with Class 1 or 2 waterways
- A discussion on surface discharge of water (e.g., produced water from CBNG development), including the regulations associated with discharged waters
- Historic and present resources and resource uses that could affect surface water quality
- A description of the state 303(d) list and Total Maximum Daily Load (TMDL) allocation of pollutants
- Waterways in the planning area on the Wyoming DEQ 303(d) list of water bodies with impaired water quality

The planning area is comprised of two distinct hydrologic regions: the mountainous region where snowmelt is the dominant influence on streamflow, and the plains region where runoff from convective storms is the dominant factor controlling peak flow rates (Lowham 1988). Mean annual precipitation in this semi-arid region ranges from about 10 inches to more than 15 inches in the plains region of the planning area, and up to 30 inches in the mountainous region (Lowry et al. 1986). Approximately half of the annual precipitation falls in April, May, and June (Rankl and Lowry 1990). Average annual snowfall ranges from less than 30 inches to more than 100 inches. Annual lake evaporation averages approximately 40 inches, greatly exceeding annual precipitation (Whitehead 1996).

The planning area is within portions of six major watersheds: the Belle Fourche, the Little Bighorn, the Cheyenne, the Little Missouri, the Powder, and the Tongue.

The Powder River is the largest watershed in the planning area, and drains more than half (65%) of the planning area. Other drainages in the planning area include the Little Bighorn and Tongue River, which drain the northwestern area (14%); the Belle Fourche River, which drains the eastern area (11%); the Cheyenne River, which drains the southeastern area (6%); the Little Powder River, which drains most of the northeast area (3%); and the Little Missouri River, which drains a strip along the eastern part of the planning area adjacent to the state line (1%). The Powder River, along with several other larger streams in the planning area, including Clear Creek, Crazy Woman Creek, the Little Bighorn River, and the Tongue River, have headwaters in the Big Horn Mountains. The U.S. Geological Survey (USGS) classifies these as perennial streams. Except for the main stem of the Powder River, which courses through the middle of the PRB, these streams generally flow with clear water, and carry little suspended sediment. The southern Big Horn Mountains contain approximately 50 miles of perennial streams on public land. All of the perennial streams in the planning area and their associated vegetation communities represent important fish and wildlife habitat on both public and private land. Intermittent streams that have enough seasonal flow to support growth of riparian vegetation also provide important wildlife habitat.

Most of the streams and tributaries with headwaters in the plains region are ephemeral, flowing only in direct response to precipitation events or snowmelt. These channels are formed in fine-grained, unconsolidated Tertiary sedimentary units or Quaternary basin fill. This material is easily eroded, especially in areas where vegetation is relatively sparse. These conditions often result in high sediment delivery to the Powder River.

Additional surface water information can be found in the PRB Final EIS page 3-36 (BLM 2003c). This information is specifically incorporated by reference here.

Surface Water Quantity

Major contributions to streamflows in the planning area include direct precipitation, surface runoff, produced water discharges, and releases from surface reservoirs. Evaporation, evapotranspiration, water rights withdrawals and infiltration cause decreases in streamflow (BLM 2003c).

Flow statistics have been compiled from selected USGS stream gauging stations to provide a perspective of perennial streamflow within the planning area. Information gathered prior to 2001 is summarized in Table 3-8 in the PRB Final EIS (BLM 2003c, page 3-41). Information gathered since 2001 is summarized below in Table 3.6, “Mean Monthly Discharge, 2001–2012” (p. 336). Baseflow conditions in the streams are represented by the low of the mean monthly flows, and typically occur in the winter months. Conversely, high flow conditions in the streams are represented by the maximum of the mean monthly flows, and typically occur during periods of snowmelt runoff or major precipitation events (BLM 2003c).

Table 3.6. Mean Monthly Discharge, 2001–2012

River	Mean Monthly Discharge (cfs) 2001–2012

Streamflow characteristics in the planning area depend on the specific features unique to each drainage basin. These features include geology, topography, vegetative cover, size, and climate. Flow regimes in the Middle Fork Powder River are representative of streams that originate in the mountainous areas of the planning area. Flows in these streams are perennial and influenced by snowmelt in the late spring and early summer (Clark et al. 2001). Base flows are generally sustained by groundwater discharge. Flow regimes in the Little Powder River are representative of the streams that originate in the plains region of the planning area. Flows in these streams generally are more variable than are flows in the mountain streams and are influenced by lowland snowmelt during the late spring and early summer, as well as from rainstorms during the remainder of the summer and fall. These streams are more likely to have little or no flow during the late summer and early winter (Clark et al. 2001). Flow regimes in the Upper Powder River exhibit characteristics of streams originating in both the mountainous and plains regions of the planning area. Flows are generally more variable throughout the year than flows in mountain streams, and periods of little or no flow still occur but with less frequency than for plains streams (Clark et al. 2001). Flows in the planning area are further influenced by irrigation diversions and releases from storage reservoirs. Additional analysis of surface water flows prior to 2001 is included in the PRB Final EIS (BLM 2003c). Monthly mean flows for major water bodies in the

planning area since 2001 are provided in Table W.1, “Monthly Mean Discharge (cubic feet per second) 2001 to 2011” (p. 2627).

A considerable amount of water has been produced as a result of CBNG activities in the planning area. The PRB Final EIS (BLM 2003c) analyzed this development thoroughly. Much of that produced water has been discharged into streams in the PRB. This water was projected in the PRB Final EIS to gradually increase flow rates in the various streams as CBNG development escalated. However, as shown in Table W.2, “Coalbed Natural Gas Water Production” (p. 2642), the actual volumes of water that has been produced by CBNG activities is much less than predicted, primarily because fewer CBNG wells have been drilled than predicted. According to the data collected by the Wyoming Oil and Gas Conservation Commission (WOGCC), actual cumulative water production associated with CBNG through 2011 totaled 754,271 acre-feet, or 26 percent of the 2,912,756 acre-feet of water predicted to be produced in the PRB Final EIS (BLM 2003c). Additionally, since the PRB Final EIS was published, Wyoming DEQ revised its produced water discharge standards, which prompted many producers to store much more water in surface water impoundments or re-inject it to subsurface formations rather than discharge to streams. Therefore, the corresponding water volumes discharged into Wyoming streams has also been substantially less than predicted. Wyoming DEQ is unable to provide summary data of how much water has been discharged on a large scale because the Wyoming DEQ does not track discharge by hydrologic basin (telephone discussion with Wyoming DEQ 11/5/2013). They can provide that data on a site specific basis, but that data would be beyond the scope of this document. Table 3.7, “Comparison of Mean Flows and PRB Final EIS Predicted Flows” (p. 337) shows a comparison of actual flow in the primary sub-basins in the planning area and predictions made in the PRB Final EIS (BLM 2003c).

Surface Water Storage

Reservoirs in the planning area are used to hold water supplied from precipitation and snowmelt, and to make stored water available during summer and fall, periods of limited precipitation and heavy demand (BLM 2003c). Additionally, numerous small reservoirs or impoundments are used throughout the planning area to manage CBNG produced water.

Produced water impoundments can be constructed on- or off- channel, and the regulatory authority varies based on which type of impoundment they are. Impoundments can be used for a variety of water management options including: disposal by evaporation and/or infiltration; storage prior to another water management option including injection or irrigation; or for beneficial use such as a livestock and wildlife watering (ALL Consulting 2003).

In the State of Wyoming the WSEO, Wyoming DEQ, and WOGCC regulate impoundments. The Wyoming DEQ requires WYPDES permits for the discharge of produced water to unlined impoundments to ensure the quality of the discharged water will meet water quality standards. The WSEO has the responsibility to permit reservoirs relative to water rights, and sets design standards, while the WOGCC regulates off-channel impoundments over private and state mineral leases used for retention of produced water and reserve pits. BLM reviews the facilities relative to siting criteria and environmental impacts as part of site specific NEPA analyses.

All impoundments in the planning area used for containment of CBNG produced water require the posting of a reclamation bond. BLM administers bonds for any impoundment that lies over a federal mineral estate. Wyoming DEQ administers bonds for on-channel impoundments that lie over private or state mineral estates, and WOGCC administers bonds for off-channel impoundments over private or state mineral estates. The bonds are retained by the administering authority until the impoundment is satisfactorily reclaimed or signed over to the landowner.

Most impoundments are permitted by WSEO for multiple beneficial uses. Impoundments used for CBNG are designed not only to manage produced water, but to provide water for livestock and wildlife. In those efforts, the point at which CBNG produced water is discharged to the impoundment usually incorporates a stock tank to allow easy access to the water. The stock tanks are required to be designed to allow birds and other small animals to easily escape.

As of 2011, WSEO had 3106 active permits in the planning area for impoundments to store CBNG produced water. Those permits allow the storage of 39,170 acre-feet of water, with a total

surface area of 7,524 acres. Many of these impoundments have not been constructed, and are unlikely to be constructed; however it is difficult to get an accurate assessment of the number of these. Regulatory restrictions, economics, and an overestimation of needed storage capacity have led some operators to look at alternative water management techniques that require less storage.

Surface Water

The chemical composition of surface water changes continuously. Most changes are related to the amount of water and the source of water flowing in a stream at a given time. Surface water quality is directly influenced by higher amounts of precipitation associated with the mountainous regions and the composition of rocks in the area. Streamflows resulting from snowmelt and precipitation are in contact with soils and rocks for only a limited time; thus, these waters have only small amounts of dissolved minerals. Surface water type also changes with elevation. Streams in the higher elevations are typically calcium bicarbonate type waters. As the streams flow across the lowlands, both as natural flow and irrigation return flow, they change to sodium SO₄ type waters. The waters are typically alkaline and have moderate to high levels of hardness.

Ambient Water Quality

Data on surface water quality summarized from historical water quality records obtained at USGS monitoring stations in the planning area are presented in Table 3-11 of the PRB Final EIS (BLM 2003c, page 3-49). Table 3.8, “Comparison of EC and SAR Data, Pre and Post PRB Final EIS (2001)” (p. 339) shows a comparison of electrical conductance (EC) and Sodium Absorption Ratio (SAR) values compiled for the PRB Final EIS and data collected since the PRB Final EIS was published.

Salinity

Water quality in surface streams within the planning area is commonly a function of streamflow. Consequently, the streamflow variations presented in Table 3-8 of the PRB Final EIS (BLM 2003c, page 3-41) and Table 3.8, “Comparison of EC and SAR Data, Pre and Post PRB Final EIS (2001)” (p. 339) above, can influence water quality throughout the year. Water quality in most of the drainages varies inversely with streamflow. A general indicator of water quality is salinity. Salinity refers to the amount of dissolved solids in a water sample and is generally expressed as milligrams per liter (mg/L) of total dissolved solids (TDS). EC can also be used as a measure of salinity and is considerably easier to measure and monitor. Results for EC are expressed as microSiemens per centimeter ($\mu\text{S}/\text{cm}$).

Sodium Adsorption Ratio

A second indicator of water quality in streams within the planning area is sodium adsorption ratio (SAR), which can be used to assess the suitability of the water for irrigation of crops. SAR represents the proportion of sodium ions to calcium and magnesium ions in water. SAR is an indicator of the potential for water to affect soil structure. Surface waters with high SARs that are used for irrigation pose a potential hazard to the health of individual plants growing in the irrigated soils, and thus, to the productivity and yield of the irrigated cropland. The application of irrigation waters with high SAR values results in a disproportionate concentration of sodium adsorbed by the soil at the expense of calcium and magnesium, which alters the physical condition of the soil growth medium. The sodium imbalance can cause soil structure to break down and the soil particles to disperse, particularly with clayey soils.

In surface water systems, there is a dynamic relationship between EC and SAR; for a given SAR, potential effects to soil structure decrease as the EC increases. However, when evaluating SAR values for the protection of irrigated agriculture, a number of interrelated factors should be considered, including: the crop or native plant species to be irrigated or exposed to these conditions; the texture of the irrigated soils; predominant clay mineralogy; soil chemistry; water management practices; and the chemistry of the irrigation water. Additional discussion of SAR can be found in the PRB Final EIS (BLM 2003c, page 3-47).

Trace Metals

Concentrations of trace metals in surface waters that drain the planning area are generally low. Levels of iron and manganese that exceed the secondary drinking water standards of 0.3 mg/L for iron and 0.05 mg/L for manganese have been detected occasionally in samples of surface water in the planning area. Manganese and iron can cause staining and bitter tastes but are not present in concentrations that would limit use of the water for stock watering or irrigation.

Concentrations of selenium greater than 10 micrograms per liter ($\mu\text{g/L}$) have been measured in surface water from localized streams in the planning area (Lowry et al. 1986). The drinking water criterion for selenium is 50 $\mu\text{g/L}$; however the chronic criterion for protection of aquatic life is 5 $\mu\text{g/L}$. Sources of selenium within the planning area generally are geologic in origin (Seiler et al. 1999). Although concentrations of selenium exceed the drinking water standard, the streams of concern are not used as public water supplies (EPA 2001). Concentrations of selenium do not limit use of the water for stock watering; however, certain vegetation could become toxic to livestock through uptake of selenium. Concentrations of selenium greater than 2 to 5 $\mu\text{g/L}$ can cause reproductive failure in fish and wildlife (USFWS 1987).

Suspended Sediment

Concentrations of suspended sediment are high throughout the planning area. Concentrations reflect the highly erosive nature of the shale deposits through which the rivers flow. Concentrations of sediment increase in a direct relationship to flow. Suspended sediment particles provide a surface onto which moderately soluble chemical constituents can adsorb and be transported downstream. Thus, chemically enriched sinks can form in sediment deposition areas (Lowry et al. 1986). Quantities of suspended sediment in a flowing stream limit the stream's capability to acquire and transport additional sediment. Suspended sediment loads are often trapped in downstream reservoirs.

Temperature

The temperature of water in streams within the planning area can range from 0 °C during winter to 25°C or more during late summer (Lowry et al. 1986). Water temperatures in streams also vary as a function of elevation. The temperature of water in streams depends on physical conditions, such as shading, stream width, depth and velocity, and can be further altered by groundwater inflows, waste dischargers, and reservoirs (Lowry et al. 1986).

Changes in water temperature can have an effect on water quality. As water temperatures increase, dissolved oxygen concentrations decrease due in part to the lower saturation capacity of the water and additional oxygen consumption by aquatic life (Lowry et al. 1986). The solubility of various chemical constituents in water also change with temperature, which could affect the levels of chemical constituents potentially harmful to aquatic life.

Water Quality Trends

Clark (2012) evaluated trends for the 10-year period of water years 2001–2010 at sites in the Tongue River drainage basin (4 sites); Powder River drainage basin (9 sites); and the Belle Fourche River drainage basin (4 sites). Most of the sites evaluated for trends for water years 2001–2010 are on the main-stem rivers or on primary tributaries in those drainages. In addition to specific conductance and SAR, trends were evaluated for dissolved concentrations of calcium, magnesium, sodium, alkalinity, chloride, and SO_4 to determine which of the primary components may be contributing to a trend in specific conductance or SAR.

Specific Conductance

Clark (2012) did not observe consistent basinwide trend patterns for specific conductance for water years 2001–2010 in the Tongue, Powder, and Belle Fourche River drainage basins. Upward trends in flow-adjusted specific conductance values were determined for 3 sites, a downward trend was determined for 1 site, and no significant trends were determined for 13 sites.

In the Tongue River drainage basin, flow-adjusted specific conductance values for water years 2001–2010 indicated upward trend on the Tongue River at the state line. No trends were determined for flow-adjusted specific conductance values on Little Goose Creek, Goose Creek, and Prairie Dog Creek near Acme.

Upward trends also were observed for flow-adjusted concentrations of calcium, chloride, and SO_4 on the Tongue River at the stateline, which would contribute to the upward trend in specific conductance. An upward trend in flow-adjusted chloride concentrations was observed on Prairie Dog Creek near Acme, which may have contributed to increasing chloride concentrations of the Tongue River. Clark found that determining the source of trends for the Tongue River at the state line for water years 2001–2010 is complicated by several factors. Large concentrations of calcium, chloride, and SO_4 are not directly associated with coalbed waters. The subsurface movement of major ions dissolved from soils as a result of infiltrating CBNG-produced waters is one potential source of calcium, chloride, or SO_4 to streams; however, other land uses also may have contributed to trends in major ions. Irrigation, which occurs in the Tongue River drainage basin, can increase concentrations of dissolved constituents in the soil profile or in return flows as a result of evaporation and transpiration (Hanson et al. 2006). Rural septic systems in the drainage basin may also contribute to dissolved solids (Canter and Knox 1984), as well as the city of Sheridan. Drought conditions that persisted in the Tongue River drainage basin during water years 2001–2006 may have produced an accumulation of salts at the surface and in the near subsurface through evaporation. When precipitation returned to normal (NRCS 2011b), some of these accumulated salts may have been flushed to streams. Quillinan et al. (2012) reported that increased dissolved solids observed in the Tongue River during early spring runoff are likely the result of soluble salts being mobilized from the soil profile in the basin interior.

In the Powder River drainage basin, flow-adjusted specific conductance values for water years 2001–2010 indicated an upward trend on Clear Creek near Buffalo. A downward trend in flow-adjusted specific conductance values was determined for the Powder River below Burger Draw. No trend in flow-adjusted specific conductance values were determined for Salt Creek, Powder River at Sussex, Crazy Woman Creek, the Powder River at Arvada, Clear Creek near Arvada, the Powder River at Moorhead, and the Little Powder River above Dry Creek.

Upward trends in flow-adjusted concentrations of calcium, magnesium, and alkalinity contributed to the upward trend in specific conductance for Clear Creek near Buffalo. Calcium, magnesium, and alkalinity commonly are associated with carbonate rocks, which are present in the upper basin. Trends in these constituents may indicate that groundwater composed a relatively larger part of the streamflow as a result of drought conditions, because concentrations of calcium, magnesium, and alkalinity typically are larger under base-flow conditions compared to surface runoff. Sparse CBNG development has occurred in the upper Clear Creek drainage basin upstream from Clark's study site (based on compilation of data retrieved from WOGCC 2011).

Clark found that a downward trend for flow-adjusted SO concentrations contributed to the downward trend in specific conductance for the Powder River below Burger Draw. The CBNG production occurs in drainages upstream from the study site on the Powder River, including the

Burger Draw drainage basin, which is immediately upstream from the site. Because coalbed waters typically do not contain large SO_4 concentrations, discharges of CBNG-produced waters in the Burger Draw drainage basin may dilute SO_4 concentrations in the Powder River below Burger Draw, particularly during low flows. Because flow is occurring more regularly in some of the plains ephemeral drainages, some flushing of surficial SO_4 salts also may have occurred, which may decrease SO_4 concentrations through time. Precipitation of barium SO_4 also may contribute to the downward trend in flow-adjusted SO_4 concentrations. Barium is a constituent commonly associated with CBNG-produced waters that will precipitate when mixed with SO_4 in drainages (Wyoming DEQ 2000a; Brinck et al. 2008).

Clark noted downward trends in flow-adjusted SO_4 concentrations downstream on the Powder River at Arvada and at Moorhead, as well as on Clear Creek near Arvada; however, no trends were determined for flow-adjusted specific conductance values for these sites. Upward trends in flow-adjusted alkalinity concentrations were determined for the Powder River at Arvada and at Moorhead. The CBNG-produced waters that typically have bicarbonate as their dominant anion may be the source affecting the upward trend in alkalinity on the Powder River at the study sites.

In the Belle Fourche River drainage basin, an upward trend in flow-adjusted specific conductance values was determined for the Belle Fourche River near Piney. No trend in flow-adjusted specific conductance was determined for Donkey Creek or for two sites downstream on the Belle Fourche River.

Clark indicated that an upward trend in flow-adjusted sodium concentrations contributed to the upward trend in specific conductance on the Belle Fourche River near Piney. Water production associated with CBNG development has been declining in the upper Belle Fourche River drainage basin since 2003 when it was at its peak (based on compilation of data retrieved from WOGCC 2011). Specific conductance values and sodium concentrations generally were smaller during water years 2001–2010 compared to values reported by Peterson (1998) for water years 1975–1981. This indicates that CBNG-produced waters may have had a dilution effect on the water quality of the Belle Fourche River near Piney and as a result of declining CBNG production, concentrations are returning to larger levels that occurred prior to CBNG development.

Although no corresponding trends were determined for flow-adjusted specific conductance values, Clark indicated a downward trend in flow-adjusted alkalinity concentrations on the Belle Fourche River below Moorcroft. Upward trends in flow-adjusted concentrations of calcium, magnesium, and chloride concentrations also were determined for Belle Fourche River below Moorcroft. Increases in chloride have been reported for Donkey Creek, and the Belle Fourche River downstream from Donkey Creek has been listed as impaired for chloride (Wyoming DEQ 2012). One source of magnesium and chloride concentrations may be magnesium chloride, which is used as a deicing agent for roads in the winter and, as a dust suppressant applied to roads in the summer.

Sodium Adsorption Ratios

Clark did not observe consistent basinwide trend patterns for SAR values for water years 2001–2010 in the Tongue, Powder, or Belle Fourche River drainages basins. Upward trends in flow-adjusted SAR values were determined at 2 sites and no significant trends were determined for 15 sites.

In the Tongue River drainage basin, flow-adjusted SAR values for water years 2001–2010 indicated no trends for Little Goose Creek, Goose Creek, Prairie Dog Creek near Acme, or the Tongue River at the state line. As previously described for specific conductance trends, an

upward trend in flow-adjusted calcium was determined; however, a corresponding downward trend in flow-adjusted SAR was not determined. A downward trend was observed for unadjusted SAR values at the state Line.

In the Powder River drainage basin, flow-adjusted SAR values for water years 2001–2010 indicated an upward trend on the Powder River at Arvada. The trend in flow-adjusted SAR values was not significant for other sites on the Powder River, including at Sussex, below Burger Draw, and at Moorhead. No significant trends in flow-adjusted SAR values were determined for tributary sites in the Powder River drainage basin, including Salt Creek, Crazy Woman Creek, Clear Creek, and the Little Powder River.

No trends were determined for flow-adjusted concentrations of calcium, magnesium, and sodium for the Powder River at Arvada. Flow-adjusted calcium concentrations indicated the trend in flow-adjusted SAR values may be primarily the result of decreasing calcium concentrations. One of the geochemical effects of adding sodium bicarbonate produced waters to streams is the precipitation of calcium carbonate. This results in a decrease in calcium concentrations and a corresponding increase in SAR (Patz et al. 2004). Decreases in calcium concentrations in CBNG impoundments compared to CBNG outfalls also have been attributed to the precipitation of calcite (Jackson and Reddy 2007). The SAR trend, combined with the upward trend in flow-adjusted alkalinity concentration, is additional evidence that CBNG-produced waters may be causing the water-quality changes to the Powder River at Arvada during water years 2001–2010. Frost et al. (2010) used strontium isotopes and mixing models to show that CBNG-produced waters account for less than 1 percent of the flow of the Powder River, but that it is possible for even a small amount of CBNG-produced waters to affect SAR values of the Powder River.

In the Belle Fourche River drainage basin, flow-adjusted SAR values for water years 2001–2010 indicated an upward trend on the Belle Fourche River near Piney. Trends in flow-adjusted SAR values were not significant for Donkey Creek or downstream on the Belle Fourche River. The upward SAR trend for the Belle Fourche River near Piney corresponded with a significant upward trend in flow-adjusted sodium concentrations at that site. Because trends in flow-adjusted concentrations of calcium or magnesium were not significant, the increase in sodium, which is directly related to SAR, likely is the primary factor affecting the upward trend in SAR for the Belle Fourche River near Piney.

Summary

Data published by the USGS (Clark 2012) summarized water quality for four major watersheds in the PRB for the period between the beginning of full scale CBNG development (2001) through peak production (2008) to 2010. The watersheds evaluated are the Powder, Tongue, Belle Fourche and Cheyenne drainage basins. Clark concluded that CBNG developments may have contributed to some trends in the PRB, with upward trends (concentration of constituents) noted at some locations, and downward trends (dilution of constituents) noted at other locations.

Water Classifications

The Wyoming DEQ, in compliance with the federal CWA, requires that water quality be maintained or improved for outstanding (Class 1) and most of high-quality (Class 2) waters (Wyoming DEQ 2007). Table 3.9, “Surface Water Classes and Uses in Wyoming” (p. 345) describes water quality classes. The Wyoming DEQ manages all surface discharges in the state through the WYPDES permit process. Water produced and discharged in association with any industrial activity, including O&G development, must be permitted

through the WYPDES process. WYPDES permits typically require compliance with specific water quality effluent standards that vary by stream class, and are periodically reviewed and revised for existing uses. Water discharged on the surface must be suitable for existing or planned uses, such as agriculture and livestock, and cannot result in a violation of water quality standards in the receiving stream. The Wyoming DEQ defines stream classes and water quality standards (Wyoming DEQ 2002), and a list of classified segments is maintained and available from the Wyoming DEQ.

Table 3.9. Surface Water Classes and Uses in Wyoming

Surface Water Classes	Surface Water Uses
Class 1, Outstanding Waters	No further water quality degradation by point source discharges other than from dams will be allowed. Nonpoint sources of pollution shall be controlled through implementation of appropriate best management practices.
Class 2, Fisheries and Drinking Water	Support fish or drinking water supplies or where those uses are attainable. Class 2 waters may be perennial, intermittent, or ephemeral.
Class 3, Aquatic Life Other than Fish	Intermittent, ephemeral, or isolated waters and waters that, because of natural habitat conditions, do not support or have the potential to support fish populations or spawning, or certain perennial waters that lack the natural water quality to support fish (e.g., geothermal areas).
Class 4, Agriculture, Industry, Recreation and Wildlife	Aquatic life uses are not attainable. Uses include recreation, wildlife, industry, agriculture, and scenic value.
Source: Wyoming DEQ 2013d	

The Wyoming Nonpoint Source Program operates under the Watershed Management Section of the Wyoming DEQ, Water Quality Division (WQD). Unlike point source pollution, which can be traced back to a single defined source, nonpoint source pollution is caused by surface water runoff diffuse in nature and often widespread, making it difficult to assess the source of the problem. Nonpoint source pollution occurs when runoff from rainfall or snowmelt travels over and/or percolates through the soil and picks up contaminants. These contaminants are deposited into streams, lakes, rivers, and groundwater. While some types of nonpoint source pollution can be natural in origin, Wyoming's Nonpoint Source Program typically only addresses those associated with anthropogenic land-disturbing activities such as urban development, agriculture, recreation, and silviculture. Common nonpoint source contaminants include fertilizers and pesticides from agricultural and residential activity; oil, grease, sediment and toxic chemicals from urban runoff; sediment from construction activity or stream bank erosion; and bacteria and nutrients from livestock and pet waste or failing septic systems (Wyoming DEQ 2012).

Impaired Water Bodies

Section 305(b) of the CWA requires that each state prepare and submit a biennial report to EPA by April 1st of even numbered years. The report must contain a description of the water quality of navigable waters of the state for the preceding year, including the extent to which current conditions allow for the "protection and propagation of a balanced population of shellfish, fish, and wildlife, and allow recreational activities in and on the water." Section 305(b) also requires each state to report the water quality and the elimination of pollutants that would be necessary to provide for designated use support. Specifically, each state is to identify waters not meeting the above conditions, recommend strategies to achieve these objectives and to estimate the environmental impacts, economic and social costs and benefits, and the predicted timeline for project completion. Lastly, Section 305(b) requires that the sources and extent of nonpoint

source pollution in each state be estimated, including a description of the current program used to mitigate these pollutants and associated financial costs.

Section 303(d) of the CWA requires that states identify and list waters for which the effluent limits outlined in Section 301 are not effective in attaining designated uses. Section 303(d) also requires that states develop a separate TMDL for each pollutant/segment combination on the 303(d) List. States are required to prioritize waters on the 303(d) List for TMDLs based on the severity of each pollutant/segment combination, or listing. TMDLs are to be completed on these impaired waters "to assure the protection and propagation of a balanced, indigenous population of shellfish, fish and wildlife, and allow recreational activities in and on the water." Each state must submit a 303(d) List of impaired waters to EPA by April 1st of each even numbered year. EPA is required to review the 303(d) List within 30 days of submittal.

The quality of water in the rivers and streams within the planning area is protected for designated uses in accordance with the State of Wyoming's water quality standards. The State of Wyoming's 305(b) Report for 2012 lists water-bodies with impairments to water quality in the Tongue River Basin, PRB, and Belle Fourche River Basin (Wyoming DEQ 2012). Listed impairments within the planning area are caused primarily by pathogens, trace metals (arsenic and selenium), chloride, temperature, oil spills, and habitat alterations. Most sources of the impairments are unknown, although some have been attributed to natural background sources. The complete Wyoming Water Quality Assessment and Impaired Waters List (2012 Integrated 305(b) and 303(d) report can be found on Wyoming DEQ's website.

The 2012 303(d) list includes 519 miles of impaired water bodies within the boundaries of the planning area (Wyoming DEQ 2012). Of these 519 miles, 16.4 of these miles pass through or are adjacent to BLM-administered surface. Table 3.10, "Summary of Impaired Water Bodies within the Planning Area" (p. 347) shows a summary of Impaired Water Bodies within the planning area. Additionally, a general description of the impaired water bodies in the planning area is included in Appendix W (p. 2623). To address the issues causing the impairments, the Wyoming DEQ is developing TMDL allocations for impaired water bodies throughout the state. A TMDL is the amount of pollutant which a stream can accept and still meet its designated uses. TMDLs must be established for each pollutant which is a source of stream impairment. They must be measurable and must consider both point and nonpoint source pollutant loads, natural background conditions, and a margin of safety. When the Wyoming DEQ develops TMDLs for the water bodies in the planning area, the BLM will comply with any standards established by the TMDL. Additionally, if BLM has standing in the target water body, they will offer to be a cooperating agency with Wyoming DEQ to help develop and implement the TMDL. In addition to the water bodies directly in the planning area, it is possible that in the future, some impaired stream or river segment may flow out of the planning area into South Dakota or Montana. In such a case the receiving state would coordinate with Wyoming DEQ to implement a TMDL. BLM would work with Wyoming DEQ or the receiving state to manage that TMDL. Conversely, impaired water bodies outside of the planning area may flow into the planning area. This is likely to occur in the southern portion of the planning area. Water quality in these streams and rivers would be under the authority of Wyoming DEQ, therefore, management would vary little. However the management of BLM resources would likely be under the authority of the Casper Field Office. In such a case, the BFO would work directly with the Casper Field Office to implement any TMDL prescriptions.

Wyoming DEQ has conducted studies regarding surface waters used for drinking water supplies as part of their Source Water Assessment and Protection evaluation process. The Source Water Assessment and Protection program defines evaluation and delineation protocols to prevent

impairments to drinking water sources. As of 2013, the Source Water Assessment and Protection program is operated on a voluntary basis in the State of Wyoming and is not subject to regulatory oversight. Therefore, no geographic data is available that defines areas that fall under Source Water Assessment and Protection controls. If in the future Wyoming DEQ or other agencies adopt regulations, or define areas for source water protection, BLM will cooperate with those efforts. If lands identified as source water protection areas are proposed for leasing, BLM will evaluate the offering of those parcels, and their associated surface disturbance or occupancy as part of the review process. During any O&G leasing activities, all split-estate landowners are notified of proposed lease parcels that intersect their surface estate, and are given the opportunity to comment on the leasing of those lands at that time. These processes will allow the BFO to ensure that water quality objectives associated with any federal activity are met. Further information on the Wyoming Source Water Assessment and Protection program can be found on Wyoming DEQ's website (<http://deq.state.wy.us/wqd/www/SWP%20WHP/>).

Table 3.10. Summary of Impaired Water Bodies within the Planning Area

Surface Water Name HUC Number	Location	Water Classification	Impairment	Impairment Cause	BLM-Administered Land	Basin Area (Acres)	Percent BLM-Administered Area in Basin	Listing Date
Donkey Creek HUC1601010106	Planning area boundary upstream to Brorby Boulevard in Gillette	3B	Not supporting designated uses	Fecal Coliform	None	151,757 (Donkey Creek Level 10)	0.24% Surface 63.86% Minerals	2000
Gillette Fishing Lake HUC1601010106	Within the City of Gillette	2AB	Not supporting designated uses	Phosphate and Sediment	None	41,331 (Headwaters Donkey Creek Level 12)	0.00% Surface 92.85% Minerals	1996
Stonepile Creek HUC1601010106	From confluence with Donkey Creek upstream to junction of Hwy 14/15, 59	3B	Not supporting designated uses	Fecal Coliform	None	38,785 (Upper Donkey Creek Level 12)	0.52% Surface 83.37% Minerals	2002

Surface Water Use

Surface water resources within the planning area typically meet existing needs on public lands, but natural climatic fluctuations, such as drought, can make marginally adequate sources unreliable.

Surface water rights in the planning area are permitted through the WSEO. A permittee can apply for water rights on BLM-administered land; if the permittee demonstrates beneficial use, then the WSEO can permit the water right. The issuance of the water right in no way authorizes a permittee to develop water on BLM-administered lands, or any lands that they do not own. This requires independent negotiations between the permittee and the BLM to acquire the appropriate special use permit or ROW. The WSEO does not require that landowner authorization be obtained before it issues the water right.

Surface water withdrawals in the planning area totaled 365 million gallons per day (mgd) in 2005. Table 3.11, “Surface Water Use per County (million gallons per day)” (p. 354) summarizes water use within the three counties that comprise the planning area in 2005 (USGS 2005a). Surface water use in the planning area is predominantly associated with irrigation use. About 95 percent of the surface water withdrawals (347 mgd) are used for irrigation. Mining use accounts for only 3 percent, or 11 mgd of the total surface water withdrawals. About 25,781 people living in the planning area obtained their water supply from surface water sources in 2005, consuming 5.1 mgd, or about 1 percent of the surface water withdrawals (USGS 2005a). Additional discussion about surface water use can be found in the PRB Final EIS (BLM 2003c, page 3-51).

Table 3.11. Surface Water Use per County (million gallons per day)

Source: USGS 2014						

Coal Use

As of 2011, there are 12 active and two proposed surface coal mines in the planning area that occupy over 100,000 acres of reclaimed and unreclaimed surface (BLM 2013j). Each coal lease has been issued after an extensive site specific environmental analysis (as an EIS) is approved which discloses current conditions and presents potential impacts related to the removal of the coal resource and associated mitigation. For additional information, refer to *Leasable Minerals—Coal*.

Initially, surface coal mining requires that any surface water be removed or relocated in preparation for topsoil removal. Perennial streams are diverted in coordination with the Wyoming DEQ as well as the United States Army Corps of Engineers. Other water bodies, such as impoundments or natural surface playas in the mine area have been drained as necessary to facilitate removal.

In the planning area, the volume of water produced through the dewatering procedure averaged between 1,386 to 2,258 acre-feet per year (Hay Creek II Final EIS, pg. 4-11 to 4-12). For the most part, the water is used by the mines for maintenance, dust control or other consumptive uses. If water is discharged to the surface, the mine operator would be required to obtain a WYPDES discharge permit.

Municipal Water Use

Communities in the planning area that use surface water as a municipal water supply include the Cities of Sheridan and Gillette, and the towns of Buffalo and Dayton (Wyoming State Engineer’s Office 2013). Surface water sources in the Tongue River sub-watershed supply the communities of Sheridan and Dayton. Buffalo uses surface water from the Clear Creek sub-watershed. Gillette has municipal surface water rights in Donkey and Stonepile Creeks. The majority of municipal water supplies in the planning area are acquired from groundwater sources and are discussed further in the *Groundwater* Section.

Surface Water Monitoring

In the Record of Decision (ROD) for the PRB Final EIS (BLM 2003c), the BLM committed to cooperate with the Wyoming DEQ, WSEO, USGS and others fund a network of surface

water monitoring sites in the planning area. Currently BLM cooperates with USGS to operate 20 surface water monitoring stations throughout the planning area. These stations continuously record streamflow on major rivers and streams in the area. Many of these sites include periodic water quality analysis as well. This analysis typically includes major cations and ions (calcium, magnesium, sodium, bicarbonate, chloride, and SO_4), selected nutrients (nitrate and phosphorus), and trace metals (arsenic, barium, iron, manganese, and selenium). The USGS compiles the data and presents it to the public on their website (<http://waterdata.usgs.gov/wy/nwis/current/?type=flow>).

Groundwater

Information in this section includes:

- The geological features in which groundwater resources occur
- The major regional aquifers in the planning area and estimates of recoverable groundwater
- Uses of groundwater in the planning area
- Groundwater quality conditions related to TDS and trends in the planning area, and areas that are highly vulnerable to groundwater contamination

Groundwater resources are contained in permeable underground aquifers composed of rock and sediments through which water can flow. Water moves slowly in aquifers in response to the prevailing hydraulic gradient, through tiny open spaces in the rock and sediment. Groundwater is replaced, or recharged, from precipitation that falls directly on the aquifers or by leakage through the beds of streams that intercept aquifers or from adjacent aquifers. Movement of groundwater is from recharge areas down the hydraulic gradient to discharge areas.

Aquifer permeability is directly related to the nature and type of porosity of the material that makes up the aquifer. Primary porosity is the open space between individual grains or rock clasts. Secondary porosity consists of joints and fractures that form after a rock is consolidated (Whitehead 1996). Primary porosity is the porosity type of unconsolidated-deposit aquifers and consolidated sandstone aquifers in the PRB (Whitehead 1996). Coal aquifers in the PRB contain substantial secondary porosity.

Davis (1976) describes groundwater resources as part of a hydrologic system. The components that describe a hydrologic system are the following: aquifer type (or geologic unit); water chemistry; confined (artesian) or unconfined conditions; and groundwater recharge or discharge areas (BLM 2003c).

Regional Characterization

Aquifer Types

The groundwater resources of the PRB are described by Whitehead (1996). Groundwater resources that are at or near the land surface within the PRB are contained in unconsolidated Quaternary alluvial or basin fill deposits or in semi-consolidated to consolidated lower Tertiary sandstones and coalbeds that are the uppermost aquifers in the Northern Great Plains aquifer system. Clinker (porcellanite; locally called “scoria”), which is a geologic formation in locations where sediments have been altered in place by spontaneous combustion of coalbeds, which act as an aquifer, has formed from some of the lower Tertiary sediments (Heffern and Coates 1999). These Quaternary and Tertiary aquifers are described below in more detail (BLM 2003c).

Quaternary Alluvial Aquifers

Aquifers in stream-valley alluvium generally occur along rivers and major drainages within the PRB. The groundwater resources contained in alluvial aquifers are described by Whitehead (1996). These unconsolidated deposits of silt, sand, and gravel occur as floodplains, stream terraces, and alluvial fans. Coarser alluvial deposits occur in valleys of the Belle Fourche, Cheyenne, Powder, Tongue, and Little Powder rivers and in the larger tributaries of the Powder and Tongue rivers. Alluvium overlying formations of Tertiary age in the central part of the PRB is mostly fine to medium grained (Hodson et al. 1973).

The thickness of alluvial deposits within the planning area is mostly less than 50 feet, but may be as much as 100 feet in some valleys near mountains (Hodson et al. 1973). Wells (1982) describes alluvial deposits as commonly 30 feet thick or less, but also reports that deposits 100 feet thick have been measured. Lowry et al. (1986) also describe alluvial deposit thickness and water yield from the PRB. The thickest and coarsest-grained alluvium occurs near the Big Horn Mountains along the western margin of the PRB, where saturated horizons are thick and high yields of water are possible. Mostly fine-grained alluvial deposits with a saturated thickness less than 20 feet occur distant from the mountains, resulting in low yields of water (BLM 2003c).

Northern Great Plains Aquifer System

The Northern Great Plains aquifer system is an extensive sequence of aquifers and confining units arranged in a stack of layers that may be discontinuous locally within the PRB, but that functions regionally as an aquifer system. This system includes the lower Tertiary aquifers that are exposed at the surface in the PRB and underlying, deeply buried regional aquifers that are stacked with intervening confining layers. The deeply buried aquifer systems are composed of upper Cretaceous sandstones and coals, lower Cretaceous sandstones, upper Paleozoic limestones and dolomites, and lower Paleozoic sandstones, limestones, and dolomites (Whitehead 1996). These deeply buried regional aquifers are stratigraphically below, isolated from, and older than the aquifers that may be affected by CBNG development in the PRB (BLM 2003c).

Lower Tertiary Aquifer System

The lower Tertiary aquifer system consists of semi-consolidated to consolidated Oligocene to Paleocene sediments (Whitehead 1996). The Oligocene White River Formation is present in the planning area only as isolated erosional remnants, such as Pumpkin Buttes in southwestern Campbell County (Lewis and Hotchkiss 1981).

The lower Tertiary aquifers consist of sandstones and coal seams contained in the Eocene Wasatch Formation and the Paleocene Fort Union Formation (Whitehead 1996). Both of these geologic units are continental deposits consisting of sandstones, siltstones, claystones, and beds containing lignite and subbituminous coal. Stratigraphically, from youngest to oldest, the Lower Tertiary Aquifer System consists of the Wasatch aquifers, the Fort Union aquifers contained in the Tongue River member of the Fort Union Formation, the Lebo confining layer, and the Tullock aquifer. Clinker has been formed from these geologic formations in locations where these sediments have been altered in place by spontaneous combustion of coalbeds (Coates and Heffern 1999).

Clinker plays an important role as an aquifer in the storage and flow of water within the PRB. Rainfall and snowmelt infiltrate rapidly in clinker exposure areas. The stored water is discharged slowly to springs, streams, and aquifers, which helps maintain flow in perennial streams during dry periods (Heffern and Coates 1999). Clinker outcrops cover about 460 square miles of the planning area and are concentrated in the following areas: along the eastern boundary of the planning area in the Rochelle Hills, within the Powder River Breaks in the northern portion of

the planning area, within the Tongue River Breaks north of Sheridan, within the Lake DeSmet area north of Buffalo, and within the Felix coal outcrop area west of Gillette and northeast of Wright (Heffern and Coates 1997; BLM 2003c).

Wasatch Aquifers

The Wasatch Formation consists of fine- to coarse-grained, lenticular sandstone interbedded with shale and coal (Hodson et al. 1973). Minor constituents include coarse conglomerates occurring along the western margin of the PRB, carbonaceous shales, and thick coalbeds (Seeland 1992). Sandstone layers comprise an estimated one-third of the sequence and are important PRB aquifers. High percentages of sand (from 30 to 50% and more) have been documented along a trend paralleling the western margin of the PRB, beginning east of Buffalo and west of the Powder River and continuing toward the southeast (Seeland 1992). Wasatch coalbeds are thickest in the central and western portions of the PRB (Seeland 1992). Locally, in the northwest part of the PRB near the Big Horn Mountains, the Wasatch is divided into two conglomeratic members.

The Wasatch Formation is as much as 1,800 feet thick in the southern portions of the PRB (Keefer 1974). Southeast of Buffalo, the maximum preserved thickness of the Wasatch Formation is about 3,000 feet (Seeland 1992; BLM 2003c).

Fort Union Aquifers

The Fort Union Formation yields water from fine-grained sandstone, jointed coal, and clinker overlying the Lebo confining layer (Zelt et al. 1999). The sandstone content of the Fort Union aquifer ranges from 21 to 91 percent and is hydrologically confined, except near the land surface (Hotchkiss and Levings 1986). The Fort Union Formation is as much as 3,900 feet thick in the southern part of the PRB (Hotchkiss and Levings 1986).

Numerous thick and laterally widespread coalbeds occur within the Fort Union Formation and are important PRB aquifers (Lewis and Hotchkiss 1981). The thickness of the Fort Union coal aquifers varies greatly within the PRB. The maximum thickness of a single Fort Union coal seam is less than 25 feet along the western margin of the PRB and in the northern portion of PRB in southeastern Montana. The maximum thickness of a single Fort Union coal seam is more than 100 feet near Wright and extending west and northwest of Wright, within the central portion of the PRB in Wyoming (Seeland 1992; BLM 2003c).

Lebo Confining Layer

The lower Paleocene Tullock member of the Fort Union Formation is partially isolated and confined by the overlying Lebo member (Brown 1993). The Lebo confining layer generally retards water movement (Hotchkiss and Levings 1986).

The Lebo confining layer consists predominantly of dark shales containing discontinuous zones of white calcareous banding (paleosol horizons). The Lebo confining layer in the northern portion of the planning area contains rare beds of gray sandstone as much as 10 feet thick. Some coalbeds, a few thicker than 2 feet, occur within the Lebo member and form clinker horizons in the southern PRB. The Lebo member ranges in thickness from about 500 feet in the northwestern portions of the PRB to about 1,700 feet in the southwestern portions of the PRB (Brown 1993; BLM 2003c).

Tullock Aquifer

The lower Paleocene Tullock member of the Fort Union Formation contains alluvial sediments deposited in a continental fluvial environment and is an important PRB aquifer. The Tullock aquifer consists of fine-grained sandstone, sandy siltstone, shale, rare thin limestone, and coal. Sandstone content of the Tullock aquifer ranges from 21 to 88 percent (Hotchkiss and Levings 1986). On average, an estimated one-third of the sequence is composed of channel sandstones. An estimated two-thirds of the sequence is composed of fine-grained overbank deposits containing thin coalbeds (Brown 1993).

Tullock sediments have a maximum thickness of about 370 feet in the north and 1,440 feet in the south (Brown 1993). Tullock sediments are thickest in the southeastern and western portions of the PRB.

Figure 3.23, “Regional Cross Section of the Powder River Basin” (p. 358) displays a generalized cross section of the PRB.

Figure 3.23. Regional Cross Section of the Powder River Basin

Groundwater Quality

Two systems of differing groundwater chemistry are described within the PRB (Bartos and Ogle 2002; Rice et al. 2002). A shallow, chemically dynamic system, generally 200 to 500 feet deep, exhibits localized flow and consists of groundwater with a mixed composition of ions (charged particles in solution). Shallow groundwater contains calcium, magnesium, and lesser amounts of sodium as cations (positively charged ions) and bicarbonate or SO_4 as the dominant anion (negatively charged ion). A deeper, underlying system that is chemically static exhibits regional flow and consists of groundwater with sodium and bicarbonate as the dominant ions.

Bartos and Ogle (2002) discuss the variation in water chemistry with depth. The zonation appears to be related to geochemical processes such as dissolution and precipitation of minerals, ion exchange, SO_4 reduction, and mixing of waters. Substantial differences in concentrations of SO_4 exist between the coalbed aquifers and the overlying Wasatch aquifer. SO_4 reduction is probably the dominant geochemical process in the coalbed aquifers.

Rankl and Lowry (1990) describe the same change in water chemistry with depth in their overview of water chemistry in water wells within the PRB. Water wells, excluding municipal

water supply wells, generally are shallow (less than 500 feet deep) and yield calcium SO₄ or calcium-sodium-sulfate waters. There is a decrease in calcium, magnesium, and SO₄ an increase in bicarbonate down to a depth of about 500 feet; however, the concentration of dissolved constituents is relatively uniform deeper than 500 feet. Deep wells generally yield sodium bicarbonate type water.

Hydraulic connections among aquifers in the PRB result in some degree of groundwater mixing, affecting groundwater chemistry of the aquifers involved. Hydraulic connections among aquifers in the PRB are not well understood and are subject to interpretation; however, some leakage between layers probably occurs where the hydraulic gradient allows for vertical groundwater flow and where sandstones directly overlie other sandstones or coalbeds (Rice et al. 2002).

Rice et al. (2002) provide the following overview of the chemistry of groundwater in the PRB. Groundwater associated with recharge typically consists of oxygenated water dominant in calcium, magnesium, bicarbonate, and SO₄, with lesser amounts of sodium. Away from the recharge area, interactions among water, aquifer minerals, and bacteria change the chemical composition of the groundwater. The net result of these reactions and processes is a decrease in calcium, magnesium, and SO₄ and a corresponding increase in sodium and bicarbonate as groundwater flows away from the source of recharge.

Rice et al. (2002) also summarize the reactions and processes that affect the composition of groundwater in the PRB. Sodium enrichment likely results from dissolution of plagioclases (feldspar minerals), cation exchange of calcium and magnesium for sodium on clay minerals, or removal of calcium and magnesium by carbonate precipitation. Initially, oxygen-rich water near the recharge area oxidizes pyrite minerals, increasing the relative abundance of SO₄ over bicarbonate. As water moves farther from the source of oxygen at the recharge area, evidence suggests that bacterial SO₄ reduction occurs, depleting the water of SO₄ and enriching it in bicarbonate. The precipitation of gypsum may remove SO₄ along with calcium from the water.

Processes associated with coalification (coal formation) also influence the composition of groundwater (Rice et al. 2002). A series of bacterially mediated processes occurs in a progressively more reducing environment. Reactions include reduction of nitrate, manganese, and iron oxides, SO₄ reduction, and methanogenesis (CH₄ formation), that produce NH₄⁺, Mn²⁺, Fe²⁺, HS⁻, CO₂, and CH₄. The overall effect of coalification processes that produce CH₄ of biological origin in the PRB is to deplete SO₄, increase bicarbonate, and establish a reducing environment in groundwater within the coal zone aquifer.

Analysis of tritium in groundwater in the PRB has been used to date the recharge of the water (Bartos and Ogle 2002; Rice et al. 2002). Groundwater that contains little or no tritium is defined as submodern or older and is referred to as “prebomb” water that was recharged before 1952; modern groundwater contains tritium. Analysis indicates that although the groundwater in the Fort Union coals is meteoric in origin, it is older than 1952. Water samples from springs at two locations provide evidence that they were recharged after 1952. Water samples from Wasatch sandstones at two locations provide evidence that they contain a mixture of submodern and modern water, but are mostly submodern water. Concentrations of tritium in all other samples from coal zones within the Wasatch and Fort Union Formations suggest the water is submodern.

Groundwater data can be found at the USGS website (USGS 2013).

Alluvial Aquifers

Water quality in alluvium within the PRB is variable. Lowry et al. (1986) report concentrations of TDS for alluvial aquifers that vary from 106 to 6,610 mg/L and averaging 2,128 mg/L for 38 samples. Water from surficial deposits that contains less than 600 mg/L TDS may be divided into two chemical types: a calcium magnesium carbonate type, and a calcium-magnesium SO₄ type (Rankl and Lowry 1990). Concentrations of TDS greater than 600 mg/L generally are a result of increased values for sodium and SO₄ (Rankl and Lowry 1990).

Hodson et al. (1973) characterize alluvial groundwater in various geographic areas within and near the PRB. Water in alluvium near the Big Horn Mountains and the Black Hills is of better quality than water in alluvium within the central part of the PRB. Water in alluvium within the southwest part of the basin and the Powder River valley is generally of poorer quality than water in alluvium elsewhere in the PRB. No dominant water type is prevalent (Hodson et al. 1973).

The chemical compositions of water in the Powder River and in the river's alluvium are similar (Ringen and Daddow 1990). Water in the Powder River is dominated by sodium and SO₄ ions, while water in the river's alluvial deposits is dominated by sodium, calcium, and SO₄ ions. The water in the underlying bedrock is dominated by sodium and bicarbonate ions. The quality of water in the alluvium limits its use as a water supply, as it is unacceptable for drinking water, acceptable for most livestock, and marginal for irrigation or industrial use.

Springs and Seeps

Rice et al. (2002) report the results of sampling at two clinker springs. The locations of springs that were sampled are shown in Rice et al. (2002). One spring located north of Gillette was sampled. The other spring that was sampled is located near the southeastern corner of Campbell County. When compared with groundwater conditions in the Wasatch Formation, the clinker springs contain lower concentrations of TDS, sodium, bicarbonate, chloride, and fluoride, and have lower temperatures. When compared with groundwater conditions in the Fort Union Formation, the clinker springs contain lower concentrations of sodium, bicarbonate, chloride, and fluoride, higher concentrations of calcium and SO₄, and have lower temperatures.

Heffern and Coates (1999) describe groundwater conditions in clinker areas within the PRB. The concentration of TDS within clinker varies widely from under 200 mg/L to more than 10,000 mg/L. Water in clinker from recharge areas near the burn line tends to be a calcium SO₄ type, and water in clinker from discharge areas tends to be a sodium bicarbonate type, similar to water in the coal. Ash residue at the base of the clinker may contribute to high concentrations of TDS (Heffern and Coates 1999). The interaction of groundwater with ash and clinker results in higher TDS values for water in coal near clinker areas. Additional information is available in Table 3-1 of the PRB Final EIS (BLM 2003c).

Lower Tertiary Aquifer System

The major dissolved-ion chemistry of water from the Wasatch Formation in the PRB has been described based on information from four wells completed in coals and eight wells completed in sandstones (Bartos and Ogle 2002; Rice et al. 2002). The locations of wells completed in Wasatch coals or sandstones that were sampled are shown in Rice et al. (2002). Wells located in the central portion of Campbell County, north of Buffalo, and north of Sheridan were sampled. Water produced from the Wasatch Formation varies in composition from mixed-type waters (calcium-magnesium-bicarbonate-sulfate) at relatively shallow depths (less than 200 feet) to sodium-bicarbonate waters at greater depths.

The pH of some samples from Wasatch aquifers exceeds the secondary maximum contaminant level for drinking water established by the EPA (Bartos and Ogle 2002). Bartos and Ogle (2002) also report dissolved concentrations of some constituents in groundwater from sandstones and coals within the Wasatch Formation. The median concentration of TDS reported for sandstones is 1,010 mg/L, which also exceeds the secondary maximum contaminant level for drinking water. The median concentration of SO_4 is 130 mg/L, which is below the secondary maximum contaminant level for drinking water. However, the concentration of SO_4 in some samples exceeds EPA's standard for drinking water. The concentration of manganese in some samples analyzed also exceeds the secondary maximum contaminant levels for drinking water. The concentration of manganese likely is relatively high because of its higher solubility as Mn^{+2} in anoxic waters. The median SAR is nine. There are no drinking water standards for SAR.

Hodson et al. (1973) provide an overview of water quality in the Fort Union aquifer. TDS concentrations range from about 200 to more than 3,000 mg/L, but commonly range between 500 and 1,500 mg/L. Water type is mostly sodium bicarbonate, and to a lesser extent sodium SO_4 . The water from deep wells is soft, meaning sodium plus potassium exceeds calcium plus magnesium, and many water samples contain carbonate as well as bicarbonate (Rankl and Lowry 1990). The dominant chemical processes that control the chemistry of Fort Union groundwater are cation-exchange softening and SO_4 reduction (Rankl and Lowry 1990).

Davis (1976) describes the chemistry of groundwater in the Fort Union aquifer within the eastern PRB. Along the coal outcrop the water generally is calcium-magnesium SO_4 type, changing to sodium bicarbonate type westward where confined aquifer conditions exist. There is a relationship between the confined and unconfined state of the aquifer and the chemical quality of water within the aquifer. As a rule, waters within unconfined portions of the coal aquifer are calcium-magnesium-sulfate type and within confined portions of the aquifer are sodium bicarbonate type.

Groundwater Impairments

There are 19 locations in the planning area that are included in the Wyoming DEQ's Voluntary Remediation Plan Program (Wyoming DEQ 2013b) of which, 11 sites are presently active. At most of these sites, the contamination being reclaimed was confined to the surface soil.

One site of groundwater contamination associated with energy development was deemed remediated in 2012. The Hoe Creek Department of Energy (DOE) Insitu Coal Gasification Project was started in 1976, when three "burns" were conducted in a 71 acre site south of Gillette. The pilot tested the potential to convert the coal in place to usable gas through controlled combustion. Groundwater contamination by Benzene, toluene, ethylbenzene and xylene was detected outside the immediate project area perimeter and in 1992, the DOE began a groundwater remediation program. The Hoe Creek aquifer restoration determination from the Land Quality Administrator (Wyoming DEQ) was dated April 9, 2012.

Wyoming DEQ has conducted studies regarding surface waters used for drinking water supplies as part of their Source Water Assessment and Protection evaluation process. The Source Water Assessment and Protection program defines evaluation and delineation protocols to prevent impairments to drinking water sources. As of 2013, the Source Water Assessment and Protection program is operated on a voluntary basis in the State of Wyoming and is not subject to regulatory oversight. Therefore, no geographic data is available that defines areas that fall under Source Water Assessment and Protection controls. If in the future Wyoming DEQ or other agencies adopt regulations, or define areas for source water protection, BLM will cooperate with those efforts.

If lands identified as source water protection areas are proposed for leasing, BLM will evaluate the offering of those parcels, and their associated surface disturbance or occupancy as part of the review process. During any O&G leasing activities, all split-estate landowners are notified of proposed lease parcels that intersect their surface estate, and are given the opportunity to comment on the leasing of those lands at that time. These processes will allow the BFO to ensure that water quality objectives associated with any federal activity are met. Further information on the Wyoming Source Water Assessment and Protection program can be found on Wyoming DEQ's website (<http://deq.state.wy.us/wqd/www/SWP%20WHP/>).

Groundwater Movement

Confined (Artesian) vs. Unconfined Conditions

The groundwater resources contained in alluvial aquifers are under unconfined or water table conditions (Whitehead 1996). Normally, clinker is an unconfined aquifer (Heffern and Coates 1999). Groundwater resources contained in the Wasatch aquifers occur under partially confined conditions (Whitehead 1996). The Fort Union coal zone aquifers are hydrologically confined, except near the land surface (Hotchkiss and Levings 1986). Artesian conditions can exist (Bartos and Ogle 2002). Gas present within the coalbeds and in underlying or overlying sandstone lenses can contribute substantially to the hydraulic head in wells within the PRB, and may cause water levels to rise higher than would be expected if only artesian pressure were present (Bartos and Ogle 2002). The underlying Lebo confining layer generally retards water movement (Hotchkiss and Levings 1986). The lower Paleocene Tullock member of the Fort Union Formation is partially isolated and confined by the overlying Lebo member (Brown 1993). The Tullock aquifer is hydrologically confined, except near outcrop areas (Hotchkiss and Levings 1986).

Groundwater Flow Systems (Groundwater Recharge vs. Groundwater Discharge Areas)

No consensus exists among experts on the interpretations and assumptions that should be used to represent groundwater flow conditions in the PRB. Flow paths, the extent of flow between hydrogeologic units, and the relationship between local and regional flow in lower Tertiary aquifers are not well understood. The results of a number of studies in the PRB are summarized by Bartos and Ogle (2002).

Bartos and Ogle (2002) present two conceptual models for groundwater flow in the lower Tertiary aquifers of the Wasatch and Fort Union Formations within the PRB: (1) separate shallow and deep systems with little vertical migration between them; and (2) substantial vertical flow through the Wasatch Formation and into the underlying Fort Union coal zone. Both of these models, and the clinker recharge model of Heffern and Coates (1999), operate at the basin scale, according to Bartos and Ogle (2002). Either of these groundwater flow models would explain the variations in groundwater chemistry within the PRB.

A similar model for shallow and deep flow of groundwater is summarized by Slagle et al. (1985) in their description of groundwater resources and groundwater flow in the northern PRB within Montana. The groundwater system can be divided into two general flow patterns: an upper localized flow pattern, controlled by topography that occurs in aquifers at depths of 200 feet or less; and a lower, regionalized, northward flow pattern that occurs at depths of 200 to 1,200 feet. Groundwater discharge areas for aquifers less than 200 feet deep primarily coincide with the valleys of perennial and intermittent streams. Water enters the shallow system by infiltration, flows downslope, and discharges to streams and rivers. Discharge areas for deeper aquifers generally coincide with the major drainages. Vertical movement between the aquifers is known to

exist, but the rate of exchange is unknown. Subsurface inflow from Wyoming into the northern PRB enters Montana primarily in three areas: along the Tongue River; along Hanging Woman Creek; and between the Powder and Little Powder Rivers. Total inflow is estimated as 500 to 1,000 acre-feet per year (BLM 2003c).

Rankl and Lowry (1990) summarize the relative amounts of regional and local groundwater flow in the Powder River structural basin of Wyoming and Montana, concluding that alluvial systems that deplete flow in the streams probably are the typical alluvial system in the basin, however, some streams may gain water from alluvial aquifers. Of the three largest streams included in the analysis, the Powder, Belle Fourche, and Cheyenne Rivers, only the Belle Fourche River had identified base flow, which was present only during the period of largest precipitation, but not during the period of minimum evapotranspiration. The loss of water to the alluvium in the reach of the Powder River between Sussex, Wyoming and Locate, Montana is attributed to evapotranspiration from the alluvium. The average loss of flow from the Powder River in the reach from Arvada, Wyoming to Moorhead, Montana and from Moorhead to Locate is about 0.3 cubic feet per second (cfs) during late fall and early winter. This type of system probably is prevalent in the basin (BLM 2003c).

Local Flow Systems

The hydrology of the alluvium along the Powder River between Sussex, Wyoming and Moorhead, Montana is described by Ringen and Daddow (1990). The fine-grained alluvium usually is 10 to 30 feet thick and about one-half mile wide. Flow-duration curves, used to identify groundwater discharge to rivers, indicate that low flows at Sussex are sustained by groundwater discharge that may be 2.8 cfs or greater, however, groundwater discharge is small in the downstream reach between Arvada, Wyoming and Moorhead. The water table is projected to be less than 15 feet below the land surface near the location where Interstate 90 crosses the Powder River.

Ringen and Daddow (1990) conclude that the alluvium of the Powder River has direct hydraulic connection with the river, as evidenced by the response of the static water level in alluvial wells to changes in river stage. The main source of water in the alluvium is seepage from the Powder River, stored during periods of high streamflow and discharged back to the river in some reaches during low flow. Groundwater storage in the alluvium declines during the growing season because transpiration exceeds recharge.

Ringen and Daddow (1990) also conclude that water levels in bedrock aquifers do not respond substantially to changes in river stage or water levels in the alluvium. A thick blue clay or shale at the top of the bedrock sequence isolates the bedrock from the alluvium hydraulically, and therefore, from the river, in some locations. In addition, the hydraulic head in the underlying confined aquifer was much higher than the water level in the alluvium.

Slagle et al. (1985) describe groundwater conditions and the hydrology of the alluvium in the northern portion of the PRB, within southeastern Montana. Alluvium along the streams generally is saturated. However, terrace deposits commonly occur above the saturated zone. Losses from perennial streams recharge the alluvium during periods of high flow. Intermittent and ephemeral streams serve as a major source of recharge during times of runoff. Much of the water recharged as a result of irrigation is recirculated to the stream from which it was obtained. Frequently, water moving downward is retarded or intercepted by relatively impermeable material, causing the water to move laterally. Water that reaches the saturated zone raises the water table in the alluvium to above-normal levels, which induces lateral flow and results in increased groundwater

discharge to the stream. Water in bedrock aquifers that doesn't drain directly into perennial streams, infiltrates the alluvium along intermittent and ephemeral streams.

Lowry and Rankl (1987) describe the alluvium in the White Tail Butte area along and west of the Little Powder River, north of Gillette. The alluvium is estimated to be 30 feet thick. Depth to water in alluvium below the land surface was reported be between 5 and nearly 14 feet, based on records from three wells included in the study.

Lenfest (1987) characterizes the hydrology of the alluvium and its relation to streamflow in ephemeral streams at several sites in the Cheyenne River Basin. Alluvium generally is more permeable and can store and transmit more water than upland soils. Surface water infiltrates into the alluvial aquifer at a relatively rapid rate because of the larger hydraulic conductivity of alluvium, and is transmitted through the bedrock aquifer at a slower rate because of the smaller hydraulic conductivity of the bedrock.

Hydrologic data from 1982-1983 for several sites in the Cheyenne River basin are presented by Lenfest (1987). In the North Fork Dry Fork Cheyenne River area (T37N R75W), the alluvial aquifer is 24 to 83 feet thick and contains silt and fine to coarse-grained sand. The unsaturated thickness of the alluvium is 30 feet or more. Alluvium in the Black Thunder area (T42N R66W) consists of silt, fine sand, and gravel that is about 20 feet thick, and has an unsaturated thickness of about 10 feet or less. In the Black Thunder area, recharge to the aquifers from streamflow is indicated. Water levels in the alluvial aquifer increased within three hours of streamflow in Black Thunder Creek. Some water in the alluvial aquifer leaked into the bedrock aquifer, causing water level rises in the bedrock aquifer. Water levels in the alluvial aquifer slope away from Black Thunder Creek, indicating movement of groundwater away from the creek after recharge. Hydraulic head in the alluvial aquifer increased during recharge; the increased hydraulic head in the alluvial aquifer caused increases in hydraulic heads within the bedrock aquifer.

Lenfest (1987) concludes that surface water infiltrates the alluvium and causes water levels in the alluvial aquifer to rise in response to streamflow. Some of the infiltrated water reaches the bedrock aquifer, causing water-level rises. The remaining water probably is lost to evapotranspiration, horizontal flow down valley, or soil moisture in the unsaturated zone.

Computed streamflow loss along a stream reach could not be equated to groundwater recharge by Lenfest (1987), because not all inflow and outflow of the system could be determined. The computed streamflow losses and lower limit of groundwater recharge along the North Fork Dry Fork Cheyenne River ranged from 0.43 to 1.44 acre feet per mile. The computed streamflow loss may be substantially underestimated because of unmeasured inflow and outflow along the reach. An estimate for recharge of 26.5 acre-feet per mile for the same reach was made using a convolution method. Along Black Thunder Creek, estimates of recharge to the alluvial aquifer ranged from 3.56 to 12.4 acre-feet per mile.

Regional Flow Systems

The regional groundwater model used in this PRB Final EIS (BLM 2003c) emphasized substantial vertical flow through the Wasatch Formation and into the underlying Fort Union coal zone. This flow model was supported by observations in monitoring wells. A downward vertical gradient from the Wasatch aquifer to the Wyodak Anderson coalbed aquifer was measured in three of four monitoring-well clusters that were completed in both zones (Bartos and Ogle 2002). However, many investigators have suggested that downward vertical flow or leakage into the coal zone aquifer is small because of the low hydraulic conductivity of the overlying rocks (Bartos and

Ogle 2002). The regional groundwater model was one representation of the complex hydrologic units and groundwater flow systems within the PRB. This model emphasized regional flow to the north, toward Montana.

The following summary of groundwater flow emphasizes the assumptions used in the groundwater model for the PRB Final EIS (BLM 2003c). The assumptions used in developing the model are not the only that could be applied to the PRB using sound professional judgment.

Groundwater discharge from the planning area is principally by groundwater outflow; by loss to gaining streams, springs, and seeps; by evapotranspiration; and by well pumpage (Hotchkiss and Levings 1986). The regional pattern of groundwater flow is complicated by lenticular (discontinuous) beds and local differences in hydraulic conductivity (how the water moves through the aquifer). Water in the lower Tertiary aquifers generally moves northward from recharge areas at higher elevations toward discharge areas at lower elevations (Whitehead 1996). The regional trend of movement changes locally where the aquifers discharge water to large streams, primarily within the lower portions of the Powder River drainage in the planning area.

Rankl and Lowry (1990) describe groundwater flow systems in the PRB. Northward regional groundwater flow is expected in the PRB from potentiometric data that relate the position of the underground aquifers with respect to the topography of the land surface and streams. Groundwater (potentiometric surface) data suggest most streams in the PRB should receive base flow (groundwater discharge) from a regional groundwater system. However, streamflow records do not support this conclusion. The locations of streams having base flows and the period of time that base flows occur indicate base flows are discharged to surface waters from local groundwater systems rather than a regional system. Additionally, groundwater discharge areas have not been identified in the northern part of the planning area on the basis of chemistry of springs and shallow wells. The chemical quality of shallow groundwater in the northern part of the PRB is affected more by local conditions than by regional flow.

Rankl and Lowry (1990) analyzed data from streamflow gaging stations on streams that originate in the area underlain by the Lower Tertiary Aquifer System and have five or more years of record. Base flow occurring during the period of greatest precipitation, but not after the growing season, indicates that base flow is from a local system dependent upon precipitation for each year's discharge. Much of the groundwater discharge from bedrock aquifers is above stream level and is lost due to evapotranspiration, resulting in no measurable contribution to base flow. Within the planning area, only the Little Powder River had measurable groundwater contribution (1 cfs) during the non-growing season. Groundwater contribution of less than 1 cfs was indicated for the Belle Fourche River and Dead Horse Creek (near Buffalo). No groundwater contribution was indicated for Black Thunder Creek or the Cheyenne River.

The major sources of groundwater recharge are infiltration of water from precipitation, streamflow on areas of outcrops, or losing streams, including some perennial stream reaches along the front of the Big Horn Mountains. Regional groundwater flow simulations performed by Hotchkiss and Levings (1986) indicate recharge by direct precipitation accounted for about 30 percent of the total recharge.

Heffern and Coates (1999) describe the role of clinker in the storage and flow of water in the PRB. Normally, clinker outcrop areas are highly permeable, allowing rapid infiltration of rainfall and snowmelt and then slowly discharging the stored water to springs, streams, and aquifers. This stored water helps maintain flow in perennial streams during dry periods. The rate of recharge is

often limited by a relatively low permeability zone that typically occurs at the contact between the clinker and the underlying coal or shale (BLM 2003c).

Davis (1976) describes groundwater recharge and discharge within the eastern PRB. Most of the eastern PRB is a recharge area for the groundwater system below the Wasatch Formation. There are no perennial streams near the coal outcrop. The scoria (clinker) along the coal outcrop appears to be an area of recharge to the coal aquifers. Stream valleys provide primary recharge areas for the Wasatch Formation.

Springs

Springs and seeps occur where groundwater or overland flow (water that infiltrated the surface and is flowing within about 20 feet of the land surface, in response to topographic relief) are discharged to the surface. The locations of springs are usually controlled by topography, faults, or contacts between rock layers or unconsolidated materials that represent a barrier to water movement.

Slagle et al. (1985) describe the nature of springs within the northern PRB. Numerous contact springs and seeps reflect the discontinuous and lenticular nature of bedding and high topographic relief characteristic of the northern PRB. Slagle et al. (1985) estimated that 2,000 springs and seeps exist within more than 10,000 acres of the northern PRB. The average discharge rate for springs is reported as 5.2 gallons per minute in the northern PRB, north of the planning area (Slagle et al. 1985). The primary source of recharge to springs and seeps in the northern PRB comes from infiltration of precipitation and seepage from streams and rivers (Slagle et al. 1985).

Within the planning area, springs also are most numerous where topographic relief is great and stratigraphic units are discontinuous. In addition, springs and seeps also emerge at the base of clinker deposits, along the contact between the permeable clinker and impermeable layers below (Heffern and Coates 1999). The primary source of recharge to springs and seeps within the planning area is assumed to be the same as is reported for the northern PRB. No comprehensive inventory of springs within the planning area is available.

Groundwater Storage

Prior to development by wells, aquifers are in a state of dynamic equilibrium, where recharge and discharge virtually balance over long periods (Lohman 1972). A natural groundwater flow system approximates steady-state groundwater flow, where there is no change in head over time (Lohman 1972).

The groundwater flow system of the PRB continues to be affected by activities that extract groundwater, preventing the flow equilibrium from being reestablished. Only a portion of the groundwater extracted would be replaced through additional recharge or reduced discharge. The remaining portion of the groundwater extracted would come from storage within the coal aquifer and surrounding aquifers, as groundwater in storage within the PRB would leak between hydrologic units.

The Lower Tertiary aquifers in the PRB consist of sandstone beds and coals within the Wasatch Formation and the Fort Union Formation. The water-yielding sandstones and coals are interbedded with claystones and siltstones. Although numerous studies have been conducted on these Lower Tertiary Aquifers, there have been no previous estimates of the volume of recoverable groundwater they contain.

Recoverable groundwater is the water present within an aquifer that can be extracted using pumping wells. Recoverable groundwater is considerably less than the total volume of groundwater in storage because a portion of the water is retained in the voids of formations by capillary forces and cannot flow to wells.

Most calculations of recoverable groundwater are determined from the specific yield of the aquifers. The specific yield is the amount of water that can be removed from the saturated pores of the aquifer by gravity drainage to wells. The specific yield can be determined or estimated through one or more of the following methods:

- Results for observation wells obtained during pumping tests conducted within the unconfined portion of the aquifer,
- Laboratory analysis of cores of aquifer materials, or
- Literature values for aquifers with similar characteristics.

These calculations of recoverable groundwater do not consider the economics of groundwater recovery. As aquifer storage is depleted, the cost of pumping and the required well spacing would usually need to increase in order to maintain yields. Generally, the recovery of groundwater becomes uneconomic before all recoverable groundwater has been removed. Estimates of recoverable groundwater do not consider the component of groundwater stored in the claystones and siltstones that would leak into the sandstones and coals when these units are pumped for water supply or CBNG production. However, the volume of groundwater released from storage in the claystones and siltstones is small relative to the recoverable groundwater in the sandstones and coals.

Volume of Recoverable Groundwater

The volumes of recoverable groundwater from the sandstones within the Tongue River-Wasatch Aquifer, the Lebo Confining Layer, and the Tullock Aquifer were determined from the volume of sandstone in each of these units multiplied by the 13 percent specific yield value for sandstone. Similarly, the volume of recoverable groundwater from the coals within the Tongue River-Wasatch Aquifer was calculated from the volume of coal multiplied by the 0.4 percent specific yield value for coal. These results are summarized in Table 3.12, “Recoverable Groundwater” (p. 367).

Table 3.12. Recoverable Groundwater

Hydrogeologic Unit	Surface Area (acres)	Average Formation Thickness (feet)	Percentage of Sand/Coal	Average Sand/Coal Thickness (feet)	Specific Yield (percent)	Recoverable Groundwater (acre-feet) ¹
Wasatch-Tongue River Aquifer Sandstones	5,615,609	2,035	50	1,018	13	743,121,790
Wasatch-Tongue River Aquifer Coals	4,988,873	2,035	6	126	0	2,516,519
Lebo Confining Layer Sandstones	6,992,929	1,009	33	250	13	227,137,336

Hydrogeologic Unit	Surface Area (acres)	Average Formation Thickness (feet)	Percentage of Sand/Coal	Average Sand/Coal Thickness (feet)	Specific Yield (percent)	Recoverable Groundwater (acre-feet) ¹
Tullock Aquifer Sandstones	7,999,682	1,110	52	430	13	447,246,784

¹ Calculated by multiplying Surface Area Average Sand/Coal Thickness Specific Yield. These numbers vary slightly from the numbers presented in table 3-5 of the Final Environmental Impact Statement and Proposed Plan Amendment for the PRB Oil and Gas Project.						
PRB Powder River Basin						

These results show the very large volumes of recoverable groundwater that occur in the Lower Tertiary aquifers within the planning area. Most of the recoverable groundwater occurs in the sandstone units. The recoverable groundwater in the coals is only a small fraction of the recoverable groundwater in the sandstones.

Estimates similar to those in Table 3.12, "Recoverable Groundwater" (p. 367) are made by the USGS (1999) in evaluating coal resources of the Wyodak-Anderson coal zone in the PRB. The coal resources in the Wyodak-Anderson coal zone within the Wyoming portion of the PRB are estimated to total 510,000 million short tons of coal, considering coals that are 2.5 feet or more thick. Using the USGS conversion factor of 1,770 short tons per acre-foot of coal, an estimated 288,000,000 acre-feet of coal exist within the Wyodak-Anderson coal zone within Wyoming. The recoverable groundwater resource within the Wyodak-Anderson coal zone can be estimated using a 0.4 percent specific yield (BLM 2003c) or an average value for the porosity of the coals (2 percent), as analyzed in the Montana portion of the PRB (BLM 2003c). Using these two methodologies to bracket the recoverable groundwater within the Wyodak-Anderson coal zone only, values ranging from 1,152,000 acre-feet to 5,760,000 acre-feet are obtained.

Groundwater Use

Rankl and Lowry (1990) describe water wells and groundwater use in the PRB. Water wells generally are less than 500 feet deep and principally support livestock and domestic uses. These shallow wells generally produce calcium SO₄ or calcium sodium sulfate waters. Yields from shallow wells completed in sandstone aquifers generally are about 20 gallons per minute. Deep wells yield larger quantities of water that generally is a sodium bicarbonate type. Water from alluvium has not been developed extensively because the underlying Tertiary aquifers contain better quality groundwater and yield higher volumes.

Lowry et al. (1986) describe the existing conditions in the PRB before CBNG development. Enough water for stock and domestic use can be obtained in most areas from wells that are less than 500 feet deep. The large thickness of saturated rocks provides potential for flowing wells in topographically low areas, such as river valleys. Flowing wells can be developed principally in the valleys of the major streams such as the Powder, Little Powder, and Cheyenne Rivers. Yields that exceed 200 gallons per minute can be developed locally from wells less than 1,000 feet deep. One flowing well often supports an extensive distribution system for stock water.

Groundwater in the planning area is used for a variety of purposes, including domestic, municipal, industrial, and agricultural uses. Domestic and livestock wells are usually low yield (1 to 25

gallons per minute). Water for domestic and livestock use is generally found at depths less than 1,000 feet. Many wells in the PRB have sufficient pressure to flow without being pumped.

Occasionally, flowing springs also provide domestic and livestock water sources in the area. Industrial water wells are used primarily for secondary recovery of petroleum.

According to a search of the WSEO water rights database, there are 6,233 groundwater wells actively permitted for domestic use within the three counties that make up the planning area (Table 3.13, “Groundwater Use Summary in the Buffalo Planning Area” (p. 369)). There are also 3,703 actively permitted stock wells and 125 irrigation wells. Additionally, there are 63 wells actively permitted for municipal use, mostly for the City of Gillette, but also for Wright, Clearmont, Kaycee, and Dayton. Any unpermitted wells are not included in these totals as no comprehensive inventory of unpermitted wells is available. Table 3.14, “Coalbed Natural Gas Water Production Summary in the Buffalo Planning Area” (p. 369) describes the estimated and actual water production from CBNG wells within the planning area between 2002 and 2012. Table 3.15, “Active Well Permits in Campbell, Johnson, and Sheridan Counties, 2001 and 2012” (p. 370) summarizes permitted wells by the planning area counties.

Table 3.13. Groundwater Use Summary in the Buffalo Planning Area

Well Type	Groundwater Use (acre-feet per year)	Number of Wells
Domestic (2000 Census)	3,125	6,233
Industrial (Includes Mining)	426	315

CBNG Coalbed Natural Gas

DWS Drinking Water Standard (Primary or Secondary Maximum Contaminant Level)

MRL minimum reporting level

µg/L micrograms per liter

The median value for TDS (838 mg/L) reported by Rice et al. (2002) exceeds the secondary maximum contaminant level for drinking water established by EPA. The TDS values reported by Rice et al. (2002) indicate that the concentration of TDS increases from south to north and from east to west in the PRB. This increase generally results from an increase in sodium and bicarbonate within the water.

The SAR, a calculation of the abundance of sodium relative to calcium and magnesium in water, also increases toward the west and north, with the lowest values reported near and south of Gillette (Rice et al. 2002). The SAR values range from 5 to 69 and the median value is 8.8 (Rice et al. 2002).

The BLM has summarized and modeled SAR and specific conductance (EC) values for CBNG produced water by sub-watershed (BLM 2003c). The SAR and EC are physical properties of water that indicate the relative suitability of water for beneficial and state-designated uses. In the near-surface environment, water that contains high SAR values would cause an exchange of ions in clay minerals within soils. In this case, calcium and magnesium are exchanged for sodium, creating sodium-rich clays with an increased swelling potential and greatly reduced permeability (Rice et al. 2002). The EC is a measure of the capacity of the water to conduct an electric current and indicates the degree of mineralization of the water (Bartos and Ogle 2002).

Beginning in the early 1990s with the onset of CBNG development, the BLM in concert with WSEO and USGS, began a groundwater monitoring program to document the changes in water levels in the producing coal zones. The PRB Final EIS (BLM 2003c) modeled the extent of drawdown in the Ft. Union coalbeds based on this historic production and groundwater levels. Since 1989, the monitoring program has been expanded to include most of the areas of current CBNG production (62 sites). The anticipated effects of CBNG production on groundwater were summarized as follows: "Because coal mining and CBM operations are dynamic, the maximum areal extent of drawdown may change over time and may increase in some areas of the PRB while it recovers in others. The maximum drawdown in any sub-watershed generally coincides with or closely follows the period of peak water production in the watershed." PRB Final EIS p. 4-15 (BLM 2003c).

Ongoing groundwater monitoring by the BLM has been documented and summarized by the Wyoming State Geological Survey in several updates available on their website at <http://www.wsgs.uwyo.edu/public-info/onlinepubs/PRB-Drawdown.aspx>. The updated data summary through 2012 will be available by the end of 2013. This summary validates the statement that the maximum area of drawdown will be the areas of peak water production. In the report, drawdown results are compared with aggregate CBNG production volumes (gas and water) within 1.5 miles of the monitoring well. In general, water levels have dropped where CBNG water production has been highest. Gas pressures at the monitor wells have increased as gas production in the surrounding area increases and water production generally decreases.

The PRB Final EIS also predicted that there could be impacts to shallow groundwater sources due to infiltration at or near surface discharge points and containment impoundments, but made no predictions regarding changes to quality or quantity (BLM 2003c). In the early days of CBNG development, BLM began monitoring shallow groundwater at selected locations around the planning area. Results from this and other monitoring eventually led the Wyoming DEQ to apply additional requirements for testing through “Compliance Monitoring for Groundwater Protection Beneath Unlined Coalbed Methane Produced Water Impoundments” June 2004. Wyoming DEQ requires that prior to new impoundment construction, the proponent must determine the class of any groundwater located below the site of installation and estimate the volume of water by drilling an investigative well to at least 150 feet below ground surface or to bedrock, depending on the proposed size of impoundment. Depending on the designated class of use determined, the operator may be required to relocate the impoundment, monitor impacts to the groundwater or perform no additional monitoring (Wyoming DEQ 2006). Table W.3, “Summary of Wyoming DEQ WQD Coalbed Natural Gas Groundwater Database: 4th Quarter 2011” (p. 2648) in Appendix W (p. 2623) presents the data collected by the Wyoming DEQ regarding the shallow groundwater protection program as of the end of 2011.

Existing Development

Coal Mining

In response to statutory requirements and concerns, several studies and a number of modeling analyses have been conducted to help predict the impacts of surface coal mining on groundwater resources in the Wyoming portion of the PRB. Some of these studies and modeling analyses are discussed below. Much of this information is derived from the Hay Creek II Coal Lease Application Final EIS (BLM 2013c).

In 1987, the USGS, in cooperation with the Wyoming DEQ and Office of Surface Mining (OSM) conducted a study of the hydrology of the eastern PRB. The resulting description of the cumulative hydrologic effects of all current and anticipated surface coal mining (as of 1987) was published in 1988 in the USGS Water-Resources Investigation Report, *Cumulative Potential Hydrologic Impacts of Surface Coal Mining in the Eastern Powder River Structural Basin, Northeastern Wyoming*, referred to herein as the USGS Cumulative Hydraulic Impact Assessment (Martin et al. 1988). This report evaluates the potential cumulative groundwater impacts of surface coal mining in the area and is incorporated by reference into this RMP. The USGS Cumulative Hydraulic Impact Assessment analysis considered 16 current mines and six proposed mines in the PRB as of 1987. It did not evaluate potential groundwater impacts related to additional coal leasing in this area, and it did not consider the potential for overlapping groundwater impacts from coal mining and CBNG development.

Each mine must assess the probable hydrologic consequences of mining as part of the mine permitting process. The Wyoming DEQ must evaluate the cumulative hydrologic impacts associated with each proposed mining operation before approving the mining and reclamation plan for each mine, and they must find that the cumulative hydrologic impacts of all anticipated mining would not cause material damage to the hydrologic balance outside of the permit area for each mine. Additionally, each project must undergo a site specific NEPA analysis by the BLM. In response to these requirements, each existing approved mining permit includes an analysis of the hydrologic impacts of the surface coal mining proposed at that mine. If major amendments to mining and reclamation permits are proposed, then the potential cumulative impacts of the revisions must also be evaluated. If the proposed tract or an alternative tract configuration is leased to the respective applicant, the existing mining and reclamation permit for the mine must be revised and approved to include the new lease before it can be mined.

The PRB Final EIS (BLM 2003c) includes a modeling analysis of the groundwater impacts if an additional 39,000 new CBNG wells are drilled in the PRB by the end of 2011. The planning area for this RMP, which covers all of Campbell, Sheridan, and Johnson counties, as well as the northern portion of Converse County, is similar to studies conducted for the Hay Creek II Final EIS.

The coal mine groundwater monitoring data are published each year by the Gillette Area Groundwater Monitoring Organization (GAGMO), a voluntary group formed in 1980. Members of GAGMO include most of the companies with operating or proposed mines in the Wyoming PRB, Wyoming DEQ, WSEO, BLM, USGS, and OSM. GAGMO contracts with an independent firm each year to publish the annual monitoring results. GAGMO also periodically publishes reports summarizing the water monitoring data collected since 1980 in the Wyoming PRB (e.g., Hydro-Engineering 1991; Hydro-Engineering 1996; Hydro-Engineering 2001; Hydro-Engineering 2007).

Another source of data on the impacts of surface coal mining on groundwater is the monitoring that is required by the Wyoming DEQ and administered by the mining operators. Each mine is required to monitor groundwater levels and water quality in the affected coal aquifers, in the shallower aquifers (overburden and alluvium), and in the subcoal aquifers in the area surrounding their operations. Monitoring wells are also required to record water levels and water quality in reclaimed areas. Hydrologic monitoring data and analyses are submitted to the Wyoming DEQ annually.

The cumulative impacts on groundwater resources associated with large-scale surface coal mining in the eastern PRB have been identified as five major issues:

1. The extent of the temporary lowering of static water levels in the aquifers around the mines due to dewatering associated with removal of aquifers within the mine boundaries.
2. Potential overlapping drawdown due to proximity of coal mining and CBNG development.
3. The effect of the removal of the coal aquifer and any overburden aquifers within the mine area and replacement of these aquifers with backfill material.
4. Changes in groundwater quality as a result of mining.
5. The effects of the use of water from the subcoal Fort Union Formation by the mines.

The first major issue is the extent of water level drawdown in the coal and shallower aquifers in the area surrounding the mines. In general, the saturated sand aquifers in the Wasatch Formation overburden have limited extent and, as a result, the drawdowns in the Wasatch Formation are much smaller and cover much less area than the coal drawdowns.

The GAGMO 25-year report provides actual groundwater drawdown information after 25 years of mining (Hydro-Engineering 2007). Of the 530 monitoring wells included in the GAGMO 25-year report, 195 are completed in the Upper Fort Union (or Wyodak) coalbeds and 193 are completed in the overlying sediments or interburden between the coalbeds located within and near the mine sites in the eastern PRB. The balance of the monitoring wells are completed in local alluvial aquifers or in strata below the lowest coal seam mined. Since 1996, some BLM monitor wells have been included in the GAGMO reports.

The USGS Cumulative Hydraulic Impact Assessment predicted the approximate area of 5 feet or more water level decline in the Wyodak coal aquifer which would result from “all anticipated coal mining.” All of the currently producing mines, including the three applicant mines in the Wright area, were considered in the USGS Cumulative Hydraulic Impact Assessment analysis (Martin et al. 1988). The study predicted that water supply wells completed in the coal may be affected as far away as 8 miles from mine pits, although the effects at that distance were predicted to be minimal

As drawdown propagates to the west, available drawdown in the coal aquifer increases. Available drawdown is defined as the elevation difference between the potentiometric surface (elevation to which water will rise in a wellbore) and the bottom of the aquifer. Proceeding west, the coal depth increases faster than the potentiometric surface declines, so available drawdown in the coal increases. Since the depth to coal increases, most stock and domestic wells are completed in units above the coal. Consequently, with the exception of CBNG wells, few wells are completed in the coal in the areas west of the mines. Those wells completed in the coal have considerable available drawdown, so it is unlikely that surface coal mining would cause adverse impacts on wells outside the immediate mine area.

Wells in the Wasatch Formation were predicted to be affected by drawdown only if they were within 2,000 feet of a mine pit (Martin et al. 1988). Drawdown occurs farther from the mine pits in the coal than in the shallower aquifers because the coal is a confined aquifer that is really extensive. The area in which the shallower aquifers (Wasatch Formation, alluvium, and clinker) experience a 5-foot drawdown would be much smaller than the area of drawdown in the coal because the shallower aquifers are generally discontinuous, of limited areal extent, and often unconfined.

When the USGS Cumulative Hydraulic Impact Assessment was prepared in 1988 there were about 1,200 water supply wells within the maximum impact area defined in that study. Of those wells, about 580 were completed in Wasatch aquifers, about 100 in the Upper Fort Union (or Wyodak coal) aquifer, and about 280 in strata below the coal. There were no completion data available for the remainder of the wells (about 240) at that time.

The coal, overburden and interburden has been permanently removed and replaced with unconsolidated backfill in a mined area will eventually become an unconfined aquifer. Mining would also cause a moderate, short-term reduction in groundwater in aquifers beyond the mined area as a result of seepage into, and dewatering from mine excavations. The extent of drawdown depends on how long the mine excavations were open, the distance of the aquifers from the mined tract, and the extent of dewatering.

Eventually, groundwater is expected to rise to similar levels as observed prior to mining, but it would not have all of the same characteristics because of the more homogeneous nature of the backfill. It is likely that recharged groundwater would be adequate for post-mining land uses such as water sources for livestock and wildlife. Mining would not disturb the aquifers below the coal. (Hay Creek II Final EIS pg. ES-27.) Wyoming DEQ requires that the water quality

in the reclaimed areas of the mines meet the class of use determined for the zones prior to the mining activity.

Uranium

An additional groundwater use in the planning area is related to in situ uranium recovery (ISR). There are several locations in the PRB where uranium is currently being solution mined (see Buffalo Draft RMP and EIS Locatable Minerals pgs. 244-257). Potential surface and groundwater issues could arise from the development of ISR uranium. However, ISR development is under the regulatory authority of the Nuclear Regulatory Commission (NRC), and water quality impacts would be under the authority of Wyoming DEQ. In these active mining areas, the ambient groundwater is circulated as mining solution when oxidants are added for dissolving the uranium in the target formation. Mine areas are maintained in an under balanced condition with respect to water quantity, which means that slightly more water is removed than the amount injected to prevent excursion of the solution from the targeted areas. The mined area is ringed with groundwater monitor wells in the target zone as well as above and below to monitor for leakage of the mine solution. Additionally, the mines are required to determine pre-mining baseline water quality which serves to set the goal for groundwater restoration after mining is complete. The Wyoming DEQ Land Quality Division (LQD) and WQD have authority over the restoration of the groundwater in a mined area, in concert with the requirements of the NRC. BLM's only nexus to the mining of uranium would be the management of BLM surface land within the mine boundary.

In areas where there is potential for conflict between O&G development of federal minerals and potential uranium extraction, BLM requires that the operator's project includes design features to minimize impacts to the fluid mineral (O&G) as well as the locatable mineral (uranium).

Water supplied through groundwater wells are almost always a component of uranium exploration drilling operations. Groundwater for is typically supplied from existing wells from previous uranium exploration activities, converted O&G wells, or in some cases, new purpose-built water wells drilled onsite by the uranium exploration operator. Generally, impacts from these types of wells are limited because of the relatively small amounts of groundwater required for exploration operations. However, improperly completed or abandoned water wells or monitoring wells can contribute to degraded groundwater quality where waters of differing quality are allowed to communicate through the borehole.

Conventional Oil

Processes for the development of conventional oil resources is described in Appendix V (p. 2599). Water for drilling and well completion of the associated wells may be hauled or piped to drilling locations. Water sources are usually commercial water sources that may have been derived from groundwater resources or recycled water if drilling is below the surface casing and fresh water aquifer zones. When drilling commences, and as long as it progresses, water is continually transported to the rig location. Depending on the type of well being drilled anywhere from 5,000 barrels to 100,000 barrels of water is needed for drilling and completion activities. More water would be required if circulation is lost, or permeable zones that cannot withstand the pressure of the drilling fluid are encountered.

Appendix V (p. 2599) thoroughly describes procedures used to protect groundwater resources, including casing and cementing wellbores in proximity to fresh water aquifers. Such measures are designed to ensure wells cannot contribute to degraded groundwater quality by communication through the borehole.

As presented in Table G.2, “RFA-1B Reasonable Foreseeable Development Assumptions: Other Resource Uses” (p. 1942) in Appendix G (p. 1937) there are 6421 total conventional O&G wells in the planning area, of which 3090 are actively producing from 30 zones. Cumulative water production from these wells is estimated at 3,505,145,196 barrels or 45,761 acre-feet of water. On average, for each barrel of oil produced, that means that 2.8 barrels of formation water were co-produced.

Water quality in the PRB varies by producing formation as well as location in the basin. TDS concentrations (salinity) range from very fresh (300 mg/l) to saturated brine (over 300,000 mg/l). Given the variety in water quality, there are also a number of water management strategies in use. For many fields in the planning area, produced water is used to increase oil and/or gas production by re-injecting into the producing formation as a waterflood or for formation pressure maintenance. Where the water quality is acceptable, many operators discharge water to the surface under a WYPDES permit. Water quality criteria for conventional production permits are normally set as listed in Table 3.18, “Conventional Oil Produced Water Quality Limits” (p. 377). with limitations on the amount of specific components that can be discharged to the surface. Wyoming DEQ regulates the WYPDES discharge program and enforces compliance.

Additionally, the Wyoming DEQ applies limits to the volume of water that may be discharged at a permitted outfall on a site specific basis. Both Wyoming DEQ and BLM would monitor surface impacts such as erosion at and downstream of water discharge points and require mitigation as necessary.

Table 3.18. Conventional Oil Produced Water Quality Limits

Effluent Characteristic	Daily Maximum

Groundwater Trends

Continued groundwater monitoring has documented that in areas of continuing CBNG production, water levels continue to decline. The Big George Coal is currently the most prolific coals, showed continued decline in groundwater levels as gas production increased. The Upper Wyodak showed areas of groundwater recovery where gas production has ceased or is declining. Big George production is primarily concentrated in the middle of the basin closer to the basin axis with well completions generally deeper (depths ranging from 1,000 to 2,500 feet). The PRB Final EIS predicted that all the recoverable groundwater stored in the coal zone could feasibly be produced by the end of 2009 (pg. 4-12). The groundwater model predicted the drawdowns for four coal bearing intervals, as well as the Wasatch sandstone aquifers above the coals. Maximum drawdown in any zone would generally coincide with peak water production. For the Big George coal drawdown, the model predicted that “in deep areas of the basin, such as the central and northwestern portions, maximum drawdowns would exceed 800 feet.” Pg. 4-16. In general, the

water in the Big George is not utilized as drinking or stock water source in areas of development due to depth and poorer water quality.

The drawdown magnitude as documented in the BLM Groundwater Monitoring report results for the Big George coal ranges from a recovery of 65 feet to maximum drawdown of 1,445 feet (Juniper). There are 5 locations where drawdown exceeded 900 feet as shown in Table 3.19, “CBNG Well Production and Drawdown” (p. 378).

Table 3.19. CBNG Well Production and Drawdown

Well Site	Initial Date	Producing Wells within 1 1/2 mile radius	CBNG Cumulative Production, mcf	Water Cumulative Production, bbls	Maximum Drawdown, ft.
Big Cat	10-Jul-03	51	7,700,038	14,729,862	1131.1
Bullwhacker	11-Apr-02	47	14,422,781	17,941,550	1070.7
Carr Draw	26-Sep-07	45	517,330	21,785,000	909.3
Juniper	21-Mar-01	76	65,438,526	24,334,287	1445.5

 mcf Million Cubic Feet

The Wyodak coals have shown recent recovery in water level (formation pressure) due to decline in CBNG production in the eastern and southern edges of the basin. Gas production has decline to the economic cut off in many cases. Offset producing wells are being shut in and abandoned. Water production has also declined substantially as the wells are shut in.

3.1.5. Cave and Karst Resources

3.1.5.1. Regional Context

The Federal Cave Resources Protection Act of 1988 (16 United States Code [U.S.C.] 4301-4309) Section 3(1) defines a cave as any naturally occurring void, cavity, recess, or system of interconnected passages beneath the surface of the earth or within a cliff or ledge (including any cave resource therein, but not including any mine, tunnel, aqueduct, or other man-made excavation), and is large enough to permit an individual to enter, whether or not the entrance is naturally formed or man made. Ritter et al. (2002) defines karst as “terrain with distinctive landforms and drainage arising from greater rock solubility in natural water than is found elsewhere.” There are millions of acres of cave and karst resources within the Rocky Mountain West. Cave and karst resources provide habitat for common and Endangered species, research potential for numerous scientific disciplines, and challenges for recreationists. Cave and karst resources in the region are generally in good condition. Challenges to resource managers that oversee cave and karst resources vary by planning area and include: mineral exploration and extraction, recreational activity, looting, and vandalism.

3.1.5.2. Indicators

Previously, the BFO did not actively manage the cave and karst resources within its jurisdiction. Nothing is known about the prior condition of these resources and there are no established indicators for cave and karst resources in the planning area.

3.1.5.3. Current Condition

There is substantial karst topography throughout the Big Horn Mountains. However, most of Buffalo planning area karst in the Big Horn Mountains, is concentrated in the southern end of the range. This area extends from the Natrona County line, west to the Washakie County line, and north to Highway 16, east to Crazy Woman Road, and south along the face of the Big Horns to the Natrona County line. This karst region is primarily comprised of Madison and Amsden limestone layers overlying Bighorn dolomite and constitutes about 456,266 acres. In this same area Tensleep, Gallatin, and Deadwood sandstones provide for the formations of rock shelters. To the east of the Big Horn Mountain range, Wasatch sandstone frequently outcrops in the short-grass plains. Rock shelters also occur in this environment. Karst features, caves and rock shelters contain various types of cave-adapted animal and plant life. These formations are also frequently associated with significant cultural resources. There are numerous caves, karst features, and rock shelters in the planning area. BLM specialists developed descriptions of karst lands, primarily based on regional geographic features. Map 7 displays cave and karst formations in the planning area. Files for each cave or sensitive location on BLM surface are being compiled and will be maintained at the BFO.

Cave and karst resources in the planning area are generally in remote and extremely rugged terrain. These areas have limited options for access. Most cave and karst resources are well protected by virtue of their locations. Remote cave and karst resources are at greatest risk from the secondary effects of management decisions. At present, accessing most of the cave and karst resources in the planning area requires a substantial expenditure of time and effort. Generally, only those who are specifically interested in seeking out caves will utilize most of the area's cave and karst resources. These individuals are likely to be aware of Tread Lightly and Leave No Trace principles that will minimize impacts to cave and karst resources. Caves near access roads and recreation areas are the most vulnerable to casual use and vandalism. These caves are often well known and heavily visited. Graffiti, accumulations of trash, and damage to cave resources (e.g., plants, animals, and formations), are all common results of frequent casual use. It is expected that visitation to all cave and karst resources, remote and easily accessible alike, will increase. White-nose syndrome (WNS) has not been detected in the state of Wyoming. WNS is a concern, but it is not an immediate threat to cave resources.

The Federal Cave Resource Protection Act of 1988 directs the Secretary of the Interior to prepare and maintain a listing of significant caves. The criteria for listing of significant caves are found at 43 CFR 37.11(c). It has been determined that seven caves on BLM-administered public land in the planning area meet one or more of the significant-cave criteria. Section 5(a) of the Federal Cave Resource Protection Act requires that the location of significant caves be kept confidential to protect these resources from unauthorized use and vandalism.

3.1.5.4. Trends

There are no available quantitative and qualitative trend data for cave resources in the planning area. Given the lack of condition or trend data for caves in the planning area, forecasts for the area's resources are likewise not available. The BFO is now collecting data to enable the successful management of cave and karst resources within its jurisdiction. However, as Wyoming populations grow and more people recreate in the planning area, impacts to cave and karst resources will increase. In addition, given the large amount of karst topography in the planning area, future cave discoveries are very likely. WNS has not yet been detected west of Oklahoma. It is impossible to gauge whether or not caves in the planning area will be affected by WNS; however, currently, WNS has not been detected in Wyoming.

3.1.5.5. Key Features

Key features in the planning area are limited to geological formations likely to produce or contain cave and karst resources. These formations are useful for planning purposes as they highlight areas that require careful scrutiny prior to permitting or allowing activities that may impact cave and karst resources.

3.2. Mineral Resources

The federal government classifies minerals into three categories: locatable minerals, leasable minerals, and salable minerals. Locatable minerals are the mining claim minerals, and these are typically uncommon minerals, such as sodium bentonite (also called Wyoming-type bentonite), gypsum, uranium, most metals, and gemstones, among others. Leasable minerals are typically specific minerals, such as crude oil, natural gas, coal, oil shale, trona, geothermal energy, and others. Salable minerals (also called mineral materials) are typically common minerals, such as common varieties of stone, sand, gravel, clinker (locally called "scoria"), and many clays, among others. The location of, exploration on and development of mining claims (and mill or tunnel site claims), the exploration for and leasing of leasable minerals, and the exploration for and disposal of salable minerals on federal lands are authorized by a number of Congressional Acts, and regulated under the CFR. The appropriate sections of the CFR include: for O&G – 43 CFR 3100; for geothermal energy — 43 CFR 3200; for coal – 43 CFR 3400; for solid leasables other than coal — 43 CFR 3500; for salables – 43 CFR 3600; and for locatable minerals – 43 CFR 3800. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c), or the statutes and regulations themselves, for more information.

The following sections describe the locatable, leasable, and salable minerals that occur in the planning area. Each mineral resource is addressed individually in accordance with BLM Manual 3031, *Energy and Resource Assessments* (BLM 1985a). Three other reports associated with this RMP provide more in-depth discussions of certain minerals: the *Mineral Occurrence and Development Potential Report* (BLM 2009c), the *Reasonable Foreseeable Development (RFD) Potential for Oil and Gas* (Stilwell et al. 2012), and the *Summary of the Analysis of the Management Situation* (BLM 2009h).

Most of the planning area lies within the Wyoming portion of the PRB, a major energy development area. It is the largest coal-producing region in the United States. Almost all of this coal is used to generate electricity inside and outside the region. Large quantities of crude oil and natural gas are also produced in the PRB. The only leasable minerals known to occur in the

planning area in economically viable quantities are coal, crude oil, and natural gas. Although geothermal energy exists in the planning area, the known depths at which temperatures potentially useful for commercial application to occur are too deep to be economically viable to develop at this time. Other leasable minerals also occur in the planning area, but are also uneconomical to produce (often quantity and/or quality is insufficient for commercial production, and/or the material is prohibitively far from the nearest market area). Locatable minerals occurring in the planning area include bentonite (Wyoming-type sodium-containing bentonite), gypsum, and uranium; of these three, sodium bentonite and uranium are economically viable to develop. Gypsum has not been economically viable to develop to date, and is expected to remain uneconomical well into the future given current technology, market conditions, and its' remote location. Other locatable minerals are either not known to occur in the planning area or do not occur in quantities currently economically viable to produce. Salable minerals occurring in the planning area include sand, gravel, clinker (locally called "scoria"), moss rock, and stone (building and decorative). Other salable minerals are either not known to occur in the planning area or do not occur in quantities currently economically viable to produce.

Although development of the various mineral resources in the planning area tends to decrease their overall quantity over time, the quantities of many of these resources remaining after many years of mining and development are still quite plentiful (see the various sections below). In addition, erosion and weathering are not anticipated to affect these resources to a material degree; average erosion rates for the major rock types occurring in the planning area range from 0.74 inch to 3.51 inches per 1,000 years (Ferrier et al. 2007; Allred 2004; Riebe et al. 2001).

Determination of the ownership of the mineral estate (the subsurface under a given parcel of land) can often be relatively simple, but can sometimes be more difficult. Mineral ownership is determined based on the content of land patent documents. For leasable and salable minerals, the owner of the mineral estate also administers that mineral estate, meaning they determine if, how, and when the minerals in that land may be developed. The specific minerals under federal ownership for a given parcel of land are determined by the type of federal mineral ownership. The following abbreviations (and their meanings) are used on DOI BLM Master Title Plats (MTPs): "All Min" (all minerals are federally owned), "Coal" (only coal is federally owned), "Coal OG" (only coal, oil, and gas are federally owned), "OG" (only O&G are federally owned), and "Coal OG Sod Pot" (only coal, oil, gas, sodium, and potassium are federally owned). A number of other federal minerals ownership abbreviations are also used on MTPs to denote minerals reserved to the federal government other than through the Homestead Acts (see Appendix A (p. 1771), and the *Mineral Occurrence and Development Potential Report* [BLM 2009c], for more information regarding these acts). Two examples are "All Lsbl Min" (federal government owns only the leasable minerals) and "Min Only 50%" (federal government owns 50% interest in the minerals, and the surface owner owns the other 50% interest). Lands that have no federal mineral ownership have no mineral descriptors on their MTPs. Whether the federal mineral estate for a given parcel is administered by the federal agency that also administers the federally owned surface depends on the mineral classification. For example, locatable and salable minerals are administered by USFS on lands within USFS administrative boundaries (including non-USFS surface), but BLM administers the leasable minerals such as O&G for those lands. All federally owned leasable and salable minerals occurring under private, State of Wyoming, or BLM surface outside USFS administrative boundaries are administered by the BLM. Whether BLM administers the federally owned locatable mineral resource for a given parcel is a bit more complex; see below for more information.

Below are listed the main federal mineral ownership types which comprise the main BLM-administered minerals in the planning area:

- The total acres of the federal locatable minerals resource (federally owned locatable minerals) are lands with federal mineral estate ownership type “All Min,” no matter who owns the surface estate (except those lands under administration of the USFS). However, BLM has administrative authority over locatable minerals projects (exploration and development) only on those lands that contain all federally owned mineral estate (“All Mins”) and BLM-administered surface estate. Only those lands that contain the combination of both this surface ownership type and mineral ownership type comprise the federal locatable minerals resource that BLM administers. All lands with mineral ownership type “All Mins,” though, are open to mineral entry — mining claim location, and exploration and development of locatable minerals. Mining claims (lode and placer mining claims, as well as mill and tunnel site claims) may be located on any acreage with mineral ownership type “All Min,” and BLM records these claims. However, BLM only administers the exploration and development of locatable minerals on those lands with both “All Mins” and BLM surface; these are the acres in the planning area analyzed in Chapter 4. These are the acres for which a Notice would be required to be accepted (for five acres or less disturbance for exploration) or a Plan of Operations (POO) approved (for more than five acres exploration disturbance, or any size development) by BLM before those intended exploration/development activities could occur. The other acres of “All Mins,” those with non-BLM surface estate, or those administered by USFS, are administered for locatable minerals by those respective surface estate owners, or USFS, respectively. See *Locatable Minerals* below for more information.
- The total acres of federal salable minerals resource are lands with federal mineral ownership type “All Min,” and occurring under any surface ownership type (not including USFS-administered lands). These lands comprise the total federal salable minerals resource as analyzed in Chapter 4.
- For leasable minerals, a number of federal mineral ownership types could apply, depending on the particular mineral:
 - The total acres of federal coal resource are lands with federal mineral ownership types “All Min,” “Coal,” “Coal OG,” and “Coal OG Sod Pot.”
 - The total acres of federal O&G resource are lands with federal mineral ownership types “All Min,” “Coal OG,” “OG,” and “Coal OG Sod Pot.”
 - The total acres of federal geothermal energy resource are lands with federal mineral ownership type “All Min.”
 - For all other leasable minerals, it depends on the specific mineral. For example, the total acres of federal phosphate resource are lands with federal mineral ownership type “All Min,” while the total acres of federal sodium resource includes those with ownership types “All Min,” and “Coal OG Sod Pot.” As another example, minerals that would ordinarily be locatable are in one specific circumstance leasable; this only occurs on acquired lands. Therefore, the total acres of federal leasable uranium resource are only those acquired lands with federal mineral ownership type “All Lsbl Min.”

For the analyses summarized in the *Mineral Resources* sections of Chapter 4, the various acreages listed as impacted or potentially impacted by the various management actions indicated are the acreages with the federally owned mineral types appropriate to that particular mineral (as identified and explained above). For example, the federal coal acres (acres of federal coal resource) impacted are acres of federally owned coal (lands with federal mineral ownership types “All Min,” “Coal,” “Coal OG,” and “Coal OG Sod Pot”) in the areas impacted or potentially impacted by the management decision(s) proposed or enacted on behalf of another resource. The

percent of federal coal acres impacted is calculated by dividing the total acres of federal coal by the acres of impacted federal coal, and then multiplying by 100. However, there may be other factors that alter the number of acres likely to be impacted. For many minerals in the planning area, especially those that tend to be explored for and/or developed here, there are areas that are more likely to contain potentially commercial amounts than other areas. Federal coal acreage is somewhat different from other minerals in that there are areas currently identified as acceptable for further coal leasing consideration (BLM 2001a). These areas are selected for coal leasing based on a number of factors (the coal screening process — see *Leasable Minerals– Coal*). One such factor is an increased likelihood in those areas of encountering coal subsurface that is of quantity and quality suitable for mining. The federal coal acreage outside these areas would very likely not be development targets during the life of the RMP, depending on the specific alternative for coal management that is selected in this RMP. Therefore, although another resource's management action may impact some number of the total federal coal estate acres, its impact on those acres of federal coal estate most likely to be developed during the life of the RMP may be greater or lesser. The percentage of acres of federal coal most likely to be developed may be more greatly impacted, or less impacted, than that of the total federal coal acres. Similar situations are likely with all minerals analyzed in Chapter 4, and are discussed as appropriate there.

3.2.1. Locatable Minerals

3.2.1.1. Regional Context

The primary locatable minerals developed in Wyoming are sodium bentonite (also called Wyoming-type bentonite), gypsum, uranium, and decorative building rock. The locatable minerals occurring in commercially viable quantities in the planning area are sodium bentonite, gypsum, and uranium (see Map 9 for the locations these minerals are most likely to be found in the planning area). Sodium bentonite and uranium are currently economic to produce; gypsum is not, nor is it likely to be during the life of the RMP. Other locatable minerals are known to exist in the planning area, but are currently uneconomic to produce. See below and also refer to the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information.

3.2.1.2. Indicators

Indicators used to describe resource condition and assess the status of the locatable minerals resources in the planning area include currently known quantities (both actual known and estimated quantities), historic and forecasted demand, and historic and forecasted production. See the subsections below for more information by mineral. Often there is a production time lag; it takes time for mines to increase production to meet an increase in demand, or for planned mines to come into production. Therefore, previously stockpiled amounts can be quickly depleted when demand increases quickly.

Changes in prices (actual and forecasted) over time for these resources also can be indicators. However, because a change in commodity price often drives changes in supply and/or demand for that commodity, the changes in production and/or demand over time often closely either mirror or parallel price changes. Price changes are usually more volatile, occurring much more quickly and frequently, than changes in demand or production, and can occur for numerous reasons possibly unrelated to the actual supply or demand for the commodity itself. Therefore, price changes are not addressed here.

Additionally, changes in price and/or demand for a particular commodity (either increases or decreases) can lead to additional materials being introduced into the market as suppliers attempt to remain economically solvent. This factor, the introduction of substitute materials into the marketplace, often makes the accurate predictions of demand, supply, and price for individual minerals extremely difficult, both in the short term and in the long term. Development and/or use of substitute materials is not as common for energy minerals like uranium (as well as coal, oil, and natural gas), due to the sometimes vast and capital-intensive infrastructure needed to utilize these minerals as energy sources. However, it can be common for industrial minerals, even those with very special properties such that of sodium bentonite; new materials are being tested and developed continually in efforts to find cheaper, more abundant materials with similar properties.

The levels of mineral exploration and development activities, and the areas where they take place, are integrally linked to supply and demand for these commodities. This often involves local, national, and international economics and politics, and is therefore difficult to predict on the scale of the planning area. Note also that societal, political, and economic priorities, decisions, and events can affect locatable minerals activities through increases or decreases in exploration and/or development activities, and where they occur. Conversely, increases or decreases in locatable minerals activities could impact societal, political, and economic priorities, decisions, and events. As it is difficult to accurately predict future trends in mineral demand and production on the scale of the planning area, only the indicators quantity, demand, and production, and the trends they might reveal, are discussed here, and in relatively general terms.

3.2.1.3. Current Condition

Locatable minerals (both metallic and nonmetallic) are those that are open to mining claim location under the provisions of the *General Mining Law of 1872*, as amended. This and other laws and regulations (such as 43 CFR 3800) outline the requirements for mining claim location and maintenance, for submitting exploration and/or development plans, and for obtaining a patent on a mining claim. Note that provision for obtaining mining claim patents has been under a moratorium by Congress since 1994, and the backlog of pending decisions from that date is quickly reaching an end. See for more information the *Mineral Occurrence and Development Potential Report* (BLM 2009c), or contact the BLM field office closest to the area desired for locating a mining claim and/or conducting exploration and/or developing operations on a claim.

Locatable minerals known to exist in the planning area include sodium bentonite (also called Wyoming-type) and uranium, both currently economic to produce. The only other locatable mineral known to exist in the planning area in commercial quantities (quantities large enough to support a commercial mining operation) is gypsum. Gypsum however, has not historically been, nor is currently, economic to produce; this is not likely to change during the planning period. Other locatable minerals are known to exist in the planning area, including gold, silver, platinum, copper, and many other metals, as well as gemstones, and REEs. Like gypsum, none of these are currently economic to produce, and are not likely to be during the planning period. Unlike gypsum, these minerals are not known to exist in commercial quantities. Limestone deposits occur in the southern Big Horns (see *Cave and Karst Resources*), and some metallurgical-grade limestone (95% or greater purity) is suspected to exist in this area. Economically viable production is unlikely for this commodity, however, due to the remoteness of the area, and long distance to markets. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information. See also *A Citizen's Guide to Uranium*, for more information regarding uranium occurrences, use, regulations, and potential health impacts (Wyoming Mining

Association 2013). There are several reports (many unconfirmed) of the occurrence of REEs in the planning area: in the Big Horn Mountains (in areas administered by the USFS), and in southwestern Johnson County (King and Harris 2002; Sutherland et al. 2013).

Unless formally withdrawn from (closed to) mineral entry, all federal lands in the planning area (including federally administered surface/federal minerals and split estate), are open to the location of mining claims and mill or tunnel site claims, as well as exploration for and development of locatable minerals; this includes other “operations” as defined at 43 CFR 3809.5. To explore for and develop locatable minerals (excluding casual use), either an accepted Notice or an approved Mine POO is required, depending on the amount of surface disturbance, the particular mining activity, and other factors. To develop locatable minerals, an approved Mine POO is required. See 43 CFR 3809.10. More than one locatable mineral may be located on a mining claim (see Table 3.20, “Active Mining Claims in the Buffalo Planning Area” (p. 387)) and explored for and/or developed on the same land at the same time; therefore, the plural, “locatable minerals,” is used. Mining and reclamation plans and reclamation bonding requirements are developed in cooperation with the State of Wyoming DEQ LQD; these items are also required and mutually developed by the NRC for uranium development projects. All locatable minerals projects are reviewed to ensure that no undue or unnecessary degradation would occur, and for compliance with bonding policy for reclamation during and after cessation of project activities.

Areas withdrawn from locatable mineral entry are not available to the location of mining claims or the exploration or development of locatable minerals under a Notice or POO; casual use may likely still be allowed. Section 103 of FLPMA defines the term “withdrawal” to mean “withholding an area of Federal land from settlement, sale, location, or entry, under some or all of the general land laws, for the purpose of limiting activities under those laws in order to maintain other public values in the area or reserving the area for a particular public purpose or program.”

Section 204 of FLPMA identifies the process to withdraw areas from locatable mineral entry. The Secretary of the Interior (but not the BLM) is authorized to withdraw lands from operation of the mining laws following certain procedures. These vary depending on whether the proposed withdrawal is less than 5,000 acres or greater than 5,000 acres. The primary difference between the two processes is that a withdrawal greater than 5,000 acres requires the preparation of an extensive report to support the withdrawal, including a specialist’s analysis of the area’s mineral potential, and notification to Congress of the proposed withdrawal. Congress may then choose to terminate the withdrawal by concurrent resolution.

Withdrawals aggregating more than 5,000 acres made after FLPMA’s enactment in 1976 cannot be for a period longer than 20 years. The process of requesting or applying for the Secretary of the Interior to withdraw certain lands can be started by the identification of those lands in the RMP for which to pursue a withdrawal. In order to make a withdrawal determination, a mineral potential report must be prepared to include all of the information required by FLPMA, 43 CFR 2310, and BLM Manual 3060. The withdrawal request, including the mineral potential report, is ultimately submitted to the Secretary, who then determines if it should be sent to Congress, withdrawn, or denied.

The RMP is not the decision that withdraws the lands from the mining laws. Rather, the RMP recommends lands for withdrawal. It is possible that areas proposed for withdrawals identified in the RMP’s ROD will not ultimately be withdrawn. For purposes of this analysis, however, lands proposed for withdrawal under the different alternatives are identified in this document as “recommended for withdrawal” and the different process for a withdrawal of less than 5,000

acres is not separately discussed. It is assumed in this analysis that areas identified for proposed withdrawal under the different alternatives will actually result in those withdrawals occurring. In addition, unless a withdrawal of public domain land specifically provides otherwise, the land withdrawn is presumed to be available for O&G leasing on a discretionary basis as specified in the Mineral Leasing Act of 1920 (as amended), and any other applicable land use decisions, including remaining open to casual use.

The following three areas in the planning area are not open to mining claim location, or locatable minerals exploration/development (except casual use) as they have been withdrawn from mineral entry through formal Congressional actions:

- Amsden Creek Big Game Winter Range – This area was originally named the Tongue River Deer Refuge and Winter Pasture. Withdrawn are 523 acres of BLM-administered surface/federal mineral lands in northwestern Sheridan County. The Amsden Creek Wildlife Habitat Management Area (WHMA) overlaps this area, and is administered by the WGFD.
- Kerns Big Game Winter Range – Also called the Kerns WHMA, this area was originally named the Sheridan County Elk Winter Pasture. Withdrawn are 155 acres of BLM-administered surface/federal mineral lands in north central Sheridan County.
- Ed O. Taylor Big Game Winter Range – Also called the Ed O. Taylor WHMA, this area was originally named the Middle Fork Powder River Area. Withdrawn are 10,955 total acres of BLM-administered surface/federal mineral lands; approximately 10,695 acres in southwestern Johnson County in the Buffalo planning area, and approximately 260 acres in southeastern Washakie County in the adjacent Big Horn planning area.

There are three areas in the planning area that remain open to mineral entry (location of mining claims, and locatable mineral exploration and development; casual use is also still allowed) while they are under review by Congress for formal designation as Wilderness Study Areas (WSAs). However, such activities must be conducted under the purview of 43 CFR 3802, which includes stringent requirements for maintaining non-impairment of the suitability of these lands for inclusion in the wilderness system. There are no 43 CFR 3802 locatable minerals operations occurring or planned in the three WSAs, likely due to the low potential for commercial amounts of locatable minerals in these areas. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information. These areas are also currently restricted from leasable and salable minerals exploration and development, unless such activities would also not impair these areas' suitability conditions. If Congress acts to have any of these areas formally designated as WSAs, then withdrawal from mineral entry (closure to mining claim location, and locatable minerals exploration and development) will be pursued for that area. If Congress denies formal designation for any of these areas, then that area will still remain open to mineral entry, although management of the area would likely include requirements to maintain much of the areas' unique features. The BLM's recommendation for all three areas is to not become wilderness. None of these three areas are known to contain locatable minerals in currently commercially viable quantities. See *Special Designations – WSAs* for more information. These three areas are (see Map 75):

- Fortification Creek WSA – This area consists of 12,419 acres of BLM-administered surface/federal mineral lands in northeastern Johnson and northwestern Campbell counties.
- Gardner Mountain WSA – This area consists of 6,423 acres of BLM-administered surface/federal mineral lands in southwestern Johnson County.
- North Fork WSA – This area consists of 10,089 acres of BLM-administered surface/federal mineral lands in southwestern Johnson County.

Sodium bentonite, gypsum, and uranium are the only locatable minerals for which the BFO has received Notices or POOs since the Buffalo RMP ROD was signed in 1985. These minerals are known to occur in the planning area in commercial quantities; however, only bentonite and uranium have been or are currently economic to produce. There are five authorized POOs in the planning area: three for developing sodium bentonite, and two for developing uranium. There is also one pending POO: for developing uranium (see Table 3.22, “Current Authorized and Pending Bentonite Plans of Operation in the Buffalo Planning Area” (p. 391) and Table 3.23, “Current Authorized and Pending Uranium Plans of Operation (all ISR operations) in the Buffalo Planning Area” (p. 395)). See Table 3.20, “Active Mining Claims in the Buffalo Planning Area” (p. 387) for a listing by mineral(s) of active mining claims located on federal lands (both federal surface/federal minerals and split estate) in the planning area.

Table 3.20. Active Mining Claims in the Buffalo Planning Area

Mineral	Number of Claims
Bentonite	47
Gold	3
Gypsum	1
Uranium	3,604
Two or more minerals (minerals not identified) ^{1, 2}	4,793
Total Active Mining Claims	8,448
Source: BLM 2012f	
¹ Based on known exploration interest and production, it is assumed that most of these claims were located for bentonite and uranium.	
² Mining claimant(s) are not required to indicate what mineral(s) they are locating their claim(s) for.	

Most bentonite mining in the planning area is concentrated west to southwest of Kaycee; gypsum also occurs in this area. Uranium mining is currently occurring in the Pumpkin Buttes Uranium District between Kaycee and Wright. This district surrounds the Pumpkin Buttes, in southeastern Johnson and southwestern Campbell counties. Some historic mining of uranium occurred in the Kaycee Uranium District, just east of Kaycee; no uranium mining occurs there currently. More information is provided in the following subsections by mineral. As mentioned earlier, other locatable minerals exist in the planning area, such as base and precious lode metals (such as gold, silver, platinum, and copper), and metallurgical-grade limestone, gemstones, and REEs. However, as these minerals are not known to occur in commercial quantities in the planning area, they are not discussed further or analyzed in Chapter 4. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information.

As with all mineral resources, the actual or potential occurrence of a locatable mineral in a given area does not mean that a “deposit” of that mineral exists there. Nor does it mean that any existing mineral deposit might be economically viable to produce, either now or in the future. Actual occurrence of a mineral means that the mineral is known to occur in that area; potential occurrence of a mineral indicates an increased probability of finding the mineral in that area, due to the occurrence of a rock type or geological structure that is likely to contain that mineral. The number of mining claims located, accepted Notices, and pending and approved POOs in the planning area may lead one to presume that the minerals indicated (such as sodium bentonite, gold, gypsum, uranium, etc.) are profitable to mine here. However, the numbers of these claims may be more suggestive overall of the public's interest in these minerals and demand for them than their profitability or probability to be mined here. Due to the greater financial investment needed to conduct activities described in a Notice or POO, the numbers of each of these types

of projects are greater indicators of the likely probability and profitability in developing those minerals in the planning area.

3.2.1.4. Trends

Bentonite is used in hundreds of products, ranging from household and beauty products, food products, in ore processing, and in the O&G and construction industries. According to the Wyoming Mining Association (WMA), bentonite deposits appear to be abundant in Wyoming, comprising approximately 70 percent of the world's known supply (Wyoming Mining Association 2002). Worldwide demand for bentonite (including the high-swelling sodium-containing “Wyoming-type” bentonite) has been rising nationwide, and worldwide production has been rising to meet the rising demand (USGS 2005b; USGS 2009). The current economic downturn (beginning in late 2008) could see worldwide demand for all types of bentonite decrease over the long term, although production of Wyoming-type bentonite might not keep pace with demand (Global Information, Inc. 2009). Nationwide bentonite production increased 30 percent between 2000 and 2008 (USGS 2005b; USGS 2009), while planning area bentonite production increased 92 percent during that period, and 45 percent between 2000 and 2012 (Wyoming Office of the State Inspector of Mines 2000 - 2010). Wyoming-type bentonite will likely continue to be in demand, due to its unique high-swelling property, which few other materials can match (Global Information, Inc. 2009). Table 3.21, “Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area” (p. 388) lists amounts of bentonite produced in recent years from all mines in the planning area (on BLM surface/federal mineral lands, and split estate).

Table 3.21. Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area

Year	Bentonite (tons)	Uranium (pounds U ₃ O ₈)
2000	312,482	63,381 ^a
2001	400,309	37,990 ^a
2002	338,507	33,284 ^a
2003	431,718	23,693 ^a
2004	458,770	8,174 ^a
2005	492,368	3,104 ^a
2006	491,188	0 ^a
2007	548,066	0 ^a
2008	600,000	0 ^a
2009	497,796	0 ^a
2010	506,034	29,666 ^b
2011	549,379	215,635 ^b
2012	453,287	643,892 ^b
2013	461,888	940,000 ^b

U ₃ O ₈ Triuranium Octoxide		

Gypsum is used in numerous products, including construction materials, fertilizer, as a water softener and clay binder, and for some medicinal purposes. There is no history of commercial gypsum mining in the planning area. Although gypsum occurs in the planning area near where sodium bentonite does, the development potential for gypsum is considered low. Despite fairly easy access to the deposits along the same roads used for bentonite mines, gypsum's low price,

the relatively long distance from outcrops to the nearest processing facility in Casper, and the plentiful availability of gypsum elsewhere, has made development of gypsum in the planning area not cost-effective to date. This combination of factors is likely to continue well into the future, at least through the duration of the planning period.

The amount of uranium resources occurring worldwide, nationwide, and statewide (including the planning area), is substantial. Deposits can be identified and defined through exploration; interpretation of certain well logs from O&G wells can also provide information. Various worldwide uranium resources (as measured in pounds of triuranium octoxide(U_3O_8)) are anticipated to supply the forecasted rising worldwide demand through 2045, or longer. These include identified (and speculated) deposits, and uranium obtained from secondary sources (World Information Service on Energy 2007; World Nuclear Association 2013). Conventional uranium production (mining uranium deposits) has varied greatly over the last 25 years, but has steadily risen worldwide. Since 1993, all uranium production in Wyoming has been from mines using ISR methods (Wyoming State Geological Survey 2009), and 45 percent of uranium is produced worldwide from ISR methods (World Nuclear Association 2013). However, two conventional mines (open-pit and/or underground) have been recently proposed in Wyoming, although neither are in the planning area. Secondary sources include reprocessing and re-enrichment of partially spent fuel rods and other products from military programs; processing and enrichment of lower grade deposits and mine tailings; and from inventories held by utilities, other fuel cycle companies, and governments (World Information Service on Energy 2007; World Nuclear Association 2013).

For several years before the somewhat recent economic downturn beginning in late 2008, the price of U_3O_8 increased dramatically, leading to increased interest in uranium development and increased staking of mining claims (including in the planning area). Since then, the price has been quite volatile, and is now still relatively low. However, worldwide demand still remains high, and is projected to continue increasing (World Nuclear Association 2013). Statewide production has experienced an overall decline between 1980 and 2006, with recent resurgence in production beginning in 2010 (Uranium One, Inc., 2015; Wyoming Office of the State Inspector of Mines 1980, 2006 – 2014; Wyoming State Geological Survey 2009). There are three uranium ISR POOs in the planning area: 2 approved (Willow Creek and Ruth), and one pending (Hank). Willow Creek began groundwater restoration and partial mine reclamation in one portion in 2000 (Irigaray), while the other portion (Christensen Ranch) was placed on standby status, awaiting an increase in price; operations at both portions restarted in 2010. Ruth has been inactive since about 1990, and will need major refurbishment and expansion to become operational again. Although the price has varied widely in recent years, it still remains too low for some operations to produce uranium economically. Some of these operations have decreased their production to just that needed to maintain their previously contracted production figures, and some others have begun arranging to have larger operations process their uranium until the price rebounds enough for them to finance building their own processing facilities. Amounts of uranium produced in recent years from all mines in the planning area (on BLM surface/federal mineral lands, and split estate) are given in Table 3.21, “Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area” (p. 388). Increased commercial use of fast breeder reactors and commercial use of neutron efficient reactors may help reduce the worldwide demand of uranium (World Nuclear Association 2013).

3.2.1.5. Key Features

Three locatable minerals occur in the planning area in quantities sufficient for commercial production: bentonite, gypsum, and uranium. However, only bentonite and uranium are currently mined; there is no history of gypsum production from the planning area, and it is not likely that gypsum will be mined during the planning period. Bentonite is volcanic ash-based clay, and is widely used as an absorbent and/or thickener in many products. The type of bentonite being mined in the planning area is a unique high-swelling sodium-containing type (also called Wyoming-type) that can absorb up to 10 times its own weight in water, and swell up to 16 times its original size. Gypsum is a water-soluble mineral used primarily in the construction industry. Both bentonite and gypsum occur in the planning area along the western PRB margin, and near the base of the Big Horn Mountains in southwestern Johnson County. The bentonite layers being mined occur in Cretaceous sedimentary rocks west to southwest of Kaycee, where the bentonite is relatively close to the surface. Gypsum occurs in Jurassic sedimentary rocks just west of the bentonite-containing strata. Uranium is a radioactive metallic element used primarily as a fuel for nuclear power generation, in various military applications, and in medicine and biology. Uranium deposits are found in scattered “roll-front” deposits in relatively shallow Eocene and Paleocene sedimentary rocks in southeastern Johnson and southwestern Campbell counties. See the subsections below by individual mineral for more information.

3.2.1.6. Locatable Minerals – Bentonite

3.2.1.6.1. Regional Context

Refer to *Regional Context* under the *Locatable Minerals* section above.

3.2.1.6.2. Indicators

Indicators that could be used to describe resource condition and assess the status of the bentonite resource in the planning area include the currently known quantities (actual and estimated quantities), historic and forecasted demand, and historic and forecasted production. As indicated earlier, these indicators, and the trends they reveal, are discussed here in relatively general terms.

3.2.1.6.3. Current Condition

Bentonite is a type of light-colored clay that is soft and plastic, and formed through chemical alteration of volcanic ash that was deposited millions of years ago. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more detailed information on bentonite formation. Three prominent bentonite beds are exposed in the planning area. The lowermost is the Clay Spur bed in the upper part of the Lower Cretaceous-age Mowry Shale, and ranges from 3 to 5 feet thick. Two other bentonite beds, averaging 2 feet each in thickness, are exposed in the Upper Cretaceous-age Frontier Formation above the Clay Spur bed. These three beds exhibit the very distinctive characteristics of bentonite deposits: they lack vegetation, the dry, weathered surfaces appear popcorn-like, and the fresh, unweathered surfaces appear waxy. Hard bentonite (chip material) occurs in scattered areas of both formations. These three beds are exposed near the western edges of the PRB, along the eastern flank of the Big Horn Mountains (Map 9).

Bentonite's property of absorption is largely due to its ion-exchange characteristics. Wyoming-type bentonite is a unique high-swelling sodium-containing type, which can absorb up to 10 times its own weight in water and swell up to 16 times its original size (Wyoming Mining Association 2002). Because sodium is a readily exchangeable ion, the sodium in many Wyoming bentonite deposits allows it to swell by absorbing water. This absorptive capacity is desirable for many uses, and few other materials can mimic this property. Bentonite is used in hundreds of products. Uses include absorbents, animal feed, drilling fluids, foundry, iron-ore pelletizing, sealants, and cat litter. It is used in drilling mud to lubricate oil-field drilling equipment, to hold back formation pressure, and to help prevent caving of the drill hole. It is used in the foundry industry for binding iron pellets which are later processed into a variety of metal alloys. Bentonite also provides the water-tight seal engineered into the layers placed under reservoirs and landfills. Other uses include crayons, medicine, cosmetics, and as both a food and non-food thickener.

All active bentonite production in the planning area is occurring in southwestern Johnson County, west to southwest of Kaycee (Map 9). Bentonite production varies from year to year with market demand and available stockpiles. Table 3.21, "Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area" (p. 388) provides annual bentonite production from the planning area for recent years (2000 through 2014). Currently, there are three authorized active open-pit bentonite mines (Table 3.22, "Current Authorized and Pending Bentonite Plans of Operation in the Buffalo Planning Area" (p. 391)), and 47 active bentonite mining claims (see Table 3.20, "Active Mining Claims in the Buffalo Planning Area" (p. 387)) on federal lands in the planning area. The three mines and the claims are on both federal surface/federal minerals and split estate.

3.2.1.6.4. Trends

Wyoming bentonite deposits (known and estimated) appear to be abundant, comprising approximately 70 percent of the world's known supply, and Wyoming is the primary producer of high-swelling sodium-type bentonite in the world (Wyoming Mining Association 2002).

Demand for bentonite (including Wyoming-type) has been somewhat steady nationwide between 2000 and 2010 (USGS 2005b; Virta 2011). However, the current economic downturn beginning in late 2008 could see worldwide demand decrease over the long-term, as construction and O&G development continues to slow; alternative materials may also be discovered (Global Information, Inc. 2009). However, new uses for bentonite continue to be found, and worldwide dips in demand for some uses may be countered by increases for others. A modest worldwide increase in demand of 2.2 percent per year through 2012 is forecast (Global Information, Inc. 2009). Although worldwide demand for Wyoming sodium-type bentonite is expected to decrease, it is likely production may not keep pace, leading to tighter supplies in the short term (Global Information, Inc. 2009). It is likely that Wyoming-type sodium-containing bentonite will continue to be in demand, due to its unique high-swelling capability, which few other currently-known materials can match (Global Information, Inc. 2009).

The nationwide production of bentonite has been somewhat steady, with 4.5 billion tons produced in 2000 and 4.4 billion tons in 2010 (USGS 2005b; Virta 2011). During the same period, Wyoming bentonite production remained somewhat steady, from 4.18 million tons to 4.04 million tons, and was 4.98 million tons in 2014 (Wyoming Office of the State Inspector of Mines 2000 - 2014). Production of bentonite in the planning area has risen 62 percent during that period, from 312,482 tons to 506,034 tons, and more currently was 435,567 tons (Wyoming Office of the State Inspector of Mines 2000 - 2014). Wyoming bentonite production has steadily risen over the years, from 1,141 tons in 1927 to 4.98 million tons in 2014 (Wyoming Office of the State Inspector of Mines 2000 - 2014). During the economic downturn that began in late 2008, Wyoming production is anticipated to slow (Global Information, Inc. 2009). Production in the planning area is currently only occurring west to southwest of Kaycee; this is likely to remain the main producing area, with one new POO received for this area. Table 3.21, "Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area" (p. 388) lists production amounts for bentonite mines in the planning area between 2000 and 2014.

3.2.1.6.5. Key Features

Bentonite beds are exposed along the western edge of the PRB near the eastern flank of the Big Horn Mountains (Map 9). There are three prominent bentonite beds in the planning area: lowermost is the 3- to 5-foot thick Clay Spur bed in the upper part of the Lower Cretaceous age Mowry Shale; the other two beds average 2 feet thick each and each occur in the Upper Cretaceous age Frontier Formation, above the Clay Spur bed. Although it is likely that some amount of bentonite can be found in these two formations all along the western edge of the PRB, the quantity and quality in a given area might not be sufficient to make it economically viable.

3.2.1.7. Locatable Minerals – Gypsum

3.2.1.7.1. Regional Context

Refer to *Regional Context* under the *Locatable Minerals* section above.

3.2.1.7.2. Indicators

There is no history of gypsum mining in the planning area. The long distance from outcrops to the nearest processing facility, gypsum's relatively low price, and plentiful availability elsewhere has made development of gypsum in the planning area not cost-effective. This combination of factors is likely to continue well into the future (including the duration of the planning period).

3.2.1.7.3. Current Condition

Gypsum is a water-soluble mineral used in numerous products, including drywall (also known as wallboard or sheetrock), plaster, cement, and fertilizer, and as a water softener and clay binder, and for some medicinal purposes. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information on the formation of gypsum. There is no history of gypsum mining in the planning area. The development potential for gypsum in the planning area is considered low. Despite fairly easy access to these deposits along the same roads used for bentonite mines, the low price of gypsum, the long transport distance to the nearest processing plant (in Casper, approximately 150 miles), and abundant occurrences of gypsum elsewhere, combine to make gypsum not cost-effective to develop in the planning area. This set of circumstances is not likely to change during the planning period. There is only one active mining claim for gypsum in the planning area (see Table 3.20, “Active Mining Claims in the Buffalo Planning Area” (p. 387)).

3.2.1.7.4. Trends

As noted above, the development potential for gypsum in the planning area is considered low. This is due to the low price of gypsum, the long distance to the nearest processing facility, the remoteness of the area, and abundant occurrence elsewhere. This situation is not likely to change well into the future.

3.2.1.7.5. Key Features

Gypsum occurs in the same areas in the planning area as bentonite – all along the western edge of the PRB near the eastern flank of the Big Horn Mountains (Map 9). Most gypsum in the planning area occurs within three formations: the redbeds of the Goose Egg and Chugwater Formations, and in the Gypsum Springs Formation. These gypsum beds vary in thickness, quality, and areal extent throughout these formations, making it difficult to estimate the amount of this resource.

3.2.1.8. Locatable Minerals – Uranium

3.2.1.8.1. Regional Context

Refer to *Regional Context* under the *Locatable Minerals* section above.

3.2.1.8.2. Indicators

Indicators that could be used to describe resource condition and assess the status of the uranium resource in the planning area include currently known quantities (known and estimated quantities),

historic and forecasted demand, and historic and forecasted production. As indicated earlier, these indicators, and the trends they reveal, are discussed here in relatively general terms.

3.2.1.8.3. Current Condition

Uranium is a radioactive metallic element used primarily as a fuel for nuclear power generation, in various capacities in military arms and armor production, and in certain fields of medicine and biology. In the planning area, uranium is known to occur in economically viable quantities in two formations: the Paleocene age Fort Union Formation, and the Eocene age Wasatch Formation. Uranium is also known to occur in a number of other formations in the PRB, but the quantity and/or quality is generally very low and these will not be discussed further. There are two uranium districts in the planning area: the larger Pumpkin Buttes Uranium District in southeastern Johnson and southwestern Campbell counties between Kaycee and Wright, and the smaller Kaycee Uranium District in south-central Johnson County (Map 9). Most uranium in the planning area has been produced from the larger Pumpkin Buttes District; all current mining is occurring in this district. These two areas contain “roll-front” type uranium deposits in a number of the sandstones occurring in the Fort Union and Wasatch formations. These deposits form when water carrying dissolved and oxidized uranium (picked up while passing through uranium-containing rocks and sediments) encounters a chemically reducing environment (created by the presence of sulfides such as pyrite or H_2S) and/or organic matter (such as plant matter, coal, crude oil, or natural gas), or even certain bacteria, in the sandstone and the uranium precipitates out of solution. These deposits accumulate over millions of years, as very large amounts of groundwater containing small amounts of uranium pass through the sandstones. Typical ore bodies in the planning area contain only 1 to 2 percent uranium (this equates to 10,000 to 20,000 ppm uranium). See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more detailed information on the formation of this deposit type. See also *A Citizen’s Guide to Uranium*, for more information regarding uranium occurrences, use, regulations, and potential health impacts (Wyoming Mining Association 2013).

Uranium is mined using surface mining, underground mining, or ISR techniques (also sometimes called in-situ leaching). Since 1993, all uranium production in Wyoming has been from mines using ISR methods (Wyoming State Geological Survey 2009), although two recently proposed mines in Wyoming (not in the planning area) will be mined via surface and/or underground methods. In the ISR method, the uranium is dissolved back into the groundwater of the sandstone aquifer using an oxidizing chemical, such as sodium bicarbonate, gaseous CO_2 , or sulfuric acid. This is a reversal of how the uranium was deposited in the aquifer via reduction as it encountered organic material or certain bacteria. The groundwater containing the dissolved uranium is pumped to the processing facility on the surface. Using ion exchange columns containing tiny beads of polymer resin, the uranium is “stripped” out of the groundwater solution by converting it to a solid once again. The solid uranium is flushed from the ion exchange column with water into large collection vessels. The uranium is now much more concentrated than it was in the aquifer. The water gained during the flushing from the column is removed by dewatering, and the solid uranium is dried and packaged for shipment. The resulting uranium ore (called yellowcake, as it’s a bright yellow) is shipped to an enrichment facility to concentrate the radioactive isotopes of uranium to a level useful for the desired application. The quantity of uranium resources in Wyoming, including the planning area is substantial. Deposits are identified and defined through exploration and from information interpreted from certain well logs from O&G wells, and then evaluated for economic potential.

The price of U_3O_8 increased dramatically over the past several years before the recent economic downturn beginning in late 2008, resulting in increased staking of mining claims, including in the planning area's Pumpkin Buttes District. Table 3.21, "Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area" (p. 388) provides production amounts from all uranium mines in the planning area for recent years (2000 through 2013), those containing BLM surface/federal mineral lands and split estate. In the planning area, there are two uranium ISR POOs approved by BLM and one pending authorization. One authorized POO (Willow Creek) is currently producing uranium (see Table 3.21, "Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area" (p. 388)); they began producing again in 2010 after nearly 9 years on standby status. The second authorized uranium POO (Ruth) remains inactive since approximately 1990; it is uncertain when this mine will restart operations. The pending uranium POO pending authorization (Nichols Ranch/Hank Unit) has already obtained an NRC Source Material License and a Wyoming DEQ LQD Mine Permit; production of uranium has begun from the already constructed portion of the POO not on BLM-administered lands (Nichols Ranch portion). See Table 3.23, "Current Authorized and Pending Uranium Plans of Operation (all ISR operations) in the Buffalo Planning Area" (p. 395) for the list of uranium POOs in the Buffalo Planning area.

3.2.1.8.4. Trends

The amount of uranium resources worldwide, nationwide, and statewide (Wyoming; including the planning area), is substantial. However, estimates of these resources and reserves can vary widely, depending on many factors that may be taken into account during estimation calculations. Deposits can be identified and delineated through drilling, and interpretation of certain well logs from O&G wells can provide some information as well; the deposits are then evaluated for economic potential. Known recoverable worldwide uranium resources from conventional mineral deposits (as measured in pounds of U_3O_8) were estimated to range from 6.6 to 20 billion pounds (World Information Service on Energy 2007), before the 2011 Fukushima nuclear reactor accident. A more recent study estimates the range to be from 14 to 34 billion pounds from conventional mineral deposits (primary sources), and further estimates that unconventional mineral sources (certain secondary sources) may yield another 4.7 billion pounds (World Nuclear Association 2013). Other secondary sources include reprocessing and re-enrichment of partially spent fuel rods and other products from military programs; processing and enrichment of mine tailings; and from inventories held by utilities, other fuel cycle companies, and governments (World Information Service on Energy 2007). At around current spot prices, the current known recoverable world resource (14 to 34 billion pounds) is believed to last for about 80 years, if used only in conventional reactors and at current usage rates; at increased usage rates, these resources could last as little as 30 years (World Nuclear Association 2013). However, if the price were to double, measured economic resources would likely increase over time 10-fold, due to increased exploration and delineation of deposits, and the reclassification of currently uneconomic resources as economic due to the increased price (World Nuclear Association 2013). Total U.S. uranium reserves are estimated to range from 0.54 to 1.23 billion pounds at the end of 2008, and from 52 to 304 billion pounds at the end of 2012, depending on the forward cost used in the calculations, whose typical cutoffs are 30 U.S. dollars (\$), \$50, and \$100 per pound, and even up to \$250 per pound for some unusual secondary sources (Energy Information Administration 2010, 2013). Total Wyoming uranium reserves at the end of 2012 were estimated to be approximately 32.4 percent of the U.S. total, which equates to a range of 16.8 to 98.5 million pounds, depending on forward costs (Energy Information Administration 2013). See Table 3.23, “Current Authorized and Pending Uranium Plans of Operation (all ISR operations) in the Buffalo Planning Area” (p. 395) for a list of the current uranium Plans of Operation in the planning area.

Uranium production has experienced many ups and downs worldwide, nationwide, and statewide since the existing RMP was implemented in 1985. Production worldwide has steadily risen, and the domestic uranium market faces strong competition from foreign sources (World Information Service on Energy 2007; World Nuclear News 2013). Total nationwide and worldwide (respectively) uranium mine production in 2005 was 2.70 and 108.5 million pounds, and despite yearly ups and downs, in 2012 was 4.15 and 151.8 million pounds (World Nuclear Association 2013; World Nuclear News 2013). Statewide production has experienced an overall decline between 1980 and 2010, with a high of 2.5 million pounds in 2000, down to 0 pounds for years 2006 through 2009 (Wyoming State Geological Survey 2009; Wyoming Office of the State Inspector of Mines 1980, 2006 — 2012). However, one of the two authorized POOs in the planning area (see Table 3.23, “Current Authorized and Pending Uranium Plans of Operation (all ISR operations) in the Buffalo Planning Area” (p. 395) for a list of the current uranium POOs in the planning area) has been producing uranium since 2010: Willow Creek (Uranium One USA, Inc. 2013). A portion (Irigaray) of this uranium ISR project began groundwater restoration and partial mine reclamation in 2000, while the other portion (Christensen Ranch) was placed on standby status, awaiting an increase in price. Operations at both portions restarted in 2010

(Uranium One USA, Inc. 2013). The other authorized POO in the planning area, Cameco's Ruth, has been inactive since around 1990; due to the age of this operation and how long it's been inactive, it will need major refurbishment and expansion to be brought up to operational and production status. The POO pending authorization, Uranerz' Hank, is the second portion of a larger project: the Nichols Ranch/Hank. Both portions of the project were approved by NRC and Wyoming DEQ in 2011, and the Nichols Ranch portion has been constructed and is now producing uranium. The Nichols Ranch portion contains no BLM-administered lands, while the Hank portion does. Therefore, the Hank portion will only begin construction after receiving BLM's approval. There are numerous other uranium ISR projects in the planning area, in all stages from proposed to producing uranium, but none of these incorporate any BLM-administered lands, except one. This one project is a planned expansion of the Willow Creek project, originally set to begin in late 2013. Uranium One installed water wells for water monitoring purposes in the expansion area under a BLM ROW (on BLM-administered lands). Submission of the POO for this expansion has been delayed due to the recent downturn in price, leading to the company resetting some priorities; they hope to submit the POO to BLM in another two to three years' time.

Since 1993, all uranium production in Wyoming has been from mines using ISR methods (Wyoming State Geological Survey 2009). However, two conventional mines (open-pit and/or underground) have been recently proposed in Wyoming, with neither in the planning area. Worldwide, 45 percent of uranium is now being produced from ISR methods (World Nuclear Association 2013). For several years before the somewhat recent economic downturn beginning in late 2008, the price of U_3O_8 increased dramatically, leading to increased interest in uranium development and increased staking of mining claims (including in the planning area). Just those few years of increased price (roughly 2006–2009) led to the discovery and delineation of vast new resources. Since then, the price has been quite volatile, and is now still relatively low. The 10/21/2013 spot price for U_3O_8 was \$35.25 per pound, while the highest ever price of \$136.00 per pound was seen in 2007 (Ux Consulting Company 2013). Although the price has varied widely in recent years, it still remains too low for some operations to produce uranium economically. Some of these operations have decreased their production to just that needed to maintain their previously contracted production figures. Others, mostly smaller, independent companies, are considering, and some have even contracted with other companies, to utilize larger uranium operations for processing their uranium until the price rebounds enough for them to finance building their own processing facilities. Many new and existing projects are intended to be developed as or switched to "satellites" to existing operations with processing facilities; this reduces costs for these "satellite" projects, making more projects more likely to be economically viable. Amounts of uranium produced in recent years from all mines in the planning area (on BLM surface/federal mineral lands, and split estate) are given in Table 3.21, "Annual Production of Bentonite and Uranium From All Mines in the Buffalo Planning Area" (p. 388).

Despite the fact that public and governmental fears were rekindled by the 2011 Fukushima accident, projected worldwide demand for nuclear energy is still high. Demand in 2005 was 133.7 million pounds, and projected to be up to 166 millions pounds per year by 2020, and to range from 350 to 530 million pounds per year by 2050 depending on how much electrical generation capacity is transferred from conventional fuels (such as coal) to nuclear power plants (World Information Service on Energy 2007). Demand in 2012 was 137 million pounds, and more recent projections are that demand will range from 214 to 262 million pounds per year by 2030 (World Nuclear News 2013). There are 435 operational nuclear reactors worldwide (the Fukushima reactor is on long-term shut down and not included in this total), 100 of which are in the US and 18 in China, while there are 147 reactors in permanent shut down, with 32 of these in the US and zero in China (International Atomic Energy Agency 2013). There were slightly more operational

reactors in 2009: 443 worldwide, 104 of these in the US (Nuclear Regulatory Commission 2009). In 2013, there were 69 reactors under construction worldwide, with three of these in the US and 29 in China (International Atomic Energy Agency 2013).

Although worldwide demand for uranium has been increasing, and is likely to continue increasing in the near future given the number of reactors under construction, there are two important developing technologies that might temper the longer term future demand. First, fast breeder reactors utilize uranium more efficiently; the initial reaction is started using plutonium, then the reaction is continued using uranium. Widespread use of these reactors could result in up to a 50-fold increase in the efficiency of uranium utilization as a nuclear energy source (World Nuclear Association 2013). Second, thorium can be used as a nuclear reactor fuel, although it is not yet in commercial use. Neutron efficient reactors, which are designed specifically to utilize thorium, are started using uranium or plutonium, and then continued using thorium (World Nuclear Association 2013). As thorium is about three times more abundant in Earth's crust than uranium, thorium-fed reactors may be a viable alternative to supplement or increase the production of nuclear—derived energy, and potentially reduce dependence on uranium (World Nuclear Association 2013).

3.2.1.8.5. Key Features

In the planning area, commercial amounts of uranium are known to be found in the sandstones in the Fort Union and Wasatch formations. There are two uranium districts in the planning area: the Pumpkin Buttes Uranium District in southwestern Campbell and southeastern Johnson counties between Kaycee and Wright, and the Kaycee Uranium District in south-central Johnson County (Map 9). Most historic, and all current, production in the planning area has been from the larger Pumpkin Buttes District. Since 1993, all uranium production in Wyoming has been from mines using ISR methods (Wyoming State Geological Survey 2009), although two recently proposed mine plans to produce using conventional methods (open-pit and/or underground), though neither of these are in the planning area. These two uranium districts contain “roll-front” type deposits of uranium in sandstones. Ore-grade mineralization generally averages a few tenths of one percent uranium, up to 2 percent uranium (20,000 ppm uranium) near the center of the ore body. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information regarding the formation of these types of deposits.

3.2.2. Leasable Minerals – Coal

3.2.2.1. Regional Context

The PRB in Wyoming and Montana contains some of the largest accumulations of low-sulfur sub-bituminous coal in the world. Being aware of the value of these coal deposits, as the lands were settled in the early 1900s, the federal government retained the mineral rights to the coal. As part of the Federal Coal Management Program, the PRB of Wyoming and Montana was designated a federal coal production region in the 1970s.

Thick coal deposits occur at or near the surface along the eastern boundary of the planning area, along a north-south trend situated east of both Gillette and Wright, and in the northwestern portion of the planning area. Coal occurs at depth, below the surface, throughout most of the remainder of the planning area. Coal from the PRB in Wyoming is valued for its clean-burning properties. The majority of the coal activity within the Wyoming PRB lies within the BFO administrative boundary.

The PRB is the Nation's largest coal-producing region, and coal from the region is shipped nationwide. Most PRB coal production comes from the Buffalo planning area. In 2011, the 426.1 million tons of coal produced from the planning area represented 38.8 percent of U.S. domestic coal production. While both PRB and U.S. production began to decrease in 2009 in response to a national recession, Buffalo planning area production still accounts for approximately one-fifth of total U.S. production.

The PRB also has been the nation's fastest growing coal producing region. U.S. coal production increased 6.0 percent from 1,029 million tons in 1990 to 1,095 million tons in 2012. PRB coal production increased from 184.0 million tons in 1990 to 426.1 million tons in 2011, an increase of 232 percent.

Coal Resource Description

Glass (1997) describes important coal seams of the Powder River Coal Field in Wyoming. The following paragraphs summarize these descriptions. Important coal seams in the Wasatch Formation, from oldest to youngest, include the School, Badger, Felix, and Lake DeSmet coals. Important coal seams in the Fort Union Formation, from oldest to youngest, include the Canyon, Anderson, Wyodak, and Big George coals. Thousands of CBNG holes drilled during the past decade have given us a much more comprehensive idea of where the coalbeds are. More current assessments of coal stratigraphy are now available. According to Flores et al. (2010), for example, the Anderson and Canyon, as well as the Badger and School coalbeds, are splits of the Wyodak coal zone and the Big George is also associated with the Wyodak. Luppens et al. (2008) consider the Big George to equate with the Smith coal deposit above the Wyodak. Coalbeds split and merge in a more complex fashion than previously recognized, and even may “corkscrew” above themselves on a regional basis according to Goolsby and Finley (2000). Individual coal layers are the most continuous rock units in the Fort Union and Wasatch Formations and may extend for tens of miles, splitting and merging with other coal layers, before pinching out, or burning to form clinker or eroded away where exposed along an outcrop. The Wyodak coal deposit consists of both the Anderson and Canyon, and is not a separate deposit of coal. Tongue River Member coals in the Fort Union that are mined include from youngest to oldest are – Roland; Wyodak Rider-Smith (also known as Big George); Upper Wyodak – Anderson; Lower Wyodak – Canyon.

The Wyodak coal zone has the largest strippable reserve base of any coal in Wyoming. It lies near the top of the Fort Union Formation, and formed from decay of plants that lived and died in swamps about sixty million years ago. The coal mines east of Gillette and Wright produce from the Wyodak, near its outcrop where the overburden thickness is lowest, and therefore most profitable to mine. As-received quality of this coal generally ranges from 8,200 to 8,800 British thermal units (BTU) per pound (higher towards the south). Sulfur content averages 0.2 to 0.4 percent, and ash content averages 5 to 7 percent; the low sulfur content makes it attractive to supply power plants nationwide. In the Gillette coal field, the main Wyodak beds (Anderson, Rider, Anderson, Dietz, and Canyon beds) contain a total of 125 billion tons of in-place resources, of which 6 billion have been mined as of 2008 (Luppens et al. 2008). The overlying Smith and Roland beds contain an additional 38 billion tons. Where the beds have merged in the areas of Gillette and Wright, the Wyodak (Anderson) is as much as 202 feet thick, but generally averages 45 feet thick (Luppens et al. 2008). The merged Wyodak coal splits to the north, west and south into several beds, including the Anderson and Canyon, and is eroded or burned to the east (Flores et al. 2010). There are extensive clinker (scoria) deposits east of the coal mines, which resulted from the natural burning of the Wyodak coal near its outcrop in prehistoric to recent times.

The School and Badger coals were developed in the Dave Johnston deposit in the southern part of the PRB. Mining in this area is no longer active. The Felix coal is a persistent coal deposit in the northern and central portions of the planning area, and varies from 5 to 20 feet thick, but is up to 50 feet thick in the central and southern portions of Campbell County. Felix coal exposures east of the Powder River in southern Campbell County have been burned to form reddish clinker-capped hills in the vicinity of Gillette and Wright (Coates and Heffern 1999). The Felix coal is not currently mined.

The Lake DeSmet coal is the thickest known coal deposit in the contiguous United States. Although limited in areal extent, in the northwestern portion of the planning area the Lake DeSmet coal is 250 feet thick. The Lake DeSmet coal is not currently mined, and the uppermost portions of this coal deposit are burned over much of its area of occurrence. Lake DeSmet itself occupies a basin formed by the natural burning of this thick coal.

The Big George coal is not exposed at the surface. It occurs in the subsurface of the west central portion of the PRB at depths between 1,000 and 2,000 feet and is not currently mined. The Big George is up to 216 feet thick and is correlative with the Smith coal, this coal is mined north of Gillette as part of the Wyodak Rider coal zone.

In 2012 the USGS completed their resources assessment of the Wyoming and Montana PRB coal fields (Scott and Luppens 2013). They estimate that the PRB contains approximately 1.07 trillion tons of in-place coal resources. Assuming a maximum 10:1 stripping ratio and minimum five feet of thickness for economically recoverable coal, they further estimate that the PRB contains approximately 25 billion tons of economically recoverable coal resources under present economic conditions and assumptions.

3.2.2.2. Indicators

PRB coal is a very important commodity and plays a large role in the economy of the State of Wyoming and the U.S., and an important role in determining electric power prices and availability nationwide. Demand for PRB coal relates directly to national electric power demand. Historically, PRB coal production has increased at a more rapid rate than national electric demand, because environmental and cost factors make PRB coal favored in the competitive coal market. PRB coal is sulfur compliant; therefore, it costs less to reduce SO₂ emissions, the coals are surface mined in high volume (efficient mines resulting in low production costs), and reclamation has been demonstrated effective and reliable. These advantages indicate the PRB coal will maintain or improve its presence in the domestic coal production mix.

The BLM role in PRB coal production is to lease coal reserves in an environmentally responsible manner at a rate that will maintain reserves under lease to reliably meet coal demand. The BLM also must conduct its coal leasing program to ensure that the public receives fair and full value for the coal resources and that leasing for speculation does not occur.

3.2.2.3. Current Condition

Development Activity

There has been small scale coal mining throughout the Buffalo planning area since the early 1900s, primarily in Sheridan and Campbell counties. There was substantial coal leasing activity between 1955 and 1970; however, much of the leasing was speculative because actual coal production

decreased during this period. In the early 1970s, there was an extensive period of major mining starts and production growth. Almost all of this development was in Campbell County where 16 major coal mining operations opened. The 1980s were a time when these operations matured into major national coal producers. During the 1990s, one additional mining operation opened and three were consolidated with existing mines. After 2000, there were three more consolidations.

There are currently 12 (13 counting the Jacobs Ranch mine which was recently consolidated with the Black Thunder mine) operating mines in the planning area. All are in Campbell County (part of the Antelope Mine is in Converse County). There are presently two mining operations proposed to be opened on existing federal coal leases or on privately owned coal. One of these proposed mining operations is located in Sheridan County. All of the existing or proposed mining operations would be surface coal mines, using truck/shovel or dragline mining methods. Table 3.24, “Status and Ownership of Wyoming Powder River Basin Coal Mines ” (p. 401) lists the names of these mining operations and the 2009 coal production from each.

Table 3.24. Status and Ownership of Wyoming Powder River Basin Coal Mines

Mine	1994 Mine Owner	2009 Mine Owner	2009 Coal Production (million metric tons) ¹	Permitted Production Level (million metric tons) ²	Status and Additional Comments
Buckskin	SMC (Zeigler)	Buckskin Mining Properties	25.4	42	Active
Dry Fork	Phillips/WFA & Fort Union Ltd	Western Fuels - Wyoming	5.2	15	Active (includes former Fort Union Mine)
Eagle Butte	Cyprus-Amax	Alpha Coal West	21.5	35	Active
Rawhide	Carter (Exxon)	Caballo Coal LLC	15.8	24	Active
Wyodak	Wyodak Resources	Wyodak Resources	6.0	12	Active (includes former Clovis Point Mine)
Belle Ayr	Cyprus-Amax	Alpha Coal West	28.7	45	Active
Caballo	Carter (Exxon) & Western Energy	Powder River Coal Co.	23.3	50	Active (includes Rocky Butte and West Rocky Butte leases)
Cordero Rojo	Kennecott & Drummond	Cloud Peak Energy LLC	39.4	65	Active (consolidation of former Cordero and Caballo Rojo Mines)
Coal Creek	ARCO	Arch Coal Inc.	9.8	50	Active
Antelope	Kennecott	Cloud Peak Energy LLC	34.0	42	Active
Black Thunder	ARCO	Arch Coal Inc.	81.1	100	Active
Jacobs Ranch	Kerr-McGee	Arch Coal Inc.	29.3	50	Active (purchased in 2009 by Arch – being consolidated with Black Thunder)
N. Antelope/Rochelle	Peabody	Powder River Coal Co.	98.3	140	Active (consolidation of former North Antelope and Rochelle Mines)

Mine	1994 Mine Owner	2009 Mine Owner	2009 Coal Production (million metric tons) ¹	Permitted Production Level (million metric tons) ²	Status and Additional Comments

Coal Management

Congress enacted the Mineral Leasing Act in 1920. As a result, coal was no longer subject to mineral location (mining claims). Coal became a leased commodity, with development by a federal coal lessee in compliance with the terms and conditions of the lease. The BLM is the DOI agency responsible for mineral leasing under the Mineral Leasing Act.

Under the Mineral Leasing Act, coal was leased both competitively and non-competitively. Competitive leasing occurred in areas identified as “known coal leasing areas” (KCLAs) based on the knowledge that minable coal was in these areas. Non-competitive leasing was allowed outside KCLAs, based on a party obtaining a prospecting permit, and through prospecting, establishing a preference right to a lease by proving that the lease area contained coal in commercial quantities.

The 1976 Federal Coal Leasing Amendment Act (FCLAA) amended the Mineral Leasing Act specific to coal. The FCLAA eliminated new non-competitive coal leasing. It required diligent development and continued operations on coal leases, required the public get fair market value for leases sold, and required that the BLM ensure maximum economic recovery. The FCLAA further required that lands available for federal coal leasing be identified as the result of a multiple-use, interdisciplinary land use planning process.

The Federal Coal Management Program was adopted in 1979 in line with the above legislation, and the contemporaneously enacted FLPMA and Surface Mining Control and Reclamation Act. The 43 CFR 3400 regulations guide the BLM coal program management, setting requirements for land use planning, leasing (whether by regional, lease-by-application, and lease modifications), and post lease maintenance.

Since 1985, federal coal resources in the Buffalo planning area have been managed under the guidelines of the existing Buffalo RMP, including a major update in April 2001. The RMP

provides a framework for coal resource management, including exploration and leasing. The RMP includes specific land use planning and coal screening, and direction on competitive coal leasing. All pending preference right lease applications (PRLAs) have been processed under the RMP's direction. The BLM goal for coal resource management in the Buffalo planning area is to meet reserve needs to maintain currently operating mines, consistent with environmental protections, coal resource conservation, and fair market value return to the government and public.

On February 9, 1989, the DOI proposed to decertify all or a portion of the PRB Coal Production Region. This notice described the process the Regional Coal Team (RCT) would follow if total decertification was implemented (54 *Federal Register* [FR] 6339) and added “The RCT [Regional Coal Team] would recommend to the Secretary of the Interior to revise its charter to allow it to guide lease-by-application within the region.” After the decision to decertify the Powder River Coal Production Region was published on January 9, 1990 (55 FR 784), the Secretary of the Interior signed the new Charter for the Powder River Regional Coal Team on June 6, 1990.

The PRB coal production region had reached production maturity by 1989. As noted earlier, new mining operations were not starting, and producing mines were well established, with some consolidation. Several existing mines had substantially depleted the reserves that the mine had opened on, and created a need for leasing so that existing mines could maintain production capability. Such production maintenance leasing could only work effectively in a decertified coal production region. In a coal production region where the regional lease sales mechanism was required, all tracts had to be offered in one large regional lease sale, with sales scheduled not in response to reserve depletion, but instead based on a single sale date. This works in an area where new mines will be developed, and for competition for new coal mining properties, but is unworkable where existing mines compete for sales in an open coal market, deplete their existing leases at market rates, and need to replace reserves throughout time. Regional leasing, if continued in the PRB, would have resulted in a reduced return to the public from coal sales (due to sale timing), a higher potential for bypass, and likely speculation in leases.

Aware that production maintenance leasing must be actively managed, the BLM has timed and sized the offering of leasing by application (LBA) tracts so that leasing new reserves parallels depletion of leased reserves. This is important to ensure that coal operators have adequate reserves to compete in the open coal market into which PRB coal is sold, while not offering coal resources in amounts that would encourage speculation. Figure 3.24, “Recoverable Tons of Federal Leased vs. Tons of Federal Coal Mined since 1990, Campbell and Converse Counties, Wyoming” (p. 403) shows the results of this management since 1990.

Coal Planning

For federal coal resources, there are specific planning requirements beyond the BLM land use planning regulations. These coal planning regulations are found in 43 CFR 3420.1. Specifically, under 43 CFR 3420.1-4, federal coal lands must be: (1) screened for development potential; (2) reviewed against specific coal unsuitability criteria (see 43 CFR 3461); (3) screened for multiple use constraints; and (4) where the surface is privately owned (as in the PRB), surface owners must be consulted. This process results in a determination of areas acceptable for further consideration for coal leasing, under 43 CFR 3420.1-8. Leasing during the lifetime of the RMP is limited to those acceptable areas, unless the RMP is amended.

Coal planning was originally done in 1977 as part of a Management Framework Plan (a predecessor of RMPs), then done again for the 1985 RMP, and was done once again for the 2001 RMP update. In addition, as part of each coal leasing environmental assessment (EA) or EIS, coal planning is reviewed and updated using the most recent site-specific data for the application area.

In the 1985 RMP, the priority areas available for consideration of coal leasing covered approximately 484,000 acres. After the coal screening process, approximately 378,000 acres

containing approximately 26 billion tons of coal remained. All areas available for coal leasing consideration was limited to the high-priority area. Coal lands available for leasing in the Thunder Basin National Grasslands is constrained by USFS land use plans.

As presented in the April 2001 update of the Buffalo RMP, the four coal planning screens were applied and coal decisions updated in coordination with the USFS and other cooperators. The area of coal development potential was revised, the application of the 20 unsuitability criteria was reviewed and revised based on current data and policy, multiple use decisions were carried forward, and surface owner consultation was conducted (BLM 2001a).

The 2001 coal planning update is the basis for current coal management in the planning area. In this update, BLM reviewed 567,200 acres in two areas identified as acceptable for further coal leasing consideration in the BFO (494,000 acres in Campbell County and 73,200 acres in Sheridan County). These areas contain an estimated 50.25 billion tons of coal. As a result of the update, 63,600 acres over 6.2 billion tons of coal were determined to be unsuitable for surface coal mining operations, while the remainder of the coal lands in these areas remained available for further consideration for coal leasing. Areas were found unsuitable for surface coal mine operations. The primary multiple use conflict was between O&G operations and coal mining, which is resolved by a special condition on leases. Surface owner consultation was completed and documented.

In 2002, there were three plan maintenance actions to clarify the 2001 updated description of existing management.

Preference Right Lease Applications

As explained in the 1985 Buffalo RMP, there were a number of pending PRLAs. The PRLAs covered more than 76,000 acres and about 5.7 billion tons of coal. The RMP directed that existing PRLAs be processed. All remaining PRLAs were processed (they were either rejected or withdrawn) and the cases closed.

Regional Sales

After the PRB federal coal production region was established in 1979, federal coal lands were available for leasing through the competitive process outlined in 43 CFR 3420. This method required leasing regional sales. A number of coal tracts are identified based on industry interest and the tracts addressed in a regional EIS. After the EIS process is completed, a number of sale tracts are chosen and all offered in one sale. The first regional sale was in 1982; six tracts were offered and sold. Most of the tracts sold during the sale had one bidder. One tract did not receive the minimum bid value and was later re-offered and sold. One tract had two bidders.

The second sale referred to in the 1985 RMP had been proposed in a 1984 PRB regional coal Draft EIS issued in 1984. Several tracts were identified in this round of leasing. The Round II (1984) sale was canceled. This was partly due to allegations of misconduct by government officials stemming from the 1982 lease sale, partly from concerns that regional sales were causing increased socioeconomic impacts, and partly due to a flattening coal market. The sale was suspended by a Federal Bureau of Investigation and other law enforcement investigation of some of the persons involved in the Round I (1982) sale for criminal wrongdoing. No individual was indicted or prosecuted because there was no evidence of criminal intent; however, the investigation and attention identified vulnerabilities in the regional sale process. The investigation triggered the Linowes Commission, which studied the regional sale process and made several findings and recommendations for improvement that were integrated into the program by Secretarial decision.

Between 1985 and 1990, the coal lands outlined as priority for coal leasing in the existing plan were the only lands considered for competitive leasing. These lands were available for leasing through the regional sale process. There was no leasing between 1982 and 1989 because there was not enough industry interest or regional need for a second regional sale. However, existing operators were running short on reserves in many cases.

Leasing by Application

The PRB began operating in 1990 as a decertified coal production region, and continues to operate in that way. The RCT is still in place and meets periodically to review regional activity and make recommendations on coal leasing. Since decertification to present, 21 LBA tracts have been offered for competitive lease sale in the PRB and 20 leased. At present 12 LBA tracts are pending, all of which have been recommended for processing by the PRB RCT and are in various stages of processing. Table 3.25, “Successful Lease Sales” (p. 406) lists successful production maintenance sales since 1990. Table 3.26, “Lease by Application Pending, Powder River Basin, Wyoming” (p. 407) lists pending LBAs that have been reviewed by the RCT.

Table 3.25. Successful Lease Sales

Lease by Application Name	Lease Number	Effective Date	Acres	Tons	BID	Cost per Ton

LBA Lease by Application		

Coal leased in the planning area using the LBA process must conform to the Buffalo RMP. If the application is determined to conform, the applicant must supply detailed environmental and coal resource information before the BLM addresses the application. The BLM then completes two separate but concurrent evaluations of the application before a lease is offered for competitive sale.

Detailed coal data is necessary prior to processing a LBA. Coal exploration on federal coal requires an exploration license from the BLM. The BLM reviews exploration programs to ensure they will provide sufficient data to meet adequacy standards for leasing. Licenses are issued after a site inspection, an environmental analysis to consider the impacts of exploration, and public notice inviting other interested parties to participate in the exploration program. Licenses are conditioned as necessary to mitigate impacts. Licensees post a bond to ensure damages and disturbances are repaired. Exploration data are considered confidential and are available only to the BLM, the licensee, and any participating parties. The PRB is the most actively explored federal coal region. This area accounts for as many open licenses and newly issued licenses as the rest of BLM-administered lands nationwide. Table 3.27, “Coal Exploration Licenses” (p. 407) lists recent license activity.

Table 3.27. Coal Exploration Licenses

Year	New Licenses	Open Licenses
2003	2	6
2004	2	4
2005	5	6
2006	4	8
2007	3	7
2008	1	10
2009	2	6
Source: BLM 2013g		

All actions and evaluations of coal lease applications must use data that meets or exceeds the PRB coal region data adequacy standards. This includes environmental and geological data standards.

All lease applications undergo an environmental analysis with full public involvement, including public scoping, completion of an EA or EIS, a public hearing, issuance of a decision and an appeal period.

All lease applications also undergo an analysis to determine fair market value, including the BLM determining in-place reserve; determining an optimum mine plan; determining mining costs, revenues, and net present value; accepting and considering fair market value comments at a public hearing; determining an adjusted comparable sale from other valid sales; preparing a sealed pre-sale estimate; and evaluating bids after the sale before accepting any bid.

In addition, lease tracts in response to a lease application are configured by the BLM to achieve maximum economic recovery and to promote competition. To ensure this, the BLM establishes a study area to encompass all reasonable economic reserves, requires geologic data to meet or exceed data adequacy standards for the study area, and considers maximum economic recovery comments at a public hearing. The BLM independently delineates the sale tract to be offered.

All leases are offered competitively by sealed bid, and successful lease tract bonus bids must meet or exceed fair market value as established by the BLM.

Existing leases can be modified, and reserves and acreage added. The process is similar to LBA, with a limit on the amount of acreage that can be added and the requirement that the BLM find the coal added to be non-competitive. Lease modifications are offered to the existing lessee at the presale fair market value as determined by the BLM.

A federal coal lease conveys the right to explore, develop, and remove the coal leased. The BLM offers coal leases on a deferred-bonus basis. Sealed bids are accepted before the lease sale. The successful high bidder (lessee) is required to submit the first installment, representing 20 percent of the total bid, with their bid before the lease sale. The balance of the bid is paid in equal annual installments on the next four anniversary dates of the lease. The lessee must pay the bonus bid in the first 5 years in equal annual payments. Since the mining in this planning area is surface mining, the lessee must pay a royalty of 12.5 percent of the sale value of coal severed and sold (underground mine leases have an 8% royalty rate). The lessee must comply with the requirements of the Mineral Leasing Act, the Surface Mining Control and Reclamation Act, any relevant state and federal laws, and the terms and conditions of the lease. The lessee has 10 years to achieve diligent development (produce 1% of the recoverable reserve as established by the BLM) and must maintain continued operations in each subsequent year (continue to produce 1% per year). Advanced royalty may be paid in lieu of continued operations for up to 10 years during the initial 20-year term of the lease. The BLM currently requires the lessee to post an annual bond to cover 25 percent of their annual estimated royalty, and 100 percent of annual rental. The BLM also requires a bonus bond unless the lessee requests a waiver and has maintained their payments to the Office of Natural Resources Revenue (ONRR) in good standing. A reclamation bond is required at the time the lease is permitted for mining. That bond amount is established by the Wyoming DEQ.

Mining operations are permitted under the authority of the Surface Mining Control and Reclamation Act. A different DOI agency than the BLM, the OSM, has authority under the Surface Mining Control and Reclamation Act. Before mining may commence on a federal lease, the DOI Assistant Secretary must approve a mine plan. For mine plan approval on a federal lease, the OSM requires a mine and reclamation plan prepared by the lessee; a State Decision Document

from the Wyoming DEQ LQD approving the mine and reclamation plan under Surface Mining Control and Reclamation Act requirements; a Resource Recovery and Protection Plan approved by the BLM establishing the recoverable reserve on the lease, mining limits, and recovery methods; and the BLM findings that the mine and reclamation plan complies with the Mineral Leasing Act; an EA or EIS prepared by the OSM as lead agency for compliance under NEPA for the mine plan approval; concurrence from any federal surface management agency to implement the mine and reclamation plan on surface they administer; and compliance with the Endangered Species Act (ESA), the National Historic Preservation Act (NHPA), and any other applicable federal law.

Coal Exchanges

Coal is a public commodity that lends itself to use for exchanges in the public interest. Coal reserves can be accurately measured and tested, and have considerable value. A lease exchange is authorized either by special acts of Congress or under the authority of the Surface Mining Control and Reclamation Act for alluvial valley floors designated critical to farming. An exchange results when coal lease rights on lands for which Congress has deemed coal mining an undesirable use are exchanged for equal valued lease rights in an area acceptable for further consideration for coal leasing. An exchange requires a NEPA analysis, an appraisal of value, and a finding that the exchange is in the public interest. Several lease exchanges were completed under the Interstate 90 Lease Exchange Act to eliminate coal lease rights under the routing of Interstate 90, and a recent lease exchange to eliminate the lease rights on an alluvial valley floor called Gold Mine Draw.

Coal Lease Management

The BLM administers coal leases. Lease administration includes setting lease bonds, lease readjustment, relinquishment, assignment, advance royalty, and royalty rate reductions. The lessee is required to produce commercial quantities (1% of the established reserve) annually from each lease, starting before the tenth year after lease issuance. Annual production is monitored to verify that each lessee is meeting diligent development and continued operations. The BLM inspects active leases at least every three months and inactive leases annually to determine and enforce compliance with lease terms and conditions. Any coal trespass is resolved under trespass rules. The BLM verifies production and attainment of maximum economic recovery on producing leases every three months. Reported production is compared to independently calculated production based on survey data. Any irregularities are reported to the ONRR, formerly the Minerals Management Service. Reported production during the three-month period is compared to the coal volume mined during the three-month period to determine the effectiveness of recovery practices and to verify the lessee is recovering coal consistent with the recoverable reserves available.

3.2.2.4. Trends

The BLM reviewed projected development activity and related environmental and social effects for the PRB. The PRB Coal Review, Task 2 (AECOM 2011) projected development activity in five-year increments to 2030. Chapter 3 – Past, Present and Reasonably Foreseeable Development – is complete and posted to the BLM website.

The lands determined acceptable for consideration for coal leasing under the coal screening performed for the April 2001 updated description of existing management were estimated to contain about 26 billion tons of coal reserves. Since 1985, about 10.8 billion tons have either been leased or are under consideration for leasing. Coal reserve demand has been projected to

2030 in the Task 2 report for the PRB Coal Review (AECOM 2011) and can be met within the lands currently screened and acceptable.

Coal forecasts for the PRB through 2030 indicate total production is expected to grow at an annual rate of 0.1 to 1.1 percent, consistent with electric power demand. It is expected that interest and demand for new leasing will continue through 2030 based on forecasting. The forecasts indicates a slower rate of increase in PRB coal demand compared with previous forecasts, primarily due to new natural gas discoveries, a greater national priority given to nuclear and renewable energy generation, and potential impacts to coal-fired electric generation from regulation of GHGs. These forecast are consistent with the Energy Information Administration 2012 Energy Outlook Report (Energy Information Administration 2012). Therefore, by 2030 the BLM expects PRB coal production to be between 400 and 500 million tons annually.

3.2.2.5. Key Features

Key features are the areas identified as acceptable for further coal leasing consideration.

3.2.3. Leasable Minerals – Fluids

O&G resources are often found in the pore spaces of sedimentary rocks such as sandstone and limestone, having migrated there from source rocks rich in organic material, such as marine shales. When rocks containing organic material are subjected to heat and pressure, the organic compounds break down over time, resulting in oil and natural gas. As the O&G are generated, they migrate through the pore spaces of the rock or along fractures until they encounter a structural or stratigraphic trap with an impermeable layer. Another mode of occurrence for natural gas is CBNG, where the gas is trapped in the coal where it was generated. A well-known hazard in coal mines, CBNG has become economically important with some of the largest reserves found in the PRB.

3.2.3.1. Regional Context

The PRB is an area of 14 million acres in northeastern Wyoming and southeastern Montana that is roughly bounded by the Big Horn Mountains in the west, the Black Hills in the east, the Miles City Arch in the north, and Wyoming's Laramie Mountains, Casper Arch, and Hartville Uplift in the South. It is managed by four BLM offices in two states; the BFO, the Casper Field Office, and the Newcastle Field Office in Wyoming, and the Miles City Field Office in Montana.

Oil: Wyoming ranks seventh in the United States in the production of oil. Collectively in Wyoming, more than 38,000 wells produced 52.9 million barrels of oil in 2006. In the three counties in the planning area, approximately 9.8 million barrels of oil were produced in 2007.

Natural gas: Wyoming ranks second in the United States in the production of natural gas. Collectively in Wyoming, more than 38,000 wells produced 2.11 trillion cubic feet of natural gas in 2006. In the three counties in the planning area, approximately 13.2 billion cubic feet were produced in 2007.

Coalbed Natural Gas: The PRB CBNG field ranks eleventh in proven gas reserves in the United States (DOE 2008). Proven reserves are (1) the portion of an oil or gas reservoir delineated by drilling and defined by oil/water, gas/oil/water, or gas/water contacts, if any, and (2) the immediately adjoining portions not yet drilled, but that can be reasonably judged as

economically productive based on available geologic and engineering data. In the planning area, the PRB CBNG covers portions of Campbell, Johnson, and Sheridan counties. Map 24 depicts the CBNG potential in the planning area. Collectively in the three counties in the planning area, approximately 429 billion cubic feet of CBNG were produced in 2007.

3.2.3.2. Indicators

The planning area has very few surface geologic structures (anticlines, faulted anticlines, and domes), which was the most successful method of discovering new reservoirs in Wyoming through the earliest periods of exploration. Most of the O&G fields have been and continue to be found using subsurface geologic techniques. These techniques mostly involve 2D seismic and more recently 3D seismic. The data from the seismic reveals the structures underground that may hold the fluid minerals. This data is then used to develop an exploratory drilling program to verify the data.

Another leasable mineral in the Buffalo planning area with some potential for development is geothermal energy. Geothermal energy is not being developed in the Buffalo planning area at this time, and it is not likely to be developed during the planning period.

3.2.3.3. Current Condition

There were few documented test wells drilled until the mid 1900s, when subsurface geologic techniques and acquisition of seismic reflection data began to be employed in Wyoming. The first oil field discovered in the planning area was Billy Creek in 1923. The Adon and Sussex fields were discovered in 1948, and the North Tisdale field in 1952. More fields have since been discovered and developed. Conventional (non-CBNG) fields in the planning area most often are considered to be stratigraphic traps, but structural and combination structural/stratigraphic trap types are also common. Most fields are considered to be oil fields. Gas fields were rarely discovered in the planning area until CBNG exploration began in recent years. The RFD provides a more detailed description and history of O&G development in the Buffalo planning area (Stilwell et al. 2012). For the context of this document, the term conventional well is used to describe those wells that occur at a greater depth than the CBNG wells. This includes vertical wells, directional wells and horizontal wells that are drilled into both conventional and unconventional reservoirs.

Exploration

O&G reservoirs can be discovered by direct or indirect exploration methods. Direct methods include mapping of surface geology, observing seeps, and gathering information on hydrocarbon shows observed in drilling wells. Indirect methods, such as gravity, magnetic, and seismic surveys, are used to delineate subsurface features that could contain O&G that are not directly observable. The petroleum industry utilizes two-dimensional and three-dimensional seismic technology to gather subsurface stratigraphic information to aid in the search for O&G reserves. Seismic technology utilizes explosives in drilled shot holes for source points along linear survey lines and vibroseis or shaker trucks and buggies for source points in a grid pattern over a large area that can cover hundreds of square miles.

Leasing and Production

The BLM reviews and approves Notices of Intent, applications for permits to drill (APDs), and applications from companies to lease, explore, develop, and produce oil, gas, and geothermal

resources on federal lands. The BLM also is responsible for inspection and enforcement of oil, gas, and geothermal wells and other development operations, to ensure that lessees and operators comply with lease requirements and BLM regulations.

The main objectives of the O&G program are to foster a fair return to the public for its resources, ensure environmentally acceptable activities within the program, and provide for conservation of the fluid mineral resources without compromising the long-term health and diversity of the land. BLM management of the O&G program accomplishes several functions in support of the main objectives, including: (1) supporting the domestic need for energy resources, (2) making eligible lands available for leasing through proper planning, (3) timely processing of applications and notices for exploration and development, and (4) inspecting operations and ensuring compliance with lease terms and regulations.

As of October 1, 2008, federal O&G leases covered approximately 2,533,975 acres in the planning area (Map 12) (BLM 2008g). Table 3.28, “Number of Oil and Gas Leases by County in the Planning Area” (p. 412) lists the number of leases and total number of acres under lease by county in the planning area. Federal mineral estate in coal-bearing areas of the PRB has not been offered for lease since 2004 as a result of a Tenth Circuit Court of Appeals ruling (*Pennaco Energy v. Department of the Interior*, 377 F.3d 1147). O&G leasing within coal bearing areas is being analyzed in this RMP revision, and leasing will resume on completion of the RMP revision if O&G leasing is determined to be an appropriate use within the planning area. With the majority of the planning area currently leased, the actions in this document are subject to valid existing rights. These leases are an existing contract between the lessee and the federal government and the stipulations as part of that cannot be changed unless an exemption, modification, or waiver of the lease stipulations occur. The management actions in this document are not an exemption, modification or waiver of the original stipulations. However, based on site specific analysis and the management actions of this document, conditions of approval (COAs) may be placed on the approved APD to mitigate the effects of the proposed action to be in compliance with the management actions of this document.

Due to No Surface Occupancy (NSO) restrictions, three areas in the Buffalo planning area are not open to leasable mineral development (unless those activities cause no surface disturbance) – the Fortification Creek WSA in northeastern Johnson County and northwestern Campbell County, and the Gardner Mountain and North Fork WSAs in southwestern Johnson County in the southern Big Horn Mountains. Three other areas are not open to mineral location (and also not open to leasable mineral development due to their NSO restrictions), because they have been officially withdrawn through Congressional Acts from such activities – Amsden Creek Big Game Winter Range in Sheridan County, part of the Ed O. Taylor Big Game Winter Range in Johnson and Washakie counties, and part of the Kerns Big Game Winter Range in Sheridan County.

Table 3.28. Number of Oil and Gas Leases by County in the Planning Area

County	Number of Leases	Acres Under Lease
Campbell	3,149	1,428,517
Johnson	1,092	803,511
Sheridan	255	301,947
Source: BLM 2008f		

Table 3.29, “Well Statistics for Campbell, Johnson, and Sheridan Counties, November 2008” (p. 413) lists well statistics for the planning area. After the BLM approves an APD on federal O&G leases, the developing company may proceed with drilling in accordance

with applicable regulations, Onshore Oil and Gas Orders, Notices to Lessees, lease terms and conditions, and the approved APD (with the COAs attached to the permit).

Geothermal Energy

Geothermal energy is energy derived from the natural heat of the earth. Typically, geothermal resources consist of underground reservoirs of hot water and steam; subsurface areas of dry hot rock also occur, although more rarely (BLM 2008e). Geothermal reservoirs can have temperatures well over 450°F (235°C), and can be found at various depths below Earth's surface (BLM 2008e). Often, it is either the temperature or depth of a geothermal resource that can determine whether it might be viable to develop; both hotter resources and resources closer to the surface are more likely to be developed for their geothermal energy. Although the potential for geothermal development is defined as heat flow above 140°F (60°C) (BLM 2008e), geothermal resources of lower temperatures are also utilized.

A geothermal lease is for the Earth's heat resources where there is federal mineral estate (BLM 2008e). The BLM has the delegated authority to issue geothermal leases on federal mineral estate, including those underlying lands whose surface is administered by the USFS (BLM 2008e). See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) or contact the BFO for more detailed information regarding mineral leasing.

Geothermal steam and hot water often naturally reach Earth's surface due to the often high subsurface pressures created by the hot steam and hot water. Hot springs, geysers, mud pots, and steam vents all result from hot water and steam that are under pressure and reach the surface (BLM 2008e); typical examples of these features can be seen in Yellowstone National Park, Wyoming. Hot water and steam often can be directly used for their heat energy. However, the heat energy of dry hot rock reservoirs often is captured by injecting cool water, allowing the water to absorb heat from the rock, with extraction as either hot fluid or steam (BLM 2008e). The cooled water is disposed of either on the surface, or injected back into the geothermal reservoir to be reheated for capturing more heat energy (BLM 2008e). Some geothermal resources are deficient in water and permeability, but can be enhanced to increase their productivity. These are called enhanced geothermal reservoirs, and treatments involve increasing the size and connectivity of the rock fractures, allowing the hot water or steam to more easily move through the rock (BLM 2008e).

Geothermal resources are often accessed by wells, with the extracted heat energy being directly used as heat energy, or indirectly used to generate steam to produce electricity (BLM 2008e). Today, geothermal reservoirs of low- to moderate-temperature water (68°F to 302°F [20°C to 150°C]) provide numerous opportunities for direct and indirect use (BLM 2008e); those with even higher temperatures are often used only for indirect use (BLM 2008e). Some direct uses of geothermal resources are heating pools, spas, greenhouses, aquaculture facilities, and buildings; melting snow on sidewalks and driveways; and drying agricultural products. Direct use applications in the United States have been growing at about 6 percent per year (BLM 2008e). These lower-temperature resources are fairly abundant throughout the western United States; a recent survey of 10 western states identified more than 9,000 geothermal wells and springs, more than 900 low- to moderate-temperature geothermal resource areas, and hundreds of direct-use sites (BLM 2008e). In general, indirect use for commercial electrical generation requires geothermal reservoirs with temperatures above 200°F (93°C), although newer technologies can utilize lower temperatures (as low as 165°F [74°C]) (BLM 2008e).

A number of publications (e.g., Williams et al. 2008; DOE 2006; National Oceanic and Atmospheric Administration 1983) state that the PRB has potential for the occurrence of geothermal resources. The potential for the existence of low-temperature geothermal resources (less than 212°F [100°C]) has been rated "good" (DOE 2006), and for moderate- to high-temperature geothermal resources, "low" (Williams et al. 2008). However, to date there has been very limited geothermal exploration; almost all existing information about subsurface

temperatures in the planning area consist of bottom-hole temperatures of O&G wells (Williams et al. 2008; DOE 2006; National Oceanic and Atmospheric Administration 1983). This data suggest that the basin (including the western edge near the Big Horn Mountains and northeastern edge near the Black Hills) might be overall too cool to provide the temperatures needed for geothermal development, except at excessive depths. Development of this resource could either be too costly to be economically feasible or require technologies not yet in existence. The level of this resource remains largely unknown (Williams et al. 2008; DOE 2006), and only with further exploration will the level of this resource become more fully understood.

3.2.3.4. Trends

The earliest recorded test well in the planning area was drilled in 1886 on the Tisdale Structure (Biggs and Espach 1960). From 1902 to 1923 there were at least 30 conventional wells that are known to have been drilled and abandoned. The Billy Creek Field was discovered in 1923. The next field discoveries were in the Adon and Sussex Fields in 1948. In 1952 the North Tisdale Field was discovered. In 1960 the amount of drilling increased reaching a peak in 1969 with 779 conventional wells drilled. The drilling then declined until 1973. From 1974 to 1984 there was a small increase with the peak in 1977 with 405 wells drilled. From 1984 to 1995 drilling decreased to its historical lows. In 1995 and 1996 there was a slight increase in drilling, but since then drilling has occurred at a rate of less than 100 new wells per year with 2007 and 2008 averaging 40 new wells a year. This is expected to continue into the future with possibly a slight increase. Beginning in 2009 horizontally drilled wells began increasing and are forecasted to be the main type of conventional drilling in this planning period.

The earliest suspected CBNG well occurred in 1916, perhaps earlier (DeBruin and Jones 1989). However, there was very little interest in CBNG prior to 1987. There were only 12 wells specifically targeting CBNG prior to 1987 with the first modern well drilled in 1979. From 1987 to 1998 drilling increased from 19 new wells in 1987 to 653 new wells in 1998. There were 1,642 wells drilled during this time period. Starting in 1999 a rapid increase in the number of CBNG wells drilled began. A method called “blanket drilling” was the dominant method of drilling. This resulted in 2507 wells drilled in 1999, more than were drilled in all previous years combined. A gradual change from blanket drilling should be expected in the next five to ten years as development will become more localized and require more geologic and engineering analysis.

There is geothermal energy in the Buffalo planning area; however, the known depths at which the required temperatures exist are too great to make this area an attractive target for current exploration. There are economically viable geothermal energy resources in many areas outside the planning area. With future technological advancements, this resource could become more viable to pursue in the planning area. However, this is not likely during the planning period given the current state of technology.

3.2.3.5. Key Features

Key features for conventional O&G development include oil seeps to surface, mapping of surface and subsurface geologic structures, and exploratory drilling to define the limits of the fields. For CBNG the key feature is drilling within the outcrops of the coal bearing formations. Key features for geothermal energy would include hot springs at the surface or geothermal vents of which there are none in the planning area.

3.2.4. Leasable Minerals – Other

The leasable mineral resources currently being developed in the planning area are coal, crude oil, and natural gas. Although geothermal energy occurs in the planning area, the depths of occurrence for temperatures useful for many commercial applications make it uneconomic to develop currently, or in the near future given the state of technology and market trends. Coal, O&G, and geothermal energy are discussed separately in the subsections above. Although leasable minerals other than these (“other leasable minerals”) are known to occur in the planning area (e.g., potassium, sodium, and phosphate, among others), none of these are known to exist in commercially viable quantities, and this situation is not likely to change during the planning period given market trends.

3.2.4.1. Regional Context

A number of other leasable minerals (e.g., trona, oil shale, and tar sands) are under development in other parts of Wyoming and the western United States.

3.2.4.2. Indicators

As discussed under *Current Condition* below, no other leasable minerals are known to occur in the planning area in quantities sufficient for commercial production. There have never been any requests submitted for leasing of other leasable minerals in the planning area, and this is not likely to change during the planning period.

3.2.4.3. Current Condition

Other leasable minerals, as used in this document, are leasable minerals other than coal, crude oil, natural gas, and geothermal energy. Other leasable minerals in the planning area include potassium, sodium, and phosphate, among others. However, from well logs, well cores, and other information, no other leasable minerals are known to exist in the planning area in commercially viable quantities. There is no history of the development of (or requests for the leasing of) other leasable minerals in the planning area; this is not likely to change during the planning period.

3.2.4.4. Trends

The current situation in the planning area regarding other leasable minerals is not likely to change during the planning period. Therefore, these resources are not discussed further in this chapter, and are not analyzed in Chapter 4.

3.2.4.5. Key Features

There are no known other leasable minerals present in the planning area in quantities sufficient for commercial production.

3.2.5. Salable Minerals

3.2.5.1. Regional Context

The main salable minerals (also called mineral materials) developed in Wyoming are aggregate (e.g., sand, gravel, and rip rap), building stone, common clay, decorative stone (including moss rock), clinker (or porcellanite, locally called “scoria”), and soil. The salable minerals currently being developed for commercial purposes in the planning area are aggregate (sand, gravel, and rip rap), clinker (scoria), building stone, and decorative stone.

3.2.5.2. Indicators

Indicators used to describe resource condition and assess the status of the salable minerals resource in the planning area include currently known quantities (including both actual known and estimated quantities), historic and forecasted demand, and historic and forecasted production. Often there is a production time lag: it takes time for mines to increase production to meet an increase in demand, or for planned mines to come into production. Therefore, previously stockpiled amounts can be quickly depleted when demand increases quickly.

Changes in prices (actual and forecasted) over time for these resources also could be indicators. However, because a change in commodity price often drives changes in supply and/or demand for that commodity, the changes in production and/or demand over time often closely mirror or parallel price changes. Price changes are usually more volatile, occurring much more quickly and frequently, than changes in demand or production, and can occur for numerous reasons possibly unrelated to the supply or demand for the commodity itself. Therefore, price changes are not addressed here.

Additionally, changes in price and/or demand for a particular commodity (either increases or decreases) can lead to additional materials being introduced into the market as suppliers attempt to remain economically solvent. This factor, the introduction of substitute materials into the marketplace, often makes the accurate predictions of demand, supply, and price for individual minerals extremely difficult, both in the short and long term. Use of substitute materials can be quite common for industrial minerals, even for relatively common and abundant ones such as sand, gravel, and clinker (scoria).

The levels of mineral exploration and development activities, and the areas where they take place, are integrally linked to supply and demand for these commodities. This often involves local, national, and international economics and politics, and is therefore difficult to predict on the scale of the planning area. Note also that societal, political, and economic priorities, decisions, and events can affect salable minerals activities through increases or decreases in exploration and/or development activities, and where they occur. Conversely, increases or decreases in salable minerals activities could impact societal, political, and economic priorities, decisions, and events. As it is difficult to accurately predict future trends in mineral demand and production on the scale of the planning area, only the indicators quantity, demand, and production, and the trends they might reveal, are discussed here, and in relatively general terms.

3.2.5.3. Current Condition

Salable minerals are typically used in everyday construction, road building and repair, mining, agriculture, and decorative applications. Most of the federal salable minerals resource in the planning area occurs on split estate lands; these lands have federally owned mineral estate, but its' surface estate component is most often owned by private parties, but also state and other entities – see Appendix X (p. 2661). Salable minerals are disposed of according to the *Materials Act of 1947* (as amended), and other laws and regulations. The regulations at 43 CFR 3600 outline the requirements for obtaining a sales contract for commercial operations or a free-use permit (FUP) for government entities or non-profit organizations. See Chapter 2 or the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information.

Unless closed to salable minerals activities, all federal lands in the planning area (including federally administered surface/federal minerals and split estate) are open to the exploration and development of salable minerals. To explore for salable minerals (excluding casual use), a letter of authorization is required. To develop a salable minerals deposit, an appropriate mining and reclamation plan is required. Mining/reclamation plans and reclamation bonding requirements are developed in cooperation with the State of Wyoming DEQ LQD. All salable minerals projects are reviewed to ensure that no undue or unnecessary degradation would occur, and for compliance with bonding policy for reclamation after cessation of project activities.

Three areas in the planning area are not open to salable minerals activities, as they are under review by Congress for formal designation as WSAs. These areas also are currently restricted from leasable mineral activities, unless such activities (salable or leasable minerals activities) would not impair the areas' suitability conditions for designation as wilderness. If Congress acts to have any of these areas formally designated as a WSA, then the restriction on salable minerals activities for that area will become a permanent prohibition. If Congress denies formal designation for any of these areas, then that area will then become open again to salable minerals activities, although management of the area would likely include requirements to maintain much of the areas' unique features. The BLM recommendation for all three areas is to not become wilderness. See *Special Designations – WSAs* for more information. These three areas are (see Map 75):

- Fortification Creek WSA – This area consists of 12,419 acres of BLM-administered surface/federal mineral lands in northeastern Johnson and northwestern Campbell counties. Clinker (scoria) is the only salable mineral known to occur in commercial quantities in this area, and adequate quantities are available outside its boundaries.
- Gardner Mountain WSA – This area consists of 6,423 acres of BLM-administered surface/federal mineral lands in southwestern Johnson County. Moss rock and building stone are the only salable minerals known to occur in commercial quantities in this area, and adequate quantities of each are available outside its boundaries.
- North Fork WSA – This area consists of 10,089 acres of BLM-administered surface/federal mineral lands in southwestern Johnson County. Moss rock and building stone are the only salable minerals known to occur in commercial quantities in this area, and adequate quantities of each are available outside its boundaries.

Those salable minerals useful for road construction and maintenance (sand, gravel, clinker [scoria], and rip rap) are in greatest demand in the planning area. Most clinker (scoria) in the planning area is used by the coal mines near Gillette to keep their haul roads passable. They need large volumes of mineral materials for this, and scoria is relatively abundant in and near the coal mine areas, while sand and gravel are much less abundant in those areas. Sand and

gravel are used mostly for O&G development, general construction purposes, and non-mine road surfacing and maintenance (highways, county roads, etc.). Some sandy shale deposits occur in the planning area, and two current sales contracts are for this material, for use on nearby oil/gas and bentonite mine roads. Building and decorative stone (including flagstone and moss rock) and other mineral materials have typically experienced much less demand from public lands in the planning area than sand, gravel, and clinker (scoria). Disposals of these materials are typically small (fewer than 5 tons), although occasionally a larger sale has been requested. There is one Common Use Area (CUA) in the planning area (comprised of seven small collecting areas scattered across Johnson County), and currently all moss rock and flagstone sales from public lands occur from the CUA. Because the demand for and production of these mineral materials from public lands in the planning area are typically very low (especially as compared to that of sand, gravel, and clinker (scoria)), they are only briefly addressed below. For the same reason (typically very low volumes), they are not addressed or analyzed in Chapter 4. See the *Mineral Occurrence and Development Potential Report* (BLM 2009c) or Chapter 2 of this RMP for more information regarding these mineral materials.

Sand and gravel are typically the same substance: fragments or particles of rock, but of different sizes. In addition, they more often occur as mixed deposits (mixed sand and gravel), rather than just one or the other. Most importantly, these, and the sandy shale, are used for generally the same purposes in the planning area. For these reasons, they are not discussed or treated separately in this chapter, nor are they separately addressed and analyzed in Chapter 4. Clinker (scoria), though, is a very different material from sand and gravel. Table 3.30, “Current Authorized Salable Mineral (Mineral Materials) Disposals in the Buffalo Planning Area” (p. 419) lists the current authorized disposals (both contracted sales and FUPs) for salable minerals (mineral materials) on BLM-administered lands in the planning area. Note that the table lists only sand and gravel and clinker (scoria) disposals. Recent and current sales of other salable minerals are typically very small (1 to 5 tons per year total), and only from the CUA; due to the small volumes sold, these are not included here or in the analysis and discussion in Chapter 4. The Buffalo planning area has the greatest number of mineral material sales and FUPs of any field office in Wyoming, nearly twice that of the field office with the next largest number.

3.2.5.4. Trends

Sand and gravel deposits tend to occur along major drainages throughout the planning area and along the eastern flank of the Big Horn Mountains, but can occur in more isolated deposits across nearly the entire planning area (Map 10). Although the areal extent of clinker (scoria) in the planning area is fairly well known (Map 10), the thickness and quality of these rocks is not. The thickness and quality of sand and gravel and clinker (scoria) deposits can often only be determined through exploration, usually by trenching and sometimes by drilling. Note that where sand and gravel and clinker (scoria) deposits have been identified as occurring or likely to occur (Map 10) is not necessarily where they are likely to be mined. Such common, low-priced, bulk commodities are most likely to be developed as near the point of use as possible, to keep transportation costs low. The demand for sand and gravel is moderate in the planning area, and the largest consumers have been O&G companies for use in development of those resources. Given the estimated areal extent of these deposits and somewhat lower demand for these minerals, it is very likely that there is enough sand and gravel in the planning area to meet local demand during the planning period. The demand for clinker (scoria) in the planning area is high, and the coal mines along the eastern edge of the PRB are the main users of this mineral. Given the areal extent of clinker (scoria) in the planning area (a total of 350 square miles), there is very likely enough to meet local demand during the planning period.

Building and decorative stone of various types also occurs in the planning area, but the demand for and production of these minerals is typically of a much lower volume than that for sand, gravel, and clinker (scoria). Due to low demand and production, trends for these minerals are not discussed. Moss rock consists of lichen-encrusted scoria, limestone, and sandstone. Moss rock occurs in various areas of often limited size and extent, scattered across the planning area. Flagstone is the main building stone of interest in the planning area, and this consists of light tan to reddish to purplish sandstone layers that tend to break into predominantly flat pieces. Flagstone outcrops typically occur along the edges of the PRB.

Table 3.31, “Authorized Amounts for Salable Mineral (Mineral Materials) Disposals in the Buffalo Planning Area” (p. 422) lists amounts for recent (2000 through 2010) authorized salable minerals (mineral materials) disposals on BLM-administered lands in the planning area. The indicated amounts are only of sand, gravel, and clinker (scoria), as discussed above. These disposal authorizations are separated into contracted sales to private entities and FUPs to

government entities; no nonprofit organizations currently have approved free use of mineral materials in the planning area. All amounts authorized (cubic yards or tons) in each year for each type of mineral and by type of authorization are presented below as summations. Converting between cubic yards and tons is not always straightforward and there are a number of factors to consider; therefore, the table lists the volumes (cubic yards) and weights (tons) separately to maintain accuracy of reporting.

Table 3.31. Authorized Amounts for Salable Mineral (Mineral Materials) Disposals in the Buffalo Planning Area

Year	FUPs (cubic yards)	FUPs (tons)	Sales (cubic yards)	Sales (tons)
2000	60,000	57,500	745,100	6,450
2001	100,000	222,000	550,450	8,600
2002	60,000	182,000	897,250	18,000
2003	62,800	423,650	1,122,650	14,900
2004	37,000	121,500	881,100	107,200
2005	73,000	290,000	679,935	22,000
2006	30,000	275,000	698,650	158,000
2007	400,000	113,000	1,306,050	87,800
2008	45,000	100,500	950,000	50,000
2009	60,000	225,000	650,000	85,000
2010	58,000	185,000	800,450	65,000
2011	0	0	382,092	0
2012	200,000	0	482,075	0

Source: BLM 2008f

Note: The amounts listed in this table are the amounts that had been authorized to be produced, not actual produced amounts; actual production may have been less than the amounts authorized.

fup free-use permit

Demand for salable minerals nationwide has been increasing in recent years due to an increase in construction and general growth. However, this trend has slowed very recently due to the economic downturn beginning in late 2008, and the also decreasing price for natural gas. Matching this trend, BLM had seen a consistent increase in the amount of salable minerals sold and in the number of contracts and requests for contracts for salable minerals over recent years (Table 3.31, “Authorized Amounts for Salable Mineral (Mineral Materials) Disposals in the Buffalo Planning Area” (p. 422), above), with this trend starting to slow in the last few years. Scoria comprises the largest portion of the salable minerals mined in the planning area – approximately 75 percent of the amount (cubic yards plus tons) of all mineral materials disposals. Coal companies use most of the scoria mined in the planning area on their haul roads to allow year-round safe access in and around the coal mining areas; all from just five scoria mines. Private entities operate 13 scoria mines in the planning area. Most of these mines sell the scoria to CBNG and oil companies, mostly for use in local O&G development; and one scoria mine provides materials solely for use on a very large ranch. Three scoria mines are operated by county governments via FUPs, and this material is used for county road maintenance. The demand for scoria should remain high into the future because coal production in the PRB is expected to grow 2 to 3 percent annually (see *Leasable Minerals – Coal*) and coal companies will continue to need scoria to maintain their haul roads. Scoria is also used in O&G development, which also is anticipated to continue at a good pace (see *Leasable Minerals – Fluid*).

Sand and gravel are mined in less substantial quantities, constituting approximately 25 percent of the amount (cubic yards plus tons) of all mineral materials disposals in the planning area.

Private entities operate 16 sand and gravel mines for sales in the tri-county area to CBNG and oil companies for use in O&G development, and to construction companies for use in general construction purposes. Local counties operate 14, and a local city operates one sand and gravel mine. These agencies tend to use more sand and gravel for road maintenance than scoria, because scoria tends to break down more rapidly and often creates more dust than sand and gravel. Although sand and gravel production has decreased somewhat very recently as O&G development began to slow, production in the future will likely be at a lower volume than the current level, but is anticipated to be sufficient to meet demand.

The demand for building stone and moss rock is very low. These materials are typically sold to residents from across the planning area in small quantities, five or fewer tons, from the CUA's seven small collecting areas in Johnson County. This amount of demand is not likely to change significantly over the planning period.

3.2.5.5. Key Features

The salable minerals being developed in the planning area tend to occur at or very near the surface (Map 10). As the prices of most of these minerals are relatively low, operators look for deposits that will have lower mining, preparation, and transportation costs. This means that the deposits being explored for and developed either occur at the surface or have relatively thin overburden (the rock, sediment, and/or soil on top of a deposit and which needs to be removed prior to mining the deposit), and as near as possible to the area of use. The formations in which these minerals occur are summarized here; see *Geological Resources* or the *Mineral Occurrence and Development Potential Report* (BLM 2009c) for more information regarding these minerals.

Most aggregate (sand, gravel, and rip rap) in the planning area were derived from alluvial deposits consisting of detritus (eroded rocks) exposed in the Big Horn Mountains, or from other formations such as the Wasatch and Fort Union Formations in the PRB. Gravel deposits in the Kingsbury Conglomerate and Moncrief Members of the Wasatch Formation are especially predominant along the western and southern edges of the PRB. Aggregate from more eastern areas comes from other portions of the Wasatch and Fort Union Formations. A relatively small amount of aggregate is mined from stream beds. Clinker (scoria) is reddish- to brownish-colored to black rock, that often breaks into thinnish slabs although some areas can be vesicular (bubbly-looking). It is the vesicular portions that gave rise to the local name of scoria, as these portions can look nearly identical to that volcanic rock. Clinker formed in the PRB when rocks and sediment overlying a coal seam were baked and/or melted as the coal seam burned. Scoria is found in the Wasatch and Fort Union Formations where coal seams had caught fire along their surface outcrops or exposures along river and stream courses. It is especially prominent in the Rochelle Hills east of the coal mines in eastern and northern Campbell County, as well as north-central and south-central Sheridan County, and north-central Johnson County near Lake DeSmet, and east of Buffalo (Heffern and Coates 1997). Building and decorative stone of various types (including moss rock and flagstone) typically outcrop in localized areas, where these harder layers of sedimentary rock are exposed through erosion. Moss rock occurrences are usually limited in size and extent, and consists of lichen-encrusted scoria, limestone, dolomite, and sandstone. These are found in the Wasatch and Fort Union Formations, Madison Limestone, Bighorn Dolomite, and Lance Formation (respectively). Flagstone is the main building stone of interest in the planning area, and consists of light tan to reddish to purplish sandstone layers in the Lance Formation which tend to break into predominately flat pieces.

3.3. Fire and Fuels Management

The goals of fire management are to protect life and property; protect or enhance natural resources; and restore or maintain landscape-level fire regimes and associated vegetation characteristics. These goals are broadly defined through federal fire policy, with specific objectives identified in the local RMP.

There are two types of wildland fire: unplanned ignitions (wildfire), and planned ignitions (prescribed fire). Unplanned ignitions occur from an act of nature such as lightning, or from accidental or intentional human causes. Planned ignitions are management actions which are developed and implemented to meet resource and fire management objectives. With safety a priority, both types of fire are managed to achieve the objectives of this RMP whether those objectives are for protection or for resource benefit, or both.

Fire management on BLM-administered lands in the BFO planning area is guided by the goals and objectives in the 1985 RMP and 2001 RMP update, and is implemented by the current Wyoming High Plains District (WHPD) Fire Management Plan (FMP). Safety receives the highest priority in every situation and the costs of operations must be commensurate with the values being protected. To meet resource objectives in the RMP, fire and fuels management strategies are based on resource constraints, land and vegetation characteristics, fire histories, fire regime condition classes (FRCC) values at risk, and wildland urban or industrial interface areas.

Table 3.32, “Total Acres of Planned and Unplanned Fires in Different Vegetative Types in the Planning Area from 1990 through 2007” (p. 424) lists the acres of planned and unplanned fires from 1990 to 2007 that have occurred in different vegetation types in the planning area. For unplanned fire the data include only fires in which BLM responded or assisted, and for planned fire the data are from BLM-administered projects. In both cases, land status may include mixed surface ownership.

A summary of the 18 years of fire data show 89 fires burned about 150,000 total acres with an average of 8,300 acres burned per year. For BLM-administered lands exclusively in that same period, 79 fires burned about 25,000 total acres with an average of 1,400 acres burned per year. Years with the most fires reported were 1996 (21 fires) and 2006 (12 fires). The most acreage burned in a single year was in 2006, with approximately 58,000 acres burned across the planning area and about 7,770 acres burned on BLM surface (BLM 2007d). Lightning causes the most wildfires in the planning area. Human-caused fires are usually accidental from fireworks, open-air burning, wood cutting, railroad and vehicle malfunction, cigarette smoking, escaped campfire, and escaped prescribed fire.

Table 3.32. Total Acres of Planned and Unplanned Fires in Different Vegetative Types in the Planning Area from 1990 through 2007

Vegetation Type	Unplanned Fire	Planned Fire
Agriculture	72	0
Aspen	109	0
Ponderosa pine	9,726	470
Lodgepole pine	3,891	63
Douglas-fir & limber pine	1,787	438
Spruce/Fir	518	0
Mixed grass prairie	93,033	4,308
Mountain shrub	1,622	47

Vegetation Type	Unplanned Fire	Planned Fire
Riparian forest-dominated	173	0
Riparian herbaceous-dominated	5	0
Riparian shrub-dominated	298	0
Sagebrush	36,296	1406
Other (sparse vegetation or no record)	2,445	138
Total	149,974	6,869
Source: BLM 2012f		

In areas with scattered parcels of BLM surface estate, suppression response to small (1 to 100 acre) wildfires is often managed unilaterally by the county fire resources. These fires are oftentimes not reported to BLM or the Casper Interagency Dispatch Center and are likely not included in BLM's fire database. BLM estimates that within the planning area an annual average of 15 wildland fires burning 120 acres are not included in the database.

The counties in the planning area have each developed Community Wildfire Protection Plans (CWPP) which identify fire prevention and protection needs and establish priorities for fire mitigation projects in wildland urban interface (WUI) areas. The county Fire Mitigation Coordinators and Wyoming State Forestry Division (WSFD) guide collaboration among agencies to produce and implement the plans. In the CWPPs, areas of concern such as WUI, are identified and prioritized based on fuel hazards, risk from wildfire, FRCC assessments, infrastructure, and other values such as view-sheds and watersheds. The Healthy Forest Restoration Act (HFRA) facilitates federal involvement by requiring interagency collaboration, especially when counties have completed CWPPs.

Fire management activities must comply with the smoke management requirements of the Wyoming DEQ-AQD. For planned ignitions, BLM projects are usually large enough that they must be registered with the Wyoming DEQ AQD, and air quality must be visually monitored and reported. For unplanned ignitions in which the BLM has jurisdictional authority, there are communication, monitoring, and reporting requirements when the fire exceeds 50 acres.

Emergency stabilization and rehabilitation ES&R projects are implemented where undesirable effects from wildfire have caused resource damage or threaten public safety. Repair of firelines is not funded through the ES&R program, and must be included as part of the emergency management of the wildfire.

3.3.1. Unplanned Fire (Wildfire)

Where geographically allowed within an RMP planning area, current federal fire strategies allow a naturally caused unplanned ignition to be managed for both protection and resource benefit (multiple objectives). Currently there are no geographic areas designated in the planning area to manage unplanned ignitions for multiple objectives, so the single objective is suppression. However current and past suppression strategies include where appropriate, conditional or limited actions (indirect tactics such as burning out or holding at natural barriers) which may indirectly benefit resources by allowing more acres to burn while minimizing suppression damages. These actions are generally safer and typically reduce costs as compared to more aggressive actions such as direct fireline construction.

BMP or standard operating procedures (SOP) are applied to wildfire response strategies in sensitive areas or habitats. For example, BLM has developed nationwide BMP for Greater

Sage-Grouse habitat conservation for wildfire and fuels management (BLM 2011e). The WHPD has developed district-level fire suppression BMP to reflect objectives in the field office's RMPs. These district BMPs address heavy equipment and fire retardant use, Greater Sage-Grouse habitat and leks, big game winter ranges, bald eagle winter roosts, cultural and historic properties, historic trails, highly erosive soils, range allotments, and noxious weed areas.

The BFO emphasizes minimal use of heavy equipment for fireline construction, except where protection from wildfire is critical for safety or to preserve sensitive resources. In special management areas with BLM surface restrictions, the BLM attempts to coordinate actions with interagency cooperators. Currently, special management areas include the Welch Management Area, the Weston Hills Recreation Area, the Burnt Hollow Recreation Area, the Fortification Creek WSA, the Gardner Mountain WSA, the North Fork Powder River WSA, the Dry Fork Petrified Tree Education Area, Cantonment Reno, and the Middle Fork Management Area. In areas where mineral resources have been developed, road networks offer fuel breaks and access to wildfires.

There are several coal seam fires in and near the planning area which pose unique management issues and concerns. Coal seam fires may ignite wildfires and wildfires may ignite coal seam fires. Where ignitions can be prevented by removing vegetation, fire and fuels management strategies can be effective. Where these fires are discovered, fire personnel document and report the fires. Otherwise, coal seam fires are beyond the capabilities of wildland fire management and are discussed further in the *Health and Safety* sections of the RMP.

3.3.1.1. Regional Context

The BFO coordinates its fire suppression resources and operational support for pre-suppression planning and suppression actions at the WHPD level with the USFS, the WSFD, county fire departments, and local fire protection districts. The BLM maintains Interagency Annual Operating Plans (AOP), which include operating agreements with county fire organizations and the WSFD, Medicine Bow National Forest, Bighorn National Forest, Crow Tribal Agency, and neighboring BLM offices. The WHPD fire program coordinates activities through the Rocky Mountain Area Coordination Center (RMACC), which includes most of Wyoming and South Dakota, and all of Colorado, Nebraska, and Kansas.

3.3.1.2. Indicators

Fire as a disturbance mechanism on the landscape affects vegetation communities in terms of structure and species composition. For most vegetation settings, natural or historic fire frequency and severity maintain a characteristic range of seral stages on the landscape. If these fire effects are altered, some seral stages may become too abundant, underrepresented, or disappear. This in turn may affect future fire size or severity. Other factors such as invasive plants, or other types of disturbances may contribute to uncharacteristic conditions.

FRCC methodology is a standardized interagency process to assess and monitor fire disturbance regimes and associated vegetation conditions. FRCC uses five fire regime groups (Fire Regime Condition Class 2008) as shown in Table 3.33, "Fire Regime Condition Class System" (p. 427), and three condition class categories (see bullets below the table) that indicate the departure of a plant community/setting from its historic fire regime. If a plant community/setting has missed fire cycles, there may be changes to key ecosystem components such as species composition, richness, and structure; fuel load characteristics; fire size, severity, and burn pattern; and other associated disturbances such as insect or disease-related mortality.

Table 3.33. Fire Regime Condition Class System

Group	Frequency	Severity	Severity Description
I	0 to 35 years	Low/mixed	Generally low-severity fires replacing less than 75% of the dominant overstory vegetation; can include mixed-severity fires that replace up to 75% of the over story.
II	0 to 35 years	Replacement	High-severity fires replacing greater than 75% of the dominant overstory vegetation.
III	35 to 200 years	Mixed/low	Mixed-severity with less than 75% of the overstory vegetation replaced.
IV	35 to 200 years	Replacement	High stand replacement-severity fires with greater than 75% of the dominant overstory vegetation replaced.
V	200 or more years	Replacement/any severity	Any (stand replacement) severity.

Source: Havlina 2010

Condition class describes ecosystem health as follows:

- **Condition Class 1 (CC1):** Fire regimes on these lands are mostly within historical ranges. Vegetation composition and structure are intact. Therefore, the risk of losing key ecosystem components from the occurrence of fire is relatively low.
- **Condition Class 2 (CC2):** Fire regimes on these lands have been moderately altered from their historical range by increased or decreased fire frequency. A moderate risk of losing key ecosystem components has been identified on these lands.
- **Condition Class 3 (CC3):** Fire regimes on these lands have been substantially altered from their historical return interval. The risk of losing key ecosystem components from fire is high. Fire frequencies have departed from historical ranges by multiple return intervals. Vegetation composition, structure, and diversity have been substantially altered. Consequently, these lands verge on the greatest risk of ecological loss.

Regardless of disturbance mechanism, some lands fall into the CC3 category if they exhibit uncharacteristic vegetation such as non-native invasive plant species. For example, areas of high density annual bromes would be classified as CC3.

3.3.1.3. Current Condition

One of the goals of the fire program is to improve CC3 and CC2 conditions by implementing fire and fuels treatments, including appropriate management of unplanned ignitions. A district-wide FRCC assessment has been done for the planning area utilizing LANDFIRE National layers. Though there may be inaccuracies in the data inputs for this planning area, the coarse-scale results are helpful to broadly identify current conditions and the priority settings in which management actions could focus efforts. For BLM-administered lands in the BFO, Table 3.34, “Fire Regime Condition Class Assessment for the Buffalo Field Office” (p. 428) outlines the most common LANDFIRE BioPhysical Settings, the fire regime group of each setting, and the acres of each condition class. As improved or local data become available, the assessment will be updated and monitored via the WHPD FMP.

In the assessment it is important to view the general results rather than specifics such as names and exact acres. In general the fire regime groups and condition classes agree with local knowledge and experience, particularly in conifer settings where stand structures have generally become more dense or closed-canopy in the past 20 to 40 years. The assessment is helpful to prioritize, in conjunction with other land health assessments, areas where planned and unplanned

fire might be managed to improve FRCC in forest settings, wildlife habitats, WUI areas, and other resource objectives. See the *Planned Fire* section for further discussion about FRCC in relation to vegetation treatments.

Based on localized project data in conifer settings of the planning area, FRCC closed stand structures are generally overrepresented on the landscape and open stand structures are generally underrepresented. In plain terms there are too many thick conifer stands and not enough open stands, which is likely due to interactions among natural disturbances, climate change, and human activities such as fire suppression, grazing, and forest management in the last several decades (Brown and Sieg 1999; Meyer et al. 2005). Management actions can directly improve this situation through vegetation treatments such as thinning or prescribed fire to create more open structured stands. Conversely in some lower elevations of the planning area, it is likely that early seral structures of ponderosa pine have become overrepresented on the landscape due to recent and repeated occurrence of high severity stand-replacement fire. Thinning or prescribed fire treatments in this latter situation can indirectly improve landscape conditions by preserving mature stands while early seral stages establish pine seedlings and continue to mature.

In sagebrush settings, due to current and anticipated levels of disturbance from human actions and wildfire, management actions must prioritize preservation of Greater Sage-Grouse habitat over FRCC objectives. Prescribed fire or other treatments may be used to protect or enhance sagebrush stands which in turn would likely improve FRCC.

Where annual bromes occur on the landscape, in FRCC terms it is considered uncharacteristic and is classified as CC3 and the associated fuel loading may shift fire regimes (Balch et al. 2013) and further jeopardize resource loss from wildfire. It is estimated that 50 percent of the planning area has a moderate to high probability of annual bromes presence (Meinke et al. 2009) due to past and current human activities such as mineral development, livestock grazing, vegetation treatments, and wildfire.

Table 3.34. Fire Regime Condition Class Assessment for the Buffalo Field Office

LANDFIRE BioPhysical Setting Name	Fire Regime Group	Stand FRCC Acres for BLM-Administered Lands			
		Condition Class 1	Condition Class 2	Condition Class 3	Total Acres
Northwestern Great Plains Mixed grass Prairie	2	217,566	155,575	15,021	388,161
Inter-Mountain Basins Big Sagebrush Steppe	4	99,578	83,577	3,258	186,413
Inter-Mountain Basins Montane Sagebrush Steppe	4	61,764	777	8,277	70,817
Middle Rocky Mountain Montane Douglas-fir Forest and Woodland	1	9,679	0	23,160	32,838

3.3.1.4. Trends

Wildland fire management has been shaped by several forces in the past 100 years. Nationally, catastrophic fires (loss of life and property) at the beginning of the 20th Century resulted in 100 percent suppression policies for much of the next 70 years. This approach came into question as fuel loads increased in forests across the country. As a result some land management agencies instituted a let-burn policy in the 1980s. In the late 1980s, several of these fires became larger than intended. These fires, followed by another intense season in 1994, caused another shift in management toward prescribed burning as a way to reduce fuel loads and prevent such high severity fires. The focus on prescribed fire remained strong until several prescribed-fire disasters in 2000. After the 2000 wildfire season, the National Fire Plan (National Fire Plan 2009) was developed, with emphasis on developing firefighting resources; rehabilitation of fire-damaged lands; hazardous fuels reduction treatments; community assistance for fire mitigation and education projects; and accountability. In recent years, land managers have recognized the benefits of a wide range of fire management strategies, including not only prescribed fire and other vegetation treatments but managing wildfires where possible to meet fuels reduction and other resource objectives. These strategies are reflected in the Guidance for Implementation of Federal Wildland Fire Management Policy (USDA and DOI 2009).

Across most of the US, fire seasons are generally lasting longer with larger and higher severity fires becoming a common occurrence. It is anticipated that climate change will further extend fire seasons. Invasive plants such as annual bromes have expanded to create extensive areas of fine fuels (Balch et al. 2013; Meinke et al. 2009), through which fire moves quickly and thoroughly. WUI and industrial interface areas have become more complex and extensive than previously considered in the 1995 and 2001 Federal Fire Policy reviews. To ensure firefighter and public safety, fire management activities in developed areas have required close coordination among all agency fire managers, including federal, state, local, and tribal lands. The National Fire Plan's guiding documents, and the Healthy Forest Initiative and Restoration Act address and facilitate this coordination.

Within the planning area, new or expanding concerns have changed the focus of wildland fire management. Energy development and human activity in the PRB will expand industrial interface areas and likely increase human-caused fires. Urban residential development is expanding throughout the planning area, especially in the southern Big Horn Mountains and foothills. With the potential listing of the Greater Sage-Grouse as a Threatened species, response to wildfires in Greater Sage-Grouse habitat has changed from limited or conditional suppression (indirect, least-cost tactics) to full protection. All of these changes increase costs and add complexity to wildland fire management.

3.3.1.5. Key Features

Key features are sensitive resources or important areas in the planning area that outline objectives for fire management. Specific to unplanned fire, other important features are BLM developed sites, industrial interface areas, and urban interface areas identified in the CWPPs. These areas would receive priority for wildfire protection and for hazardous fuels reduction treatments.

Depending on the alternative selected, unplanned ignitions may eventually be managed for multiple objectives in predefined areas. Key resource features in these future areas would indicate circumstances and strategies to meet resource benefit objectives with unplanned fires.

The Campbell County CWPP encourages BLM to consult and coordinate the development of resource benefit fires in areas with larger blocks of federal lands.

3.3.2. Planned Fire (Prescribed Fire)

Prescribed fire is a wildland fire intentionally ignited by management under an approved plan to meet specific objectives. Implementation of prescribed fire projects is subject to the same policies, practices, and constraints that guide all fire management actions. As a planned activity, prescribed fire projects are subject to NEPA analysis, BLM policies, and Wyoming state requirements. In the planning area, mechanical treatments and chemical treatments are used in conjunction with fire or instead of fire to meet resource objectives.

Developed sites on or adjacent to BLM-administered lands receive highest priority for fuels management activities. The counties in the planning area have each developed CWPP which identify and establish areas of concern such as WUI or industrial interface, and prioritize the areas for treatments or other actions. The BLM fuels and forestry programs have worked with other agencies and fire authorities to collaborate hazard fuels assessments, mitigation plans, and treatments in urban interface areas. The BLM has initiated and funded cooperative agreements in the southern Big Horn Mountains to support defensible space protection for structures adjoining public lands.

Fuels treatments in non-interface areas are based on interdisciplinary objectives such as forest and rangeland health, and wildlife habitat protection or improvement. In forest treatments, prescribed burning typically follows mechanical treatments to reduce activity fuels such as slash piles, but sometimes fire treatments may include broadcast burning to reduce surface fuels and encourage shrub, grass, and forb regeneration. To complete some forest treatment projects, several years may be required to implement all phases of mechanical and prescribed fire treatments.

Fuels management objectives in Greater Sage-Grouse habitat reflect current guidance for Greater Sage-Grouse habitat conservation, including maintenance and protection of existing habitat, and restoration of previous habitat. BMPs for fuels treatments would be applied to project design, including required habitat assessments.

Limber pine was listed as a Wyoming BLM sensitive species in 2010 because of high mortality from white pine blister rust and bark beetle epidemics in the central and northern Rockies. In addition, there is incomplete understanding of the species' potential ecotone shift and future range as climate change progresses. In the past several decades, limber pine and juniper have expanded into mountain shrub communities and foothill sagebrush communities and have affected important wildlife habitat. Prescribed fire treatments and more recently mechanical treatments have targeted removal of conifers in these shrubland habitats. Other vegetation treatments in limber pine stands have included forest health projects in the southern Big Horns, which have attempted to alleviate insect and disease problems and hazardous fuel loadings. With limber pine listed as a BLM sensitive species, projects must consider the limber pine and maintain an appropriate limber pine component on the site. To assist with these assessments, the BLM has developed statewide management guidelines for whitebark pine and limber pine (five needle pines) which include general guidelines for fire management, and general silvicultural prescriptions for mechanical treatments in a wide range of limber pine settings.

3.3.2.1. Regional Context

The BFO coordinates implementation of prescribed fire projects at the district level and uses nearest available resources such as adjacent BLM districts, the USFS, the WSFD, county fire departments, and qualified contractors. Where non-BLM-administered lands are included in treatment areas, the BLM enters into MOUs with affected parties.

3.3.2.2. Indicators

See the *Unplanned Fire (Wildfire)* section for the discussion of the FRCC system used to classify ecosystem fire characteristics and prioritize areas for treatments.

3.3.2.3. Current Condition

See the *Unplanned Fire (Wildfire)* section for further discussion of the FRCC assessment and current conditions in the planning area. In the assessment it is important to view the general results rather than specifics such as BioPhysical Setting names and exact acres. In general the fire regime groups and condition classes agree with local knowledge and experience, particularly in conifer settings where vegetation treatments may focus attention on CC3 acres. In Greater Sage-Grouse habitat, sagebrush preservation and protection would be prioritized over FRCC objectives and restoration of fire regimes. Alternatively, in forest and woodland settings, especially where there are interface developments, treatments would be prioritized to reach CC1 conditions. Elsewhere, the assessment is helpful to prioritize, in conjunction with other land health assessments, areas where vegetation treatments could improve FRCCs in forest health treatments, wildlife habitat projects, and other resource improvement projects.

3.3.2.4. Trends

The BFO has maintained a prescribed fire program since the early 1980s. From 1985 through 2001, most prescribed fires were broadcast burns of sagebrush/grass fuels performed to meet livestock and big game wildlife forage objectives. Secondary objectives were to reduce or break the continuity of fuels, thereby reducing the risk of high severity or uncharacteristic effects from wildfire. Most of the prescribed burns were implemented in cooperation with individual grazing lessees and WGFD-managed habitat units. During the 17-year period, the BLM had the lead role in performing 12 prescribed fires covering an estimated 6,000 acres, of which approximately 30 percent was public land surface.

With passage of the National Fire Plan (National Fire Plan 2009) and subsequent Congressional actions and Executive Orders (EOs), the emphasis on prescribed fire shifted toward hazardous-fuel reduction, especially in the WUI. Hazardous-fuel reduction objectives have been accomplished in the planning area using both prescribed fire and mechanical treatments. From fiscal years 2003 through 2008, the BFO implemented 15 prescribed fire projects within WUI to treat approximately 3,100 acres of public land, and 17 prescribed fire projects outside WUI to treat approximately 5,200 acres of public land. During that same period, the BFO implemented 13 mechanical fuel treatments within WUI to reduce hazardous fuels on approximately 224 acres of public land. Outside WUI in that period, eight mechanical fuel treatments were applied to 582 acres of public land. Most of the non-WUI mechanical treatments were associated with forest management treatments, or salvage actions following wildfire. Two mechanical projects were implemented to improve rangeland conditions.

With the warranted but precluded listing of the Greater Sage-Grouse and the expansion of annual bromes in the planning area, prescribed fire treatments have declined in sagebrush settings. Fuels treatments have focused on reducing conifer expansion in Greater Sage-Grouse habitat, and will trend towards treatments that protect or restore sagebrush habitats from fire damage or invasive plant species.

An important part of future treatments in any site will utilize native plant materials developed through BLM's Seeds of Success program. This program facilitates local seed collections that may be grown out as seedlings or seed stock for use in rehabilitation or restoration projects.

3.3.2.5. Key Features

Key features are important areas or sensitive resources that outline objectives for fire and fuels management. Relative to planned fire and fuels treatments, key features could be vegetation situations which do not meet management objectives and may require treatments. Examples include fire, mechanical, or chemical treatments in shrubland habitats to remove conifer expansion, or forest health treatments to reduce the risk of insect and disease infestations.

Specific to hazardous fuels management, key features include the WUI areas of concern identified in the CWPPs. These areas are considered at risk from wildfire and have been prioritized in the WUI to receive fuels treatments and fire education efforts. Where BLM-administered lands intermix with these areas of concern, BLM prioritizes treatments to match the priorities of the WUI. In Johnson County, BLM-administered lands in the Clear Creek watershed and lands accessed by the Hazelton Road are current priorities for BLM treatments. Current priorities in Sheridan County are the BLM-administered lands along Red Grade Road; and in Campbell County, the BLM is encouraged to continue hazardous fuels reduction and resource improvement projects in general.

3.3.3. Stabilization and Rehabilitation

Repair of firelines is part of the fire suppression emergency response and should be done with suppression or contract resources as soon as possible after fire containment. ES&R projects are done after fire containment to repair damages from the fire itself. ES&R projects must compete for funding at the national level.

Emergency stabilization actions are implemented soon after the fire to protect life and property; to stabilize soils and watersheds; to protect unique biological resources; and significant heritage sites. These stabilization actions include project planning and NEPA documentation, and must be implemented within 1 year of fire containment.

Burned-area rehabilitation projects are developed to restore fire-damaged lands which are unlikely to recover naturally. In rehabilitation plans there is no immediate threat to safety or a specific resource, and treatments may include repair or replacement of minor facilities such as fences and campgrounds. These plans must undergo NEPA analysis and must be completed within 3 years of fire containment.

3.3.3.1. Regional Context

Until 2005, the WHPD has reported only four ES&R burned-area rehabilitation projects; three in the Newcastle Field Office and one in the BFO. In contrast hundreds of projects have been

reported in other western states since 2005, where annual bromes have altered fire behavior and severity, or where damaged watersheds affect WUI areas.

3.3.3.2. Indicators

Large fires in conifer settings, important habitats, critical watersheds, WUI areas, or areas at risk from invasive plants could be cause to initiate formal ES&R planning.

3.3.3.3. Current Condition

The current RMP and update provide for ES&R of any area affected by wildfire. ES&R projects are implemented to stabilize slopes which threaten public health or safety or to rehabilitate lands that are unlikely to recover from undesirable wildfire effects.

See *Unplanned Fire (Wildfire)* and *Planned Fire (Prescribed Fire)* for a discussion of the FRCC assessment. Condition Class 3 (CC3) situations in forested settings or from annual brome expansion could create large fire size or undesirable fire effects which require ES&R treatments.

3.3.3.4. Trends

From 1985 to 2003, the BFO developed only one ES&R plan for the 2003 Big Spring Fire, which was in the southern Big Horn Mountains adjacent to the Billy Creek area where there is a high density of summer cabins. The plan included emergency actions such as hazardous tree felling, and non-emergency rehabilitation actions such as road grading and facilities replacement. With the warranted but precluded listing of the Greater Sage-Grouse and the probable expansion of annual bromes in the planning area (Meinke et al. 2009), it is likely there will be increased need for rehabilitation of burned areas and restoration of sagebrush/grasslands after wildfire. In fact, since 2011 two additional ES&R plans have been developed to treat annual bromes and other weeds in Greater Sage-Grouse habitat, and other funding will follow up with sagebrush seeding treatments. Although other large fires in 2012 burned Greater Sage-Grouse priority habitat (Core Population Areas and Core Population Connectivity Corridors), ES&R plans were not developed primarily because funding was not available in that program. Weed treatments and restoration of Greater Sage-Grouse habitat have been and will be done as possible with other funding sources.

Approximately 50 percent of the wildfires in the planning area have required repair of suppression damages on BLM-administered lands, consisting primarily of re-contouring slopes along blade lines and water barring fire lines. Occasionally fire lines require weed treatments or are reseeded. It is anticipated that repair needs in the future will require more actions to prevent the spread of invasive plants in important habitats.

With the development of BLM's national Seeds of Success program, native and local native plant materials will become more widely available for ES&R work.

3.3.3.5. Key Features

Key features are sensitive resources or important areas in the planning area that outline objectives for fire management. Specific to unplanned fire and ES&R treatments, important areas would include WUI watersheds, high severity burns in forested settings, areas with important wildlife habitat, and areas where invasive plant species threaten the burned area.

3.4. Biological Resources

3.4.1. Vegetation – Forests and Woodlands

This section describes existing conditions for forest and woodland vegetation communities within the planning area. Table 3.35, “Distribution of Forests and Woodlands on BLM-Administered Land in the Buffalo Planning Area” (p. 434) lists the acreages of forests and woodlands in the planning area.

Table 3.35. Distribution of Forests and Woodlands on BLM-Administered Land in the Buffalo Planning Area

Classification	Planning Area (Acreage)	BLM Acreage
Forests	651,000	51,224
Woodlands	26,147	26,005
Total	670,225	77,229
Source: BLM 2012f		
Note: Acreages do not sum to total because of resource overlap.		
BLM Bureau of Land Management		

3.4.1.1. Regional Context

The planning area lies on the east side of the Big Horn Mountain and extends into the PRB. The ecoregions for the forest lands are the Granite Subalpine Zone, the Dry Mid-Elevation Sedimentary Mountains, and the Pryor Bighorn Foothills. There are seven major forest management units and smaller units that are scattered tracts from the north end of the planning area west of Sheridan, Wyoming on the Red Grade Road and larger contiguous tracts that extend from Mosier Gulch to the Hole in the Wall campground in the South Big Horns. The geographical area includes the Billy Creek forest management area at the North end of Hazelton Road on the east facing slopes of the Big Horns, the Powder River Management Area, Hazelton Road Management Area, the Horn, Bear Trap Management Area, Garden Mountain Management Area, and the Graves Corral Management Area on the southern end.

There are scattered woodlands throughout the tri-county area with concentrations of woodlands in Campbell and Johnson counties. They are concentrated in the Pine Scoria Hills, the Casper Arch, the Mesic Dissected Plains, and the PRB Ecoregions. The woodlands in Campbell County, extend from Dead Horse Creek to Bitter Creek on the Montana border, on the east side from Homestead Draw to Horse Creek, and in the southeast from Corral Creek to 7 Prong Creek. The woodlands extend on the east side of the south Big Horns to the Middle Fork Powder River in Johnson County.

3.4.1.2. Indicators

The forest and woodlands need to be managed for ecosystem health and integrity, for the purpose of discussion in this RMP, the following are considered characteristics of forest and ecosystem health: the resources that play a role in the forest and woodland health, such as soil and water should be conserved and maintained. Indicators of forest and woodland health are the amount, diversity, and age class structure of the forest and woodland communities. The goal is for

healthy forest and woodland communities sustained in their desired ecological conditions while also considering clear management objectives of each forest and the supply and demand of the communities. These forest and woodland communities should be resilient, diverse, and able to recover from natural and human disturbances.

The BLM uses the Forest Vegetation Information System for storage, retrieval, and analysis of both tabular and spatial data about forest lands. Outputs of this system include descriptions of existing vegetation, classifications of sites relative to current conditions, potential vegetation and site productivity, data to run forest growth and structure models, inputs for wildlife habitat models, landscape descriptions, quantification of forest products, aids for developing silviculture or forest restoration treatments, and records of treatments and disturbance events.

3.4.1.3. Current Condition

The BFO administers 77,229 acres of forests and woodlands. Forests and woodlands are distinguished by type (species composition) and the physical environment in which they grow.

Forest Communities

The dominant forest species include lodgepole pine, ponderosa pine, Douglas fir, Engelmann spruce, subalpine fir, and aspen. Forest composition ranges from pure single species stands, to stands of mixed species. Ponderosa pine dominates at the lower elevations and on the northern aspects, Douglas fir and lodgepole pine are often present. As the elevations rise, ponderosa pine forests become scattered and less frequent while lodgepole pine and Douglas fir forests increase and become dominant.

Aspen stands are influenced by soil moisture and fertility. Therefore aspen stands are often small and scattered throughout the lodgepole pine and Douglas fir zone. Aspen is an early successional species, intolerant of shade, and therefore is replaced by the shade tolerant conifers.

Forests support, define, and create stability for a multitude of resources, including watersheds (soil and water), wildlife (provide protection, food, and habitat), recreation, air quality (carbon sequestration), other plant communities, products for mankind (e.g., homes and paper products), and are aesthetically pleasing. Forest communities and forest management areas in the planning area are displayed on Map 26. Forest products are discussed further in their own section.

Past harvesting activities, fire suppression, and natural succession have promoted the development of dense forest stands throughout these mountains. Lodgepole pine, ponderosa pine, and Douglas fir stands are unnaturally dense and dominated by a single canopy layer from mid-age to over-mature trees. Consequently, competition among trees for water, light, and nutrients is pronounced.

The distribution of aspen and limber pine is declining. Aspen is a successional species that benefits from fire and other disturbances. Reduced burning and competition from conifers has decreased the number, the health, and the vigor of aspen clones. According to a report on forest health published by the WSFD, the average age of aspen forests is 68 years (Wyoming State Forestry Division 2001). The limber pine is being infected by blister rust disease that is resulting in mortality. The USFS (2008) estimates blister rust has caused a 60 percent mortality rate. Limber pine, though not a desirable commercial species, is favored by the Clark's nutcracker and many small rodents for its seeds.

Woodland Communities

Woodland communities are scattered throughout the three-county planning area (Map 26). They range from small monotypic stands to large mixed stands of quaking aspen, limber pine, ponderosa pine, Rocky Mountain juniper, and Utah juniper. The largest woodland stands occur in the southern Big Horn Mountains. Woodlands differ from forests because woodlands typically grow as a savannah. The trees are widely dispersed with grasses, forbs, and shrubs in the understory. Because of the open growing conditions, woodlands exhibit different growth characteristics from forests. The tree crowns extend from the base of the bole to the top of the crown. Woodlands play an important role in the landscape as they provide cover, food, and protection for many wildlife species.

Woodland communities typically do not produce wood that is desirable for high-quality wood products. However, woodlands play an important role in the woody biomass market. They are utilized as firewood, furniture, decorative, and hobby wood products.

Fire suppression and other human management activities have enabled the expansion of woodlands into meadows. This is desirable in some locations, but undesirable in others. Concerns with encroachment include woody fuel buildup, especially in the wildland-urban interface, and the loss of open meadows. Woodland encroachment into meadows typically reduces biological diversity and available forage.

3.4.1.4. Trends

Stressed trees have poor resistance and are therefore vulnerable to attacks by the mountain pine beetle, ips engraver beetle, Douglas fir beetle, rust, and diseases. The USFS Forest Health Protection report indicates a growing Douglas fir beetle problem and an increase in acres affected by insects and disease in the Big Horns.

Increased pressure on forest and woodland communities will continue with increasing energy development. Woodland communities would be affected most with their greater distribution within the planning area; the predominant threat to forest communities would be the introduction of renewable energy development to the southern Big Horn Mountains and restrictions placed on forest and woodland management by other resource values. The Middle Rockies and Northwest Plains Rapid Ecological Assessments, which encompass the planning area, will be released in 2014.

3.4.1.5. Key Features

Aspen and limber pine communities are key features due to their declining trend within the planning area and across their geographic ranges. Table 3.36, “Acres of Dominant Tree Species in the Planning Area” (p. 436) portrays the acreage of dominant tree species in the planning area.

Table 3.36. Acres of Dominant Tree Species in the Planning Area

Dominant Tree Species	Acres on BLM-Administered Land
Ponderosa pine	28,521
Lodgepole pine	10,289
Douglas fir/Limber pine	12,208
Spruce/Fir	3,045
Aspen and Riparian mix	1,759

Dominant Tree Species	Acres on BLM-Administered Land
Juniper	3,716
Ponderosa woodlands	17,485

3.4.2. Vegetation – Grassland and Shrubland Communities

Grasslands and shrublands are the most productive grazing land in the planning area. These two community types can be found from the foothills of the Big Horn Mountains to the east boundary of the planning area (Map 25). These communities symbolize the “open” prairie landscapes that typify Wyoming. Grasslands represent most of the topographical positions, from the open plains to the foothills, to dry mountain slopes. Grasslands in the plains are dominated by cool-season grasses, sedges, and shrubs, mainly sagebrush. The warmest and driest grasslands can also have warm-season species with few shrubs. Sagebrush is the most dominant shrubland type within the planning area, found primarily on the open plains, but also in mountain settings. It is dominated by Wyoming big sagebrush, mountain big sagebrush, mountain mahogany, and greasewood. Wyoming big sagebrush tends to grow in the low to mid elevations on the drier sites, while mountain big sagebrush occurs in upper elevations in moister conditions, in the southern Big Horn Mountains. Vegetation supports clean water, soil health, fish and wildlife habitat, livestock forage, recreation, natural carbon sequestration, and scenery.

Vegetation characteristics that are common indicators of vegetation health include cover, composition, amount of bare-ground and litter, structural diversity, species diversity, and the presence or the ability to maintain unique or special status species, and density of invasive species. These indicators are associated with ecological sites and with Standards 1, 3, and 4 of the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for Public Lands Administered by the BLM in the State of Wyoming* (BLM 1997). Ecological sites are determined from NRCS for MLRA (geographically associated land resource units): 58B – Northern Rolling High Plains.

Grassland and shrubland communities account for approximately 6,293,727 acres of the planning area, of which 718,636 acres are BLM surface. Most of the grassland and shrubland communities in the planning area have been influenced by livestock grazing, fire or fire suppression activities, and surface-disturbing activities.

3.4.2.1. Regional Context

The BFO lies within one MLRA: the Northern Rolling High Plains, Southern Part – 58B (NRCS 2008). This area is characterized by grasses and shrubs with gently rolling to steep slopes and occasional flat-topped, steep sided buttes rising above the plains. Elevations range from 3,800 to 11,000 feet, with elevation increasing gradually from north to south.

3.4.2.2. Indicators

The condition of the grassland and shrublands in the planning area was evaluated utilizing the ecological site inventory. Any land inventory, analysis, and resulting management decisions require knowledge of these individual sites and their interrelationships to one another on the

landscape. The ecological site description contains information about the individual ecological sites.

The data comprising an ecological site description is presented in four major categories:

- Site Characteristics – Identifies the site and describes the physiographic, climate, soil types and limitations, and water features associated with the site.
- Plant Communities – Describes the ecological dynamics and the common plant communities comprising the various vegetative states of the site. The disturbances that cause a shift from one state to another are also described.
- Site Interpretations – Interprets information pertinent to the use and management of the site and its related resources.
- Supporting Information – Provides information on sources of information and data utilized in developing the site description and the relationship of the site to other ecological sites.

Congress mandated natural resource inventories in Section 201(a) of the FLPMA. Congress reaffirmed this mandate in Section 4 of the Public Rangelands Improvement Act of 1978 – in particular, to develop and maintain an inventory of range conditions and trends on public rangelands, and to keep that inventory updated. The BLM does and will continue to use land health status to report conditions and trends of rangelands in compliance with FLPMA and the Public Rangelands Improvement Act of 1978. Ecological Site Descriptions will be used as the foundation for determining rangeland health status by identifying the soil types and potential vegetation communities. The process spelled out in BLM Handbook H-4180-1, Rangeland Health Standards, will be used to assess and evaluate land health status.

3.4.2.3. Current Condition

Livestock grazing is the largest and most historic use of grasslands and shrublands in the planning area (see the *Livestock Grazing Management* section of this chapter for more information).

The second largest impact on grasslands and shrublands, in the planning area, is mineral development. This impact occurs throughout the ecosystems in northeastern Wyoming and involves the extraction of gas, oil, coal, uranium, bentonite, and other minerals. Extraction of these minerals has resulted in direct removal of sagebrush and grasslands. Mine excavation, roads, drill pads, fences, powerlines, pipelines, and other mining activities fragmented habitat. Surface-disturbing and other activities caused removal or mechanical damage to plants, invertebrates, and biological soil crusts. Damage occurred in terms of both the amount (overall biomass, density, and cover) and diversity (species presence and richness). These activities can be associated with the recent increases in the introduction and spread of invasive species, and compaction of soils.

The continuation of CBNG and energy development drives conditions on grasslands and shrublands. Conditions include the number of acres of soil and vegetation disturbance from construction of roads, trails, well sites, and utility corridors. Disturbance also includes the number of water-holding impoundments, which often are in the most productive vegetative areas (draw bottoms) and their associated seeping, which provides a premium medium for the establishment of invasive species. Reclamation practices on these disturbed sites included the introduction of non-native species to stabilize soils, which out-competed native species, disrupted grazing systems during site development and reclamation, and provided opportunities for invasive species, including the annual brome species, to occupy exposed soils. Other drivers include disposal of CBNG produced water, which altered soil capabilities and functions and the

vegetative community, moving the vegetative community from a natural xeric plant community to a mesic community.

The impacts to grassland and shrubland communities from drought has varied widely. The primary impacts of extended drought were reduced vegetative production, cover canopy, diversity, microbial function, and heights of grasses, and increased soil erosion. Drought also provided a growing advantage to annual bromes because even low amounts of snowfall were adequate to provide enough moisture to initiate growth in late winter through seedset in spring. Additional factors that brought change to the planning area included the occurrence or lack of wildfires, climate change, development of recreational sites and opportunities, and sprawl of human dwellings in rural settings.

Management challenges for grassland and shrubland communities include the spread of invasive species; lack of a natural fire regime; integrating treatments of multiple resource programs to achieve landscape-level objectives; future energy development; the potential impacts of climate change; competition for forage between native ungulates and livestock; habitat fragmentation; restoration of areas damaged by surface-disturbing activities to mitigate potential impacts related to erosion and water quality; competition between resource users; and maintaining a distribution and diversity of these communities sufficient to support wildlife, special status species, livestock, and other competing multiple-use demands on BLM-administered lands.

Table 3.37, “Distribution of Grasslands/Shrublands on BLM-Administered Land and BLM-Administered Mineral Estate in the Buffalo Planning Area” (p. 439) lists the acreages of grasslands and shrublands in the planning area.

Table 3.37. Distribution of Grasslands/Shrublands on BLM-Administered Land and BLM-Administered Mineral Estate in the Buffalo Planning Area

Vegetation Class	BLM Surface Acres	Percent of BLM-Administered Land within the Planning Area	BLM-Administered Mineral Acres	Percent of BLM-Administered Minerals Land within the Planning Area
Mixed Grass Prairie	93,349	11	765,546	16
Short Grass Prairie	453,153	58	2,454,815	51
Other Shrubland (Mesic Upland Shrub Steppe and Xeric Upland Shrub Steppe – Mountain Mahogany)	14,250	2	21,988	0.5
Sagebrush shrubland (Wyoming Big Sagebrush and Grassland and Mountain Big Sagebrush and Grassland)	167,884	21	1,320,672	28

See the *Livestock Grazing Management*, *Fire and Fuels Management*, and *Invasive Species and Pest Management* sections of this document for additional information.

The following sections describe the grassland and shrubland vegetation communities in the planning area.

Grasslands

Short-grass Prairie

This vegetative type represents very sparse, sparse, and thin dry herbaceous rangeland types, as defined by the WGFD. The 453,153 acres of short-grass prairie comprises approximately 58 percent of the BLM surface in the planning area. This vegetative type occurs on drought-prone, mildly alkaline, medium-textured, and fine-textured soils. Few shrubs grow consistently in short-grass prairie because the soils are too dry and compacted to support them. In the planning area, short grass prairie habitats are most common in the south, occurring as the dominant plant community from the southern foothills of the Big Horn Mountains to the eastern boundary of the planning area. The topography consists of gentle rolling plains occasionally dissected by draws, creeks, and rivers. Pine-covered ridges with numerous draws are common. According to NRCS MLRA 58 B Northern Rolling High Plains, this area is mapped in the 10-inch to 14-inch precipitation zone. Precipitation is an important determinant of the composition of plant species in grasslands. The dominant vegetation species are blue grama, western wheatgrass, sand dropseed, needle and thread, scarlet globemallow, and four-wing saltbush.

Mixed-grass Prairie

This vegetative type is a combination of low, medium, and high herbaceous rangeland types, as defined by the WGFD. The 83,349 acres of mixed-grass prairie comprises about 11 percent of the BLM surface in the planning area. The topography consists of gentle rolling plains occasionally dissected by draws, creeks, and rivers. Precipitation is an important determinant of the composition of plant species in grasslands. Mixed-grass prairie can be divided into several types and is characterized by several common species, including needle and thread, western wheatgrass, blue grama, pricklypear cactus, and scarlet globemallow. Wyoming big sagebrush is a common shrub of this grass community in the PRB (Knight 1994). In the planning area, mixed-grass prairie habitats are most common along the eastern foothills of the Big Horn Mountains and occur throughout much of the northern and central portions of the planning area. According to NRCS MLRA 58 B Northern Rolling High Plains (NRCS 2008), the foothills area is mapped in the 15-inch to 19-inch precipitation zone and the northern and central areas are mapped in the 10-inch to 14-inch precipitation zone, but generally receives 8 inches to 12 inches of precipitation annually, the majority of the precipitation comes in late winter and early spring.

Shrublands

Sagebrush Shrubland

This vegetative type includes a combination of sparse, moderately dense, and dense big sagebrush crown closure with a variety of understory grasses and forbs. The sagebrush shrubland is widely distributed and occupies a large portion of the planning area — approximately 167,884 acres (21%). Generally, Wyoming big sagebrush communities are found below 6,000 feet and mountain big sagebrush communities above 7,000 feet. However, between 6,000 and 7,000 feet the two plants often are found growing together and are difficult to discern. Black sagebrush is generally found at mid elevations, between 5,000 and 7,000 feet, on shallow to very shallow rocky soils, in areas with 10 to 14 inches of precipitation. Black sagebrush grows in association with both

Wyoming and mountain big sagebrush. Basin big sagebrush is generally restricted to moderately deep to deep soils in drainage bottoms and stream terraces. Basin big sagebrush communities do not cover much area and are mostly components of other shrub communities. Silver sagebrush is usually found at lower elevations on sandy soils. It is more abundant in the southern part of the planning area and is the principal shrub on sand dunes.

Sagebrush communities are important sources of food and cover for numerous wildlife species in Wyoming. Sagebrush-obligate species include the sage sparrow, Brewer's sparrow, sage thrasher, Greater Sage-Grouse, sagebrush vole, sagebrush lizard, and pronghorn. See the *Fish and Wildlife Resources – Wildlife* and *Special Status Species – Wildlife* sections of this chapter for more information.

Wyoming Big Sagebrush and Grassland

Wyoming big sagebrush is usually found on drier sites, occurring throughout the lower elevations across the majority of the planning area. Shrub height varies from as little as 8 inches on shallow soils to approximately 30 inches on deeper soils. The canopy cover for Wyoming big sagebrush communities usually does not exceed 20 percent.

Wyoming big sagebrush often appears as the dominant plant in mosaic communities intermixed with other shrubs and open grasslands. On shallow or rocky to gravelly soils, Wyoming big sagebrush may be co-dominant with black sagebrush and yellow rabbitbrush. On lighter-textured soils, such as sandy loams, Wyoming big sagebrush may be co-dominant with silver sagebrush, yellow rabbitbrush, and winterfat. Grass and forb species vary depending on soil texture, aspect, and slope. Common grass and grass-like species include bluebunch wheatgrass, western wheatgrass, Sandberg bluegrass, muttongrass, Indian ricegrass, needle and thread, green needlegrass, prairie junegrass, threadleaf sedge, and squirreltail. Common forbs include phlox, sandwort, buckwheat, penstemon, Indian paintbrush, scarlett globemallow, milkvetch, and pricklypear cactus.

Many of the Wyoming big sagebrush communities consist of even-aged stands of mature and often decadent plants. This presents a problem on winter ranges because of the poorer forage quality of the plants and lack of recruitment of younger plants.

Mountain Big Sagebrush and Grassland

Mountain big sagebrush is found on shallow to deep soils at elevations above 7,000 feet. It occurs along the western edge of the planning area, throughout the Big Horn Mountains. In areas where it grows in conjunction with Wyoming big sagebrush, it generally grows on the deeper soils and in areas that receive more moisture either through runoff or snow accumulation. At lower elevations, annual precipitation levels average 15 inches to 19 inches, and at higher elevations annual precipitation averages more than 20 inches.

At higher elevations, mountain big sagebrush occurs as smaller plant communities in mountain areas and is often intermixed with aspen and conifer woodlands. Shrub height will vary from 10 to 30 inches, with canopy cover reaching 20 to 40 percent.

Other shrubs that can be found in mountain big sagebrush communities are antelope bitterbrush, Saskatoon serviceberry, threetip sagebrush, and snowberry. Grasses present include Idaho fescue, spike fescue, green needlegrass, Colombia needle grass, muttongrass, western wheatgrass, and

basin wildrye. Common forbs found in these areas include Indian paintbrush, lupine, larkspur, ragwort, and violets.

Mountain big sagebrush is palatable to wildlife, although browsing is limited during winter when these habitats become unavailable due to snow. Mountain big sagebrush provides hiding and nesting cover for various wildlife species. Following fire, mountain big sagebrush reestablishes as the dominant species more quickly than do other sagebrush types, often resuming dense canopy cover after only 20 to 30 years.

Other Shrubland

This vegetative type is composed of shrub-dominated vegetation communities – mountain mahogany and greasewood shrubland. Mountain mahogany shrubland is the largest component of the other shrubland vegetation type and occurs primarily in the foothills of the Big Horn Mountains in southwestern Johnson County. Mountain mahogany grows on xeric (drier) sites, usually in isolated, pure patches that are often very dense on rocky areas with shallow, poorly developed soils derived from sandstone, limestone, and shale. Their ability to use nitrogen from the soil enables these shrubs to establish on relatively infertile soils. They grow most vigorous on sites without forest canopy and provide important browse for wildlife and livestock. The sustained protein levels of the plants through the winter provide considerable value as forage (Knight 1994). Plant species in the undergrowth of this community include fringed sage, sulfurflower buckwheat, bluebunch wheatgrass, and junegrass.

Greasewood-dominated shrublands occur primarily on lowland positions adjacent to streams, playas, and ponds. They usually occur in areas that receive lower amounts of precipitation and on soils that are at least moderately saline or alkaline. Greasewood does well in very saline soils; however, it needs more soil moisture than most of the local shrub species. Where greasewood is the dominant shrub, subdominant shrubs include Gardner saltbush, shadscale, rubber rabbitbrush, Wyoming big sagebrush, and basin big sagebrush. The understory is limited to salt-tolerant herbaceous vegetation, such as inland saltgrass, western wheatgrass, alkali sacaton, squirreltail, Sandberg bluegrass, spiny phlox, and pepperweed. Although greasewood is not considered to be very palatable to livestock or big game animals, pronghorn and sheep will eat the spiny twigs and leaves in spring and early summer, and cattle use this species in summer and fall as a source of salt. Greasewood contains soluble oxalates that can be poisonous to both sheep and cattle. Greasewood does provide food and cover for small animals and birds.

Mesic Upland Shrub Steppe

Chokecherry is the primary shrub in this community. It often grows in conjunction with snowberry, currant, Woods' rose, and serviceberry. This community type is usually present at lower to mid elevations in areas that receive greater moisture due to snow accumulation, runoff, or subsurface flow. These areas include drainage bottoms, north slopes, and leeward sides of hills and are primarily located in the northern portions of the planning area. This community usually exists as dense but scattered stands of shrubs and is often adjacent to aspen and willow communities. Chokecherry and Saskatoon serviceberry can grow to 15 feet high. Herbaceous understory vegetation includes basin wildrye, green needlegrass, Columbia needlegrass, bluebells, columbine, common yarrow, and violet. Precipitation ranges from 15 inches to 19 inches annually.

This community provides hiding and thermal cover for deer, elk, and other wildlife species. The dominant shrubs provide excellent forage for browsing animals when their softer leaves and shoots stay within reach. These shrubs will reestablish following fire, often in less dense patches,

making them more accessible to wildlife and livestock. The new growth is highly palatable and is sought by browsing animals.

Xeric Upland Shrub Steppe – Mountain Mahogany

Mountain mahogany is present in the southern portions of the planning area along the southern slopes of the Big Horn Mountains. The species grows on dry sites, usually rocky slopes and ridges with very shallow soils. Mountain mahogany usually occurs as the dominant shrub but sometimes grows in conjunction with juniper, antelope bitterbrush, currant, snowberry, yellow rabbitbrush, and Wyoming and mountain big sagebrush. Grass species present in the understory include bluebunch wheatgrass, Indian ricegrass, Sandberg bluegrass, muttongrass, and western wheatgrass. Forb species present in the understory include phlox, locoweed, and milkvetch.

Mountain mahogany can grow to a height of 5 to 7 feet, depending on the amount of browsing and the soil depth. Fire generally decreases the density of the shrub stands, allowing grasses and other herbaceous plants to increase, while still providing wildlife browse. If cheatgrass is present, fire can lead to an increase of this species. Mountain mahogany is an important fall and winter forage for deer and elk, and also is utilized by livestock. Mountain mahogany communities usually provide crucial winter range for mule deer. Many of these communities consist of mature and often decadent plants with little recruitment of young plants.

3.4.2.4. Trends

It is estimated that the trend for grasslands and shrublands will remain about the same. Range trend data from the RMP (BLM 1985c) in the South Big Horns area and the Powder River Breaks area combined, was 18 percent of rangeland acres in an upward (improving) trend, 73 percent of acres in a static (stable) trend, and 14 percent of acres in a downward (degenerating) trend. The most recent cumulative trend date (BLM 2007l) shows 20 percent of rangeland acres in an upward trend, 45 percent in a static trend, one percent in a downward trend, and 34 percent undetermined. Some areas, especially those subject to CBNG development, will likely experience a slight downward trend in vegetative health due to the number of associated impacts, as described in the preceding sections. In other areas, the health trend will be upward due to monitored grazing practices, conservation use, deferred rotation for a portion of the ranch, and set asides for wildlife habitat.

Impacts to grasslands and shrublands from drought will vary widely. Other impact trends to these vegetative communities include division of ranches into smaller, more affordable, smaller acreage ranchettes. Impacts from this include increased fencing of property, increased roads and trails, intensified grazing management, and increased wildfire costs. Other secondary impacts include habitat fragmentation and an increase in the presence of invasive species.

3.4.2.5. Key Features

Key features include shrublands currently in Greater Sage-Grouse Priority Habitat (Core Population Areas and Core Population Connectivity Corridors); potential habitat for sensitive, Threatened, or Endangered species, including black-tailed prairie dog colonies; and important wildlife habitats that contain mountain mahogany.

3.4.3. Vegetation – Riparian/Wetland Resources

Riparian and wetland areas occur throughout the planning area. They are influenced by adjacent creeks, streams, rivers, lakes, and ponds. Riparian areas are often called riparian corridors or riparian zones because of the dependency of the ecosystem on water. Riparian communities vary considerably from small, sedge-dominated wetlands to large, willow-dominated stream corridors, to spruce bogs and alpine wet meadows. Riparian aspen communities are scattered on streams and springs.

Riparian and wetland communities are defined as having persistent water or obligate vegetation (e.g., sedges, rushes, and willows) reflecting the availability of surface water or groundwater. Healthy riparian areas provide vertical structural complexity, canopy, and subcanopy layers and a ground layer that supports species diversity. In addition to being an integral part of watershed health, riparian areas are prized for their cultural, historical, and recreational values, fish and wildlife habitat, water supply, and their economic values stemming from their use in livestock production, forest production, and mineral extraction.

The USFWS (Cowardin et al. 1979) developed and uses the scientific definition of a wetland as follows: Wetlands are lands transitional between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water. Wetlands must have one or more of the following three attributes: (1) at least periodically, the land supports predominantly hydrophytes, (2) the substrate is predominantly undrained hydric soil, and (3) the substrate is nonsolid is saturated with water or covered by shallow water at some time during the growing season of each year.

Functions

Riparian and wetland communities provide important functions, such as improving water quality, sustaining base flows, decreasing the impacts of floods, and providing wildlife habitats and forage, shade, and water for livestock. Vegetation in riparian and wetland areas influences stream communities by shading the stream (lowering water temperature), controlling dissolved nutrient inputs, stabilizing stream banks, and contributing organic matter. Streamside vegetation provides cover for fish by creating quiet, shaded resting areas beneath overhanging vegetation. The roots of riparian vegetation are crucial to the development and maintenance of undercut banks that also provide cover for certain fish species and help to stabilize the stream banks. Root stabilization of stream banks also allows soils to absorb extra water during spring runoff that is later released during drier months, thereby improving late summer streamflows.

3.4.3.1. Regional Context

Wetlands and riparian areas between the Rocky Mountains and the Sierra Nevada are incredibly diverse and valuable habitats. Wetlands are regionally sparse and very few are located within Wyoming. More than 80 percent of the wildlife species in this intermountain region depend on these wetlands—which account for less than two percent of the land area—for their survival. At the same time, the wetlands also serve the water needs of ranchers and farmers, recreationists, vacation communities, and cities. It is no exaggeration to call water the "liquid gold" of the West, and the burgeoning human demands on this scarce resource make it imperative to understand and properly manage the wetlands and riverine areas of the Intermountain West (McKinstry et al. 2004).

3.4.3.2. Indicators

All riparian habitats depend on a balanced combination of physical (stream bank, channel, and soil characteristics), hydrologic (regular occurrence of surface water), and vegetative (hydrophytic communities) components. When any of these three components – soils, water, or vegetation – are adversely affected, the functional capacity of a riparian habitat can be degraded. Riparian-wetland areas are properly functioning when adequate vegetation, landform, or large woody debris is present to dissipate stream energy associated with high-water flows and flooding, thereby reducing erosion and improving water quality. Vegetation filters sediment and aids in floodplain development, improving floodwater retention and groundwater recharge. Deep soil-binding root masses stabilize stream banks against erosion. Stream channels develop to provide diverse ponding and channel characteristics that support enhanced water quality, fish production, waterfowl breeding, and greater biodiversity.

Due to the importance of riparian and wetland areas, the BLM performs assessments of the functional condition of these areas using a method referred to as the assessment of PFC (Prichard 1998). The qualitative assessment process consists of an approach that considers the hydrology, vegetation, and erosion and deposition (water, soil, and vegetation) attributes of riparian-wetland areas. The on-the-ground condition (called PFC) refers to how well the physical processes that have been assessed are functioning. PFC is a state of resiliency that will allow a riparian-wetland area to hold together during high-flow events with a high degree of reliability. This resiliency allows an area to then produce desired values, such as fish habitat, neotropical bird habitat, or forage, over time. Riparian-wetland areas that are not functioning properly cannot sustain these values.

A riparian-wetland area is considered to be in PFC when adequate vegetation and landforms are present to:

- Dissipate stream energy associated with high-water flow, thereby reducing erosion and improving water quality
- Filter sediment, capture bedload, and aid floodplain development
- Improve flood-water retention and groundwater recharge
- Develop root masses that stabilize stream banks against cutting action
- Develop diverse ponding and channel characteristics to provide the habitat and the water depth, duration, and temperature necessary for fish production, waterfowl breeding, and other uses
- Support greater biodiversity

For areas that are not functioning properly, changes have to be made that allow them to recover (e.g., acquire adequate vegetation). A change such as acquiring vegetation leads to other physical changes, which allows the system to begin to function. If a riparian-wetland area is not in PFC, it is placed into one of three other categories:

- Functional at-risk – Riparian-wetland areas that are in functional condition, but an existing soil, water, or vegetation attribute makes them susceptible to degradation.
- Nonfunctional – Riparian-wetland areas that clearly are not providing adequate vegetation or landforms to dissipate stream energy associated with high flows, and thus are not reducing erosion, improving water quality, etc.
- Unknown – Riparian-wetland for which there is not sufficient information on to make any form of determination.

3.4.3.3. Current Condition

Riparian habitats in the planning area are generally dominated by willow or aspen communities along foothills streams, and usually represent stringers of habitat extending below forested areas into sagebrush and grassland habitat. Most riparian habitat on public land is between higher elevation habitats on USFS lands and lower elevation private lands in the major river bottoms. Habitats occur on wetlands and streams throughout the planning area at elevations from approximately 4,000 feet to alpine areas more than 9,000 feet.

There are four types of riparian ecosystems, in the planning area – forest-dominated riparian, willow and wet site shrub riparian, moist grass/sedge/rush/riparian, and wet meadow. On the open plains, riparian systems can be found adjacent to the Powder River and Clear Creek in Johnson County, Little Powder River and Cow Creek in Campbell County, and the Tongue River, Clear Creek, and Powder River in Sheridan County. These systems contain a variety of species, including plains cottonwood, some willow, currant, chokecherry, and sedges and rushes. The mountain systems for most of these are in the south Big Horn Mountains and include the North, Middle, and South Forks Powder River, the multiple forks of Red Fork, Big Creek, Little Eagle Creek, Buffalo Creek, Poison Creek, and many more. These systems generally have more species variety, both in composition and in structure, than their plains counterparts. Species include a variety of willows, aspen, and shrub species, including gooseberry and chokecherry, and bluegrass species, sedges, and rushes. Approximately 88 percent of the riparian areas in the planning area are on private lands. The proportions of riparian areas in the planning area on BLM-administered public lands are 2.5 percent forest dominated riparian, 1.3 percent willow and wet shrub riparian, 3.6 percent herbaceous riparian, and 0.5 percent wet meadow.

Riparian areas support more wildlife diversity than any other habitats and are the most productive wildlife habitat type in Wyoming. Many wildlife species depend on these habitats for all or part of their life-cycles; some are present in no other habitat types (for example, certain plant and bird species, amphibians and turtles), while other wildlife species such as shorebirds, waterfowl, and weasels frequent these habitat types. These small but important ecosystems serve as a biological oasis and represent a vegetative structure, soil, and hydrology that is unique relative to the vast expanses of sagebrush and prairie grass that dominate the landscape of the region. Riparian habitats support extended forb production and diversity in vegetation and structural complexity that provides for biological communities rich in insect composition. Emerging aquatic insects are a large part of the diet of birds using riparian areas. These factors make riparian areas the most important habitats to avian biodiversity across the West. Upland game birds, raptors, and migratory birds do not depend solely on riparian systems for cover or as a direct food source, but do depend on those areas as sources of water for consumption. Greater Sage-Grouse, for instance, depend on riparian areas in the summer for late brood-rearing habitat. After upland forbs have expired, Greater Sage-Grouse move into riparian habitats, as forbs generally are still available in these areas for several more months. Small mammals residing close to water sources provide a secondary food source for upland game birds, raptors, and migratory birds. Raptors will inhabit these areas if cottonwoods, alive or dead, are present for perching and nesting.

Riparian areas are ecosystems that have distinct vegetation and soil characteristics. Riparian ecosystems are uniquely characterized by the combination of high species diversity, high species densities, and high productivity. Typical plant species present in riparian and wetland communities in the planning area include cottonwoods, willows, rushes, sedges, reedtop, bluegrass, saltgrass, horsetail, dock species, iris, wild licorice, arrowgrass, bulrushes, and cattails. In addition to these native plant species, several invasive species are prevalent in riparian areas in

the planning area, including Russian knapweed, Canada thistle, musk thistle, houndstongue, tamarisk (salt cedar), and leafy spurge. Invasive species have been shown to decrease biological diversity, affect stream functions, degrade the quality of wildlife habitat, and decrease forage production for livestock and wildlife. See the *Invasive Species and Pest Management* section of this chapter for more information.

Forest Dominated Riparian

In the planning area, forest dominated riparian areas are usually characterized by plains cottonwood species, but can also be aspen, boxelder, green ash, balsam poplar, or a variety of conifer species. Deciduous tree species generally dominate at lower elevations in the planning area, whereas conifers and aspen dominate the higher elevations. Trees must occupy more than 25 percent of the vegetative cover within the riparian zone to be considered forest dominated riparian.

Willow and Wet Site Shrub Riparian

These riparian areas are characterized by areas where shrubs comprise more than 25 percent of the vegetative cover and where trees occupy less than 25 percent of the total vegetative cover. Shrubs often include willow species, sagebrush species, or greasewood. Other shrubs (e.g., hawthorn, American plum, birch, alder, tamarisk, and shrubby cinquefoil) could be present or dominant. These areas include alpine riparian zones dominated by willow species or other shrubs.

Moist Grass/Sedge/Rush Riparian

This vegetative type consists of a variety of riparian moist grasses, sedges, and rushes. The herbaceous riparian vegetative type occurs near drainages, including rivers, streams, and creeks.

Wet Meadow

This vegetative type is a combination of green and very green herbaceous rangeland types as defined by the WGFD, including bluegrass, salt grass, horsetail, bulrushes, and cattails. Wet meadow is a grassland community that typically occurs on fine-textured soils. In addition, this community commonly occurs where springs emerge, along reservoirs, and in irrigated pastures (Knight 1994).

Ecosystem Types

For management purposes, the BLM separates riparian-wetland areas into those associated with flowing water (lotic) or those associated with non-flowing water (lentic).

Examples of lotic systems are creeks, streams, rivers, springs, and channels. Examples of lentic systems are ponds, basin marshes, reservoirs, seeps, lakes, and pools. Table 3.38, “Wetland Inventory Data, 2007” (p. 447) lists the results of the wetland inventories that were performed in the planning area.

Table 3.38. Wetland Inventory Data, 2007

	Lentic Wetlands (acres)	Lotic Wetlands (miles)
Wetlands evaluated	533	110
Proper functioning condition	24	74

	Lentic Wetlands (acres)	Lotic Wetlands (miles)
Functioning at-risk, upward trend	0	7
Functioning at-risk, downward trend	0	2
Functioning at-risk, no apparent trend	22	17
Non-functioning	103	11
Unknown	384	0

Management Challenges/Management Objectives

The BLM goal for riparian and wetland areas is to maintain, rehabilitate, and improve riparian ecosystems to achieve maximum long-term benefits in conformance with the *Buffalo Resource Area Wetland Habitat Management Plan (HMP)*. This plan was developed in cooperation with WGFD. Management challenges for riparian and wetland communities include balancing the sometimes conflicting demands of livestock grazing and wildlife habitats; managing for PFC; protecting water quality; avoiding improper livestock grazing, especially during dry summer months without sufficient alternative water supplies; and fencing or other livestock exclusion options along riparian areas and wetlands. Placement of livestock supplements near riparian areas and wetlands could result in impacts to terrestrial, wetland, and aquatic habitats. One of the greatest challenges is managing for PFC when riparian areas and wetland systems involve different landowners with different resource objectives, and public lands are the minority surface. Because riparian and wetland areas provide all the basics for vegetation to thrive, they are also prime locations for the invasion and spread of invasive species.

Livestock grazing is the most widespread activity that influences riparian habitat conditions in the planning area. Energy development, roads, forest management, dispersed recreation, and localized wildlife impacts also affect the functional capability of riparian-wetland areas. The cumulative impacts of overlapping uses complicate the effectiveness of applying management constraints to a single activity to achieve riparian objectives.

When CBNG development reaches its peak, lentic and lotic systems in the planning areas also will reach their peak acreages. Once all the permitted wells are developed and the excess water disposed of, these CBNG-created “wet” systems will decline. When impoundments are no longer needed for excess water holding and disposal, most of these structures will be reclaimed and the artificial riparian-wetland systems created by these temporary structures will dissipate.

Because of all the benefits riparian-wetland areas offer, there needs to be more emphasis on these systems. Past restoration projects have proven these communities are quick to recover if they are currently not functioning properly. Resource programs need to analyze and adjust projects and management to minimize potential adverse impacts.

3.4.3.4. Trends

Habitat potential has been altered on many riparian areas where channel alteration has lowered the water table and reduced the extent of riparian habitat. This has altered riparian vegetation communities and allowed the encroachment of upland herbaceous species, such as sagebrush and juniper. Overcrowded woodland and forest conditions could be contributing to lower water yields and shrinking riparian zones in some areas, particularly during drought cycles. Riparian-wetlands in the planning area are anticipated to increase in acreage so long as impoundments are the primary way to address disposal of CBNG produced water. As the number of impoundments and

the use of natural drainages for CBNG produced water transportation and disposal increase, the acreage of lentic and lotic systems also will increase.

3.4.3.5. Key Features

Because of the multiple high values of these systems, all riparian and wetland areas are considered key features and will be managed according to each system's values.

3.4.4. Invasive Species and Pest Management

3.4.4.1. Regional Context

In Wyoming, as in other western states, invasive species are considered the single most serious threat to natural habitats. The spread of invasive species contributes to the loss of rangeland productivity, increases soil erosion, reduces water quantity and quality, reduces species and structural diversity, the loss of wildlife habitat, and in some cases invasive species pose an important threat to multiple-use management of public land. There are currently 25 Wyoming State designated noxious weeds and six designated pests (mostly insects) (Table 3.39, "Wyoming Weed and Pest Control Act Designated List" (p. 449)). Table 3.40, "Declared List of Weeds and Pests by County in the Planning Area for 2012" (p. 449) lists the declared invasive species and pests by county in the planning area for 2012.

Table 3.39. Wyoming Weed and Pest Control Act Designated List

Noxious Weeds			
Canada thistle	Field bindweed	Perennial sowthistle	Scotch thistle
Common burdock	Hoary cress (whitetop)	Plumeless thistle	Skeletonleaf bursage
Common St. Johnswort	Houndstongue	Purple loosestrife	Spotted knapweed
Common tansy	Leafy spurge	Quackgrass	Yellow toadflax
Dalmatian toadflax	Musk thistle	Russian knapweed	-
Diffuse knapweed	Ox-eye daisy	Russian olive	-
Dyers woad	Perennial pepperweed (giant whitetop)	Saltcedar	-
Pests			
Beet leafhopper	Grasshopper	Mountain pine beetle	-
Black-tailed prairie dog	Mormon cricket	Wyoming ground squirrel	-

3.4.4.2. Indicators

The indicators of management success would be the trend of invasive species or pest persistence. Monitoring, field observation, agency input, field counts, and reporting findings are important in measuring management success.

The FLPMA and the *Wyoming Standards for Healthy Rangelands* direct the BLM to manage vegetative resources toward the maintenance or restoration of the physical function and biological health of vegetative ecosystems. On public lands, the degree of impact from an invasive species depends on the type of invader (e.g., plant, insect, and parasite), the specific specie(s), the growth characteristics of that specie(s), density, size of infestation, the land cover type being invaded, the resources threatened, and the potential economic impacts to the resources and the cost of control or eradication of the invader. Some of the repercussions of weed proliferation are reduced forage, desertification of upland and riparian habitats, decreased animal health and increased mortality, devaluation of animal commodities, equipment decontamination, and reduced land values.

3.4.4.3. Current Condition

Invasive species are plants that can cause serious problems when introduced into a new environment. They have the potential to disrupt or alter the natural ecosystem function, the composition, or the diversity of the sites they occupy. Non-native species often have a competitive advantage that results from the lack of natural controls in their new environments. In areas where these species have invaded, the ecology of the area is altered, native plants that provide habitat and forage for animals are reduced or eliminated. These species can complicate the use of local natural resources and can interfere with management objectives for a site. Organisms that have been moved from their native habitat to a new location (often in a different country) are typically referred to as non-native. Most invasive species are non-native, but a distinction is made in this document because they can and do include undesirable native plants. Noxious weeds are native or non-native plants invasive species that are undesired in a particular area at a particular time, as “designated” by the State of Wyoming or “declared” by Weed and Pest Control Districts. With the exception of vascular plants classified as invasive species, a pest can be any biological life form that poses a threat to human or ecological health and welfare. To date, and only occasionally, the BFO has dealt with grasshoppers, Mormon crickets, mosquitoes, and predator control.

The primary invasive species being targeted on public lands include leafy spurge, tamarisk, Russian knapweed, spotted knapweed, diffuse knapweed, Scotch thistle, Canada thistle, houndstongue, Russian olive, halogeton, black henbane, dalmation toadflax, and hoary cress (whitetop). Some species, including annual bromes, plains pricklypear, and Canada thistle, have become so ubiquitous throughout the planning area that it is considered economically unfeasible to attempt to control them, and they are considered part of the vegetative landscape despite their adverse impacts to other vegetation. Canada thistle, although common throughout the planning area, is not treated on a plant-by-plant basis, but is treated when plant populations reach densities

high enough to make it the majority species, when it is present in the bottom of dry reservoirs, on recreational sites, and along established roads and undeveloped vehicle trails.

Two non-native annual bromes – cheatgrass and Japanese brome – have populations that have steadily increased, invaded every type of plant community, and received minimal control treatments. These annual bromes, particularly cheatgrass, are invading grassland, sagebrush grassland, mixed grass prairie, and mountain shrub community types. These plant species are very competitive with native plants for soil nutrients and available water. Using currently approved available herbicides, funding, and methodologies, it is not economically feasible to initiate large-scale control efforts on non-native annual bromes at this time but may be feasible for small-scale acreages and specific projects.

In addition to invasive plant species, there also are invasive insects (called pests) in the planning area. These insects include slant faced grasshoppers, Mormon crickets, mosquitoes, and the mountain pine beetle. See the *Vegetation – Forests and Woodlands* and the *Fire and Fuels Management* sections for more information about the mountain pine beetle and other forest and woodland pests.

Invasive plants are present throughout the planning area. In general, road corridors and water systems (rivers and creeks) are the main sources of infestation. Infestations can occur or spread when seeds are spread by vehicles, carried by livestock or wildlife, or dispersed by water or wind. In addition, ground-disturbing activities provide open sites for these plants to invade. Control methods vary as site conditions vary and often several treatment methods are used for the same infestation. Different types of invasive species control can be found in the *Invasive Plant Species Control* section, including grazing as a method. Further discussion of grazing as a means for invasive plant control can be found in Chapter 4.

Any vegetative community is susceptible to invasive species, but sites that are especially vulnerable include areas where soils have been disturbed and the native plant community has been displaced or destroyed. The occurrence of invasive species expansion is very high in areas of CBNG development. Roads, trails, and O&G locations constructed or created for energy development created new areas of disturbance and acted as vectors for transporting seeds to other locations. Utility corridors and their soil-disturbing activities also acted as a prime medium for invasive species to establish. All these disturbances occur on a variety of soils, soil depths, slopes, and in differing plant communities, making management of invasive species difficult. Construction of reservoirs and ponds and other produced-water disposal methods for CBNG development provided areas of soil disturbance and the perfect medium for establishment of invasive species, especially tamarisk. To date, approximately 400 reservoirs have been constructed on public land in association with CBNG development. These reservoirs and ponds provide breeding habitat for mosquitoes carrying West Nile virus (WNV). The use of mulch to stabilize disturbed areas is a common practice in areas of energy development; this mulch is sometimes infested with invasive species seeds. Mining areas are also disturbance locations for invasive species to establish, and transporting solid minerals can move unwanted seeds. Reclamation of energy sites provide opportunities for invasive species, as does the planting of weed-infested seed on reclamation projects. Riparian corridors also provide the perfect growing medium, including nutrient-rich soils, ample moisture, remote locations, and a moving medium to transport plants and seed. Areas of livestock confinement, wildfires, recreational sites, undeveloped vehicle trails, range improvement projects, and OHV use also can create disturbances or result in total removal of native vegetation, which makes sites and landscapes more susceptible to invasive species. Other means of invasive plant species establishment can

result from plant and seed transport with purchased forage and hay for supplemental livestock feeding that is not certified weed seed-free. Expansion of ranchettes and small-acreage dwellings in rural areas also increases the opportunity for invasive species to expand onto the public lands.

Although Weed and Pest Control Districts in Johnson, Campbell, and Sheridan counties, and other BLM permitted entities are controlling invasive plant species, invasive species management objectives are not being fully met due to the scale of infestations and lack of appropriate resources.

Invasive Plant Species Control

The weed management program continually changes as a result of new weed introduction, additional inventory, and the ongoing implementation of weed management projects. The invasion and proliferation of weeds increases the costs of invasive species control. If invasive species become established, treatment can be difficult and expensive, and eradication is often impossible. Areas might require several treatments over many years with mechanical equipment, biological controls, and herbicides designed to kill the invasive species, with possible loss of native vegetation. The BLM uses a full range of integrated pest management in the planning area. Basic management involves the following:

- Early detection and rapid response (new invasive species)
- Containment and management (widespread infestations)
- Inventory, monitoring, and evaluation
- Public awareness, education, and outreach

A full inventory of invasive plant species in the planning area has never been completed. In some areas, efforts have gained substantial control and reduced the spread of certain species, such as leafy spurge. Other species, especially diffuse knapweed, Russian knapweed, white top, Russian olive, and tamarisk, which have continued to expand their populations and the number of infested acres is increasing. In addition, new invasive plant species such as Dalmatian toadflax and black henbane are beginning to appear in multiple locations in the planning area.

The BLM controls invasive plant species on public lands through cooperative agreements with the Johnson, Sheridan, and Campbell County Weed and Pest Control Districts, and with commercial applicators. In addition to the County Weed and Pest Control Districts, the BLM works in cooperation with other federal and state agencies, private landowners, and energy production companies for management of both invasive plants and pests. Control methods used include chemical, mechanical (hand pulling and mowing), biological (insects, diseases, and grazing), and cultural (revegetation, mowing, reseeding). The BLM also addresses invasive plant species management by incorporating prevention and control measures in realty, wildlife, range, recreation, and O&G and other mineral-related actions.

All primary invasive plant species continue to colonize new areas. Invasive plants are typically present in sagebrush-grassland, mixed grassland, and riparian-wetland community types. It is not likely that most of these invasive plant species will ever be eradicated. Large-scale energy development in the planning area will require intensive invasive species management to keep populations and infested sites to a minimum. The present goal is to contain and reduce densities of invasive species populations to levels considered manageable. The tolerance level depends on the species, location, and resources at risk. Generally, the County Weed and Pest Control Districts, and BLM have not been able to meet all the BLM invasive species management needs. According to the BLM Wyoming 2012 reclamation policy (BLM 2012i), all ground-disturbing activities will require an invasive plant management plan.

Management of annual brome species will depend on the cost and feasibility of available treatment methods. Resource management strategies, minimizing adverse impacts from wildfires, reducing wildfire fuels, constructing fuel breaks, minimizing surface disturbance and surface-disturbing activities, and other preventive measures will all contribute to maintaining current levels or reducing the expanse of annual brome species communities. Research into developing new herbicide formulations continues, as does research into the existence and effectiveness of biological agents, including pathogens, to serve as future tools in controlling annual brome species and other species that create a similar threat, such as medusahead.

Table 3.41, “Treatment of Invasive Plant Species in the Planning Area” (p. 453) lists the acreages of invasive plant species being treated annually in the planning area.

Table 3.41. Treatment of Invasive Plant Species in the Planning Area

Species Treated	Acres of Treatment per year
Leafy spurge	212
Diffuse knapweed	27
Scotch thistle	32
Halogeton	38
Salt cedar	62
Canada thistle	43
Houndstongue	21
Common mullein	19

Pest Control

Pests – Pest species such as grasshoppers can be detrimental to all ecological sites because they chew grass stems, break the stalks, remove reproductive structures, destroy seeds, and leave the forage to die to dry matter. In addition to reducing plant production, pests can reduce the nutrient content, palatability, and serve as vectors to introduce threatening pathogens such as bacteria, spores, and viruses. Forbs and shrubs also can be directly and adversely affected if pest populations exceed their natural threshold. Control treatments are designed to reduce pest populations to natural or economic thresholds, not complete eradication. In an average year, pests are negligible; however, populations above economic thresholds cycle every 7 to 10 years and can last approximately 3 years. The effects of these cycles can be minor to moderate. Insecticides are effective in controlling pest populations.

The mountain pine beetle is native to the forests of western North America. Outbreaks develop regardless of property lines, and are equally evident in wilderness areas, mountains, back yards, and windbreaks. Landscape pines many miles from the mountains can succumb to beetles imported in infested firewood. Mountain pine beetles develop in pines, particularly ponderosa, lodgepole, Scotch, and limber pine. Attacks are limited largely to trees under stress from injury, unhealthy ecological states, fire damage, overcrowding, root disease, or old age. A key part of the infestation is the ability of mountain pine beetle (and other bark beetles) to transmit bluestain fungi. Spores contaminate the bodies of adult beetles and are introduced into the tree during attack. Fungi grow in the tree and help the beetle kill the tree. The fungi give a blue-gray appearance to the sapwood. Once mountain pine beetles infest a tree, nothing practical can be done to save that tree. Chemical control options for mountain pine larvae have been greatly limited in recent years. At present, there are no labeled pesticides for use on the mountain pine beetle (Leatherman et al. 2011).

West Nile Virus – WNV is a mosquito-borne disease that can cause encephalitis or brain infection. WNV is expanded from infected mosquitoes that produce their young in standing water.

Since its discovery in 1999 in New York, WNV has become established and spread across the United States. Birds are the natural vector host and serve not only to amplify the virus, but to spread it. Though less than one percent of mosquitoes are infected with WNV, they still are very effective in transmitting the virus to humans, horses, and wildlife. *Culex tarsalis* appears to be the most common mosquito to vector WNV.

Although most of the attention focused on human health issues, WNV had an impact on vertebrate wildlife populations. In 2003, at the Smithsonian Environmental Research Center, scientists disclosed WNV had been detected in 157 bird species, horses, 16 other mammals, and alligators (Marra et al. 2004). In the eastern U.S., avian populations have incurred very high mortality, particularly crows, jays, and related species. Raptor species also appear to be highly susceptible to WNV. In 2012, seven human, four avian, and five equine cases were reported in Wyoming (Wyoming Department of Health 2012). Although the number of fatal cases reported for bird species was low in Wyoming, actual mortality is likely to be greater.

The avian WNV cases reported in Wyoming in 2012 included Greater Sage-Grouse, red-tailed hawk, and Swainson's hawk (Wyoming Department of Health 2012). Population impacts of WNV on raptors are unknown at present, yet the species may be quite susceptible to the disease (Wesenberg et al. 2012). The Wyoming State Veterinary Lab determined 22 Greater Sage-Grouse in one study project (90% of the study birds), succumbed to WNV in the PRB in 2003. Current evidence demonstrates that Greater Sage-Grouse have little biological resistance to the virus and the effects are usually fatal.

Surface water issues from CBNG-related water disposal, livestock water facilities, and natural ponds have complicated (WNV) control efforts. These pits, which number in the thousands, were created to hold CBNG produced waters. The most common control method in the planning area is the use of bacteria in biological control, which has proved to be quite successful. *Bacillus thuringiensis israelensis* has been very effective as a larvicide. It was approved by the EPA in 1981 as effective on 30 species of mosquitoes. The bacterium does not harm other aquatic life or mammals, but results in a 90 percent to 100 percent kill on most types of mosquito larvae. Larvae eat *Bacillus thuringiensis israelensis* when it is sprayed over water. Knockdown activity begins within a few hours, and total kill takes place within 24 hours. *Bacillus thuringiensis israelensis* will remain active in the water for up to 3 days; after that, it too will die. *Bacillus thuringiensis israelensis* does not endanger the ecology of the area by persisting and reproducing and it is effective only on larvae. Altosid® is a commonly used larvicide that contains the active ingredient methoprene, an insect growth regulator. It commonly comes in a briquette, pellet, or granular form and is designed to release effective levels of methoprene over a period of up to 150 days as the briquettes dissolve. Larvae in treated waters continue to develop normally to the pupal stage, but at this stage, they are affected by the chemical and die.

Quagga and Zebra Mussels – Aquatic invasive species are non-native organisms that can cause great harm to an ecosystem. Aquatic invasive species like quagga mussels and zebra mussels are small organisms that could have major adverse effects on Wyoming's waters, boaters, and anglers. These species are able to multiply quickly and form thick, dense clusters that can impede water delivery and increase maintenance costs to power plants, municipalities, irrigation systems, and other water users by clogging pipes, pumps, turbines, and filtration systems. Fisheries are destroyed by the presence of these invasive filter-feeding mussels. Quagga and zebra mussels

remove plankton from the water; plankton are the primary food source for forage fish, and forage fish are the food of sport fishes. Treatment options are few and expensive; the best treatment is prevention. This species has not yet been found in the State of Wyoming, but due to their potential adverse impacts, large-scale education and awareness efforts are ongoing. The mussels are most likely to be found in larger waterbodies, but could be found in ponds and reservoirs on public lands.

Pest management depends on whether there is a health or economic risk due to the presence of pests. In February 2003, the U.S. Department of Agriculture (USDA) Animal and Plant Health Inspection Service (APHIS) and the BLM signed a MOU detailing cooperative efforts between the two entities on suppression of grasshoppers and Mormon crickets on BLM-administered lands (BLM 2009f). This MOU clarifies that APHIS prepares and issues to the public site-specific environmental documents that evaluate potential impacts associated with proposed measures to suppress economically damaging grasshopper and Mormon cricket populations. The MOU also states that these documents will be prepared under the APHIS NEPA implementing procedures with cooperation and input from the BLM. The MOU further states that the responsible BLM official will request in writing the inclusion of appropriate lands in the APHIS suppression project when treatment on BLM-administered land is necessary. The BLM must also approve a Pesticide Use Proposal (Form FS-2100-2) for APHIS to treat infestations. According to the provisions of the MOU, APHIS can begin treatments after the appropriate decision document is issued and the BLM approves the Pesticide Use Proposal.

The preferred method for treating grasshoppers and Mormon crickets is by Reduced Agent Area Treatments (RAATs). RAATs are a grasshopper suppression method in which the rate of insecticide is reduced from conventional levels, and treated swaths are alternated with swaths that are not directly treated. The RAATs strategy relies on the effects of an insecticide to suppress grasshoppers within treated swaths while conserving grasshopper predators and parasites in swaths not directly treated. Grasshopper and Mormon cricket treatments occur on a 7- to 10-year cycle and occur for 1 to 3 years concurrently in the planning area.

Management challenges for invasive species include managing BLM-authorized activities in the planning area that disturb the soil or otherwise create an opportunity for the establishment of invasive species, especially in the CBNG development areas, the interstate corridors, the larger river and creek corridors, and other watersheds. Other challenges include educating resource specialists and users, early detection for rapid response, and diminishing funding. These challenges require coordination across all of BLM resource programs to develop, integrate, and implement aggressive management techniques and the strategies for controlling the adverse impacts and the spread of invasive species in the planning area.

See the *Vegetation – Forests and Woodlands* and the *Fire and Fuels Management* sections of this document for more information on mountain pine beetle and other forest and woodland pests.

3.4.4.4. Trends

Mosquito control will continue in an effort to reduce the transmittal of (WNV) to wildlife and human health and safety.

Historically, the highest populations of grasshoppers and Mormon crickets are south of Kaycee, Wyoming, from Salt Creek west to the Hole-In-the-Wall. Grasshopper populations have also been

at levels capable of forage destruction northeast of Buffalo, Wyoming, between Clear Creek and Crazy Woman Creek.

3.4.4.5. Key Features

Key features for invasive species include areas of known infestations identified on County Weed and Pest Control Maps, and areas of potential infestations, including CBNG and associated developments, riparian zones, and transportation and utility corridors.

3.4.5. Fish and Wildlife Resources – Fish

3.4.5.1. Regional Context

Riparian and wetland habitat conditions in the planning area are described under *Vegetation – Riparian/Wetland Resources*. The *Water* section of this chapter provides information about surface-water bodies, water quality, and water quantity.

There are approximately 46 fish species in the planning area (Table 3.42, “Fish Species Known to Occur and Their Preferred Habitat in the Planning Area” (p. 456)). The planning area is centrally located within the distribution ranges for fourteen of these species (yellow perch, walleye, rainbow trout, smallmouth bass, green sunfish, golden shiner, common carp, channel catfish, brown trout, brook trout, bluegill and black crappie), on the eastern edge of the distribution ranges for ten of these species (Yellowstone cutthroat trout, Snake River cutthroat trout, sand shiner, mountain whitefish, mountain sucker, longnose sucker, longnose dace, lake chub, and Arctic grayling), and on the western edge of the distribution ranges for 22 of these species (white sucker, white crappie, western silvery minnow, sturgeon chub, stonecat, shovelnose sturgeon, sauger, rock bass, river carpsucker, plains topminnow, plains minnow, shorthead redhorse, grass carp, goldeye, flathead chub, finescale dace, fathead minnow, emerald shiner, creek chub, brook stickleback, brassy minnow, and black bullhead). There are few fish-bearing streams on BLM-administered lands due to the fragmented land ownership pattern. Most fish-bearing streams occur on lands under state or private ownership. Where fish-bearing streams do occur on public lands, they generally occur on small isolated land parcels. The *Special Status Species – Fish* section of this chapter describes special status fish species, including federally listed fish species. Species identified by the WGFD as a priority for management include 16 fish species classified as Native Species Status (NSS) 1 to 4 (see Appendix K (p. 2161)).

Table 3.42. Fish Species Known to Occur and Their Preferred Habitat in the Planning Area

Common Name	Preferred Habitat
Arctic grayling	Alpine lakes and streams
Black bullhead	Small muddy lakes; pools in large and small streams
Black crappie	Lowland lakes, pools, and backwaters in rivers
Bluegill	Lowland lakes, pools, and backwaters in rivers
Brassy minnow	Weedy streams; clear creeks with sand and gravel bottoms; lakes (occasionally)
Brook stickleback	Lowland lakes, pools, and backwaters in rivers
Brook trout	Small, cold stream and beaver ponds; mountain lakes and plains lakes (occasionally)
Brown trout	Larger foothill streams with slower moving waters
Channel catfish	Large clear rivers (can tolerate turbid water)
Common carp	Lakes, pools, and backwaters in rivers

Common Name	Preferred Habitat
Creek chub	Clear, gravel bottomed creeks
Emerald shiner	Lowland reservoirs
Fathead minnow	Slow-flowing, weedy streams, and shallow lakes and ponds
Fine scaled dace	Small streams and lowland ponds
Flathead chub	Large silty rivers
Golden shiner	Lowland lakes, pools, and backwaters in rivers
Goldeye	Lakes and streams (adapted for turbid conditions)
Grass carp	Reservoirs
Green sunfish	Pools in small to medium-sized streams; small lakes, ponds, and sloughs
Lake chub	Cool streams and lakes
Lake trout	Cold, deep lakes and reservoirs
Largemouth bass	Ponds and reservoirs
Longnose dace	Riffle areas in streams and rivers
Longnose sucker	Clear, gravel bottomed creeks
Mountain sucker	Clear, gravel bottomed creeks
Mountain whitefish	Prefers deep, fast water in large, clear cold rivers. Sometimes abundant in lakes.
Shorthead redhorse	Large, turbid streams and rivers
Northern plains killifish	Large, turbid streams and rivers
Plains minnow	Large, turbid streams and rivers
Plains topminnow	Lowland streams
Pumpkinseed sunfish	Pools in small to medium-sized streams; small lakes, ponds, sloughs, and lakes.
Rainbow trout	Large foothill streams, ponds and reservoirs
River carpsucker	Large, turbid streams and rivers
Rock bass	Streams, pond, and reservoirs
Sand shiner	Large, turbid streams and rivers
Sauger	Large, turbid streams and rivers
Shovelnose sturgeon	Large, turbid streams and rivers
Smallmouth bass	Streams, ponds, and reservoirs
Snake River cutthroat trout	Relatively clear, cold creeks, rivers, and lakes at temperatures between 4 and 15°C
Splake	Alpine and lowland lakes and reservoirs
Stonecat	Turbid streams and rivers
Sturgeon chub	Large, turbid streams and rivers
Tiger musky	Lowland lakes and reservoirs
Tiger trout	Cold streams, ponds, lakes, and reservoirs
Walleye	Lowland lakes, reservoirs, and larger lowland streams
Western silvery minnow	Large, turbid streams and rivers
White crappie	Lowland lakes, pools, and backwaters in rivers
White sucker	Streams, ponds and reservoirs
Yellow perch	Lowland lakes, pools, and backwaters in rivers

3.4.5.2. Indicators

Vegetation in riparian zones serves to dissipate stream energy, store water for later release, provide areas for groundwater infiltration, and provide rearing areas for juvenile fish. Riparian vegetation occurring along drainages also serves to moderate water temperatures, control erosion by adding structure and stability to stream banks, provide in stream habitat for fish, and provide organic

material and nutrients to aquatic biota. In addition to physical habitat features such as vegetation, water quality also influences aquatic habitats. Specifically, water temperature, turbidity, dissolved oxygen, and TDS or salinity determines the quantity and quality of aquatic habitats. Other factors influencing aquatic habitats in the planning area include adjacent land uses and the locations of such habitats in relation to natural landscape features.

Fishery habitat conditions are closely tied to riparian conditions and water quality. Riparian vegetation moderates water temperatures, increases bank stability, supports insects used as important food source, filters sediment, provides in stream habitat for fish, and provides organic material for aquatic invertebrates. Water development that alters discharges, turbidities, water temperatures, and sediment transport will likely result in a change to the endemic fish community. The following are indicators of the overall health of fisheries: population densities, water quality, water quantity, bank cover, insect/macrobenthic populations, habitat quality, gain or loss of important habitats, rangeland health standards, riparian PFC ratings, and/or disease occurrence/impacts.

Development of energy and mineral resources in the Powder River (Energy) Basin of northeastern Wyoming and southeastern Montana includes rapid expansion of CBNG development in Wyoming. Changes in flow regime and water quality wrought by CBNG development in the upper Cheyenne River basin have the potential to affect stream and riparian environments (Barrineau et al. 2007). Small irrigation diversion structures and impassable road crossings fragment habitat and could be interfering with some life-cycle requirements of some native fish species. Improving and maintaining water quality in streams and rivers, and improving the conditions of riparian habitats are key components to managing aquatic resources throughout the planning area.

The Aquatic Task Group developed a monitoring plan to meet two main objectives: (1) establish current ecological conditions for aquatic biota and their habitat, and (2) determine existing and potential effects of CBNG-produced water on aquatic life (Peterson et al. 2011). In response to this monitoring effort, an ecological assessment of streams in the PRB was performed by the USGS in cooperation with the BLM, the Wyoming DEQ, the WGFD, the EPA, the Montana DEQ, and Montana Fish Wildlife and Parks to determine current (2005 to 2008) status and to establish a baseline for future monitoring and reporting (Peterson et al. 2010). On the basis of the 2005 to 2008 results, sampling of the macroinvertebrate and algae communities was conducted at 18 sites on the mainstem Powder River and six sites on the mainstem Tongue River in 2010. The data collected (and incorporated in the previous sections) provides a snapshot of conditions in streams of the PRB during 2005 to 2008, and again in 2010, and can be used in conjunction with future monitoring to assess the impacts of CBNG and other development. Additional data analysis tools might also warrant further investigation (Peterson et al. 2010).

3.4.5.3. Current Condition

The planning area encompasses all or parts of 15 fourth-order watersheds (sub-basins). The USGS National Hydrography Dataset was used to identify these basins and the rivers, streams, and reservoirs within them (Table 3.43, “Basins and Corresponding Sub-Basins” (p. 459)). Portions or all of these sub-basins are included in WGFD Water Basin Management Plans. The *Water* section of this chapter provides additional details about the sub-watersheds. Descriptions of the existing conditions for the PRB, Tongue River Basin, Belle Fourche River Basin, Little Bighorn River Basin, Little Missouri River, and Cheyenne River Basin follow.

Table 3.43. Basins and Corresponding Sub-Basins

Basin (Acres BLM Surface) (Third-Order HUC)	Corresponding Sub-Basins in the Planning Area (Fourth-Order HUC)
Powder River 594,277	Upper Powder Salt Middle Powder South Fork Powder Middle Fork Powder Crazy Woman Clear Little Powder

Powder River Basin

The Powder River is a rare example of a free-flowing prairie stream. There are no dams over its entire length. There are, however, areas identified as potential hydroelectric sites along the Powder River. Including tributaries, the drainage basin encompasses 8,000 square miles. There are eight fourth-level hydrologic unit codes (HUCs) for the PRB in the planning area. The Powder River is formed by the confluence of the North Fork Powder River and the Middle Fork Powder River near Kaycee, Wyoming (WGFD 2008c). Fifty-two additional intermittent or ephemeral tributaries drain into the Powder River.

The Powder River is a low-gradient meandering stream with highly fluctuating flows, high turbidity, and a very unstable sand bottom (Hubert 1993). It is naturally turbid and saline because of its flows through erodible sedimentary material. The Powder River has a typical snowmelt hydrograph, driven by accumulations in the southern Big Horn Mountains. The river is generally shallow and contains portions of a shifting streambed composed of fine sands and clays that provide minimal habitat for aquatic invertebrates. Low light penetration through the turbid water also contributes to low aquatic invertebrate production by inhibiting vegetation growth (W.H. Bradshaw 1996).

Virtually all of the bottomland and riparian areas of the PRB are privately owned. Public lands, consisting mainly of sagebrush or grasslands in uplands adjacent to the river, are managed by the BLM and are concentrated in the PRB about midway down the Powder River and in the upper reach of the South Fork Powder River (W.H. Bradshaw 1996). Historically, the PRB was used extensively and almost exclusively for cattle and sheep grazing. O&G developments and recently developed coal mines have become dominant land uses over the past 80 years (W.H. Bradshaw 1996).

Twenty-eight fish species are present in the PRB. The game species in the Powder River and its tributaries include black bullhead, channel catfish, stonecat, small-mouth bass, rock bass, green sunfish, shovelnose sturgeon, sauger, and walleye (Hubert 1993). Native stream-dwelling game fish in the PRB are channel catfish, sauger, shovelnose sturgeon, and stonecat. Stonecat are rarely targeted for angling, and virtually all fishing is directed at the other three species. Channel catfish, sauger, and shovelnose sturgeon occur most commonly below the mouth of Crazy Woman Creek as seasonal migrants from Montana. There is little information about angling on streams in the Powder River (proper), but it is assumed that virtually all effort is expended on channel catfish, sauger, and shovelnose sturgeon on the lower Powder River. Gerhardt and Hubert (1991) estimated the annual exploitation rate of channel catfish to be only two percent, indicating very low overall fishing pressure.

The preservation of historical flows, turbidity, and water quality in the Powder River is an important factor in preserving the unique species assemblage. The endemic species have evolved life histories that enable them to survive in these unique conditions (Hubert 1993). Within the Powder River proper, extreme fluctuation of streamflow and temperature, low aquatic invertebrate production, high turbidity and dissolved solids, and an unstable streambed limit the population of most game fish. Consequently, sport fish management options are limited.

Some intermittent or ephemeral tributaries to the Powder River have received more constant flows since CBNG produced water discharges began. Salt Creek is a major tributary of the Powder River and during low-flow periods contributes most of the flow to the Powder River. Streamflows in Salt Creek are augmented by water discharged from O&G wells drilled in the Salt Creek Field near Midwest, Wyoming. This water contains elevated levels of TDS, chlorides, sulfates, and sodium. Depending on the time of year, these constituents can be diluted quickly after Salt Creek joins the Powder River or could retain elevated levels during low-flow periods. Although fish in Salt Creek apparently do not suffer from elevated chemical constituents or the small amounts of oil in the water, toxicity for zooplankton (*Ceriodaphnia spp.*) and fathead minnows has been documented (W.H. Bradshaw 1996). According to the WOGCC website, CBNG development has increased most dramatically in the PRB.

Standing waters in the PRB consist mainly of small (fewer than 10 acres) reservoirs and farm ponds. Many of these ponds were created with federal funds during and after the drought of the 1930s (Mueller and Rockett 1958). Some ponds were stocked privately before World War II, but stocking increased later as federal hatcheries began producing more warm-water fish. The WGFD began stocking farm ponds in 1950 where “reasonable” public access was agreed to by the landowner. Because of inconsistency among landowners providing public access to WGFD-stocked reservoirs, cutbacks in the WGFD culture system, and availability of fish from commercial sources, the WGFD generally discontinued stocking of farm ponds in 1995. Various trout species, channel catfish, and largemouth bass are the most common species privately stocked, but green sunfish and black bullhead have undoubtedly been introduced to some ponds where they probably support very little angling.

The WGFD PRB Management Plan identified that the primary concern for the Powder River was the abundance and proliferation of invasive plant species in the riparian corridor and along adjacent upland terraces. Primary invasive species included tamarisk, Russian olive, leafy spurge, and Russian knapweed. Exotic annual grasses (Japanese brome and cheatgrass) were abundant in upland sites on river terraces. Cottonwood regeneration was sporadic, but evident in many segments of the corridor. Active down-valley meander migration processes are evident along the corridor (WGFD 2008c).

The Little Powder River covers 1,836 square miles in Northern Campbell County and is host to native and non-native warm-water fishes, comprising a sub-sample of Powder River fishes. Larger-bodied native game species may occupy the main stem Little Powder River only seasonally (Barrineau et al. 2007). The Little Powder River was classified as having an expected fish community and relatively intact habitat with minimal human influence (Barrineau et al. 2007; Peterson et al. 2010). Barrineau et al. (2007) identified the biggest concern for native species conservation as the establishment of non-native piscivorous fishes (e.g., green sunfish). Ten percent of the basin is public land, including National Grasslands, BLM-administered land, and State of Wyoming land. Land use in the basin is primarily livestock grazing with hay production in the valleys (Stewart 1996).

Tongue River Basin

The Tongue River Basin covers 1,579 square miles and includes 145 streams; the Tongue River flows for 588 miles. There is one fourth-level HUC from this basin in the planning area. In addition to numerous small tributaries, there are five major streams in the basin – North Tongue River, South Tongue River, Little Goose Creek, Big Goose Creek, and Prairie Dog Creek. Most of the basin is in Sheridan County, but a few headwater streams of the Little Goose and Big Goose drainages are in Johnson County. Elevations in the Tongue River basin range from 11,700 feet in the Cross Creek drainage to 3,470 feet where the Tongue River leaves Wyoming.

The headwaters of the Tongue River drainage originate on the east side of the hydrographic divide of the Bighorn National Forest. After the North and South Tongue rivers join to form the main stem Tongue River, the flow is primarily east and north until the Tongue River enters Montana. The area surrounding the North and South Tongue rivers is predominantly conifer and alpine meadows with extensive willow complexes in some riparian areas. The Tongue River flows through a canyon for several miles before it exits onto the plains near the Bighorn National Forest boundary at the town of Dayton. From Dayton to the state line, it flows through an alluvial floodplain. Land use on this floodplain is predominantly agriculture, but there also is residential development and one coal mine (WGFD 2008d).

Land ownership in the headwaters of the Tongue River Basin primarily consists of Bighorn National Forest, of which 55 square miles are Cloud Peak Wilderness. As the basin progresses north and east, land ownership comprises a mixture of state, BLM, and private lands. Standing waters in this basin are primarily privately owned ponds, many of which are unsuitable for supporting fish populations.

The assemblage of fish in the Tongue River Basin in north-central Wyoming is diverse. Thirty-four fish species have been documented in the Tongue River Basin. Seventeen fish species have been introduced to the basin as sport fish or forage to support the sport fisheries (the Snake River cutthroat and arctic grayling are native to Wyoming, but not to the Tongue River Basin). Streams in the headwaters contain Snake River cutthroat, Yellowstone cutthroat, rainbow, brown, and brook trout, whereas a reach of the lower river contains sauger and smallmouth bass. The South Tongue and North Tongue rivers are conducive to natural reproduction of trout. There is suitable spawning habitat for sauger, smallmouth bass, channel catfish, stonecats, rock bass, mountain whitefish, and other native and non-native nongame species in the Lower Tongue River (WGFD 2008d). Although some of these streams support suitable trout spawning habitat, much of this drainage basin supports native and non-native game fish.

Stocking plays a large role in the Tongue River Basin and most waters in the basin have been stocked at one time. North Tongue River and Bull Creek are currently stocked with Yellowstone cutthroat and Snake River cutthroat trout to augment natural reproduction. Both strains of cutthroat are stocked to determine which strain will perform the best. Before 2006, the Auburn strain of Snake River cutthroat trout was stocked in the North Tongue River and Bull Creek. This strain became established (they did not leave this stretch of river), grew large, and provided excellent fishing. However, the Auburn strain Snake River cutthroat trout became domesticated and homogenized; therefore, stocking efforts were abandoned.

The absence or scarcity of deep pools in several of the headwater tributary streams limits the habitat diversity and potential for populations of larger fish. Sedimentation limits natural production of fish and macroinvertebrates in many streams, especially the Upper North Tongue River. In the Goose Creek drainage, riparian areas and stream habitat conditions vary widely from excellent to very poor and are determined largely by individual landowners. Impacts occur from livestock grazing, irrigation withdrawals, irrigation return flows, and real estate and road development. Big Goose Creek, Little Goose Creek, and Goose Creek are channelized through Sheridan. The ability of streams to support trout becomes progressively less as they approach the downstream end of the basin.

Several irrigation and municipal water supply reservoirs have been built in the Tongue River Basin to support Sheridan and surrounding communities. Fluctuations from these reservoirs limit fisheries potential in the reservoirs and could act adversely on the wild populations of trout in the streams below these reservoirs (i.e., when flows are turned off, it adversely affects downstream fisheries).

Irrigation diversions reduce flows on many streams, and these reduced flows usually occur during critical life stages of fish and macroinvertebrates. From Interstate 90 downstream to the Montana border, irrigation diversions form barriers impede seasonal upstream movements of channel catfish, sauger, smallmouth bass, and certain nongame species. Fish, especially channel catfish, move downstream in fall and winter to the Tongue River Reservoir in Montana, and the barriers impede upstream movement during spring (WGFD 2008d).

Construction of Tongue River Reservoir, several other diversions in Montana along the Tongue River, and the Welch diversion has altered sauger migrations in the Tongue River. It is assumed that sauger historically migrated from the Yellowstone River up the Tongue River and possibly as far as Goose Creek. Walleye introductions in Tongue River Reservoir might eventually contribute to the demise of this isolated population as well, but it is not known if the walleye and sauger in Tongue River Reservoir hybridize.

Several habitat improvement projects involving instream structures, boulder placement, and protection of eroding banks have been completed in the Tongue River Basin with the main goal of improving survival of stocked and wild fish and to increase wild trout production. Streams where habitat improvements have been completed include Bull Creek, the North Tongue River, the South Tongue River, Big Willow Creek, and Fool Creek (refer to Binns 2004 for more description of these projects). Recently, stream habitat improvements have been completed on the South Tongue River at the Dead Swede campground.

Logging, improper livestock grazing, and road building have accelerated the natural erosion process that contributes silt to the system. As the major streams flow off of the Big Horn Mountains and onto the plains, land use is primarily agricultural (hay, crops, and pastureland),

but residential development, coal mining, and CBNG extraction are also present in the basin. According to the [WOGCC](#) website, CBNG development has increased in the Tongue River Basin.

Little Bighorn River Basin

The Little Bighorn River Basin, encompassing 298 square miles, contains some of the most remote waters and fish populations in the planning area. There are two fourth-level HUCs from this basin in the planning area. Elevations in the basin range from almost 10,000 feet at Boyd Mountain to less than 4,000 feet near the Montana State line on Pass Creek. The Little Bighorn River sub-watershed in the planning area is at the northern tip of the basin and is exclusively located in the lower elevations. It contains portions of a few small watercourses, such as Lodgegrass Creek, Stockade Creek, East Pass Creek, West Pass Creek, and East Twin Creek.

The topography of the Little Bighorn River Basin is variable. The upper drainage is mountainous, with deeply incised canyons, coniferous forest, and alpine meadows. At lower elevations, the topography consists of rolling hills and valleys used primarily as irrigated hay and livestock pasture (McDowell 1996). The Little Bighorn River Basin is mostly comprised of public lands (79% between BLM, state, and USFS) and only 21 percent private lands. Land use practices in the basin include cattle grazing, forest management, recreational gold mining, fishing, and hunting. The privately owned, lower elevations in the basin are primarily used for irrigated hay meadows and livestock pastures. Nine fish species have been documented in the Little Bighorn River Basin. Of those, three are non-natives introduced as game species. Six species are native to Wyoming; however the Snake River cutthroat is not native to the Little Bighorn River Basin.

Most streams in the Little Bighorn River Basin have been stocked at one point. Early records indicate that brook trout were stocked in 1895 from the Sheridan Branch Hatchery on Wolf Creek (Bradshaw et al. 2008). Stocking records from the WGFD dating back to the 1930s indicate that several streams were stocked annually. Previous stockings included brook, brown, rainbow, lake, Snake River cutthroat, and Yellowstone cutthroat trout, and grayling.

Lodgegrass Creek has been historically stocked with rainbow trout, cutthroat trout, and brook trout. East Pass and West Pass creeks have historically been stocked with rainbow trout, brook trout, and brown trout. Gay Creek, a tributary to West Pass Creek, might be capable of supporting trout, but none were found during the last recorded survey in 1982 (McDowell 1996). Stockade Creek, a tributary to Gay Creek, has limited habitat for trout because of high turbidity and warm water. Flow in Twin Creek, a tributary to East Pass Creek, is insufficient to support trout. Electrofishing surveys in 1958 found small dace, fathead minnows, and numerous suckers and cyprinids (McDowell 1996).

Fish habitat enhancements and improved livestock management in the Dayton Meadows portion of the Little Bighorn River and Lick Creek have substantially increased fish habitat availability. On the Little Bighorn River at Dayton Meadows, the USFS installed a series of 21 stream improvement structures in 1980. Past mining, heavy livestock use, and public use affected the stream channel and increased sediment deposition. The deeper water and overhead cover provided by the structures was beneficial in increasing the wild brook trout population (Rockett 1983). From 1995 through 1996 new habitat improvements were completed that added to, and improved upon, the 1980 work, and expanded the area treated. Phase two of the Dayton Meadows project added 1.25 miles of improved stream habitat with the addition of 33 structures (Binns 2004). From 1984 through 1986, in the meadow area of Lick Creek just downstream of USFS Road 15, 4,276 feet of stream was improved with the installation of 47 habitat structures. In

1993, the USFS installed cattle exclosures in three segments of stream to minimize impacts from cattle. The combination of habitat structure installation and protection from the impacts of livestock has increased the potential trout production of this stream (Binns 2004). In the fall of 2007, Red Gulch Creek was treated with rotenone to remove brook trout and to increase Yellowstone cutthroat trout occupation. Approximately 1.3 miles of creek was treated, with the goal of increasing Yellowstone cutthroat trout occupation from 0.3 mile to 1.6 miles. Livestock grazing, agriculture, irrigation, and O&G development have had the greatest impact on selected segments of the basin, particularly the riparian meadows of the Little Bighorn River, Dry Fork of the Little Bighorn River, and Lick and Lake creeks.

Cheyenne River Basin

The Cheyenne River Basin includes 6,807 square miles of the northern two-thirds of Converse and Niobrara counties, the southern two-thirds of Weston County, and the southeast corner of Campbell County. Two fourth-level HUCs from this basin are in the planning area. The basin encompasses the southern end of the Black Hills, the breaks of the Rochelle Hills south of Gillette, and the rolling hills and grasslands north of Lusk. Elevations range from 3,500 feet, where the river enters South Dakota, to 6,000 feet, in the sand hills of Converse County. The drainage basin contains four sub-watersheds (Antelope Creek, Upper Cheyenne River, Dry Fork Cheyenne River, and Lightning Creek) within Campbell and Converse counties. The Cheyenne River is free-flowing in Wyoming, but dammed at Angostura Reservoir in South Dakota. There are no natural lakes in the basin, but ponds and reservoirs are common.

Sagebrush and grasslands are the predominant vegetative types in the basin, with ponderosa pine in the Black Hills and Rochelle Hills (B. Bradshaw 1996). Most of the Cheyenne River and its tributaries flow through erodible shales, claystones, sandstones, and bentonite deposits of the Belle Fourche, Arikaree, White River, and Pierre formations (Lageson and Spearing 1988). Consequently, most streams are turbid, especially during runoff or after storm events. Turbidity prevents light penetration needed for growing aquatic vegetation, channel instability, and high temperatures probably inhibiting aquatic macroinvertebrate production and creating an environment hostile to fish species that are not adapted to such conditions (e.g., game fish) (B. Bradshaw 1996). Exceptions to this general condition are streams originating in the western Black Hills, which is an area composed of less erosive formations. The hydrograph for the Upper Cheyenne River is driven by low-elevation accumulations of snow, seasonal rainfall, and periodic storms. Flows cease during most years near the South Dakota state line. The repeated withdrawal, warming, and return of irrigation water undoubtedly contributes to high water temperatures that reach 70°F to 80°F during summer.

About 75 percent of the Cheyenne River Basin is in private ownership, 11 percent is in the Thunder Basin National Grasslands, eight percent is owned by the state, six percent is BLM-administered land, and less than one percent is in the Black Hills National Forest. CBNG development, recreation, forest management, bentonite mining, O&G production, and livestock grazing are dominant uses of public lands, while grazing and hay production are the major uses of private lands. Streams on public lands are typically small, intermittent, or do not support game fish, and provide very little fishing opportunity. Most fishing occurs on small ponds in the Thunder Basin National Grasslands (e.g., Turner and East Iron Creek reservoirs and Upton ponds) and private reservoirs where unrestricted public access is provided (Black Hill Power and Light reservoir) or where free permits are used to control access (LAK and MW reservoirs).

The Cheyenne River basin supports 30 fish species, 11 of which are native. Creek chub were expected but not sampled from the basin, while mountain sucker were unexpectedly collected from Indian Creek but not from Stockade Beaver Creek, where they were previously sampled. A single brassy minnow was collected in Beaver Creek, and Barrineau et al. (2007) collected the first channel catfish and shorthead redhorse reported from the Cheyenne River Basin. Sand shiner, fathead minnow, and introduced green sunfish comprised 76 percent of all fish by number collected by Barrineau et al. (2007). Green sunfish (common), largemouth bass (uncommon), and yellow perch (rare) are non-native species present in the drainage.

Native fish species diversity is high throughout the basin, but introduced species provide virtually all of the sport fishing opportunity. Trout, largemouth and smallmouth bass, walleye, and tiger muskie are the most important game fish. The Lower Cheyenne River becomes intermittent in most years. Because the Cheyenne River and its major tributaries are intermittent most years, the drainage has been considered unsuitable for game fish, but the presence of green sunfish and black bullhead in Beaver Creek has been confirmed (BLM 2003c). These two species are abundant in the basin, but are regarded as nuisance species rather than important game species.

WGFD stocking records document the wide variety of salmonids and cool-water species stocked in standing waters since at least the 1930s. Most fishing in the basin occurs on ponds and reservoirs that are typically managed for trout, bass, or both. Standing waters primarily support local angling interests.

Stream intermittency is a historically expected basin condition (Druse et al. 1990), but increased frequency or duration of zero flow periods during drought or long-term climate change is likely to affect fish communities (Barrineau et al. 2007). Barrineau et al. (2007) details the most recent stream habitat conditions throughout the basin. Unsuitable habitat limits opportunities for salmonid fisheries. Illegally or intentionally introduced non-native fish pose predatory or competitive threats to native species throughout the Cheyenne River Basin (Barrineau et al. 2007).

Belle Fourche River Basin

The Belle Fourche River Basin covers over 3,762 square miles (WGFD 2008b). There is one fourth-level HUC from this basin in the planning area. Elevations in the basin range from 3,100 feet in the northeast corner of Crook County at the Wyoming-South Dakota state line to 6,645 feet at Warren Peak. The Upper Belle Fourche River sub-watershed is entirely within Campbell County in the western portion of the Belle Fourche River Basin.

Vegetation consists of mostly rolling grasslands and sagebrush, with the exception of ponderosa pine-dominated forestlands of the Black Hills National Forest. The principle land use of the drainage is livestock grazing and hay production. Water diversions for irrigation are common. Other land uses common to the drainage are O&G production, forest management, bentonite and coal mining, and recreation (predominately hunting, with the exception of fishing and water sports at Keyhole Reservoir) (WGFD 2008b).

The Belle Fourche River Basin is mostly comprised of private lands (82%), with only 18 percent being a mixture of state, BLM, National Forest, Thunder Basin National Grasslands, and state parks.

Thirty-six fish species have been documented in the Belle Fourche River Basin. Nineteen fish species have been introduced to the basin as sport fish or as forage to support the sport fisheries. Sixteen fish species are native to Wyoming, but the Snake River cutthroat is not native to the Belle

Fourche River Basin (WGFD 2008b). Comparisons of data collected in the 1960s and the 1990s suggest that of the fish species present in the Belle Fourche River Basin, nine have declined over this 30-year period. The fine scale dace, flathead chub, fathead minnow, lake chub, mountain sucker, shorthead redhorse, plains minnow, river carpsucker, and stonecat have declined on spatial scales described by Patton as site, stream, sub-drainage, and drainage levels, compared with that of the 1960s sampling performed by Baxter and Simon (WGFD 2008b).

Most of the streams are unsuitable for cold-water fish and offer limited potential for warm-water game fish because of water diversion and lack of suitable habitat. Beaver ponds on some minimal-flow streams provide localized trout habitat, and many of the small streams in the Black Hills depend on beaver ponds to provide habitat for fish; however, flash floods or heavy sedimentation periodically eliminate these ponds for fisheries (WGFD 2008b).

Most of the potential for game fish exists in the numerous farm ponds and reservoirs, but many are subject to periodic winter or summer kills because of limited water availability. Many of the farm ponds and privately owned reservoirs contain stunted populations of bullhead or green sunfish. The largest lentic fishery in the drainage is Keyhole Reservoir (McDowell 1995).

Urban fisheries are very important in the Belle Fourche River Basin. Gillette Fishing Lake, Panther Pond, Medicine Lake, and Sundance Fairground Pond provide fisheries where little or no fishing opportunity would otherwise exist. Several thousand fish are stocked in the Belle Fourche River Basin every year. Catchable rainbow trout, Snake River cutthroat trout, and sub-catchable brook trout are used quite frequently on public waters such as Gillette Fishing Lake, Panther Pond, Spotted Tail Pond, and Sundance Fairgrounds Pond and on private waters that allow public access, such as Medicine Lake and Driskill Reservoir (when water is available). Warm- and cool-water species are stocked quite frequently as well, not only to provide anglers with more diverse fishing opportunities but also to help control undesirable species such as green sunfish and black bullheads (WGFD 2008b).

In general, suitable habitat for game fish is rare in the Belle Fourche River Basin. Due to the small size and low flow of the Belle Fourche River and its tributaries, sport fish potential is low. Most of the basin is very arid, as indicated by negative water balances ranging from 6 to 17 inches (Marston et al. 1990). Small reservoir impoundments are abundant in the Belle Fourche River Basin. With the exception of Keyhole Reservoir, game fish habitat is restricted to small impoundments and to a relatively few stream segments. Native fishes are limited by low-oxygen and high-temperature stress during periods of low flow (Barnes 1996).

High streamflow fluctuation, streamflow alteration, long periods of low flow, high turbidity, and siltation limit the potential of most streams and standing waters in the drainage to support game fish, particularly cold-water species. Fleischer (1978) noted that morphological modifications of the drainage from rechannelization, mining, and reclamation will alter surface water drainage patterns and flow regimes, a major consequence of which could be a reduction of inflow into Keyhole Reservoir (WGFD 2008b). Impacts of coal mining and CBNG industries on fisheries and wildlife in the Belle Fourche River Basin are not well understood. According to the [WOGCC website](#), CBNG and natural gas development has increased in the Belle Fourche River Basin.

Little Missouri River Basin

The Little Missouri River Basin covers 735 square miles of northeastern Wyoming. There is one fourth-level HUC from this basin in the planning area. Most of the drainage is in Crook County,

although small headwater sections originate in Campbell County. Elevations range from 3,460 feet near the Montana-Wyoming border to about 4,600 feet at the headwaters (Gumtow et al. 1994).

Vegetation throughout the drainage area consists of mostly sagebrush and grassland, with ponderosa pine along the ridges and breaks of the low rolling hills. Agricultural activities such as hay production and livestock grazing are predominant in the valleys and riparian areas.

Although there are some state and federal lands in the drainage, no public access is available to the flowing water, all of which is on private land (Mueller and Rockett 1966).

Twenty-four fish species have been documented in the Little Missouri River Basin; most are native nongame species. Seven species are not native to the Little Missouri River Basin. In general, suitable habitat for game fish is minimal in this drainage. Due to the small size and low flow of the Little Missouri River and its tributaries, sport-fish potential is low. Fish habitat in streams is mainly confined to large pools, which can be isolated during extreme low-water conditions. Game fish habitat is mostly restricted to small impoundments in the Little Missouri River drainage. Factors limiting standing waters in the Little Missouri River drainage include drought periods, drawdowns for irrigation, and stock watering. Shallow depths of standing waters often limit overwintering for fish, resulting in fish kills. Other factors affecting fisheries in the Little Missouri River drainage include a lack of data on fish population abundance and species distribution, and lack of public access to waters that do or possibly would support sport fisheries.

Game fish habitat is restricted to small reservoirs and stock ponds, limited streamflows in the Little Missouri River below its confluence with the North Fork Little Missouri River, and in the North Fork Little Missouri River (Mueller and Rockett 1964). Mueller and Rockett (1966) reported that the WGFD had stocked 33 reservoirs in the Little Missouri River drainage with game fish, and numerous other small reservoirs have populations of largemouth bass, green sunfish, and black bullhead introduced illegally. The WGFD stream/lake database lists 58 standing waters, 31 of which are listed as unsuitable for sustaining a fishery. The WGFD or private landowners who obtained stocking authorization have stocked many of these unsuitable waters and most of the remaining 27 waters noted as suitable. Often, these unsuitable waters, when they become suitable during good water years, are stocked again (by the landowner), and might support a fishery for a few years. At present, the WGFD does not stock any of the standing waters or streams in the drainage.

Fisheries management is currently very limited in the Little Missouri River Basin. With approximately 80 percent of the land in the basin being private, management opportunities are minimal. In recent years (2004 and 2005) native nongame fish in the basin have become a priority. Although fish abundance, distributions, life histories, and conservation needs are not well known, recent surveys provide insight that can aid future fisheries management in the Little Missouri River Basin.

All Basins

Continuing threats to fish populations in the planning area include sedimentation, high concentrations of salts and metals, fuel and drilling fluid runoff, degradation of riparian habitat (including vegetation removal, cottonwood depletion, invasive plant species, and impacts from livestock), changing water levels, and introductions of predatory fish, increased clarity, flow stabilization, and construction of stream and river crossings. Refer to the *Water* section of this document for total discharges of CBNG produced water contributing to each basin.

Management actions for fish generally address water sources and rights; habitat restoration, improvement, and conservation; impacts from other BLM resource program authorized activities; floodplain connectivity; land tenure adjustments; and recreation. The BFO has developed an activity plan, the *Buffalo Resource Area Wetland Habitat Management Plan*, to focus management of site-specific riparian-wetland habitat improvements in the planning area. This activity plan is in various stages of implementation.

Powder and Tongue Rivers

The assessment of potential effects of water produced from CBNG development on macroinvertebrate and algal communities in the Powder and Tongue Rivers indicates the following:

Invertebrate community metrics and O/E scores, as well as algal metrics, indicated a substantial decline in biological condition between sites downstream of Willow Creek and upstream of Pumpkin Creek. At other site pairs, multiple lines of evidence indicate no substantial differences or an increase in biological condition, such as an increase between sites upstream and downstream of Beaver Creek. The spatial variability indicates localized noncumulative stressors might be affecting the biota. Biological condition generally declined in the middle reaches of the Powder River, indicating potential cumulative effects from CBNG discharges in some reaches from Flying E Creek to downstream of Wild Horse Creek. The middle reaches of the Powder River also contained the highest alkalinity concentrations, a potential indicator of toxicity from sodium bicarbonate. Inflow of water between Barber Creek and Wild Horse Creek might be associated with the corresponding decline in macroinvertebrate community condition and increase in facultative nitrogen heterotrophic diatoms. The increase in nitrogen heterotrophs indicates that the water contains relatively high concentrations of organic nitrogen. Comparison of invertebrate metric results from 2010 to those from 2005–08 corroborated previous findings that biological condition in the middle reaches of the Powder was lower than in the upper or lower reaches (Peterson et al. 2011).

Biological condition in the lower reaches of the Powder River was variable. Biological condition on the Tongue River showed an increase in one case and a decrease in another. Few substantial differences were noted from upstream to downstream of Prairie Dog Creek. No notable differences were noted in the Tongue River upstream and downstream of Hanging Woman Creek (Peterson et al. 2011).

3.4.5.4. Trends

A relatively small percentage of waters in the planning area have available estimates of fish populations. These estimates show that there have not been any extensive declines in overall fish assemblages in recent years. However, fish populations in the planning area fluctuate due to naturally occurring events such as drought, fire, and floods, but anthropogenic effects from road crossings, flow alterations, and changes to water quality, can also influence populations. Standing-water habitat is limited by drought periods, drawdowns for irrigation, and stock watering. Shallow depths of these standing waters often limit overwintering for fish, periodically resulting in partial or complete winterkills. Fish habitat in many streams is mainly confined to pools that might be isolated during extreme low water conditions.

3.4.5.5. Key Features

Riparian areas represent a key feature in fisheries health. Four types of riparian ecosystems, including wetlands, have been identified in the planning area – forest dominated riparian, willow and shrub dominated riparian, herbaceous riparian, and wet meadow. Approximately three percent of the planning area is comprised of riparian and wetland areas.

Hunters, anglers, bird watchers, and biologists have long recognized the value of riparian ecosystems to fish and wildlife. Riparian ecosystems are particularly valuable in a dry environment such as Wyoming. It has been estimated that, although only a small percent of the planning area is classified as riparian land, about 80 percent of the native animals depend on riparian zones for food, water shelter, and migration routes during some time of the year (Olson and Gerhart 1982).

Alteration of hydraulic conditions can affect the physical and chemical properties in a wetland, such as pH, soil salinity, sediment properties, oxygen content, and nutrient availability. Small changes in hydraulic conditions can result in massive responses by wetland biota in terms of species composition, species richness, and ecosystem productivity. Changes to the interrelationships among surface-water dynamics, groundwater level, and river channel processes can lead to changes in the establishment and maintenance of dependent riparian plant communities (Busch and Smith 1995). These changes are rapidly occurring in the planning area. Impacts to the riparian ecosystems in the planning area are: livestock grazing, which increases channel erosion and agricultural water withdrawals; physical disturbances created by the extraction of O&G resources; water depletion from invasive species such as tamarisk and Russian olive; and discharge of CBNG produced water directly into riparian corridors.

Special management of these areas will be necessary to ensure riparian corridors are healthy, that these ecosystems remain intact, and that they can meet the needs of present and future demands on public lands. Riparian areas key to fishery habitat management occur in all delineated Areas of Relative Ecological Importance and in the remaining area not included in this designation.

3.4.6. Fish and Wildlife Resources – Wildlife

3.4.6.1. Regional Context

The planning area is in the southern portions of the short- and mixed-grass prairie ecoregion. Short- and mixed-grass prairie is the largest grassland ecoregion in North America, covering almost 247,000 square miles. This ecoregion covers parts of southeastern Alberta and southwestern Saskatchewan, much of the area east of the Rocky Mountains, central and eastern Montana, western North and South Dakota, and northeastern Wyoming. Four major features distinguish this unit from other grasslands – the harsh winter climate, with much of the precipitation falling as snow; short growing season; periodic severe droughts; and vegetation.

Two environmental gradients determine species composition in short- and mixed-grass prairies – increasing temperatures from north to south and increasing rainfall from west to east. With increasing latitude, the short-grass prairies take on an aspect more similar to mixed-grass prairies such as in this ecoregion, where many cool-season species predominate (Sims 1988). In general, this ecoregion has an arid grassland ecoclimate.

Please refer to the *Vegetation* sections for descriptions of habitats comprised of forests and woodlands, grasslands and shrublands, and/or riparian/wetland communities. The short- and mixed-grass prairie is surprisingly rich in mammals for an ecoregion so far north. Much of the bird fauna is comprised of species typically associated with the prairie potholes.

In pre-settlement times, drought, fire, and wildlife grazing were likely the major disturbance factors, with fire playing a smaller role than in other grassland ecoregions. The potential for large-scale restoration is perhaps greater in this ecoregion than in almost any other in North America.

Major degradation threats are exotic invasive species such as cheatgrass, leafy spurge, and tamarisk. There is increased industrial activity (particularly O&G), road expansion, and widespread application of pesticides and herbicides. Historic, current, and predicted activities in the planning area directly contribute to all of the threats to this ecoregion. The planning area is ecologically important to the continuity of the ecoregion as a whole.

BLM and WGFD guidance documents are available regarding BMPs and management of wildlife habitats (WGFD 2009b; BLM 2005a). Although not as specific in management focus as the HMPs and action plans identified below, the existing plan does guide BLM overall management of wildlife habitats in the planning area. Due to the relationship between wildlife habitats managed by the BLM and wildlife species managed by the WGFD, a statewide agreement was established to facilitate cooperation between these agencies related to wildlife (WGFD and BLM 1990). In accordance with the cooperative relationship between these agencies, the following description of wildlife species in the planning area is organized by WGFD statutory wildlife categories to facilitate the discussions. The primary headings are game species (big game, trophy game, small game, waterfowl and other water birds, upland game birds, and furbearers), non-game species (raptors, summer and year-round resident and migratory birds, and non-game mammals), predatory animals, and reptiles and amphibians.

Sagebrush ecosystems also support a variety of species. Sagebrush obligates are animals that cannot survive without sagebrush and its associated perennial grasses and forbs; that is, species requiring sagebrush for some part of their life-cycles. Sagebrush obligates in the planning area listed as sensitive species by BLM Wyoming include Greater Sage-Grouse, Brewer's sparrow, sage thrasher, and sage sparrow; these species are further addressed in the *Special Status Species – Wildlife* section. Other sagebrush-obligate species in the planning area include sagebrush vole, pronghorn, and sagebrush lizard. Pronghorn are often associated with sagebrush, but also occupy grasslands in the planning area.

In addition, regional context for each species or species group are included where available/appropriate.

3.4.6.2. Indicators

Road density has been correlated with habitat effectiveness (BLM 2003c). The measurement of road density provides an approximation of the potential for impacts to wildlife in several ways. First, it allows for an estimate of the amount of wildlife habitat that might be adjacent to roads and, therefore, the amount of habitat that might be less effective because wildlife species sensitive to human disturbance avoid the habitat. Second, it provides a measure of the amount of habitat fragmentation, which is important in assessing impacts to wildlife species that require large tracts of habitat free from development. Third, it allows an estimate of other parameters important

to wildlife populations, such as the potential for road-kill and the potential for disturbance and mortality related to hunting. The locations of many existing roads in the planning area, particularly associated with recent non-federal O&G development, are not known; therefore, neither a spatial analysis using buffers on existing roads nor a road density estimate are possible.

Fragmentation of shrub-steppe habitat is a major disruption that has consequences for sagebrush-obligate species (Braun et al. 1977; Rotenberry and Wiens 1978). In fragmented habitats, suitable habitat area remains only as remnants surrounded by unusable environments (Urban and Shugart 1986; Fahrig and Paloheimo 1988). Populations of sagebrush-obligate species decline because areas of suitable habitat decrease (Temple and Cary 1988), because of lower reproduction, and because of higher mortality in remaining habitats (Robinson 1992; Porneluzi et al. 1993).

The extent of indirect impacts to wildlife species from human uses adjacent to their habitats varies by species and other factors such as topography, vegetative screening, habituation to disturbance, and frequency and intensity of disturbance. Mule deer, for example, tend to reduce their habitat use within 0.125 mile of roads (Rost and Bailey 1979). Elk tend to reduce their use of habitats within 0.5 mile of roads (Ward 1976). By applying a buffer to existing roads, it is possible to estimate the amount of habitat that has been reduced in effectiveness for a species.

Please refer to the *Vegetation* sections for descriptions of indicators of vegetation health for habitats comprised of forests and woodlands, grasslands and shrublands, and/or riparian/wetland communities. In addition, indicators for each species or species group are included where available/appropriate.

3.4.6.3. Current Condition

All of the vegetative types listed in the *Vegetation* sections provide habitat for some wildlife species. In an undisturbed condition, the major vegetative types in the planning area provide high-quality habitats for many wildlife species. Because these habitats tend to occur in a mosaic across the landscape, many wildlife species use more than one habitat. Most of the habitat consists of mixed-grass prairie, sagebrush shrubland, other shrubland, and riparian areas (including herbaceous, willow and shrub dominated, and forest dominated riparian areas). In addition to the common vegetative types, wet meadows tend to provide habitat for wildlife species associated with nearby dominant vegetation cover types, such as prairie or sagebrush shrubland, although in areas of large wet-meadow complexes, species common to riparian habitats can also occur. Furthermore, although they occur only sporadically throughout the planning area, coniferous woodlands support a different set of wildlife species than the main habitat types, primarily as a result of seed production and potential nest substrates provided by the various conifer species; varying forest conditions can provide specialized habitat for several forest-dwelling wildlife species.

The terrestrial vertebrate wildlife species in the planning area represent all major vertebrate classes – reptiles, amphibians, birds, and mammals. The following paragraphs list some of the wildlife species present in the common vegetative types in the planning area, although these species can also be present in other habitat types if the necessary habitat components are available. The *Special Status Species* sections that follow this discussion of wildlife address species of special concern (Threatened, Endangered, and BLM sensitive species).

Common wildlife species that typically occur in mixed-grass prairie habitats include prairie rattlesnake, golden eagle, prairie falcon, ferruginous hawk, Swainson's hawk, plains sharp-tailed grouse, lark bunting, horned lark, western meadowlark, lark sparrow, vesper sparrow, chestnut collared longspur, McCown's longspur, badger, coyote, swift fox, thirteen-lined ground squirrel, black-tailed jackrabbit, Ord's kangaroo rat, deer mouse, western harvest mouse, plains pocket gopher, black-tailed prairie dog, mule deer, and pronghorn.

Common wildlife species that may occur in sagebrush shrublands include eastern short-horned lizard, prairie rattlesnake, northern harrier, Swainson's hawk, Greater Sage-Grouse, Say's phoebe, western kingbird, horned lark, sage thrasher, Brewer's sparrow, vesper sparrow, sage sparrow, western meadowlark, desert cottontail, black-tailed jackrabbit, thirteen-lined ground squirrel, northern pocket gopher, Ord's kangaroo rat, deer mouse, prairie vole, pronghorn, and mule deer.

Common wildlife species that can occur in other shrublands are similar to those that inhabit sagebrush shrublands, and include garter snake, chukar, plains sharp-tailed grouse, western kingbird, horned lark, black-billed magpie, rock wren, sage thrasher, lazuli bunting, spotted towhee, Brewer's sparrow, lark sparrow, lark bunting, bobolink, masked shrew, desert cottontail, least chipmunk, Wyoming ground squirrel, thirteen-lined ground squirrel, deer mouse, northern grasshopper mouse, coyote, western spotted skunk, pronghorn, and mule deer.

Wildlife species that can occur in riparian areas (including herbaceous, willow and shrub dominated, and forest dominated riparian areas) include bull snake, tiger salamander, northern leopard frog, northern harrier, Virginia rail, sora, common snipe, short-eared owl, marsh wren, common yellowthroat, savannah sparrow, song sparrow, red-winged blackbird, yellow-headed blackbird, deer mouse, meadow vole, red fox, pronghorn, mule deer, and white-tailed deer. Wet meadows tend to provide habitats for wildlife species associated with nearby dominant vegetation cover types (such as prairie or sagebrush shrublands), although in areas of large wet-meadow complexes, species common to riparian habitats can also be present.

Common wildlife species in coniferous forest include ruby-crowned kinglet, downy woodpecker, hairy woodpecker, mountain chickadee, golden eagle, mountain bluebird, northern flicker, western tanager, pinyon jay, chipping sparrow, Nuttall's cottontail, mule deer, elk, moose, black bear, porcupine, bushy-tailed woodrat, and mountain lion.

Prairie dog colonies are of particular importance to the planning area because these unique ecosystems create habitat for many species of wildlife (King 1955; Reading et al. 1989). Agnew et al. (1986) found that bird species diversity and rodent abundance were higher on prairie dog towns than on mixed-grass prairie sites. Several studies (Agnew et al. 1986; Clark et al. 1982; Campbell and Clark 1981; Reading et al. 1989) suggest that species richness increases with colony size and regional colony density. Prairie dog colonies attract many insectivorous and carnivorous birds and mammals because of the concentration of prey species (Clark et al. 1982; Agnew et al. 1986; Agnew et al. 1988). In South Dakota, 40 percent of the wildlife taxa (134 vertebrate species) are associated with prairie dog colonies (Agnew 1983; Agnew et al. 1986; Apa 1985; McCracken et al. 1985; Uresk and Sharps 1986; Deisch et al. 1989). Of those species regularly associated with prairie dog colonies, six are on the BLM Wyoming sensitive species list – swift fox, mountain plover, ferruginous hawk, burrowing owl, loggerhead shrike, and long-billed curlew.

Three HMPs currently guide management in the planning area: the South Bighorns HMP (BLM 1986c); the Buffalo Resource Area; Wetland HMP (BLM 1986b); and the Middle Fork Powder River HMP (BLM 1980). Although they remain relevant, all of these plans need to be revised.

Current conditions for each species or species group are included where available/appropriate.

Big Game

Current Condition

Big game species expected to occur in suitable habitats throughout the planning area include pronghorn, white-tailed deer, mule deer, elk, and moose. The WGFD has identified various ranges for big game species, as follows:

- *Crucial Range* is any particular seasonal range or habitat component, but describes the component documented as the determining factor in a population's ability to maintain and reproduce itself at a certain level (see Map 29).
- *Summer or Spring-Summer-Fall* use is when a population or portion of a population of animals uses the documented habitats in this range annually from the end of previous winter to the onset of persistent winter conditions.
- *Severe Winter Relief* is a documented survival range that might or might not be considered a crucial range area as defined by crucial range. It is used, to a great extent, only in extremely severe winters. It might lack habitat characteristics that would make it attractive or capable of supporting major portions of the population during normal years, but is used by and allows at least a substantial portion of the population to survive the occasional extremely severe winter.
- *Winter* use is when a population or portion of a population of animals uses the documented suitable habitat sites in this range annually and in substantial numbers only during the winter period.
- *Winter-Yearlong* use is when a population or a portion of a population of animals makes general use of the documented suitable habitat sites in this range year round. During the winter months, there is a considerable influx of additional animals into the area from other seasonal ranges.
- *Yearlong* use is when a population of animals makes general use of suitable documented habitat sites in the range year round. Animals might leave the area under severe conditions.
- *Calving Areas* are documented birthing areas commonly used by females. It includes calving areas and fawning areas. These areas might be used as nurseries by some big game species.

Other than the specific ranges identified by the WGFD for each species, Map 29 shows baseline data on other aspects of each species' seasonal activities and movements (for example, fawning areas and priority migration corridors).

The planning area encompasses all or part of 26 big game populations or herd units (12 pronghorn, 5 mule deer, 4 white-tailed deer, 6 elk, and 1 moose).

Indicators

Established population size "objectives" guide management strategies for each big game herd unit. The WGFD establishes these objectives through a public and interagency review and input process and sets population size objectives at a biologically sustainable and socially acceptable level. The WGFD considers weather trends, performs habitat condition assessments, compiles population information (line transect surveys, classification surveys, and population modelling) and collects and analyzes hunter statistics and harvest information in order to assess population size and distribution of big game. Moderate to extreme fluctuations in this data typically warrants changes in hunting seasons or harvest to stabilize populations at desired objectives. For current population objectives, current population estimates, population trends, and management challenges for each herd unit, see the most recent WGFD Sheridan Region Job Completion Report.

Pronghorn

Regional Context

Pronghorn are unique to the western plains of North America and are the only living species in their taxonomic family (Antilocapridae). Wyoming is the center of the pronghorn's range and supports the largest population of pronghorn (Clark and Stromberg 1987). Pronghorn typically inhabit grasslands and semi-desert shrublands of the western and southwestern United States. This species is most abundant in short- and mixed-grass habitats and is less abundant in more xeric habitats. Home ranges for pronghorn can vary between 400 acres and 5,600 acres, according to several factors including season, habitat quality, population characteristics, and local livestock occurrence. Typically, daily movement does not exceed 6 miles. Some pronghorn make seasonal migrations between summer and winter habitats, but these migrations are often triggered by availability of succulent plants and not local weather conditions (Fitzgerald et al. 1994).

Current Condition

Pronghorn occur in the entire planning area, with the exception of most forested areas. The WGFD has divided pronghorn into herd units to estimate population sizes. The following pronghorn herd units reside entirely or partially in the planning area: 203, 308, 309, 316, 318, 339, 351, 352, 353, 354, 355, 740, and 748. The WGFD has estimated that the 2012 population size of all herd units in the planning area is 162,870 animals (WGFD 2013a). The overall population objective of this same group of herd units is 151,400 animals; therefore, population levels are currently above objective overall, but not in every herd unit.

Potential management concerns common to most herd units include obtaining adequate classification samples, inconsistent line transect density estimates, limited hunter access to private lands, high buck ratio, difficulty attaining desired harvest, limited or inaccessible public-land hunting opportunities, expanding subdivisions limit hunting opportunity and hunter access, and urban development (WGFD 2007a; WGFD 2013a). Increased activity related to the O&G industry, attempts to balance private and public land use, wildfire, fawn recruitment, forage production, and reclamation are all factors that have influenced herd numbers in recent years (WGFD 2013a).

Extensive ongoing and planned future O&G development is noted as a potential management concern for a number of herd units. The increase in O&G activity has resulted in restricted surface access on the large tracts of public land. This results in frustration from hunters seeking a public-land hunt, and has upset some non-resident hunters who had returned to the area annually and are not able to access areas they once frequented as landowners become concerned about the safety of hunters and CBNG employees on their property. CBNG development has also been an issue with hunter satisfaction; complaints have increased regarding the quality of the hunting experience while dealing with increasing CBNG traffic and land use.

Trends

The overall population trend for pronghorn in the planning area appears to be stable to decreasing (WGFD 2013a).

Deer

Current Conditions

Both mule deer and white-tailed deer occur in the planning area. Mule deer are distributed throughout the seasonal ranges, and generally prefer habitat types in the early stages of plant

succession and with numerous shrubs. They use the woody riparian, shrublands, juniper woodland, and aspen woodland habitat types extensively during spring, summer, and fall. These habitat types provide adequate forage areas with succulent vegetation for lactating females and adequate cover for security and fawning. They are often present in juniper and limber pine woodlands, sagebrush/rabbitbrush, bitterbrush/sagebrush steppe, and riparian habitat types. White-tailed deer use woody riparian habitats along creeks and rivers for forage and cover.

Mule Deer

Regional Context

Mule deer occur from southern Yukon and northwest territories of Canada, south through the western United States to Wisconsin and western Texas. Mule deer in Wyoming are among the eastern edges of this species' distribution. In Wyoming, mule deer occur in mountains and associated foothills, broken hill country, and prairie grasslands and shrublands (Clark and Stromberg 1987).

Current Conditions

Browse is an important component of the mule deer's diet throughout the year, making up as much as 60 percent of total intake during autumn, while forbs and grasses typically make up the rest of their diet (Fitzgerald et al. 1994). This species tends to be more migratory than white-tailed deer, traveling from higher elevations in summer to winter ranges that provide more food and cover. Fawn mortality is typically due to predation or starvation. Adult mortality often occurs from hunting, winter starvation, and collisions with automobiles. Typical predators can include coyotes, bobcats, golden eagles, mountain lions, bears, wolves and domestic dogs (Fitzgerald et al. 1994).

Mule deer ranges occur in almost all parts of the planning area. The WGFD has divided mule deer into herd units to estimate populations. Seasonal range maps are subject to change as new management data becomes available. The following herd units reside entirely or partially in the planning area: 208, 319, 320, 321, 322, 740, 751, and 755.

Extensive ongoing and planned future O&G development is noted as a potential management concern for a number of herd units. O&G development in some areas is creating problems for hunters. Public accessibility to BLM and state lands is particularly problematic, because intensive development activity has reduced hunting opportunity and quality. In recent years, these lands have attracted fewer hunters. Almost all landowners charge access fees or require an outfitter for buck hunting, and tend to cater to non-resident hunters. Land use by the CBNG industry create additional restrictions as landowners become concerned about safety issues and restrict hunting where CBNG activity is high. Increased traffic and other activities associated with the CBNG industry also interfere with an "enjoyable hunt," and this issue has become a more frequent complaint on landowner surveys for the region. When these factors cause landowners to more tightly control access to private lands, it increases pressure on the few areas of public land available in this herd unit. Many hunters contacted on public land (mainly Thunder Basin National Grassland) complained of the low quality and young age of bucks and the excess of does, which can mainly be attributed to increased hunting pressure on public lands (WGFD 2006b; WGFD 2007a).

Trends

The WGFD has estimated that the 2012 population of all herd units in the planning area is 131,199 animals (WGFD 2013a). The overall population objective of this same group of herd units is 201,100 animals. All herd units in the planning area are below objective, although 751 is only 2.5 percent below.

Lack of hunter access to private land, increased activity related to the O&G industry, attempts to balance private and public land use, wildfire, poor fawn recruitment due to weather factors, predators, forage production, increased competition from other species, and reclamation are all factors that have influenced herd numbers in recent years (WGFD 2007a; WGFD 2006b; WGFD 2013a).

White-tailed Deer

Regional Context

White-tailed deer occur throughout North America from the southern United States to Hudson Bay in Canada. Across much of its range, this species inhabits forests, swamps, brushy areas, and nearby open fields. White-tailed deer are present throughout Wyoming, typically concentrated in riparian woodlands, shrubby riparian and associated irrigated agricultural lands, and are generally absent from dry grasslands and coniferous forests (Clark and Stromberg 1987).

Current Conditions

Their diet is diverse, capitalizing on the most nutritious plant matter available at any time. In addition to native browse, grass, and forbs, this species relies on agricultural crops, fruits, and acorns and other nuts. White-tailed deer mortality is typically related to hunting, winter starvation, collisions with automobiles, and predation. Predators can include coyotes, mountain lions, wolves, and occasionally, bears, bobcats, and eagles (Fitzgerald et al. 1994).

In the planning area, white-tailed deer are restricted to river and stream drainages across the PRB and to riparian habitats associated with the northern foothills of the Big Horn Mountains. They tend to be absent from large expanses of prairie and shrubland.

The WGFD has divided white-tailed deer into herd units to estimate population sizes. Seasonal range maps are subject to change as new management data becomes available. The following herd units reside entirely or partially in the planning area: 201, 303, 706, and 707.

Trends

The WGFD has estimated the 2012 population size of two of these herd units at 56,719 animals (16,600) in herd unit 303, with a objective of 8,000, and 40,119 in herd unit 706, with a objective of 40,000); however, survey data were not adequate to allow estimates of the sizes of the other herd units. The population is thought to be substantially higher than the objectives for both herd units, with a stable or increasing trend (WGFD 2013a). The stated cause for populations substantially higher than objective is lack of public access for hunting, and urbanization in the northwest part of the planning area.

Elk

Regional Context

Elk formerly ranged over much of central and western North America from the southern Canadian Provinces and Alaska south to the southern United States, and eastward into the deciduous forests.

This species is present throughout Wyoming in a variety of habitats, including coniferous forests, mountain meadows, short- and mixed-grass prairies, and sagebrush and other shrublands.

Current Conditions

In the planning area, elk are concentrated in the Big Horn Mountains and associated foothills, the Fortification Creek area west of Gillette, the Pine Ridge area in the south, and the Rochelle Hills in the southeast. Similar to other members of the deer family, this species relies on a combination of browse, grasses, and forbs, depending on their availability throughout the seasons. Elk tend to be migratory, moving between summer and winter ranges, although within the planning area, the Fortification Creek and Rochelle Hills elk herds are essentially non-migratory. Specific studies on seasonal movement and range use have been completed for the Fortification Creek herd unit; therefore, data for this area are presented separately from the other herd units. Typically, mortality is a result of predation on calves, hunting, and winter starvation. Predators can include coyotes, mountain lions, bobcats, bears, wolves, and golden eagles.

The WGFD has divided elk into herd units to estimate population sizes. The following herd units reside entirely or partially in the planning area: 211, 320, 321, 322, 344, and 743. The WGFD has estimated the total population size of five of these herd units at 17,136; however, survey data were not adequate to allow a population estimate of the size of herd unit 743, but is likely to be larger than was thought by wildlife managers in the past (WGFD 2013a). The overall population objective of the same group of four herd units is around 12,000 animals; therefore, population levels are currently above objective overall. Factors influencing herd numbers include lack of public access for hunting, access to private lands for hunting at a level sufficient to allow effective herd management, wildland fire, and weather conditions. The Fortification herd harvest is limited by private land owners. WGFD Job Completion Reports, which are online, do not indicate habitat quality as limiting elk.

Extensive ongoing and planned future CBNG development was noted as a potential management concern for one herd unit. Impacts from CBNG development are not known at this time; however, increased road density, produced-water discharge, loss of vegetation, and increased human presence have the potential to adversely affect herd units subject to substantial CBNG development (BLM 2003c). Research in the Fortification herd unit to study the effects of development on elk are ongoing (WGFD 2013a).

Trends

The overall recent trend has been increasing herd numbers, except in herd unit 322, which is decreasing; however, the herd unit is still above objectives (WGFD 2013a). Elk numbers in Fortification Creek and on the Southern Big Horns are above desired objectives by 241 percent and 109 percent respectively. WGFD has increased hunter opportunities in the Southern Big Horns in an attempt to reduce the population.

Moose

Regional Context

In North America, moose occur from Alaska to the northeastern United States and south along the Rocky Mountains into Colorado. Typical moose habitats in the Rocky Mountains include willow, spruce, fir, aspen, or birch. These habitats are common to forest dominated riparian, shrub dominated riparian and wet meadow vegetative types.

Current Conditions

Moose ranges are extremely limited in the planning area and are restricted to areas along the western boundary in the Big Horn Mountains. These range data are based on seasonal range maps available from the WGFD at the time of this writing. Seasonal range maps are subject to change as new management data become available. Willow is an important dietary component on all seasonal ranges, especially in winter range when grasses, forbs, and aquatic vegetation are less available. Moose tend to have strong affinity for specific home ranges, but would make seasonal migrations in search of suitable forage and habitat. Major mortality factors include hunting, starvation, and predation. Common predators include mountain lion, wolverine, coyote, bear, lynx, wolves, and domestic dog (Fitzgerald et al. 1994).

There are existing disturbances to moose habitats attributed to agriculture, mineral development, or urban areas in the planning area. Specific data on mining, roads, compressors, and ancillary O&G facilities are not available in sufficient detail to allow a determination of their impacts on moose habitats.

The 313 herd unit is the only moose herd unit in the planning area. WGFD has estimated that the 2012 population of this herd unit is 452 animals (WGFD 2013a). The overall population objective of this herd unit is 500; therefore, population levels are currently at 90 percent of objective. Some problems associated with the management of this herd include lack of sufficient funding for data collection, lack of a reliable population estimate technique, non-hunting mortality (e.g., illegal harvest and moose-vehicle collisions), possible forage competition, weather conditions, and habitat quality.

Trends

The overall population trend for moose in the planning area is thought to be relatively stable or trending slightly downward (WGFD 2013a).

Trophy Game

The WGFD classifies mountain lions and black bears as trophy game.

Mountain Lion

Regional Context

Formerly distributed throughout North America, the mountain lion is now found mostly in remote areas of the western United States. Mountain lions are typically present in remote areas with dense cover and rocky, rugged terrain. They are present in most habitats where deer, their primary prey base, are present.

Indicators

Local and regional management objectives are developed and evaluated based on WGFD-collected harvest data. A source-stable-sink adaptive management approach is applied evaluating (1) density of human caused mortalities, (2) sex-age composition of mountain lion harvest focusing on relative proportion of adult female harvest, and (3) the relative age of harvested adult females. WGFD will implement adaptive management strategies to address short and long-term management needs where appropriate and additional research efforts will be conducted to address other management priorities as funds become available relative to other

Department needs. Mountain lion management objectives are based on ecological data and social conditions to ensure management strategies benefit both the species of concern and the people who are impacted by mountain lion conflicts (WGFD 2006a).

Current Conditions.

Incidental, non-target take (from trapping and snaring) and WGFD removal account for the majority of non-harvest mortalities (WGFD 2013b). Illegal and natural mortalities also occur.

Human safety and human/mountain lion interactions are topics vigilantly addressed and monitored where people and mountain lions coexist. Annual educational efforts continue, and if warranted, will be increased to inform the public about mountain lion behavior and safety procedures to follow when humans come in contact with mountain lions. There are preventive methods (i.e., landscaping, husbandry techniques, and outdoor awareness) that reduce the overall chance of human/mountain lion encounters. Education increases the ability of humans and mountain lions to cohabit.

Livestock (primarily sheep) depredation attributed to mountain lions will always be an issue of contention to be addressed regarding mountain lion management in Wyoming. Certain hunt areas are being managed as sinks because of depredation issues.

Trends

The WGFD mortality report for years 2010–2012 indicates that the population of mountain lions in northeast and north-central Wyoming is decreasing, while the population across the state appears to be stable to increasing; management objectives for northeast Wyoming include population reduction (WGFD 2013b).

Black Bear

Regional Context

Black bears are found in most of Alaska, southeastward through Canada to northern Minnesota, Wisconsin and Michigan and in the Maritimes, south through New England, New York, Pennsylvania and the Appalachian Mountains to Florida. They are also found on the west coast in northern California, east through the Rocky Mountain states to New Mexico as well as in Arkansas and Oklahoma.

Indicators

WGFD employs a range of harvest criteria to assess harvest impacts on black bears in Wyoming. These include percent adult males in the harvest, percent of females in the harvest and percent of adults in the female segment of the harvest. All data is analyzed using 3-year averages, compiled over 10-year periods for long-term trends. In addition to harvest data, WGFD monitors annual average human-caused black bear mortality per area of suitable habitat for each hunt area. This density provides an index of more localized impacts of human-caused mortality on black bear populations. With future population density estimates, this metric is also used to gauge the proportion of black bear population harvested annually.

Current Conditions

Black bears are present along the western boundary of the planning area in the Big Horn Mountains. Black bears prefer forested and shrubby areas. They are also known to inhabit

ridgetops, burned areas, riparian areas, agricultural fields, and avalanche chutes. Black bears can be present in dry sage and juniper habitats. In mountainous areas, they seek southerly slopes at lower elevations for forage and move to northerly and easterly slopes at higher elevations as summer progresses. Black bears use dense cover for hiding and thermal protection, and for bedding. They climb trees to escape danger and use forested areas and rivers as travel corridors.

Annual harvest totals for the Bighorns Bear Management Unit show a relatively steady rate of harvest since 1979, with a decline shortly after female quotas began in 1994. Harvest criteria indicate that harvest is beginning to affect the black bear in this Bear Management Unit. The percent of adult males in the harvest decreased in the late 1990s and then increased into the population reduction range. The percent of females in the total harvest has remained in the stable range since the mid 1990s and the percent of adults in the female harvest moved from stable to increasing (WGFD 2007a).

Healthy stands of timber, especially lodgepole pine and spruce-fir in different stages of succession, are essential to provide suitable habitats for black bears. These habitat types provide forage, cover, and bedding areas. Adverse impacts to important bear habitats can be more detrimental to bear populations than human-induced mortalities, particularly if the impacts are irreversible. Because of the difficulty in observing black bears, estimating their abundance is an ongoing management challenge. The overall goal of black bear management in Wyoming is to sustain black bear populations throughout all suitable habitats while maintaining recreation opportunities and managing black bear damage (WGFD 2007b).

Trends

Populations for black bear are thought to be stable or increasing in the planning area.

Small Game/Game Birds

Small game includes small game mammals and upland game birds. Most of the data on these species come from harvest statistics kept by the WGFD for management areas in the state.

Mammals

Regional Context

The small-game mammals are cottontails, snowshoe hares, and red, gray, and fox squirrels. Cottontails can typically be found from extreme south-central British Columbia and western Washington, south to eastern California, and east through Saskatchewan, Montana and south into northern New Mexico. Snowshoe hare distribution is throughout Alaska and most of Canada south to northern California, northern New Mexico, northern Minnesota, northern Michigan, northern New Jersey and southward through the Allegheny Mountains. Red squirrels occur throughout much of Alaska and Canada. In the United States, they occur through the Rocky Mountain states and to the east to Iowa, northern Illinois, northern Indiana, Northern Ohio, northern Virginia and through the Alleghenies. Both the fox and gray squirrels are at the western-most edges of their range in Wyoming as they typically occur in the eastern United States from New England, westward to the Dakotas and eastern Texas.

Indicators

The majority of Wyoming's mammalian Species of Greatest Conservation Need (SGCN) are not truly monitored (WGFD 2010b).

Current Conditions

These species are present throughout the planning area and are hunted during fall and late winter. Due to the wide distribution of small-game species throughout Wyoming, no management challenges have been identified in the planning area. The primary BLM management effort is directed toward maintaining the continuity of ecosystems in the planning area.

Trends

Small-game population trends in the planning area are unknown, although these populations appear to be relatively stable over time. Small-game populations likely fluctuate as a result of naturally occurring phenomena such as drought, fire, and floods.

Upland Game Birds

Upland game birds in the planning area include chukars, Hungarian partridge, ring-necked pheasant, wild turkey, Greater Sage-Grouse, and sharp-tailed grouse (Orabona et al. 2012). Greater Sage-Grouse, although listed as an upland game bird by WGFD, is a BLM Wyoming sensitive species and is addressed in detail in the *Special Status Species – Wildlife* section of this chapter.

Regional Context

Chukars are present in hilly and rolling terrain along mountain foothills, and to some extent in badland topography. This species ranges throughout the northwest and southwest from California and Western Canada eastward through the Plains and the Rocky Mountains. The Hungarian partridge prefers habitat of open, grassy areas in a cool, dry climate. Preferred nesting areas include grasslands, hay and grain fields, and especially alfalfa fields. Heavily wooded areas are almost always avoided. This species occupies a range along the northern United States and southern Canada, westward through the Plains and the Rocky Mountains to the northwest. Ring-necked pheasant habitat includes farmlands, pastures, and grassy woodland edges. These habitats are occupied by the ring-necked pheasant throughout the majority of the northern United States and southwestern Canada and scattered throughout portions of the southwest United States. Wild turkeys are present in wooded areas in the upper elevations and along riparian corridors. This species occurs throughout a large portion of the United States, from Florida to the Great Lakes, Texas to southwestern Canada, and from the Mid Atlantic to the Rocky Mountains and scattered populations in California and the northwest. The sharp-tailed grouse is present throughout much of central Canada and from Montana to central Nebraska. This species inhabits short- and mixed-grass prairie, sagebrush shrublands, woodland edges, and river canyons (Sibley 2003).

Indicators

Birds are the most monitored taxa in Wyoming. Key efforts include annual Breeding Bird Surveys (BBSs) and strategies outlined in the Wyoming Bird Conservation Plan. Additionally, the WGFD is involved in a variety of single species monitoring efforts related to raptors, waterfowl, and a few upland birds. Program adaptation occurs when new information or changing conditions trigger modification of individual actions to accomplish conservation goals or evaluation and adaptation of Wyoming Comprehensive Wildlife Conservation Strategy (WGFD 2005).

Current Condition

Chukars, Hungarian partridges, ring-necked pheasants, and wild turkeys are present in their preferred habitats throughout the planning area. These populations do periodically fluctuate as a result of naturally occurring phenomena such as drought, fire, and floods. The BLM does not specifically monitor or manage any of these species other than through normal hunting seasons.

In Wyoming, and throughout the planning area, sharp-tailed grouse are present where grasslands are intermixed with shrublands, especially wooded draws, shrubby riparian areas, and wet meadows. Species of shrubs that produce berries (such as chokecherry) provide important winter forage for sharp-tailed grouse. Each spring, the males perform elaborate mating dances on historical strutting and dancing grounds called leks (BLM 2003c). Leks are typically on hilltops, ridges, or other high points in low, open grassland habitats. Data provided by the WGFD, Nongame Division, indicate that plains sharp-tailed grouse leks are present primarily in the northern portion of the planning area, where sharp-tailed grouse preferred habitats are most common. There are 102 documented lek sites in the planning area. Past surveys have not covered the entire planning area because of the amount of private land present; therefore, the number of leks could be higher.

Management actions for game birds generally are directed at activities around delineated breeding and nesting habitats (e.g., sharp-tailed grouse leks). Wild-turkey populations are thriving; therefore, there are no opportunities for wild-turkey introductions in cooperation with the WGFD. There are opportunities for translocation of nuisance wild turkeys in the planning area, although no areas for placement of these turkeys have been identified. Current management restricts or prohibits surface occupancy within 250 yards of a sharp-tailed grouse leks and does not allow surface use within 0.64 mile of leks between April 1 and May 7. The BLM authorized officer may grant exceptions to both restrictions. Management challenges focus on maintaining or enhancing the presence of game birds and the habitats upon which they depend.

Trends

Populations of chukars, Hungarian partridges, ring-necked pheasants, and wild turkeys appear to be relatively stable.

Sharp-tailed grouse population trends are not known at this time; however, populations are thought to be declining due to habitat removal and fragmentation by O&G development and urbanization throughout the planning area.

Migratory Game Birds

Regional Context

The planning area is in the central flyway (east of the Continental Divide). The planning area includes part of the Northern Great Plains joint venture area. Appendix K (p. 2161) lists species of concern to the Northern Great Plains joint venture. Ducks Unlimited has developed a national conservation plan (Ducks Unlimited 2004) that addresses waterfowl management needs, including those in Wyoming.

Indicators

In cooperation with the USFWS, the Migratory Game Bird Section of the WGFD conducts the following annual surveys to derive population indices for management: September crane survey, mid-winter waterfowl survey, Canada goose breeding population survey, Rocky Mountain population of Canada geese molt survey and mourning dove call-count survey. The Migratory

Game Bird Section remains strongly involved in the Central and Pacific Flyway management efforts, including development and revision of management plan for various migratory game bird populations and annual season setting (WGFD 2010b).

Current Conditions

Ducks and geese are present in aquatic areas throughout the planning area. Some individuals or species breed, winter, or remain in the state year round, while larger numbers pass through during spring or fall migration. The various sources of water, natural lakes, streams, and man-made reservoirs are important resting areas for a variety of waterfowl species, including ducks, geese, snipe, rails, and shorebirds. Aquatic resources scattered throughout the planning area support various species of waterfowl during nesting periods, and private agricultural lands provide important foraging habitat where grains and hay are grown. Most of these species depend on wetlands or open water that is sufficiently shallow to support rooted vegetation, and they feed on the biotic communities developed in such habitats.

Waterfowl species that can be present in the planning area include Canada goose, wood duck, mallard, gadwall, harlequin duck, green-winged teal, American widgeon, northern pintail, northern shoveler, blue-winged teal, cinnamon teal, Barrow's goldeneye, bufflehead, canvasback, lesser scaup, tundra swan, and redhead. The occurrence and distribution of these species vary and are influenced by local conditions such as aquatic habitat, adjacent upland habitat, season, and land use practices. These waterfowl species are expected to be present in suitable habitats in the planning area during the appropriate species-specific nesting, migration, and wintering seasons.

Historic activities in watersheds that have contributed to loss or degradation of habitat in the planning area include recreation, agriculture, forest management, fire management, urbanization, and land development. Management of wetlands and riparian areas in this arid climate continues to be a challenge. Other challenges include access to public lands during breeding season, contaminants, invasive plant species, and water quantity and quality. The BLM will continue to seek opportunities to develop and enhance migratory bird habitats in the planning area.

Various methods of handling produced water could have caused impacts. At present, much of the CBNG produced water is discharged to surface drainages. Important wildlife habitat may be severely impacted or eliminated by surface discharge of produced water. Impoundment of streams receiving produced water tends to increase waterborne selenium concentrations through evaporative concentration and create a hazard for migratory aquatic birds. Fish also can bioaccumulate selenium directly from the water as well as from their diet. Top level consumers in aquatic systems, such as waterfowl, can readily accumulate selenium concentrations leading to low reproduction, embryonic deformities and increased mortality.

In an *Assessment of Contaminants Associated with Coal Bed Methane-Produced Water and Its Suitability for Wetland Creation or Enhancement Projects* (USFWS 2005), aquatic vegetation was collected from all sites where it was present. Boron concentrations in aquatic vegetation collected from these sites, where it was present, exceeded the 30 micrograms per gram level documented to effect growth in ducklings. Cadmium concentrations in aquatic vegetation from two sites and one site's levels were slightly above the 0.1 micrograms per gram wet weight level that should be "viewed with caution" in terms of wildlife dietary levels. Chromium concentrations in pondweed from two sites exceeded the wildlife dietary threshold of 10 micrograms per gram. Selenium concentrations in water, sediment, and biota were below threshold levels known to cause adverse effects to sensitive species of fish and aquatic birds, with the exception of CBNG produced water discharges and CBNG closed containment impoundments. Closed containment ponds containing

high selenium water may present a risk to aquatic birds using these ponds if the ponds provide a dietary route of exposure through submerged aquatic vegetation or aquatic invertebrates (USFWS 2005). In addition, toxic concentrations of salts could be accumulating in some containment reservoirs, making them unsuitable for waterfowl use.

Trends

No estimates of population sizes in the planning area are available for any of these species. Mourning doves are abundant in a variety of habitats in the planning area. Call-counts declined considerably throughout the Central Management Unit over the most recent 10-year and the 43-year periods. However, no obvious trends were noted.

Furbearing Animals

Badger, beaver, bobcat, American marten, mink, muskrat, and weasel are furbearing animals present in the planning area.

Regional Context

Distribution of the badger in North America includes the open plains and prairies, farmland, and sometimes edges of woods in the western United States, east to eastern Texas, Oklahoma, northern Missouri, northern Illinois, northern Indiana, and northern Ohio, north to southeastern British Columbia, Alberta, Manitoba, and Saskatchewan. The beaver occupies most of Canada and the United States except for most of Florida, Nevada, and southern California. The bobcats distribution is spotty from coast to coast, though scarce or absent in much of the Midwest. The marten occupies the extreme north of the United States, extending spotty distribution into California and the Rocky Mountains and New England. Most of the United States, except Arizona, southern California, southern and central Utah, southern New Mexico and western Texas is typically home to the mink. The muskrat's range encompasses most of the United States and Canada except for the Arctic regions, much of California and the southwest, Texas and Florida. The least weasel can be found in most of Canada, south into the Midwest of the United States, northeastern Montana, Nebraska, Iowa, northern Illinois, northern Indiana, Ohio, Pennsylvania, West Virginia, and the southern Appalachian Mountains.

Indicators

WGFD biologists use furbearer/trapper harvest survey results to monitor populations of these species and make hunting season recommendations.

Current Conditions

Badger, bobcat, and weasel are habitat generalists, occupying all vegetative types in the planning area with appropriate prey base. Marten primarily utilize mixed-conifer forest and aspen communities in the ponderosa and lodgepole pine forests and the aspen, juniper, and limber pine woodlands vegetative types. Beaver, muskrat, and mink typically are present in the aspen and riparian and wetland vegetative types. Due to the wide distribution of other furbearing animals throughout Wyoming, no management challenges have been identified for the planning area. The primary BLM management effort is directed toward maintaining the continuity of ecosystems in the planning area.

Trends

Furbearer population trends in the planning area are not known at this time. Population figures are available only on a statewide basis. Trapping seasons apply to most furbearers. These populations likely fluctuate as a result of naturally occurring phenomena such as drought, fire, and floods. Population fluctuations of their prey base also affect furbearer abundance.

Predatory Animals

According to Wyoming statute, predatory animals in the planning area include coyote, red fox, raccoon, porcupine, skunk, and jackrabbit. These species may be hunted or trapped without a license, and there is no closed season.

Regional Context

Historic coyote distribution occurred throughout eastern and southern Alaska, southern and western Canada, and all of the western United States, but is now believed to extend throughout the entire United States. The red fox can be found throughout most of Canada and the United States, except for the far north, northwestern British Columbia, much of the western United States and southern Florida. Raccoons range from southern Canada through most of the United States, except portions of the Rocky Mountains, central Nevada, Utah, and Arizona. Porcupine distribution encompasses most of Canada and the western United States, south to Mexico and in the east, south to Wisconsin, the northern half of Michigan, most of Pennsylvania, New York, and New England. Most of the United States and Canada is home to skunk. Jackrabbits can be found in the western United States from south-central Washington, south to California, east to Nebraska, western Missouri and Texas.

Indicators

No indicators for predatory animals are available at this time.

Current Conditions

USDA APHIS-Wildlife Services conducts predatory animal damage-control activities on public lands in accordance with the national MOU and local action plans (BLM 2000a). APHIS-Wildlife Services performs these activities in response to requests from individuals, organizations, and agencies experiencing damage caused by wildlife. Animal damage-control activities primarily include mechanical (trapping, shooting, and denning), chemical (poison), and nonlethal methods (e.g., noise devices and aversive conditioning). Through the Animal Damage Management Board, the State of Wyoming also performs animal damage-control activities, particularly actions involving rabies and other diseases.

The management challenge for animal damage-control activities is to implement a program that responds to predation problems and remains socially acceptable and safe in accordance with applicable laws and regulations. The BLM does not perform any habitat management activities for predatory animals. An overabundance of predatory animals can be devastating to prey populations. Future management of BLM-authorized activities should incorporate BMPs aimed at reducing supplemental habitat for predatory species throughout the planning area.

Trends

Predatory animal population trends in the planning area are not known at this time. CBNG infrastructure such as roads, pipeline corridors, and nearby metering facilities provides shelter and den sites for ground predators such as skunks and foxes. These populations likely fluctuate as a

result of naturally occurring phenomena such as drought, fire, and floods. Population fluctuations of their prey base also affect these animals' populations.

Nongame Animals

The following paragraphs briefly describe existing conditions for four categories of nongame wildlife (raptors, neotropical migrants, mammals, and reptiles and amphibians). Raptors and neotropical migrants are afforded protection under the Migratory Bird Treaty Act. Additional detail about nongame wildlife in the planning area can be found in the WGFD *Atlas of Birds, Mammals, Amphibians and Reptiles in Wyoming* (Cervoski et al. 2004). Also, the *Wyoming Partners in Flights Wyoming Bird Conservation Plan* identifies priority bird species and habitats, and population and habitat objectives for birds (Cervoski et al. 2001).

Raptors

Raptor species (eagles, hawks, owls, and falcons) in the planning area include the bald eagle, golden eagle, American kestrel, Cooper's hawk, ferruginous hawk, northern harrier, northern goshawk, red-tailed hawk, Swainson's hawk, great horned owl, short-eared owl, long-eared owl, western burrowing owl, peregrine falcon, and prairie falcon. Less common raptors in the planning area include osprey and merlin. Raptors are present in habitats throughout the planning area. The USFWS Wyoming Ecological Field Office *Raptor Guidelines* (USFWS 2013d) summarizes the typical nesting periods by raptor species. Raptors are sensitive to environmental disturbance and occupy an ecological position at the top of the food chain; therefore, they act as biological indicators of environmental quality. Several of these species (bald eagle, ferruginous hawk, northern goshawk, peregrine falcon, Swainson's hawk, and western burrowing owl) are further addressed in the *Special Status Species – Wildlife* section. Appendix K (p. 2161) identifies these and other raptor species of interest to agencies and groups in the planning area.

Indicators

Key efforts for monitoring include annual EOs and strategies outlines within the Wyoming Bird Conservation Plan. Additionally, the WGFD is involved in a variety of single species monitoring efforts related to raptors, waterfowl, and a few upland birds.

Current Conditions

Most species have specific nest-site requirements, which are key factors in nest-site selection and in reproductive success. These generally include nesting strata, available prey base, and nest-site disturbance. Nests can be present in a myriad of habitats, including steep cliffs and rock ledges, trees, and on the ground. Individual raptors tolerant of human activity might nest on manufactured structures such as barns, utility poles, and tanks. The nesting-reproductive season is considered the most critical period in the raptor life-cycle because it determines population productivity, short-term diversity, and long-term trends. Current management restricts or prohibits surface occupancy within a biologic buffer of a raptor nest and does not allow surface use within 0.5 mile of a nest between February 1 and July 31. The BLM authorized officer may grant exceptions to both restrictions.

Management challenges for raptors generally involve activities around nesting habitat, concentration sites (e.g., winter roosts), and foraging areas. Management of powerlines and contaminants for raptor conservation are ongoing issues in the planning area. Emerging issues for raptors in the planning area are energy development and impacts to raptor species from the

WNv. Human activities close to active raptor nests interfere with nest productivity. Romin and Muck (2002) indicate that activities within 0.5 mile of a nest are prone to cause adverse impacts to nesting raptors. If mineral activities occur during nesting, they could be sufficient to cause adult birds to remain away from the nest and their chicks for the duration of the activities. This absence can lead to overheating or chilling of eggs or chicks. Prolonged disturbance can also lead to adult abandonment of the nest. Both actions can result in egg or chick mortality. In addition, routine human activities near these nests draw increased predator activity to the area and increase nest predation.

Management direction for the BLM is identified in the BLM *Fish and Wildlife 2000 Raptor Habitat Management Plan* (BLM 1992b). Management procedures and activities for raptors are identified by the USFWS management guidelines (USFWS 2009) and Avian Protection Plan guidelines (Avian Power Line Interaction Committee 2006). The *Wyoming Partners in Flight Wyoming Bird Conservation Plan* identifies habitat requirements and threats for raptor species (Cerovski et al. 2001). Approximately 13,100 raptor nests have been documented in the planning area. Not all these nests are occupied; however, the BLM and the WGFD regularly survey and monitor raptor nest activity.

The following sections briefly describe the regional contexts, current conditions, and trends for the raptor species that may occur within the planning area that are not considered special status species.

- Golden Eagle

Regional Context

In North America, this species occurs throughout the mountain and grassland regions where medium-sized mammals are available and abundant (Glinski 1998). Golden eagles typically nest on open cliffs or in trees (in the planning area, most often cottonwoods). Important foraging habitats include grasslands, sagebrush, and farmlands (Barrett 1998a). Golden eagles are protected under the Bald and Golden Eagle Protection Act and the Migratory Bird Treaty Act, two statutes that are considered during the project planning and approval processes.

Current Conditions

In Wyoming, this species is considered a common year-round resident, feeding mostly on jackrabbits, rodents, small mammals, and carrion in winter (Orabona et al. 2012).

Trends

Golden eagle populations in Wyoming should remain relatively stable in the foreseeable future. However, if urbanization and industrial development continue in the state, the amount of available nesting and hunting habitat will decline. The net result will most likely be a minor reduction in eagle numbers (Phillips et al. 1984).

- American kestrel

Regional Context

The American kestrel is present throughout North and South America from Alaska south to the southernmost tip of South America. This species is known to breed in every state in the United States except Hawaii, and in every province of Canada.

Current Conditions

American kestrels prefer open country with sufficient perches (e.g., dead trees, rocky outcrops, and utility poles and wires) for hunting insects and small mammals (Winn 1998). Nesting sites often include tree cavities, crevices, cliffs, and nest boxes. Most commonly found along riparian corridors, kestrels forage for mice and voles, but would also take larger invertebrates (e.g., grasshoppers) where other prey is limited. In Wyoming, the kestrel is a very common summer resident of suitable habitats below 8,500 feet elevation.

Trends

Declines in American kestrel populations are widely reported, and BBS data suggests that the North American population declined substantially from 1984 to 2007. Population declines are attributed to habitat loss and degradation and non-breeding season mortalities (Smallwood et al. 2009). Additional factors that have been identified as causes for declining kestrel numbers that warrant further investigation include poisoning by pesticides in agricultural areas, increased predation by Cooper's hawks, and **WNv** (Farmer and Smith 2009).

- Cooper's hawk

Regional Context

Cooper's hawk is native to the North American continent and found from Canada to Mexico.

Current Conditions

The breeding pair builds a stick nest in a large tree. These birds capture prey from cover or while flying quickly through dense vegetation, relying almost totally on surprise. Birds preyed on can range in size from wood-warblers to ring-necked pheasants. Cooper's hawks also eat small mammals, especially rodents such as chipmunks and tree squirrels. Mammalian prey can be as small as mice and as large as hares. Other possibilities are lizards, frogs, snakes, and large insects. Cooper's hawks are increasingly seen hunting smaller songbirds in backyards with feeders.

Trends

In Wyoming (Keinath et al. 2003) and Montana (Bergeron et al. 1992), these hawks are considered to be common and do not have any special conservation status. In Montana, raptor survey results from 1977 to 2004 showed increasing, though not substantial, numbers of Cooper's hawks detected. Populations in the west overall appear to be relatively stable (Atkinson 2005).

- Northern Harrier

Regional Context

This species is present throughout much of North America, with highest densities in the prairie pothole region of the United States and Canada.

Current Conditions

Harriers nest in a variety of habitats, including native and non-native grasslands, agricultural lands, emergent wetland marshes, and mountain sagebrush (Carter 1998a). In Wyoming, this species is a common summer resident, feeding mostly on small mammals (often voles) that it discovers while gliding (Orabona et al. 2012).

Trends

Harrier numbers at migration sites have shown increases, with the majority occurring in western Montana (eight out of 45 sites surveyed in Montana from 1977 to 2004) (Atkinson 2005).

- Red-tailed Hawk

Regional Context

Red-tailed hawks use a variety of habitats and range from Alaska south to Panama and east to Nova Scotia and the Virgin Islands (Preston 1998b). This species typically nests in patches of tall trees or on secluded cliff faces, but will also use tree windbreaks where available.

Current Conditions

In Wyoming, this species is considered a year-round resident common to most habitats below 9,000 feet, including prairie grasslands, riparian areas, sagebrush communities, and pinyon/juniper woodlands (Orabona et al. 2012). They nest mainly in trees and are more tolerant of human activities than are other raptors. Typical prey species include rodents and other small mammals.

Trends

In Montana, from 1977 to 2004, red-tailed hawk population trends have shown an average annual increase of 20.14 percent. Western red-tailed hawk populations have shown upwards trends for some time, likely resulting from a positive response to habitat fragmentation and human-caused changes in the landscape (Atkinson 2005).

- Prairie Falcon

Regional Context

The prairie falcon ranges over the western half of North America from southern Alberta, Saskatchewan, and British Columbia south to central Mexico (Jones 1998b). This species nests almost exclusively on tall cliff faces. Prairie falcons hunt birds and small mammals from perches and while soaring.

Current Conditions

In Wyoming, the prairie falcon is considered a common resident, nesting in cliff habitats in open areas (Orabona et al. 2012). Where nesting substrates are present, as at the Pumpkin Buttes, several pairs can be found near one another; however, large areas of otherwise suitable habitats can be unoccupied if nesting substrates are absent.

Trends

Fifty-eight percent of the 43 occupied routes surveyed in Montana showed decreases (1977 to 2004) in numbers of prairie falcons observed, four of which were important. Three routes showed increasing rates. Montana's increasing rates of prairie falcons observed in similar to western migration route sites, however, some western populations have declined steeply in the last 30 years (Atkinson 2005). These declines are likely contributed to habitat loss (Steenhof et al. 2005).

- Great Horned Owl

Regional Context

The great horned owl is present from the northern edge of the boreal forest in Alaska and Canada to the southern tip of South America. This owl typically nests in wooded areas adjacent to open spaces such as shrublands, grasslands, and farm fields that provide excellent opportunities for hunting rodents and other small mammals (Boyle 1998a).

Current Conditions

In Wyoming, this owl is considered a common resident of most habitats below 9,000 feet, especially in riparian areas dominated by cottonwood (Orabona et al. 2012). Great horned owls are tolerant of human activities and will nest in a variety of structures, including industrial facilities. The nesting density of this owl varies from 18.5 to 40 square miles per pair, although the secretive nature of the species makes nest detection difficult (BLM 2003c).

Trends

Population trends appear to be stable, though no local data is available for the great-horned owl.

- Short-eared Owl

Regional Context

The short-eared owl is present throughout Canada and the central and northern United States.

Current Conditions

In Wyoming, this species is a common year-round resident (Orabona et al. 2012). This owl is a ground-nesting species, building its nest of grasses, weeds, and down feathers in short- and mixed-grass prairies and herbaceous wetlands (Boyle 1998b).

Trends

Density of nesting short-eared owls appears to be highly variable and is based on the abundance of voles and other small mammals (BLM 2003c). Data from BBS and Christmas Bird Counts show substantial declines in both breeding and wintering populations in Wyoming. Factors most likely responsible for declines in the populations are low reproductive success and poor overwintering survival, likely tied to loss or degradation of suitable nesting and/or foraging habitat, habitat fragmentation, and consequent decreases in prey abundance.

- Long-eared Owl

Regional Context

A bird of temperate forests, the long-eared owl roosts and nests in trees by day and hunts in open areas by night. Although widespread and relatively common in its range, it is rarely seen. Common habitat includes dense vegetation adjacent to open grassland or shrubland, and open forests. This owl typically uses stick nests built by other bird species, including black-billed magpie, American crow, and hawks. In rare cases, this owl nests in cavities. Like most owl species, the long-eared owl hunts almost exclusively at night, flying low over open ground, locating prey by ear.

Current Conditions

In Wyoming, breeding home range in riparian habitat varies from 34 to 106 ha (83 to 262 acres), and averages 51 ha (134 acres) (Craighead and Craighead 1956).

Trends

Populations of long-eared owls appear to be stable in most of North America, although they have declined in some areas due to habitat loss. Local trends are unavailable.

- Osprey

Regional Context

The osprey tolerates a wide variety of habitats, nesting in any location near a body of water that provides an adequate food supply. It is present on all continents except Antarctica, although in South America it is present only as a non-breeding migrant. The osprey's diet consists almost exclusively of fish. In North America, it breeds from Alaska and Newfoundland south to the Gulf Coast and Florida, wintering farther south from the southern United States through to Argentina.

Current Conditions

In Wyoming, this species breeds by freshwater lakes and streams. The nest is a large heap of sticks, built in forks of trees, on rocky outcrops, on utility poles, or on artificial platforms.

Trends

Mean annual increases of osprey migration site surveys in Montana equaled nearly fifty-six percent from 1997 to 2004. Osprey populations appear to be on an incline likely resulting from decreased DDT use and provision of nesting structures (Atkinson 2005).

- Merlin

Regional Context

Merlin nest in boreal forests below tree line from coast to coast and along the western mountains south to Oregon, Idaho, and Montana. It winters in southern latitudes from the southern United States to South America (Udvardy 1977).

Current Conditions

In Wyoming, this species is an uncommon resident in a diversity of habitats below 8,500 feet, including open grasslands and shrublands and coniferous forests (Orabona et al. 2012). In the planning area, merlin often lay their eggs in abandoned black-billed magpie nests. Most merlin nests in the planning area are known from Rochelle Hills in southeastern Campbell County (BLM 2003c). Merlin typically rely on locally abundant populations of small birds as prey species, but will also prey on toads, reptiles, and mammals (BLM 2003c). This species is a documented breeder throughout much of Wyoming, including the planning area (Orabona et al. 2012). This species can be present in suitable habitats in the planning area.

Trends

Generally stable migration counts have been seen throughout western migration sites, with slight increases noted at the Montana sites (Atkinson 2005).

Summer and Year-round Resident and Neotropical Migrant Birds

Regional Context

Neotropical migrants are birds that migrate long distances from wintering grounds in the New World tropics of Central and South America to breeding grounds in North America. A wide variety of summer and year-round resident and neotropical migrants use the planning area during migration or the breeding season. This category includes shorebirds, water birds, and songbirds.

Current Conditions

These species could use all habitat types in the planning area; the highest level of use by the most species occurs in the more productive and diverse habitats (e.g., forested riparian areas). Shrub-steppe habitats (sagebrush shrublands and other shrublands in part) and short-grass prairie habitats are both common in the planning area and are of critical importance to some of these species (Rothwell 1992).

Many species of high concern to management because of declining populations use shrub-steppe and short-grass prairie areas for their primary breeding habitats (Saab and Rich 1997). The *Special Status Species – Wildlife* section of this chapter addresses those BLM sensitive species. In response to concerns about neotropical migrants, the *Wyoming Bird Conservation Plan* (Cerovski et al. 2001) identifies two groups of high-priority species in Wyoming. Appendix K (p. 2161) lists the migratory bird species of management concern in Wyoming not addressed elsewhere in this chapter and known or expected to occur in the planning area (Orabona et al. 2012).

Management challenges focus around maintaining, enhancing, or restoring the presence of these species and the habitats upon which they depend. Ongoing conservation issues include managing hazards such as habitat degradation, powerlines, communications towers, and contaminants.

CBNG-related activities are affecting migratory bird populations in the planning area. Loss and degradation of habitats has occurred, as has disturbance to individual birds resulting from construction and production activities. In areas of concentrated development, breeding density of some species could have been reduced because of these and other impacts. Species specific to grassland and shrub-steppe habitats and sensitive to disturbance and habitat fragmentation have likely been the most affected. Human activities likely displace migratory birds farther than simply the physical habitat disturbance. Drilling and construction noise can be troublesome for songbirds by interfering with the males' ability to attract mates and defend territory, and the ability to recognize calls from conspecifics (BLM 2003c).

Habitat fragmentation results in more than just a quantitative loss in the total area of habitat available; the remaining habitat area is also qualitatively altered (Laudenslayer 1986). Ingelfinger and Anderson (2004) identified that the density of breeding Brewer's sparrows declined by 36 percent and breeding sage sparrows declined by 57 percent within 100 meters (approximately 30 feet) of dirt roads in a natural-gas field. Impacts occurred along roads with light traffic volume (fewer than 12 vehicles per day). The increasing density of roads constructed in developing natural-gas fields exacerbated the problem, creating substantial areas of impact where indirect habitat losses (displacement) were much greater than the direct physical habitat losses.

Reclamation and other activities in spring could be detrimental to migratory bird survival. Edge-sensitive species will be displaced farther away from vegetative edges due to increased human activity, causing otherwise suitable habitat to be abandoned. If the interior habitat is at carrying capacity, then birds displaced from the edges will have no place to relocate. One consequence of habitat fragmentation is a geometric increase in the proportion of the remaining

habitat that is near edges (Temple 1986). In severely fragmented habitats, all of the remaining habitat might be so close to edges that no interior habitat remains (Temple and Cary 1988). Over time, this will lead to a loss of interior habitat species in favor of edge habitat species. Other migratory bird species that utilize the disturbed areas for nesting could be disrupted by the human activity and equipment could destroy nests.

The use of the proposed water treatment facilities increases the potential for migratory bird mortality in the evaporation ponds that receive a backwash stream from the conditioning ponds. This evaporation pond will contain a concentrated brine solution. Birds entering this pond can ingest the brine and die from sodium toxicity. Salt toxicosis has been reported in ponds with sodium concentrations of more than 17,000 mg/L. Ingestion of water that contains high sodium levels can chronically affect aquatic birds, especially if a source of fresh water is not available nearby. Aquatic birds ingesting hypersaline water can be more susceptible to avian botulism. During cooler temperatures, sodium in the hypersaline water can crystallize on the feathers, affecting thermoregulatory and buoyancy functions, and causing the bird to die of hypothermia or drowning (Windingstad et al. 2004). Effective wildlife exclusionary devices, such as netting, are required to prevent access by migratory birds, or other options should be utilized to contain and dispose of the brine solution should sodium concentrations rise to more than 17,000 mg/L.

Migratory bird species in the PRB nest in spring and early summer and are vulnerable to the same affects as raptor species. Although the BLM typically does not apply timing restrictions specifically to protect migratory bird breeding or nesting, where Greater Sage-Grouse or raptor nesting timing limitations are applied to BLM-authorized activities, nesting migratory birds are also protected. Where these timing limitations are not applied and migratory bird species are nesting, migratory birds remain vulnerable.

Neotropical migrant management direction for the BLM is identified in the BLM *Fish and Wildlife Nongame Migratory Bird Conservation Plan* (BLM 1992b). *Wyoming Partners in Flight Wyoming Bird Conservation Plan* provides habitat requirements for neotropical migrant species and identifies their threats (Cervoski et al. 2001).

Trends

Ground-nesting birds are exhibiting decreasing population trends due to increased human-adapted predator populations. Similarly, disturbance-sensitive species are exhibiting decreasing population trends due to disruptive human activity (e.g., OHV use, recreation, livestock grazing, construction of O&G wells, roads, pipelines, powerlines, mines, and livestock facilities) within important buffer zones or during critical periods (e.g., breeding or nesting) (Cervoski et al. 2001; Vander Haegen et al. 2002; Ingelfinger and Anderson 2004).

Mammals

Fifty species of nongame mammals, including species such as gophers, mice, rats, voles, ground squirrels, shrews, bats, otters, and prairie dogs are known or suspected to be present in the planning area (WGFD 2006c).

Regional Context

For a complete habitat description and distribution of nongame mammals, refer to the *Atlas of Birds, Mammals, Amphibians, and Reptiles in Wyoming* (Cervoski et al. 2004). Most nongame

mammals are widely distributed in the state. These species are present in habitats throughout the planning area.

Six mammal species (black-tailed prairie dog, fringed myotis, long-eared myotis, spotted bat, swift fox, and Townsend's big-eared bat) are considered BLM sensitive species and further addressed in the *Special Status Species – Wildlife* section. Appendix K (p. 2161) lists the mammal species of management concern in Wyoming not discussed elsewhere in this document and known or expected to be present in the planning area (Orabona et al. 2012).

Current Conditions

Although these species utilize a wide variety of habitats, caves and abandoned mines represent important habitat components upon which the bat species depend for roosts, nurseries, and hibernacula. Very little habitat components have been delineated on public lands in the planning area. Inventories thus far have revealed bat occupied caves within the Southern Bighorns and in the foothills of the Big Horn Mountains in Sheridan County. WNS is caused by a fungus, and has become a threat to bats in the eastern United States, but has not been detected in Wyoming (BLM 2010c; Abel and Grenier 2011). Cave and abandoned mine-hibernating bats are at risk of contracting a fungus, *Geomyces destructans*, which invades and erodes the skin of hibernating bats, causing the bats to arouse more frequently and deplete fat stores more rapidly, which could result in mortality. Deaths can result from *Geomyces destructans* infection through starvation, dehydration, and exposure to cold temperatures (Abel and Grenier 2011).

Management challenges currently focus on increasing the understanding of habitat requirements for these species and maintaining the presence of these species in occupied habitats. Ongoing conservation efforts for nongame mammals include managing invasive species and managing hazards such as contaminants and developments.

Trends

Population trend data and specific habitat requirement information are lacking for many of these species.

Reptiles/Amphibians

Reptiles and amphibians known to be present in the planning area include one salamander species, three toad species, five frog species, three turtle species, two lizard species, and seven snake species (WGFD 2006c).

Regional Context

For a complete habitat description and distribution of reptiles and amphibians in the planning area, refer to the *Atlas of Birds, Mammals, Amphibians, and Reptiles in Wyoming* (Cervoski et al. 2004).

Current Conditions

In general, reptile habitats in the planning area include aquatic (turtles), rocky outcrops (lizards), and a variety of terrestrial vegetative types (snakes and lizards occupy a variety of habitats). Amphibians in the planning area occupy aquatic habitats, including springs, wetlands, riparian corridors, or open water for the first phase of their life-cycles. Amphibians present in the planning area include tiger salamanders, toads, and frogs. Population data for reptiles and amphibians in the planning area are not available.

Management challenges for reptiles and amphibians primarily include maintaining a variety of habitat types and components, including crucial habitat elements (e.g., rocky outcrops) nearby to provide for the requirements of these species.

Trends

In general, combined results from Wyoming Natural Diversity Database surveys in 2008 and 2009 show that boreal chorus frogs and Woodhouse's toads currently have the highest site occupancy rates in the PRB based on nocturnal call surveys (Estes-Zumpha et al. 2010). Tiger salamander mortality was documented at sixty-three percent of standing water bodies surveyed in 2009, a marked increase from the twenty-five percent of sites found to contain dead salamanders in 2008. Ranavirus infection has been found as the cause for these mortalities. It is unknown if the ranavirus outbreak is natural or if changes in water quality in the PRB could be increasing susceptibility of tiger salamanders to the virus. Other amphibians do not seem to be impacted by the virus (Estes-Zumpha et al. 2010).

3.4.6.4. Trends

Historic activities from agriculture, development, fire management, OHV use, recreation, and transportation have, in some areas, contributed to the degradation of wildlife habitats in the planning area. In other areas, historic activities have improved habitats or the ability to manage wildlife habitats.

Examples of historic activities that have contributed to the degradation of wildlife habitats include livestock concentration areas (e.g., water sources), in which vegetation has been trampled and removed and vegetation and soil has been compacted; utility and pipeline corridor installation, which has disturbed soil and provided opportunities for the spread of invasive plant species; fire suppression, which might have altered the natural fire regime with which habitats evolved; O&G well and associated infrastructure development, which has disturbed soil for well pad and road development, thereby contributing to soil erosion and habitat fragmentation; improper OHV use, which has spread invasive plant species and disturbed wildlife; recreation activities, which have disturbed wildlife; and road placements, which have contributed to habitat fragmentation in the planning area. These historic activities have occurred to varying degrees in the planning area. Consequently, wildlife habitats in the planning area exhibit a range of existing conditions, from habitats in PFC to habitats in something less than PFC, and from large, contiguous blocks of habitat to small, fragmented patches. Examples of historic activities that have improved wildlife habitats or improved the management of habitats in the planning area include prescribed fire to maintain or restore desirable vegetative types and restore a natural fire regime; livestock water developments as sediment traps and as water sources for native ungulates and other wildlife; use of OHVs to manage and monitor wildlife habitat in remote locations in the planning area; and granting public access for hunting as a tool for big game management.

Wells, roads, pipelines and other infrastructure associated with energy development constructed in prairie dog colonies directly removes habitat for prairie dog colony-obligate species. Activities that disturb these species could lead to temporary or long-term (permanent) abandonment. Continued loss of prairie dog habitat and active prairie dog towns will result in the decline of numerous sensitive species in the short-grass prairie ecosystem.

Shrubland and grassland birds are declining faster than any other group of species in North America (Knick et al. 2003). In Wyoming, existing O&G wells are located primarily in landscapes

dominated by sagebrush, causing direct habitat loss. Associated road networks, pipelines, and powerline transmission corridors also influence vegetation dynamics by fragmenting habitats or by creating soil conditions and facilitating the spread of invasive species (Braun 1998; Gelbard and Belnap 2003). Density of sagebrush-obligate birds within 100 meters (approximately 330 feet) of roads constructed for natural gas development in Wyoming was 50 percent lower than at greater distances (Ingelfinger 2001). Increased numbers of corvids and raptors associated with powerlines (Steenhof et al. 1993; Knight and Kawashima 1993; Vander Haegen et al. 2002) increases the potential predation impact on Greater Sage-Grouse and other sagebrush breeding birds (Knick et al. 2003). Fragmentation of shrub-steppe has the further potential to affect the conservation of shrub-obligate species because of the permanence of disturbance (Knick and Rotenberry 1995). Several decades are required to reestablish ecologically functioning mature sagebrush communities. Therefore, sagebrush-obligate species might not return even after habitat is reestablished.

There is considerable potential for habitat restoration due to the extent of only partially modified grazing lands. However, O&G development and the creation of road networks are very considerable factors, and tame grazing and hay crops are increasingly replacing more native grasslands. A combination of O&G pipelines and the road network contributed to further dissection of the landscape.

3.4.6.5. Key Features

Key features for special status wildlife species include: riparian corridors (see key features in the *Fish and Wildlife Resources – Fish* section) and the following:

- *Prairie Dog Colonies* – Prairie dogs have been described as a keystone species and an ecological engineer. They build prairie dog towns, which provide habitat for more than 170 species. Of species regularly associated with prairie dog colonies, six are on the BLM Wyoming sensitive species list – swift fox, mountain plover, ferruginous hawk, western burrowing owl, loggerhead shrike, and long-billed curlew. This biodiversity issue is relevant in the planning area.
- *Sagebrush Steppe Ecosystems* – Sagebrush steppe ecosystems support a variety of species. Sagebrush obligates are animals that cannot survive without sagebrush and its associated perennial grasses and forbs; that is, species that require sagebrush for some part of their life-cycle. Sagebrush obligates in the PRB, listed as sensitive species by BLM Wyoming, include Greater Sage-Grouse, Brewer's sparrow, sage thrasher, and sage sparrow.

3.4.7. Special Status Species – Plants

3.4.7.1. Regional Context

Regional context for each species is included below in each species description.

3.4.7.2. Indicators

Special status plants are present in a variety of habitats in the planning area. The landscape in the planning area exhibits diverse climates, topography, soils, and vegetative communities. Because riparian systems comprise only two percent of the land cover types in the planning area, these areas become vitally important for their species richness. Some species occur in higher altitude, alpine riparian, others occur in lower riparian systems associated with open grassland, and all

zones in between. Species have variable soil requirements from deep, organic rich soils to shallow gravelly sites. Some can only be found on the edges of snowlines, the forest understory, and in drying mud of ponds; others in dry sandy prairie; and others occur in disturbed sites. Habitat suitability models and known populations are indicators of special status plant species.

3.4.7.3. Current Condition

One Threatened plant species, Ute ladies'-tresses orchid, could be present in the planning area (see Appendix I (p. 2025) for additional information). There also are three BLM Wyoming-listed sensitive plant species in the planning area (Table 3.44, "Special Status Plant Species Potentially Present in the Planning Area" (p. 497)). Appendix K (p. 2161) lists plant species of special concern to other agencies and groups in the planning area.

Table 3.44, "Special Status Plant Species Potentially Present in the Planning Area" (p. 497) lists habitat associations for special status plants known to be or that could be present on BLM-administered land in the planning area. The Wyoming Natural Diversity Database has modeled special status plant habitat throughout the planning area. In addition, surveys have been conducted, extensively in some areas, however, few populations have been identified and therefore, there is little information about the locations and numbers of populations of special status plant species in the planning area.

Table 3.44. Special Status Plant Species Potentially Present in the Planning Area

Common Name	Habitat	Status
Ute ladies'-tresses orchid (<i>Spiranthes diluvialis</i>)	Moist stream banks, wet meadows, and abandoned stream channels. Elevation 4,750 to 5,400 feet. Flowering period: July – September.	Federally listed Threatened
Limber pine (<i>Pinus flexilis</i>)	Dominates on dry, rocky sites at many elevations (4,900 to 9,800 feet) within its range. It can occur scattered throughout forested regions on more mesic sites, especially in low density, open areas.	BLM Wyoming-listed sensitive
Porter's sagebrush (<i>Artemisia porteri</i>)	Sparsely vegetated badlands of ashy or tufaceous mudstone and clay slopes. Elevation 5,300 to 6,500 feet. Flowering period: June – July.	BLM Wyoming-listed sensitive
Williams' waferparsnip (<i>Cymopterus williamsii</i>)	Open ridgetops and upper slopes with exposed limestone outcrops or rockslides. Elevation 6,000 to 8,300 feet. Flowering period: May – June.	BLM Wyoming-listed sensitive
Source: BLM 2010d		
BLM Bureau of Land Management		

Ute Ladies'-tresses Orchid (Federally Threatened)

Regional Context

The Ute ladies'-tresses orchid is known to occur in Converse, Goshen, Laramie, and Niobrara counties of eastern Wyoming, with habitat and predicted population occurrences noted in southern Campbell County (Heidel 2007; Fertig 2000b) (Map 34).

Current Condition

The Ute ladies'-tresses orchid is ranked as rare at the global level, critically imperiled at the state level, and Threatened at the federal level. Habitat for this perennial orchid includes riparian and wet meadow habitats. Across its entire range, over 50 extant populations are documented for this species, totalling an estimated 85,000 individuals (Fertig et al. 2005). In Wyoming, nine known occurrences have been documented, with an estimated population of 3,800 individuals (Heidel 2007). Threats to this species include water developments, intense domestic livestock grazing, hay mowing, competition from invasive species, habitat fragmentation, urbanization, and collection by humans (Fertig 2000b; USFWS 1992). In 2004, the USFWS initiated a 5-year status review to determine if delisting this species is warranted (USFWS 2004). The USFWS has not yet released the results of the review, and the plant continues to be listed. See the Appendix I (p. 2025) for additional information.

Trends

Based on limited census data and loss or conversion of riparian habitat throughout its range, populations of Ute ladies'-tresses orchids are thought to be declining.

Limber Pine (BLM-listed Sensitive)

Regional Context

Limber pine occurs throughout western North America, from British Columbia and Alberta in Canada south into the United States to Arizona and New Mexico and from the coasts of California and Oregon, east to the Dakotas, Nebraska and Colorado.

Current Conditions

Limber pine are located in the western portion of the planning area along the timberline of the Big Horn Mountains and also along the side slopes of the Pumpkin Buttes in the southeast region of the planning area. Limber pine are a long-lived, but slow growing member of the pine family. In Wyoming, limber pine is distributed from 5,000 feet to over 10,000 feet in elevation, ranging from high elevation timberline to the woodland/grass/sagebrush ecotone. Associated species in Wyoming include Rocky Mountain lodgepole pine, Engelmann spruce, whitebark pine, Rocky Mountain Douglas-fir, subalpine fir, Rocky Mountain juniper, Mountain Mahogany, and common juniper. This species has been declining. The major threats are white pine blister rust, dwarf mistletoe species, increases in mountain pine beetle, fire suppression, climate change, and their synergistic effects.

Trends

Limber pine has been undergoing a downward trend and it is estimated that approximately 50 percent of stands currently are dead or dying in Wyoming (BLM 2010d).

Porter's Sagebrush (BLM-listed Sensitive)

Regional Context

Porter's sagebrush is endemic to the Wind River Basin and PRB in Fremont, Johnson, and Natrona counties in Wyoming (Fertig 2000a).

Current Conditions

This species occurs primarily in sparsely vegetated *Artemisia pedatifida*, *A. longifolia*, or *A. porteri* communities on clay flats, badlands slopes, depressions, or gullies at 4,600 to 7,000 feet elevation. The major potential threats are O&G and mining development, invasive species, such as cheatgrass, and vehicle disturbance (Fertig 2002). Specialized ecological refugia are threatened and Porter's sagebrush is thereby designated as sensitive.

Trends

Long-term trend data are not available for most populations of Porter's sagebrush. Although some habitat has been altered or lost during O&G developments throughout Wyoming, the overall population of Porter's sagebrush in central Wyoming is probably stable.

William's Waferparsnip (BLM-listed Sensitive)

Regional Context

This perennial umbel is endemic to limestone habitats in the Big Horn Mountains (Fertig 2007).

Current Conditions

A moderate number (21 to 75) of occurrences are documented for William's waferparsnip. This species is uncommon (5,000 to 50,000 individuals or 500 to 5,000 occupied acres) in abundance, and distribution is limited to four counties in Wyoming, including Johnson.

Trends

Populations are thought to be stable in part because habitat is often inaccessible and cattle and sheep apparently do not graze this species. However, limestone quarrying and other ground disturbance could threaten this species.

3.4.7.4. Trends

In addition to those listed for each species, most of the trends that affect other plant species in the planning area also affect special status species. These include habitat degradation and fragmentation, grazing practices and management, invasive species, motor vehicles, and climate.

Management of special status plant species in the planning area presents a number of challenges, including declining population trends for select species, drought and other natural events, spread and control of invasive species, maintaining PFC for riparian and wetland habitats, vegetation treatment with prescribed fire or herbicides, lack of periodic disturbance events (e.g., fire, flood, and grazing), physical trampling (e.g., OHV use), loss of habitat resulting from altered hydrology, and challenges presented by special status plant populations occurring over multiple land ownerships. While threats to some species could remain low due to the remoteness of their habitats, threats to other species could increase despite distance or restricted access. For example, special status plant species that depend on groundwater levels could be affected by upstream depletions of groundwater far removed from affected populations. Moreover, early successional special status plant species protected from habitat alteration could still be adversely affected by natural succession and the lack of fire, flooding, or other disturbance factors necessary to retain early successional habitat.

3.4.7.5. Key Features

Ute ladies'-tresses orchid is listed as Threatened under the ESA (see Appendix I (p. 2025) for additional information). It is extremely rare and occurs in moist, sub-irrigated or seasonally flooded soils at elevations between 1,780 and 6,800 feet above sea level (Map 34). Habitat includes wet meadows, abandoned stream channels, valley bottoms, gravel bars, and near lakes or perennial streams that become inundated during large precipitation events. The Wyoming Natural Diversity Database model predicts undocumented populations could be present, particularly in southern Campbell County and northern Converse County.

Before 2005, only four populations of Ute ladies'-tresses orchids had been documented in Wyoming. Five additional sites were identified in 2005 and one in 2006 (Heidel 2006). The new locations were in the same drainages as the original populations, with two on the same tributary and within a few miles of an original location. Drainages with documented populations include Wind Creek and Antelope Creek in northern Converse County, Bear Creek in northern Laramie County and southern Goshen County, Horse Creek in Laramie County, and the Niobrara River in Niobrara County.

3.4.8. Special Status Species – Fish

3.4.8.1. Regional Context

The only special status fish in the planning area is the Yellowstone cutthroat trout (*Oncorhynchus clarkii bouvieri*). This subspecies of cutthroat is found in the Little Bighorn and Tongue River drainages on the Northeastern corner of the Big Horn Mountains. These drainages are located along the eastern edge of the Yellowstone cutthroat trout's native range.

3.4.8.2. Indicators

The BLM is responsible for managing habitat for special status species fish. Special status species considered in this analysis are those listed as Threatened or Endangered, those proposed for listing or that are candidates for listing under the provisions of the ESA, and those designated by the BLM State Director as sensitive. For a discussion of indicators related to fish species, see the *Fish and Wildlife Resources – Fish* section of this chapter.

3.4.8.3. Current Condition

Special status species fisheries habitats include perennial and intermittent streams that support Yellowstone cutthroat trout fish through at least a portion of the year. Yellowstone cutthroat trout historically occur in the Tongue River and Little Bighorn River drainages. For a discussion of water quality and water quantity in the planning area, see the *Water* section of this chapter. Table 3.45, "Special Status Fish Species in the Planning Area" (p. 501) lists fish species that could be present in the planning area that are listed as Threatened or Endangered under the ESA or as sensitive by BLM Wyoming.

Table 3.45. Special Status Fish Species in the Planning Area

Common Name	Habitat	Status
Yellowstone cutthroat trout (<i>Oncorhynchus clarkii bouvieri</i>)	Relatively clear, cold creeks, rivers, and lakes at temperatures between 4 and 15 °C (approximately 32 and 59 °F).	BLM Wyoming-listed sensitive
Source: BLM 2010d Note: Species is not present in the planning area, but is present in habitat subject to hydrologic influence from actions in the planning area. BLM Bureau of Land Management °C degrees Celsius °F degrees Fahrenheit		

At present, the only special status fish species in the planning area is Yellowstone cutthroat trout, a BLM-listed sensitive species. The USFWS was petitioned in 1998 to list Yellowstone cutthroat trout under the ESA, but determined in 2006 that listing was not warranted. Yellowstone cutthroat trout are very limited on BLM-administered land, with approximately 5 miles of stream from nine distinct stream segments on the Tongue River, Little Youngs Creek, Earley Creek, SR Creek, Ash Creek, South Fork of the Little Tongue River, Middle Fork of East Pass Creek, East Pass Creek, and Red Gulch Creek within the historic range of this trout species. The last four of those listed total approximately 1.6 miles of stream on BLM-administered land and are within the current occupied range (Bradshaw et al. 2008) of the Yellowstone cutthroat trout. Bradshaw et al. (2008) estimated 986 total stream miles in the Little Bighorn and Tongue river drainages were historically occupied. There are federal minerals under virtually all the current occupied range, with most of the surface administered by the USFS. In contrast to the Yellowstone cutthroat, most of the fish in the planning area are warm-water, prairie fishes that do not cohabitate with Yellowstone cutthroat.

Today, stocking is relatively minimal in the Little Bighorn River Basin. Several attempts have been made to establish wild Yellowstone cutthroat trout populations. Most attempts have involved stocking Yellowstone cutthroat trout in headwater streams where brook trout are less prevalent (WGFD 2000). The Little Bighorn River has been stocked with Yellowstone cutthroat trout since 1990 and Gold and Little Falls creeks have been stocked since 2000. Future stocking has been cancelled because electrofishing surveys have shown that Yellowstone cutthroat trout do not retain and establish viable populations in these creeks after stockings. There could be several plausible explanations, such as poor spawning and over-winter habitat, cold water, and perhaps most importantly, competition with non-native brook trout. It is assumed that high-gradient cold-water temperatures, interspecific competition with brook trout, and poor habitat are the major contributing factors.

While fisheries habitat condition in the planning area is a function of historic activities, the BLM actively manages fishery habitat to conserve listed species and the ecosystems on which they depend, and ensure that the actions requiring BLM authorization or approval are consistent with the conservation needs of special status species and do not contribute to the need to list special status species, either under the provisions of the ESA, BLM Manual 6840 (BLM 2008d), or the BLM Wyoming Sensitive Species Policy and List (BLM 2010d). Activities and management challenges affecting special status species fish are similar to those discussed in the *Fish and Wildlife Resources – Fish* section of this chapter. Appendix K (p. 2161) lists Wyoming NSS 1 through 3 species, including potentially rare to common species with declining or vulnerable habitats.

3.4.8.4. Trends

Most of the trends that have affected other species of fish in the planning area have also affected special status species. These include, but are not limited to, the impacts of grazing practices and management, recreation, mineral development, drought, and degraded habitat conditions. See the *Fish and Wildlife Resources – Fish* section for additional information.

3.4.8.5. Key Features

Key features for special status fish species are the same as the key features for general fish species. See the *Fish and Wildlife Resources – Fish* section for additional information.

3.4.9. Special Status Species – Wildlife (including Greater Sage-Grouse)

3.4.9.1. Regional Context

For a discussion of the regional context for populations and habitat for all wildlife including special status wildlife species, see the *Fish and Wildlife Resources – Wildlife* section of this chapter. The regional context of Greater Sage-Grouse within the Western Association of Fish and Wildlife Agencies (WAFWA) Management Zone (MZ) 1 follows.

Greater Sage-Grouse MZ1 lies east of the Rocky Mountains in southern Alberta, eastern Montana and Wyoming, and extreme western North and South Dakota. MZ1 represents the eastern extent of Greater Sage-Grouse range. The primary sagebrush species associated with Greater Sage-Grouse habitat in MZ1 is Wyoming big sagebrush (*Artemisia tridentata* ssp. *wyomingensis*). Overall shrub cover is less than 10 percent (State of Montana 2012). Perennial herbaceous components typically contribute greater than 25 percent vegetative cover and consist mostly of rhizomatous and bunch-form grasses, with a diversity of perennial forbs (State of Montana 2012). Land ownership throughout is predominantly private (61%) with 26 percent on BLM managed lands and 13 percent state or other federal ownership.

Greater Sage-Grouse populations have declined in portions of MZ1 through wholesale loss of habitat as well as direct impacts to birds through disturbance and direct mortality. The most pervasive and extensive change to the sagebrush ecosystems in MZ1 is the conversion of nearly 60 percent of native habitats to agriculture (USFWS 2013c). The conversion was facilitated by the Homestead Act of 1862 in the United States and the Canada Dominion Act of 1872 (Knick 2011). Under the Homestead Act, nearly 1.5 million people acquired and plowed over 309,000 square miles, (800,000 km²) of land, primarily in the Great Plains (USFWS 2013c). The impacts of land conversion in the late 1800s and early 1900s were probably greatest for sagebrush habitats nearest perennial water sources.

Currently, native vegetation covers about 59 percent of MZ1. Much of the direct habitat loss from conversion to agriculture has occurred in the far northwestern and northeastern portions of MZ1 (Knick et al. 2011). Cropland currently covers nearly 19 percent of the MZ1 and 91 percent of the MZ1 is within 6.9 kilometers of cropland (Knick et al. 2011). Recent interest in bio-fuel production and high prices for small grains has resulted in an increase in the conversion of native grasslands or lands formerly enrolled in the Conservation Reserve Program (CRP) to cropland,

further emphasizing the importance of BLM-administered lands and associated private lands managed for grazing to maintain large blocks of native grassland and shrubland habitats.

Most sagebrush habitats in MZ1 are managed as grazing lands for domestic livestock. Livestock grazing can influence ecological pathways and persistence of native vegetation and wildlife (Bock et al. 1993). The effects of grazing on sagebrush habitats in this MZ are much different than effects noted in the Great Basin since the landscape throughout MZ1 is adapted to withstand grazing disturbance (Knick et al. 2011). Historically large numbers of bison (*Bison bison*) moved nomadically through the MZ1 in response to changes in vegetation associated with drought, past grazing, and fire. Bison were replaced with domestic livestock in the late 1800s. The intensity and duration of grazing increased as domestic livestock numbers and annual grazing pressure increased. The high intensity grazing probably increased the density and perhaps the distribution of sagebrush in MZ1 particularly in combination with a concurrent reduction in the amount of fire on the landscape. Grazing on public lands was unregulated until the passage of the Taylor Grazing Act in 1934. Since the passage of the Taylor Grazing Act, range conditions have improved due to improved grazing management practices and livestock operations related to decreased livestock numbers and the annual duration of grazing. In addition, the BLM has applied Standards for Rangeland Health since 1997 to enhance sustainable livestock grazing and wildlife habitat while protecting watersheds and riparian ecosystems. However, developments to facilitate grazing management can include elements detrimental to Greater Sage-Grouse. Perhaps the most pervasive change associated with grazing management in Greater Sage-Grouse habitats throughout MZ1 is the construction of fencing and water developments (Knick et al. 2011). Barbed wire fences contribute to direct mortality through fence collisions (Stevens et al. 2011) and water developments may contribute to increased occurrence of WNV in Greater Sage-Grouse (Walker and Naugle 2011). Water developments are particularly prevalent in the north central portion of MZ1. Additional habitat modifications associated with grazing management include mechanical and chemical treatments to increase grass production, often by removing sagebrush (Knick et al. 2011).

Other major land uses in MZ1 include energy development (primarily O&G development), and urbanization and infrastructure. O&G development has occurred throughout MZ1, but is concentrated in the southern portions (PRB), the north (Bowdoin Field), and the south and east (Williston Basin). O&G development includes direct loss of habitat from well pad and road construction as well as indirect disturbance effects from increased noise and vehicle traffic. O&G developments directly impact Greater Sage-Grouse through avoidance of infrastructure, or when development affects survival or reproductive success. Indirect effects include changes to habitat quality, predator communities, or disease dynamics (Naugle et al. 2010). Currently nearly 16 percent of MZ1 is within 3 km of O&G wells, a distance where ecological effect is likely to occur (Knick et al. 2011).

Urbanization and infrastructure development in MZ1 has also impacted Greater Sage-Grouse habitat. Development at population centers and subdivisions or smaller ranchettes and associated buildings, roads, fences, and utility corridors has also contributed to habitat loss and fragmentation in portions of MZ1. Current estimates suggest about 16 percent of MZ1 is within 6.9 kilometers of urban development, although MZ1 generally has lower population densities and lower rates of population increases compared to the other MZs (Knick et al. 2011). Infrastructure development effects to Greater Sage-Grouse habitats in MZ1 are primarily related to highways, roads, powerlines and communication towers, with nearly 92 percent of MZ1 within 6.9 kilometers of a road, 32 percent within 6.9 kilometers of a powerline, and 4 percent within 6.9 kilometers of a communication tower (Knick et al. 2011). Increased recreation and OHV

use on lands in MZ1 are also thought to impact Greater Sage-Grouse habitats, but have not been studied (Knick et al. 2011).

The cumulative and interactive impact of multiple disturbances and habitat loss has influenced the current distribution of Greater Sage-Grouse in MZ1. The cumulative extent of human caused changes, the human footprint, on Greater Sage-Grouse habitat in MZ1 one is highest at the northern edge of MZ1, but occurs throughout MZ1 (Leu and Hanser 2011). Population centers for Greater Sage-Grouse in MZ1 (Doherty et al. 2011) generally correspond to areas lacking a high human footprint and some of these areas have been designated as Core Population Area by state game agencies. Greater Sage-Grouse range in MZ1 is overall very similar to portions of the range where Greater Sage-Grouse have been extirpated (i.e., areas with high human footprints), mostly because of the abundance and distribution of sagebrush in MZ1 (Wisdom et al. 2011) suggesting that Greater Sage-Grouse in MZ1 are more vulnerable to declines than other portions of the Greater Sage-Grouse range. For additional information on the regional context of Greater Sage-Grouse within Wyoming and range-wide, see Wyoming Greater Sage-Grouse Step Down Report (BLM 2013n) and Summary of Science, Activities, Programs and Policies that Influence the Rangewide Conservation of Greater Sage-Grouse (*Centrocercus urophasianus*) (Manier et al. 2013), commonly referred to as the Baseline Environmental Report. These reports document the existing conditions and trends of resources affecting Greater Sage-Grouse and their habitat in Wyoming and range-wide respectively; the reports also identify management indicators.

3.4.9.2. Indicators

For a discussion of indicators related to special status wildlife species, see the *Fish and Wildlife Resources – Wildlife* section of this chapter. Please refer to the *Vegetation* sections for descriptions of indicators of vegetation health for habitats comprised of forests and woodlands, grasslands and shrublands, and/or riparian/wetland communities. In addition, indicators for each species or species group are included where available/appropriate.

3.4.9.3. Current Condition

Numerous special status wildlife species are present or have available habitat in the planning area (see Table 3.46, “Special Status Wildlife in the Planning Area” (p. 504)), including, one species that is a candidate for federal listing as a Threatened species (Greater Sage-Grouse). The planning area also includes habitat for 21 other species listed as BLM Wyoming sensitive. Appendix K (p. 2161) lists wildlife species of special concern to other agencies and groups in the planning area.

Table 3.46. Special Status Wildlife in the Planning Area

Common Name	Habitat	Status
Upland Game		
Greater Sage-Grouse	Sagebrush habitats	Candidate for federal listing as a Threatened species
Birds of Prey		
Bald eagle	Near large lakes and rivers in forested habitat where adequate prey and old, large-diameter cottonwood or conifer trees are available for nesting	BLM Wyoming-listed sensitive

Common Name	Habitat	Status
Ferruginous hawk	Arid and semi-arid grassland regions that is open, level, or rolling prairies; foothills or middle elevation plateaus largely devoid of trees, and cultivated shelterbelts or riparian corridors	BLM Wyoming-listed sensitive
Northern goshawk	Mature, high-elevation forests of Engelmann spruce, subalpine fir, and lodgepole pine interspersed with mature aspen stands; needs a home range of more than 2,500 acres	BLM Wyoming-listed sensitive
Peregrine falcon	Open habitats from open woodlands and forests to shrub-steppe, grasslands, marshes, and riparian habitats; nests on cliffs	BLM Wyoming-listed sensitive
Swainson's hawk	Open grasslands, prairies, farmlands, and deserts that have some trees for nesting	BLM Wyoming-listed sensitive
Western burrowing owl	Arid and semiarid environments, with well-drained, level to gently sloping areas characterized by sparse vegetation and bare ground; prefers open prairie, grassland, desert, and shrub-steppe habitats, and might also inhabit agricultural areas; depends on burrowing mammals, such as prairie dogs and ground squirrels	BLM Wyoming-listed sensitive
Migratory birds (excluding Birds of Prey)		
Baird's sparrow	Native mixed-grass and fescue prairie	BLM Wyoming-listed sensitive
Brewer's sparrow	Northern Rocky Mountains, including sagebrush and alpine meadows	BLM Wyoming-listed sensitive
Loggerhead shrike	Grasslands interspersed with scattered trees and shrubs that provide nesting and perching sites	BLM Wyoming-listed sensitive
Long-billed curlew	Plains, grasslands, and prairies; nests on the ground in habitat that usually includes grass fewer than 30 centimeters (approximately 12 inches) high; bare ground, shade, abundant invertebrate prey, and a minimum of suitable habitat	BLM Wyoming-listed sensitive
Mountain plover	Low, open habitats such as arid short-grass, and mixed-grass prairies dominated by blue grama and buffalograss with scattered clumps of cacti and forbs, and saltbush habitats of the shrub-steppe of central and western Wyoming	BLM Wyoming-listed sensitive
Sage sparrow	Sagebrush flats, alkaline flats with saltbush, and semi-desert shrublands in the lowlands	BLM Wyoming-listed sensitive
Sage thrasher	Open, shrub-steppe country dominated by sagebrush or bitterbrush, with native grasses intermixed; generally avoids cheatgrass-dominated landscapes	BLM Wyoming-listed sensitive
Trumpeter Swan	Foraging grounds during migration include wetlands, lakes, and reservoirs	BLM Wyoming-listed sensitive
White-faced ibis	Shallow lake waters, muddy ground of wet meadows, marshes, ponds, lakes, rivers, flooded fields, and estuaries	BLM Wyoming-listed sensitive

Common Name	Habitat	Status
Yellow-billed cuckoo	Riparian obligate; prefers extensive areas of dense thickets and mature deciduous forests near water; requires low, dense, shrubby vegetation for nest sites	BLM Wyoming-listed sensitive
Mammals		
Black-footed ferret	Short-grass and mid-grass prairies in close association with prairie dog colonies	Federally listed Endangered
Black-tailed prairie dog	Dry, flat, open, shortgrass, and mixed-grass grasslands with low, relatively sparse vegetation, including areas overgrazed by cattle	BLM Wyoming-listed sensitive
Fringed myotis	Hot desert scrubland, grassland, xeric woodland, sage grass steppe, mesic old-growth forest, and multi-aged subalpine coniferous and mixed deciduous forest; xeric woodlands (oak and pinyon juniper)	BLM Wyoming-listed sensitive
Long-eared myotis	Coniferous forests in mountain areas; roosts in small colonies in caves, buildings, and under tree bark	BLM Wyoming-listed sensitive
Northern long-eared bat	Ponderosa pine, mixed coniferous/deciduous forests, often dense forests. Roosts in crevices, caves and cavities of trees, under loose bark, and occasionally in buildings.	Proposed for federal listing as an Endangered species
Spotted bat	Prominent rock features in extreme, low desert habitats to high-elevation forests	BLM Wyoming-listed sensitive
Swift fox	Grasslands, plains, and foothills in short-grass prairies and deserts	BLM Wyoming-listed sensitive
Townsend's big-eared bat	Mines, caves, and structures in woodlands and forests to elevations above 9,500 feet	BLM Wyoming-listed sensitive
Reptiles and Amphibians		
Columbia spotted frog	Subalpine forests, grasslands, and sagebrush habitats at elevations from 1,700 feet to 6,400 feet	BLM Wyoming-listed sensitive
Northern leopard frog	Permanent ponds, swamps, marshes, and slow-moving streams throughout forest, open, and urban areas; waterbodies with abundant aquatic vegetation.	BLM Wyoming-listed sensitive

Trophy Game

There are no special status trophy game species in the planning area.

Small game Mammals

There are no special status small game species in the planning area.

Migratory Game Birds

There are no special status migratory game bird species in the planning area.

Furbearers

Chapter 3 Affected Environment
Special Status Species – Wildlife (including Greater Sage-Grouse)

May 2015

There are no special status furbearer species in the planning area.

Predatory Animals

There are no special status predatory wildlife species in the planning area.

Upland Game Birds

Greater Sage-Grouse

Regional Context

The Greater Sage-Grouse is a sagebrush obligate species (Schroeder et al. 1999). It is present on the plains and foothills of the arid west and can be found in short-grass and mixed-grass prairies, sagebrush shrublands, other shrublands, wet meadows, and agricultural areas, always associated with substantial stands of sagebrush. In Wyoming, this species is present as a breeding resident in suitable habitats below 8,300 feet (Orabona et al. 2012). Unlike in many other western states, the current range of the Greater Sage-Grouse in the planning area has not substantially contracted from its historical extent (WGFD 2002). Although the range of this species is relatively unchanged, the population numbers have trended downward. This decrease has been associated with the disturbance, destruction, and fragmentation of suitable Greater Sage-Grouse habitats (Martin 1970; Braun et al. 1977; Swenson et al. 1987; WGFD 2008d; Oedekoven 2001), increased predation resulting from these habitat alterations, and more recently disease in particular WNV (Wesenberg et al. 2012).

The PRB is near the eastern edge of Greater Sage-Grouse range. Vegetation communities in the planning area are naturally patchy because they represent a transition between the intermountain basin sagebrush communities to the west and the prairie communities to the east. Sagebrush coverage within the PRB is estimated to be 35 percent with an average patch size less than 300 acres (Leu and Rowland 2005). The PRB patch size has decreased by more than 63 percent in the past forty years, from 820 acre patches and an overall coverage of 41 percent in 1964 (Leu and Rowland 2005).

In 2000, the Wyoming Sage-grouse Working Group was formed to develop a statewide strategy for Greater Sage-Grouse conservation. This group prepared the Wyoming Greater Sage-Grouse Conservation Plan (WSGWG 2003) to provide for coordinated management and direction across the state. In 2004, local Greater Sage-Grouse working groups were formed to develop and implement local conservation plans. The entire planning area is part of the Northeast Wyoming local working group, in which the BLM participates.

Indicators

Birds are the most monitored taxa in Wyoming. Key efforts include annual BBSs and strategies outlined in the Wyoming Bird Conservation Plan. Additionally, the WGFD is involved in a variety of single species monitoring efforts related to raptors, waterfowl, and a few upland birds. Greater Sage-Grouse leks are extensively monitored across the state, annually, coordinated by the WGFD. The lek monitoring effort helps to estimate population, and identify trends. Program adaptation occurs when new information or changing conditions trigger modification of individual actions to accomplish conservation goals or evaluation and adaptation of Wyoming Comprehensive Wildlife Conservation Strategy (WGFD 2009a).

Current Conditions

In 2010, the USFWS determined that the Greater Sage-Grouse is warranted for federal listing across its range, but listing is precluded by other higher priority listing actions. In addition to being listed as a Wyoming BLM sensitive species, Greater Sage-Grouse are listed as a WGFD SGCN, because populations are declining and they are experiencing ongoing habitat loss. The Wyoming Bird Conservation Plan rates them as a Level I species, indicating they are clearly in need of conservation action. They are also listed by USFWS as a Bird of Conservation Concern (BCC) for Region 17.

Males of this species perform an extravagant mating display in areas called leks. Male Greater Sage-Grouse, particularly juveniles, are known to attend several different leks in a single breeding season (Schroeder et al. 1999). The components of lek habitat are discussed below. There are 371 documented lek sites (328 classified as occupied or undetermined) in the WGFD Sheridan Region, which approximates the planning area. Lek complexes are present in many locations and are defined as one or more leks within 0.5 to 2.0 miles of each other. Map 37 shows the distribution of known lek sites in the planning area. Greater Sage-Grouse in the Buffalo planning area represent a population that may provide a genetic link between much larger populations within Montana. Grouse movements in the eastern portions of the Buffalo planning area have not been well documented. There are leks on both sides of the Wyoming-Montana state line and movement between the states has been documented (Walker et al. 2007a).

Seasonal range use and movements of Greater Sage-Grouse vary considerably between populations, with movements in some populations exceeding 45 miles (Connelly et al 1988). Depending on the migratory nature of the population, these ranges can overlap or be geographically distinct (Connelly et al. 2000). Within the overall range of a population, a series of habitats are used during the year. The spatial arrangement of leks, their relative availability, and the condition of vegetation in leks all affect the potential of these habitats to support Greater Sage-Grouse. The following six seasonal habitats have been defined for Greater Sage-Grouse in Wyoming (WGFD 2002), each of which has components important for Greater Sage-Grouse reproduction and survival:

- **Winter Habitat:** Greater Sage-Grouse feed almost exclusively on sagebrush during winter. Winter habitats generally contain a canopy cover of 15 percent or greater of taller sagebrush and are in areas where snow depths do not restrict access to sagebrush, such as south-facing slopes and windswept areas (Connelly et al. 2000; WGFD 2002).
- **Breeding Habitat (Leks) – Early Spring:** Greater Sage-Grouse use leks from late March through April and the leks generally are in open areas such as broad ridges, grassy areas, and disturbed sites (WGFD 2002). Greater Sage-Grouse select sites with less sagebrush and other shrub cover than the surrounding landscape, although these sites are often surrounded by sagebrush that females attending the lek and non-displaying males use as cover and for foraging (Schroeder et al. 1999). Habitats that surround the lek site also are important because they provide the forage hens need to produce eggs and are often used for nesting (Braun et al. 1977); however, migratory populations are much less centered around lek sites than nonmigratory populations (Connelly et al. 2000).
- **Nesting Habitat – Late Spring:** Nests are generally placed under sagebrush, but other large shrubs can be used (WGFD 2002). Greater Sage-Grouse select nest sites with higher than average canopy cover of sagebrush and herbaceous plant density, which leads to increased nest success (Connelly et al. 2000).
- **Early Brood-Rearing Habitat – June to Mid July:** This habitat is used during the first month of the brood's life (WGFD 2002). The brood is moved from the nest site immediately after it

hatches and can move up to 5 miles in the first 10 days. This habitat generally has a higher herbaceous cover because brood survival is closely related to the availability of forbs and insects, which are the most important part of chick diets (Schroeder et al. 1999).

- Late Brood-Rearing Habitat – Mid July through Mid September: During this period, many upland forbs have dried up and Greater Sage-Grouse typically move to wetter locations, such as higher elevations or riparian areas (WGFD 2002). Broods tend to move to sites with higher than average forb cover and will focus on relatively small areas if the necessary forage is available (Connelly et al. 2000).
- Fall Habitat – Mid September to First Major Snow: Movement to, and use of, fall habitat is variable, depending on the weather and condition of forage. In Wyoming, this habitat is typically used from mid September until the first major snow (WGFD 2002). During this period, Greater Sage-Grouse shift from feeding mostly on forbs to relying heavily on sagebrush as frost causes forbs to become dormant (Connelly et al. 2000).

Based on the distribution of sagebrush, Greater Sage-Grouse are present in much of the planning area throughout the year. Populations in the planning area are both nonmigratory, exhibiting minimal migratory behavior, moving locally to different food resources or to escape deep snow, and migratory, moving several miles to different food resources or to escape deep snow.

Evidence suggests that habitat loss, fragmentation, and destruction across much of the species' range has contributed to extensive population declines over the past century (USFWS 2010). The Conservation Objectives Team report lists sagebrush elimination, fire, conifers, weeds/annual grass, energy, mining, infrastructure (roads and powerlines), improper grazing, and recreation as threats to the Greater Sage-Grouse population in the PRB (USFWS 2013c). As a result of past and ongoing human activities in the planning area, substantial areas of Greater Sage-Grouse habitats have been altered from their natural conditions. For example, 46 percent (3,386,530 acres) of the planning area is BLM-administered fluid mineral estate of which 75 percent (2,544,512 acres) has been leased (Map 12); the majority of which has been developed and is held by production. Much of the non-federal minerals have also been developed as the pattern is to develop the non-federal minerals prior to the federal minerals. Human disturbances include, but are not limited to, agriculture, mining, roads, urban areas, O&G well pads, compressor sites, and other ancillary facilities. Changes in land use and land development are the primary causes of habitat loss, while habitat degradation is a complicated interaction among many factors, including drought, improper livestock grazing, changes in natural fire regimes, and invasive plant species (Fischer et al. 1996; Pyle and Crawford 1996; Beck and Mitchell 2000; Nelle et al. 2000). Emerging issues include the impacts of pesticides, disease, noise, and raptor perch sites on powerlines among Greater Sage-Grouse populations. The adverse effects of fragmentation on Greater Sage-Grouse are diverse and include reduced courtship-site persistence, courtship-site attendance, winter habitat use, recruitment, yearling annual survival, and female nest-site choice (USFWS 2010).

Energy development within two miles of leks is projected to reduce the average probability of lek persistence from 87 percent to 5 percent (Walker et al. 2007a). Current research suggests that impacts to leks from energy development are discernible out to a minimum of 4 miles, and that some leks within this radius have been extirpated as a direct result of energy development (Apa et al. 2008). Even with a timing limitation on construction activities, Greater Sage-Grouse avoid nesting in O&G fields because of the activities associated with operations and production.

Another concern for Greater Sage-Grouse populations is that reservoirs created for disposal of CBNG produced water provide habitat for mosquitoes that carry WNV (Thiele 2005). WNV represents an important new stressor, which in 2003 reduced late summer survival of Greater

Sage-Grouse an average of 25 percent within four populations, including the PRB population (Naugle et al. 2004) and in an outbreak year can more than cut a population in half (Taylor et al. 2012). In northeastern Wyoming and southeastern Montana, WNV-related mortality during summer resulted in an average decline in annual female survival of five percent from 2003 to 2006 (Walker et al. 2007a). Greater Sage-Grouse losses in the planning area during 2004 and 2005 were not as severe. Summer 2003 was warm and dry, more conducive to WNV replication and transmission than the cooler summers of 2004 and 2005 (Cornish 2005). Current science suggests a synergy between WNV and energy development that amplifies the adverse impact to Greater Sage-Grouse (USFWS 2010). Persistent low-level WNV mortality, combined with severe disease outbreaks, results in local and regional population declines (Naugle et al. 2004; Naugle et al. 2005). WNV outbreak years exacerbate the impacts of other stressors, such as O&G development. The interactive effects of energy development and outbreak years are severe. Eliminating mosquito breeding habitat from anthropogenic water sources is crucial for reducing impacts (Zou et al. 2006). Reducing the threat of WNV by reducing the number of new man-made water sources is a sensible option (Walker and Naugle 2011). Although the BLM could try to fight WNV with mosquito control, the cost associated with treating tens of thousands of acres may be prohibitive, and benefits of spraying must be weighed against detrimental effects (Marra et al. 2004). Additional information on the threat of WNV to Greater Sage-Grouse can be found in Appendix D (p. 1863).

Greater Sage-Grouse avoidance of O&G infrastructure results in even greater indirect habitat loss. Doherty et al. (2008) demonstrated that Greater Sage-Grouse in the PRB avoided otherwise suitable wintering habitats once they have been developed for energy production, even after timing and lek buffer stipulations had been applied. Research indicates that oil or gas development exceeding approximately one well pad and its associated infrastructure per square mile results in calculable impacts to breeding populations, as measured by the number of male Greater Sage-Grouse attending leks (Holloran 2005; Walker et al. 2007a). The WGFD recommends avoiding a well density greater than three or greater than 60 acres of disturbance per square mile (WGFD 2009a).

Current management of Greater Sage-Grouse focuses primarily on the protection of Greater Sage-Grouse breeding and nesting habitats. Current management restricts surface disturbance and occupancy within 0.25 mile of occupied Greater Sage-Grouse leks. Current management also restricts surface-disturbing and disruptive activities in suitable Greater Sage-Grouse nesting habitats within two miles of an occupied lek from March 15 to June 15, unless site-specific circumstances warrant greater protections.

Based on research conducted by Holloran et al. (2005) and Moynahan et al. (2004), a two-mile timing limitation, given the long-term population decline and the fact that fewer than 50 percent of Greater Sage-Grouse are expected to nest in the protected area, is insufficient to reverse the population decline. The end result is that the Wyoming PRB population supports a small remaining Greater Sage-Grouse population that has experienced an 82 percent decline within the expansive energy fields (Walker et al. 2007a). Moynahan et al. (2004), like the Western Association of Fish and Wildlife Agencies (Connelly et al. 2000), recommend increasing the protective distance around Greater Sage-Grouse leks. Walker et al. (2007a) indicates the size of a no-development buffer sufficient to protect leks would depend on the amount of suitable habitat around the lek and the impact to population deemed acceptable. Research suggests additional more effective mitigation strategies include, at a minimum: burying powerlines (Connelly et al. 2000); minimizing road and well pad construction, vehicle traffic, and industrial noise (Lyon and

Anderson 2003; Holloran et al. 2005); and managing produced water to prevent the spread of mosquitoes with the potential to vector WNV in Greater Sage-Grouse habitat (Walker et al. 2007a).

In response, Governor Freudenthal issued an EO on August 1, 2008, mandating special management for all state lands in Greater Sage-Grouse “Core Population Areas.” Core Population Areas are important breeding areas for Greater Sage-Grouse in Wyoming. In addition to identifying Core Population Areas, the Sage-Grouse Implementation team recommended placing stipulations on development activities to ensure that existing habitat function is maintained within the Core Population Areas. Accordingly, the EO prescribes special consideration for Greater Sage-Grouse, including authorization of new activities only when the project proponent can identify that the activity will not cause declines in Greater Sage-Grouse populations in the Core Population Areas. These protections would apply to approximately 80 percent of the total estimated Greater Sage-Grouse breeding population in the state. In February 2010, the Wyoming State Legislature adopted a joint resolution endorsing Wyoming’s Core Population Area Strategy as outlined in the Governor of Wyoming’s EO 2008-2. BLM Wyoming has adopted Wyoming’s approach for projects under its authority, which was updated in three subsequent EOs in 2010, 2011, and 2013, EO 2010-4, EO 2011-5, and EO 2013-3, respectively.

By 2008, the PRB had already experienced a level of impact that severely reduced options for delineating Core Population Areas that would be large enough and in high enough quality habitats to sustain populations (Taylor et al. 2012). Wyoming’s core population area policy will be most effective where implemented in advance of extensive energy development, and in southwest portions of the state where high elevation populations are less susceptible to WNV impacts. In northeast Wyoming, WNV outbreak years are the wild card in Core Population Area management. One of the programs the BLM has initiated to improve the situation, is that the BLM’s High Plains District founded the PRB Restoration program, a partnership which promotes reclamation practices and habitat enhancement projects aimed at restoration of sagebrush habitats for the Greater Sage-Grouse.

While the PRB Greater Sage-Grouse population is a population at risk of extirpation, the Wyoming Basin population is at low risk, as the state designated Core Population Areas adequately capture redundancy and representation for this large population (USFWS 2013a). The USFWS views Wyoming’s Core Population Area Strategy as a sound policy and an adequate mechanism to preclude the need to list Greater Sage-Grouse (USFWS 2011). The Core Population Area Strategy is being analyzed within Alternative D of this document.

Trends

WGFD relied on lek data as the basis for analyzing trends in the population of Greater Sage-Grouse. The number of active leks and lek complexes has varied over the past 10 years, as has the estimated population. The Greater Sage-Grouse population in northeast Wyoming is exhibiting a steady long-term downward trend (WGFD 2009a). Absent a WNV outbreak year, the lower 95 percent confidence limit on the population count is 3,147 males, suggesting that immediate extirpation of the northeast Wyoming population is unlikely if all environmental conditions for Greater Sage-Grouse other than energy development, remain favorable. CBNG activity has waned in recent years with the decline in natural gas prices. To date development is approximately half that predicted in the PRB Final EIS (BLM 2003c). Additional information on the existing conditions and trends of resources affecting Greater Sage-Grouse within Wyoming and range wide are identified in the Wyoming Greater Sage-Grouse Step Down Report (BLM 2013n) and Summary of Science, Activities, Programs, and Policies that Influence the Rangeland

Conservation of Greater Sage-Grouse (*Centrocercus urophasianus*) (Manier et al. 2013) commonly referred to as the Baseline Environmental Report. The Baseline Environmental Report is anticipated to be publicly available in May 2013.

Non-Game Species

Birds of Prey

Indicators

Birds are the most monitored taxa in Wyoming. Key efforts include annual BBSs and strategies outlined in the Wyoming Bird Conservation Plan. Additionally, the WGFD is involved in a variety of single species monitoring efforts related to raptors, waterfowl, and a few upland birds. Program adaptation occurs when new information or changing conditions trigger modification of individual actions to accomplish conservation goals or evaluation and adaptation of Wyoming Comprehensive Wildlife Conservation Strategy (WGFD 2009a).

Current Conditions

Six special status raptor species are present in the planning area (Table 3.46, “Special Status Wildlife in the Planning Area” (p. 504)); all are BLM-listed sensitive species. The USFWS Wyoming Ecological Field Office *Raptor Guidelines* (USFWS 2013d) summarizes the typical nesting periods for these and other raptor species.

Current management establishes a buffer zone around raptor nest sites that considers topography and special status prey habitats surrounding the nest site. Except for bald eagles, buffer zones around nests also include a 0.5-mile seasonal restriction (timing limitation stipulation) for activities from February 1 through July 31. The bald eagle timing limitation is discussed below.

Management challenges for special status raptor species include habitat degradation, fragmentation, and loss; lack of cottonwood and aspen regeneration; collision and electrocution from powerlines; collision with wind turbines; and incompatible land use practices (e.g., land conversion, clear cutting, snag removal, industrial activities, intensive recreational activities, and removal of burrowing mammals). Other challenges include impacts from contaminants and human disturbance during sensitive periods (Cerovski et al. 2001; Barrett 1998b; Jones 1998a; Preston 1998a; WGFD 2009a).

Management actions focus on maintaining the presence of special status raptor species and the habitats upon which they depend in the planning area. Seasonal and spatial protective stipulations are currently applied around identified nest sites and roost areas (bald eagle) to afford raptors a level of protection from human disturbance and industrial activities.

Bald Eagle

Regional Context

Bald eagles are present throughout North America from Alaska to Newfoundland, and from the southern tip of Florida to southern California. In Wyoming, this species builds large nests in the crowns of large mature trees such as cottonwoods or pines. The availability of food is likely the single most important determining factor for distribution and abundance of bald eagles. Fish and waterfowl are the primary sources of food where eagles are present along rivers and lakes. Big game and livestock carrion, waterfowl and large rodents such as prairie dogs also can

be important dietary components where these resources are available (Ehrlich et al. 1988). The bald eagle is an uncommon breeding resident in Wyoming, using mixed coniferous and mature cottonwood-riparian areas near large lakes or rivers as nesting habitat (Orabona et al. 2012).

Current Conditions

The bald eagle was listed as Endangered on February 14, 1978, in all of the conterminous United States except Minnesota, Wisconsin, Michigan, Oregon, and Washington, where it was classified as Threatened (USFWS 1978). On July 12, 1995, the USFWS reclassified the bald eagle from Endangered to Threatened throughout its range in the lower 48 states (USFWS 1995). On August 8, 2007, the bald eagle was removed from the Endangered species list. The bald eagle remains under the protection of the Bald and Golden Eagle Protection Act and the Migratory Bird Treaty Act, and now carries status as a BLM Wyoming sensitive species.

In Wyoming, the availability of carrion, including big game and livestock, is an important winter food source for wintering bald eagles. Eagles winter throughout the planning area. Feeding areas, diurnal perches, and night roosts are fundamental elements of bald eagle winter habitat. Although eagles fly as far as 15 miles (24 kilometers) to and from these elements, they are present primarily where all three elements are available comparatively close (Swisher 1974).

This species is a documented breeder and winter resident of the planning area (Orabona et al. 2012). Map 41 shows documented bald eagle nests in the planning area. The bald eagle population in the planning area increases during winter when seasonal migrants and year-round residents share roost sites and foraging areas.

Human activity and development (residential and recreational) near rivers and lakes continues to escalate and is degrading bald eagle habitat (WGFD 2010a). Pioneering pairs of bald eagles often have difficulty establishing nesting territories that are disjunct from other nesting pairs. Bald eagles are still accumulating organochlorines and relatively high levels of heavy metals, and could also be at risk from organophosphate or carbamate pesticides (WGFD 2010b). These contaminants could affect production and survival.

Different from the management of all other raptor species, current management of bald eagle habitats consist of a disturbance-free buffer zone of 0.5 mile (NSO) established year round for all bald eagle nest sites. A seasonal disturbance-free buffer zone of 1 mile is established for all bald eagle nest sites (February 15 to August 15). A seasonal disturbance-free buffer zone of 0.5 mile is established for all bald eagle winter roost sites (November 1 to April 1). These buffer zones and timing can be adjusted based on site-specific information through coordination with, and written approval from, the USFWS.

Trends

Data from the North American BBS Trend Analysis (Sauer et al. 2012) indicate a positive trend for populations of this species in Wyoming during the period 1966 to 2011. The trend for the United States during the same period is positive.

Ferruginous Hawk

Regional Context

The ferruginous hawk is an uncommon occupant of grasslands, sagebrush, and desert scrub habitats in the Great Plains and Great Basin regions. On the Great Plains, breeding pairs are

normally associated with native grasslands (Gilmer and Stewart 1983). The BLM Wyoming considers it a sensitive species. In Wyoming, this species is a common breeding resident, occupying basin-prairie shrublands, short-grass prairie, rocky outcrops, and cottonwood-riparian habitats (Orabona et al. 2012). This hawk will nest in trees and similar structures when available, but also will readily nest on the ground (Preston 1998a). Nest sites include cliff faces, rocky outcrops, grassy knolls, promontories, tall sagebrush, or in junipers where numerous small mammals provide abundant prey base (Orabona et al. 2012). This hawk preys almost exclusively on small to medium-sized mammals, including jackrabbits, cottontails, prairie dogs, and ground squirrels (Preston 1998a). The ferruginous hawk is known to nest in suitable habitats throughout Wyoming and has been documented in the planning area. Wyoming has one of the largest breeding populations of ferruginous hawks when compared to any other state or province and is also the approximate center of the species breeding range. Estimates have been made indicating that there may be more than 800 pairs of ferruginous hawks within Wyoming.

Current Conditions

The USFWS BCC (USFWS 2008b) report identifies the ferruginous hawk as a “species, subspecies, and population of migratory bird that without conservation actions is likely to become a candidate for listing under the ESA.” The Wyoming Partners in Flight Wyoming Bird Conservation Plan identifies the ferruginous hawk as a “Conservation Priority Level 1 (Conservation Action).” WGFD lists the ferruginous hawk as an NSS3, indicating a restricted or declining population with extirpation possible, but not necessarily imminent. This designation generally recognizes suitable habitat as vulnerable to ongoing disturbance and loss.

Threats attributed to decline in ferruginous hawk populations range-wide may be attributed to habitat loss and degradation. Other major threats include control of prey populations via means of shooting and chemical poisoning of varmints and small mammals. Large declines in occupied prairie dog habitat have also occurred throughout every state in Region 2. Another key player is energy and mining development activities which are believed to threaten ferruginous hawks via means of disturbance, habitat alternation or loss, and reduction or loss of prey populations. The development of CBNG reserves throughout Wyoming and Colorado is relatively recent. These new developments will potentially affect a large portion of the range of ferruginous hawks in these areas. These threats include but are not limited to: increased habitat fragmentation, increased human disturbance during the reproductive period, potential changes in the abundance and diversity of primary prey species, increased exotic vegetation establishment in newly disturbed areas, increased risk of electrocution of ferruginous hawks due to additional overhead power, and increased risk of collisions with vehicles and high tension wires. This threat should be considered serious and will likely persist for many decades. Also the conversion of native shrub-steppe habitats to non-native annual grasslands through altered fire regimes is a serious threat to ferruginous hawks in the Intermountain West, and areas of the Region 2 such as Wyoming that contain large expanses of sagebrush (Collins and Reynolds 2005).

Trends

Data from the North American BBS Trend Analysis (Sauer et al. 2012) indicate a minor positive trend for populations of this species in Wyoming during the period 1966 to 2011. The overall trend for the United States during the same period is positive. Range-wide population data available for this species is limited, and it is declining in portions of its range. Population trends in certain parts of the ferruginous hawk’s range are attributed to concomitant fluctuations in the available prey base, suggesting the plasticity of the species to adapt to variation within prey

populations. Variation in ferruginous hawk annual breeding numbers range-wide and in Region 2 is primarily influenced by changes in prey abundance, while annual variation in winter abundance is primarily related to winter severity and prey abundance. As a result, during more arduous winters ferruginous hawk numbers may be drastically reduced in Wyoming and South Dakota (Collins and Reynolds 2005).

Northern Goshawk

Regional Context

The northern goshawk is a common resident in Wyoming and BLM Wyoming considers it a sensitive species. This species is known to occur from Alaska through the Rocky Mountains to New Mexico and in the mountains and forests of Washington, Oregon, and interior California (Udvardy 1977). Goshawks typically prey on squirrels, ducks, and other birds. They often forage throughout the forest, including in aspen stands, meadows, and forest openings. The northern goshawk is a documented breeding resident of Wyoming (Orabona et al. 2012). Northern goshawks nest in a variety of habitats, including conifer and aspen forests, and occasionally cottonwood trees (Barrett 1998b). Several northern goshawk nest sites have been documented in the planning area.

Current Conditions

Incompatible forest management techniques could remove suitable nest stands and degrade habitat by reducing stand density and canopy cover. Fire suppression, catastrophic fires, loss of vegetative cover, and outbreaks of insects and tree diseases can result in the deterioration or loss of nesting habitat. Human disturbances (such as forest management) can cause nest abandonment.

Trends

The population status and trends of northern goshawks in Wyoming are largely unknown; however, data from the BBS Trend Analysis (Sauer et al. 2012) indicate a minor positive trend for populations of this species in Wyoming between 1966 and 2011. For the same period across all BBS routes in the United States, the population trend was minor and negative.

Peregrine Falcon

Regional Context

A mid- to large-sized falcon, this species occurs across North America and uses a variety of habitats. The peregrine falcon is typically associated with open country near rivers, marshes, and coasts. Cliffs are preferred nesting substrate; however, they might also use tall fabricated structures. Peregrine falcons typically prey on birds such as waterfowl, shorebirds, grouse, and pigeons. In Wyoming, this species is a rare resident, with most breeding records from the western portion of the state (Orabona et al. 2012).

Current Conditions

Widespread use of pesticides, especially DDT, caused extensive eggshell thinning and reproductive failure. By the late 1970s, there were no viable breeding populations in Wyoming. In 1972, federal legislation limited the use of many pesticides, including DDT, and in 1980 the WGFD formed a partnership with The Peregrine Fund, Inc., and began a 15-year cooperative reintroduction effort. Since 1984, Wyoming's nesting population of peregrine falcons has

increased by about 35 percent every year, and more than 60 pairs nested in the state in 2002. The development and use of new chemicals, along with growing pollution, could increase environmental contamination and again threaten production and nesting populations (WGFD 2010b).

Increasing numbers and distribution of peregrine falcons in Wyoming mean a dramatic increase in survey efforts to continue adequate documentation of the population increase, but funding is increasingly inadequate to monitor peregrine falcon populations. The peregrine falcon was removed from the federal list of Endangered species in 1999 (USFWS 1999). BLM Wyoming now considers it a sensitive species. This species nests in the Big Horn Mountain portion of the planning area, but has not been observed on BLM-administered surface.

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate positive trends in population change for this species in USFWS Region 6, which includes Wyoming, and the United States between 1966 and 2011.

Western Burrowing Owl

Regional Context

The western burrowing owl, a BLM Wyoming sensitive species, occurs from south-central British Columbia eastward to southern Saskatchewan and south through most of the western United States. Burrowing owls primarily nest in rodent burrows, particularly prairie dog burrows, in grasslands, shrublands, deserts, and grassy urban settings (Jones 1998a). In Wyoming, this species uses grasslands, sagebrush and other shrublands, and agricultural areas. Burrowing owls typically feed on insects, rodents, lizards, and small birds. This species is a confirmed breeder throughout much of the state (Orabona et al. 2012). Populations of this species can vary considerably in the planning area, influenced by fluctuations in availability of prey. This species is present as a summer resident, nesting in suitable habitats in the planning area.

Current Conditions

The dramatic reduction of prairie habitat in the United States has been linked to reduction of burrowing owl populations (Klute et al. 2003). Use of roads and pipeline corridors associated with CBNG development increases owl vulnerability to vehicle collision. Overhead powerlines provide perch sites for larger raptors, which prey upon burrowing owls. CBNG infrastructure such as roads, pipeline corridors, and nearby metering facilities also provide shelter and den sites for ground predators such as skunks and foxes. The western burrowing owl is relatively tolerant of human activity, often to its detriment. Threats across the North American range of the burrowing owl are habitat loss and fragmentation, primarily due to intensive agricultural and urban development, and habitat degradation due to declines in populations of colonial burrowing mammals (Klute et al. 2003). It is listed as a sensitive species by the BLM throughout the west.

Different from the management of all other owl species, current management of western burrowing owl nests consists of a 0.25-mile timing restriction buffer zone for burrowing owl nest locations during their nesting season (April 15 to August 31).

Trends

The current population of the western burrowing owl in the United States is not well known, but trend data suggest material declines (McDonald et al. 2004). Data from the North American BBS Trend Analysis (Sauer et al. 2012) indicate a minor positive trend for populations of this species in Wyoming during the period 1966 to 2011. The overall trend for the United States during the same period, however, is negative. The last official population estimate placed them at fewer than 10,000 breeding pairs. Most of the states in the owl's range have recognized that western burrowing owl populations are declining.

Migratory Birds (Excluding Birds of Prey)

Ten special status migratory birds are known or suspected to be present within the planning area (Table 3.46, "Special Status Wildlife in the Planning Area" (p. 504)). Regional context is provided for each special status migratory bird species.

Indicators

In cooperation with the USFWS, the Migratory Game Bird Section of the WGFD remains strongly involved in the Central and Pacific Flyway management efforts, including development and revision of management plan for various migratory game bird populations and annual season setting (Roberts and Bohne 2010).

Current Conditions

Threats to migratory birds include habitat fragmentation and degradation, land conversion, incompatible land uses (e.g., industrial activities, human disturbance, contaminants, and agricultural practices), water quantity and quality, lack of cottonwood regeneration, snag removal in preferred habitats, collision with wind turbines and powerlines, and interspecific competition for nest sites.

Management actions focus on maintaining or increasing the viability and biological integrity of special status species' foraging and nesting habitats in the planning area.

Trends

Species widely distributed in Wyoming are believed to have relatively stable population trends in the planning area; however, there are no population trend data for species that exhibit a more restricted distribution. Results and analyses of 1966 to 2011 data for the North American BBS provide more information on trends (Sauer et al. 2005). Collectively, these species occupy all vegetative types in the planning area and are all seasonal migrants.

Baird's Sparrow

Regional Context

Baird's sparrow, a BLM Wyoming-listed sensitive species, ranges from Alberta, Saskatchewan, Manitoba, and Montana to South Dakota (Udvardy 1977).

Current Conditions

In Wyoming, this species is an uncommon summer resident that uses short-grass prairie habitats (Orabona et al. 2012). The typical diet for this species consists of seeds and insects. This species can be present in suitable habitats in the planning area; however, no nests have been documented due to a lack of surveying effort.

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate negative trends in population change for this species in USFWS Region 6, which includes Wyoming, and the United States between 1966 and 2011.

Brewer's Sparrow

Regional Context

Brewer's sparrow, a BLM Wyoming-listed sensitive species, ranges from British Columbia east to Saskatchewan, south to New Mexico, Arizona, and southern California (Udvardy 1977).

Current Conditions

In Wyoming, this species is a common summer resident occupying sagebrush shrubland and other shrubland habitats throughout the state (Orabona et al. 2012). Brewer's sparrow typically feed on insects and seeds. This species is present in suitable habitats in the planning area.

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate a minor negative trend for populations of this species in Wyoming between 1966 and 2011. For the same period across all BBS routes in the United States, the population trend was negative.

Loggerhead Shrike

Regional Context

Loggerhead shrike, a BLM Wyoming-listed sensitive species, occurs from North America, south of the coniferous forest region into Mexico (Udvardy 1977). The loggerhead shrike is typically associated with open vegetative types, including agricultural areas, sagebrush shrublands, desert scrub, pinyon-juniper woodlands, and montane meadows (BLM 2003c).

Current Conditions

In Wyoming, this species is a common summer resident, using pine-juniper, woodlands, short- and mixed-grass prairies, and shrublands. Loggerhead shrikes typically feed on grasshoppers, crickets, other insects, mice, and small birds. This species is known to breed throughout Wyoming (Orabona et al. 2012) and is present in the planning area.

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate a negative trend for populations of this species in Wyoming between 1966 and 2011. For the same period across all BBS routes in the United States, the population trend was negative.

Long-billed Curlew

Regional Context

Long-billed curlew, a BLM Wyoming-listed sensitive species, occurs from southern British Columbia to Manitoba, southeast to Wisconsin, Illinois, and Kansas, and south to northern California and northern Texas (Nelson 1998). The long-billed curlew nests on short-grass

prairies and feeds on insects and aquatic invertebrates in salt marshes, mud flats, and beaches (Udvardy 1977).

Current Conditions

In Wyoming, suitable habitat can include sagebrush shrublands, wet meadows, irrigated meadows, and agricultural areas (Orabona et al. 2012). This species is a common summer breeding resident throughout much of central and western Wyoming. In the planning area, breeding curlews have been reported from Johnson County (Orabona et al. 2012).

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate a minor positive trend in population change for this species in Wyoming between 1966 and 2011. During the same period across all BBS survey routes in the United States, the trend was minor and positive.

Mountain Plover

Regional Context

Mountain plovers once occupied suitable breeding habitats in many of the Great Plains states from Canada to Texas, but their breeding range is now restricted to extreme southern Alberta, Canada, portions of Montana and Wyoming, eastern Colorado, northern and eastern New Mexico, northeastern Utah, and the western panhandle of Oklahoma and Texas. There are a few records of breeding activity in extreme western Kansas and Nebraska and in northeastern Arizona. Wintering mountain plovers are typically concentrated in the Central Valley of California, Texas, and Mexico. Arizona and New Mexico also support lower densities of wintering mountain plovers (BLM 2007l).

Current Conditions

This species uses high, dry, short-grass prairie with vegetation typically shorter than 4 inches. Within this habitat, the mountain plover most often uses areas of blue grama and buffalograss, as well as areas of mixed-grass associations dominated by needle and thread and blue grama (Dinsmore 2003). Nests consist of a small scrape on flat ground in open areas. Most nests are placed in April on slopes of less than 5 degrees in areas where vegetation is shorter than 3 inches. More than half identified nests were within 12 inches of old cow manure piles and almost 20 percent were against old manure piles in similar habitats in Colorado. Nests in similar habitats in Montana (Dinsmore 2003) and other areas (Ehrlich et al. 1988) were almost always associated with the heavily grazed short-grass vegetation of prairie dog colonies.

Mountain plovers arrive on their breeding grounds in late March and begin laying eggs in late April. Clutches are hatched by late June, and chicks fledge by late July. The fall migration begins in late August, and most birds are gone from the breeding grounds by late September. In Wyoming, this species is a common breeding resident (Orabona et al. 2012) and is expected to be present in suitable habitats in the planning area. Data compiled by the BFO indicate that mountain plover nesting occurs sporadically throughout the planning area, including in northeastern Converse County near Gillette, and in Sheridan County. Records of mountain plover observations in the Wyoming Natural Diversity Database include sightings near Buffalo and Gillette and in the Thunder Basin National Grassland. Kenaith et al. (2001) characterized mountain plover habitat in the planning area as sparse and fragmented.

In 2003, the USFWS withdrew its proposal to list the mountain plover as Threatened, but reinstated it again in 2010. On May 11, 2011, the USFWS, once again, withdrew their proposed listing of the mountain plover as a Threatened species. Currently, the mountain plover is listed in Wyoming as a BLM sensitive species. Mountain plover is a WGFD SGCN, because population status and trends are unknown but are suspected to be stable, habitat is vulnerable without ongoing substantial loss, and the species is sensitive to human disturbance. The Wyoming Bird Conservation Plan rates them as a species with highest conservation priority, indicating they are clearly in need of conservation action. They are also listed by USFWS as a BCC for Region 17, which includes the project area. BCCs are those species that represent USFWS's highest conservation priorities, outside of those that are already listed under ESA. The goal of identifying BCCs is to prevent or remove the need for additional ESA bird listings by implementing proactive management and conservation actions. Mountain plovers are considered an uncommon nester in the planning area.

Current management of mountain plovers includes:

- A mountain plover nesting survey is required in suitable habitat before commencing surface-disturbing activities.
- No surface-disturbing activities are allowed in suitable habitat from March 15 to July 31 unless there has been a mountain plover nesting survey during the current breeding season.
- There is a seasonal disturbance-free buffer of 0.25 mile around occupied mountain plover nesting locations between March 15 and July 31.
- Documented nesting areas are surveyed for 5 years following project completion.
- Maximum allowed travel speed on roads within 0.5 mile of identified mountain plover nesting areas do not exceed 25 miles per hour from March 15 to July 31.
- No dogs are permitted at worksites to reduce the potential for harassment of mountain plovers.

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate a negative trend for populations of mountain plovers in Wyoming and along all survey routes in the United States between 1966 and 2011 (Map 42).

Sage Sparrow

Regional Context

The sage sparrow, a BLM Wyoming-listed sensitive species, occurs from Washington south to Baja California and throughout the Great Basin (Udvardy 1977).

Current Conditions

The sage sparrow is a common summer resident in the Wyoming grasslands and shrublands, typically feeding on insects and seeds (Orabona et al. 2012). This species is present in the planning area.

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate positive changes for populations of this species in Wyoming between 1966 and 2011. For the same period across all BBS routes in the United States, the population trend was minor and negative.

Sage Thrasher

Chapter 3 Affected Environment
Special Status Species – Wildlife (including Greater
Sage-Grouse)

May 2015

Regional Context

The sage thrasher, a BLM Wyoming-listed sensitive species, occurs from south-central British Columbia to southern Nevada, Utah, through Texas and Oklahoma, and in the San Joaquin Valley of California (Udvardy 1977).

Current Conditions

In Wyoming, this species is a common summer resident, breeding in sagebrush shrublands throughout the state (Orabona et al. 2012). Sage thrashers typically feed on insects and some fruit. This species is present in suitable habitats in the planning area.

Trends

Data from the BBS Trend Analysis (Sauer et al. 2012) indicate a minor positive trend for populations of this species in Wyoming between 1966 and 2011. For the same period across all BBS routes in the United States, the population trend was minor and negative.

Trumpeter Swan

Regional Context

The trumpeter swan breeds in southern Alaska, northern British Columbia, western Alberta, Oregon, Idaho, Montana, and Wyoming.

Current Conditions

BLM Wyoming considers the trumpeter swan a sensitive species because breeding populations are restricted in numbers and distribution, there is ongoing material loss of nesting habitat, and it is sensitive to human disturbance. Trumpeter swans typically feed on aquatic vegetation, aquatic invertebrates, and insects. As a result of habitat destruction and over hunting, this species was close to extinction, but careful management and reintroduction practices have helped return the population to several thousand individuals (Udvardy 1977). This species is an occasional migrant that nests on muskrat houses or small islands in open water; however, there are no breeding populations in the planning area. Suitable habitats for this species include lakes and ponds with developed aquatic vegetation for feeding and nesting materials (BLM 2003c). This species has been observed throughout the state, including the planning area (Orabona et al. 2012).

Trends

The BBS Trend Analysis (Sauer et al. 2012) did not include population trend data for this species. The USFWS coordinates surveys for breeding swans in the United State, including Wyoming. Overall trends from the surveys for 1993 – 2011 are minor negative for Wyoming, and positive in the overall population that breeds in the United States (Olson 2012).

White-faced Ibis

Regional Context

The white-faced ibis, a BLM Wyoming-listed sensitive species, nests from central Mexico to Louisiana and Texas and through the Great Basin, with isolated colonies in Alberta, New Mexico, California, Montana, North Dakota, Iowa, and Kansas (Ryder 1998).

Current Conditions

In Wyoming, this species is an uncommon summer resident present throughout much of the state, including the planning area (Orabona et al. 2012), although is not expected to nest in the planning area. Preferred nesting habitat includes tall emergent vegetation such as bulrushes and cattails growing as islands surrounded by water deeper than 18 inches. Feeding habitats can include wet hay meadows and flooded agricultural croplands, and marshes and shallow water ponds, lakes, and reservoirs (Ryder 1998). This species feeds primarily on aquatic invertebrates and insects.

Trends

The BBS Trend Analysis (Sauer et al. 2012) did not include data for this species in Wyoming. The trend for the United States was substantial and positive.

Yellow-billed Cuckoo

Regional Context

The western yellow-billed cuckoo, a BLM Wyoming-listed sensitive species, once ranged throughout the United States, southern Canada, and Mexico. The range of the western subspecies has been dramatically reduced and is mostly limited to California and Arizona (Carter 1998b).

Current Conditions

In Wyoming, this species is an uncommon summer resident, occupying cottonwood riparian habitats below 7,000 feet and urban areas. Typical prey includes insects, especially hairy caterpillars. It has been recorded in most areas of the state except for the montane regions (Orabona et al. 2012). Records obtained from Wyoming Birds Record Committee indicate this species, though rare, has been observed within the planning area (Wyoming Birds Record Committee 2011).

Trends

The BBS Trend Analysis (Sauer et al. 2012) did not include data for this species in Wyoming. Across all BBS routes in the United States from 1966 – 2011, the population trend was substantial and negative.

Mammals

Six special status nongame mammals are known or suspected to be present in the planning area and are designated as BLM sensitive. The black-footed ferret, a federally listed Endangered species, is not known or suspected to be present in the planning area. A discussion of this species is included because habitat is available and has been identified by the WGFD as potentially suitable for reintroduction efforts. Following is a brief description of existing conditions for nongame mammals identified in Table 3.46, “Special Status Wildlife in the Planning Area” (p. 504).

Black-footed Ferret

Regional Context

Historically, the distribution of black-footed ferrets closely matched that of prairie dogs, their primary prey, occurring throughout Texas, Oklahoma, New Mexico, Arizona, Utah, Kansas, North and South Dakota, Montana, Wyoming, Nebraska, and Colorado.

Current Conditions

Ferrets can occur in colonies of white-tailed or black-tailed prairie dogs. The USFWS has concluded that, at a minimum, potential habitat for the black-footed ferret must include a single white-tailed prairie dog colony of more than 1,000 acres, or a complex of smaller colonies within a 4.3 mile (7 kilometer) radius totaling 1,000 acres (USFWS 1988). The minimum colony size for black-tailed prairie dog is 1,000 acres (USFWS 2007). The last known wild population of black-footed ferrets was discovered in Meeteetse, Wyoming. Individuals from this population were captured and raised in protective captive breeding facilities in an effort to prevent extinction (Clark and Stromberg 1987). On March 6, 2013, the USFWS issued a letter acknowledging 'block clearance' for the State of Wyoming. That letter provided acknowledgement that the likelihood of identifying wild ferrets in Wyoming, outside of those resulting from reintroductions, was distinctly minimal (USFWS 2013d).

The WGFD has identified areas in the planning area that could be suitable for black-footed ferret reintroductions. If this were to occur, it is likely that the USFS would be the lead agency responsible for the population that would likely be managed similar to the Shirley Basin/Medicine Bow experimental population. New reintroduction projects would likely be subject to special rules similar to those included in the Shirley Basin/Medicine Bow Cooperative Management Plan.

Trends

Black-footed ferret is a federally listed Endangered species (USFWS 1970). The black-footed ferret is closely associated with prairie dogs, and depend almost entirely on the prairie dog for its survival. The decline in populations of the ferret has been attributed to the reduction in the extensive prairie dog colonies that historically existed in the western United States; it is unlikely that wild ferret populations in Wyoming have persisted (USFWS 2013d).

Black-tailed Prairie Dog

Regional Context

Found throughout the Great Plains in short-grass and mixed-grass prairie areas (Fitzgerald et al. 1994), the black-tailed prairie dog has declined in population and range in recent years because of habitat destruction or disturbance and pest control. In Wyoming, this species is primarily found in isolated populations in the eastern half of the state (Clark and Stromberg 1987).

Current Conditions

The black-tailed prairie dog is a highly social, diurnally active, burrowing mammal. Aggregations of individual burrows, known as colonies, form the basic unit of prairie dog populations. Many other wildlife species, such as the black-footed ferret, swift fox, mountain plover, ferruginous hawk, and burrowing owl, depend on the black-tailed prairie dog for some portion of their life-cycle (USFWS 2000).

The black-tailed prairie dog was added to the list of Candidate species for federal listing on February 4, 2000 (Sovada et al. 2009). On August 12, 2004, the USFWS removed the black-tailed prairie dog from Candidate status. On December 2, 2008, the USFWS posted a 90-day finding and status review for the black-tailed prairie dog. BLM Wyoming considers prairie dogs a sensitive species. This species is considered a common resident, inhabiting short-grass and mid-grass habitats in eastern Wyoming (Orabona et al. 2012). Active and inactive prairie dog colonies are present in the planning area (Map 35).

Habitat loss and fragmentation, disease, and eradication programs remain serious threats to this species. Sylvatic plague has the potential to result in substantial adverse impacts to prairie dog populations. There are currently no effective management approaches to mitigate the spread of plague. Specific management actions currently in place in the planning area for the black-tailed prairie dog include conservation measures that protect against unauthorized control of black-tailed prairie dogs on BLM-administered lands, unauthorized use of poisons for black-tailed prairie dog control on BLM-administered lands, and managing grazing allotments containing black-tailed prairie dog colonies for a mosaic of range conditions. The black-tailed prairie dog is listed as a pest under the Wyoming Weed and Pest Act, and the WGFD does not currently regulate or monitor recreational shooting. Prairie dogs have been targets of intensive eradication programs; therefore conservation efforts are often poorly understood and not supported.

Trends

Population trends and status are not well documented. Current trend data have not been readily available to the general public and resource managers. There are extreme differences of opinion concerning acceptable statewide population objectives and appropriate management responses if objectives are not maintained.

Swift Fox

Regional Context

Current swift fox distribution is estimated to occur in southern Alberta, Saskatchewan, and Manitoba south through eastern Montana and Wyoming, northeastern Colorado, the Dakotas, Nebraska, western Kansas and Oklahoma, eastern New Mexico, and northern Texas; southern Oregon and southwestern Idaho south through Nevada and western Utah to southern California and Arizona (Sovada et al. 2009).

Current Conditions

In Wyoming, this species is considered a common resident and uses grasslands in the eastern plains, agricultural areas, irrigated native meadows, and the banks of roads and railroads (Orabona et al. 2012). The swift fox is found in short- and mixed-grass prairie habitats. It appears to prefer flat to gently rolling terrain. Although not an obligate, the swift fox often is present in association with prairie dog towns. The swift fox preys on small rodents, rabbits, and birds. In addition to these, the swift fox supplements its diet with insects during summer and fall. Dens are generally along slopes or ridges that offer good views of the surrounding area (Fitzgerald et al. 1994). Pups emerge from the den in June. Where swift fox are abundant, they occur at a density of one pair per 1,200 to 2,000 acres. Individuals can roam over 2,000 to 2,500 acres during a night of hunting (Clark and Stromberg 1987). This species is present in suitable habitats in the planning area, although baseline data are limited.

In January 2001, the USFWS did not support listing this species as Threatened under the ESA (USFWS 2001) based on new biological information. Swift foxes are listed as a BLM Wyoming sensitive species. Human-related activities in the early 1800s through the mid 1900s contributed to a restricted distribution and abundance throughout the range of the swift fox. Some of these activities include the loss of native prairie habitat, predator-control campaigns, unregulated trapping and hunting, and rodent-control programs. Swift foxes are very vulnerable to trapping, poisoning, and death on highways.

Current management includes the following related to BLM-authorized activities:

- A swift fox survey is required in suitable swift fox habitat between April 15 and June 15.
 - If a swift fox den is identified, then a seasonal disturbance-free buffer of 0.25 mile is maintained between March 1 and August 31.
 - If no swift fox dens are identified, then surface-disturbing activities are allowed in suitable habitat until the following breeding season (March 1).

Trends

Population trends and distribution are poorly known in Wyoming.

Bats

There are four special status bat species present in the planning area (Table 3.46, “Special Status Wildlife in the Planning Area” (p. 504)). Although these species utilize a wide variety of habitats, caves and abandoned mines are important habitat components on which these species depend for roosts, nurseries, and hibernacula. Refer to the *Cave and Karst Resources* section of this chapter for additional information. WNS is caused by a fungus, and has become a threat to bats in the eastern United States, but has not been detected in Wyoming (BLM 2010c; Abel and Grenier 2011). Cave and abandoned mine-hibernating bats are at risk of contracting a fungus, *Geomyces destructans*, which invades and erodes the skin of hibernating bats, causing the bats to arouse more frequently and deplete fat stores more rapidly, which could result in mortality. Deaths can result from *Geomyces destructans* infection through starvation, dehydration, and exposure to cold temperatures (Abel and Grenier 2011).

Current Conditions

Management challenges for special status bats include habitat degradation, land conversion, incompatible land uses (e.g., industrial activities, human disturbance, use of contaminants, certain mine reclamation practices, cave closures, and insect control practices), lack of cottonwood and willow regeneration, bat collisions with wind turbines, and snag removal in preferred habitats. Management actions are intended to maintain and enhance the presence of bats and the habitats on which they depend.

Fringed Myotis

Regional Context

The fringed myotis, a BLM Wyoming-listed sensitive species, is known to occur from British Columbia through western North America to southern Mexico.

Current Conditions

In Wyoming, this species is present along the eastern edge of the state from the Black Hills to Laramie in Weston, Platte, Albany, and Laramie counties (BLM 2003c). This species is associated with a variety of vegetative communities, including montane meadows, sagebrush shrublands, desert scrub, mixed-grass prairies, and woodlands, although it appears to prefer coniferous forests (Fitzgerald et al. 1994). Caves, abandoned mines, and buildings are used as day and night roosts for colonies of up to several hundred individuals. Although no breeding has been reported, this species has been observed in the planning area (Orabona et al. 2012) and is suspected to be present in suitable habitats in the planning area.

Of all the populations in Wyoming, the Black Hill population of fringed myotis is considered to be of special concern due to its restricted distribution. Roosting habitat has been lost in Wyoming and continues to be threatened by abandoned mine reclamation, removal of old buildings, and renewed mining. The fringed myotis is extremely sensitive to disturbance at roost sites, particularly maternity colonies. Recreational activities (such as spelunking and rock climbing) can affect roosting bats in caves, abandoned mines, and rock crevices. Forest management and the removal of snags can result in loss of roosting habitat. Broad-scale insect control projects can affect the prey base of bats and other insectivores.

Trends

Population status, trends, and distribution of the fringed myotis in Wyoming are not known, making effective management difficult.

Long-eared Myotis

Regional Context

The long-eared myotis, a BLM Wyoming-listed sensitive species, occurs throughout the western portion of North America, south to Baja California. Wyoming is close to the eastern periphery of its range.

Current Conditions

Clark and Stromberg (1987) reported this species is distributed throughout Wyoming, with records in Park, Big Horn, Teton, Platte, Fremont, Sublette, Natrona, Sweetwater, Carbon, and Laramie counties. Scattered throughout most of the state at elevations between 5,000 and 9,800 feet, the long-eared myotis is considered uncommon. In sagebrush steppe habitat, they are likely limited to small stands of conifers. Preferred habitats include coniferous forests, including ponderosa pine and spruce-fir, forests, sagebrush shrublands, and grasslands (Orabona et al. 2012). This species roosts in caves, buildings, and mine tunnels (Clark and Stromberg 1987) and could be present in suitable habitats in the planning area.

Roosting habitat has been lost in Wyoming and continues to be threatened by abandoned mine reclamation, removal of old buildings, and renewed mining. Recreational activities (such as spelunking and rock climbing) can affect roosting bats in caves, abandoned mines, and rock crevices. Forest management and the removal of snags can result in loss of roosting habitat. Broad-scale insect control projects can affect the prey base of bats and other insectivores.

Trends

Population status, trends, and distribution of the long-eared myotis in Wyoming are not known, which precludes effective management.

Northern Long-eared Bat

The northern long-eared bat was included in the Biological Assessment for this RMP. More information on life history, regional context, current conditions, trends, habitat, and threats can be located there.

Regional Context

*Chapter 3 Affected Environment
Special Status Species – Wildlife (including Greater
Sage-Grouse)*

May 2015

The northern long-eared bat (also known as northern long-eared myotis or northern myotis) was proposed for listing as Endangered under the ESA by the USFWS in October 2013 (USFWS 2013a). The bat ranges across much of the eastern and north central United States, and all Canadian provinces west to the southern Yukon Territory and eastern British Columbia (USFWS 2013a). Wyoming is the western periphery of its range, with northeastern Campbell County being the extreme western edge.

Current Conditions

The species is known to occur in northeastern Wyoming and has been documented in Campbell, Crook, and Weston counties; however, population information is limited and the species is considered uncommon or rare outside of the Black Hills in Wyoming (USFWS 2013a). Only one positive identification of the species had been recorded in the planning area. An individual was captured by mist net and several acoustic calls were recorded in 2006 in northern Campbell county on USFS lands.

Preferred habitats include forested habitats used for roosting and foraging. The species typically roosts in live or dead trees, and occasionally in crevices or caves if available. Caves, abandoned mines, or man-made structures are utilized for hibernacula (USFWS 2013a). This species could be present in suitable habitats in Campbell County.

It has been determined that the northern long-eared bat is in danger of extinction, predominantly due to the threat of WNS. However, other threats (the present or threatened destruction, modification, or curtailment of its habitat or range; overutilization for commercial, recreational, scientific, or educational purposes; other natural or manmade factors affecting its continued existence) when combined with WNS heighten the level of risk to the species (USFWS 2013a).

Trends

Population status and trends of the northern long-eared bat in Wyoming are not well known. The WGFD plans to continue inventorying forested habitats and caves (WGFD 2010).

Spotted Bat

Regional Context

The spotted bat, a BLM Wyoming-listed sensitive species, suspected to occur in western North America from Mexico to the southern border of British Columbia, is considered rare in Wyoming. Wyoming is on the northeast periphery of its range (BLM 2003c).

Current Conditions

Suitable habitat in Wyoming includes juniper and sagebrush shrublands, and short- and mixed-grass prairies (Orabona et al. 2012). Roosting sites in rock crevices and cliff complexes are also known to be important (BLM 2003c). This species is often described using cliffs over perennial water (Clark and Stromberg 1987). In Wyoming, occurrence records are restricted to the Big Horn Mountains and the southwestern portion of the state (Orabona et al. 2012). This species has been observed within the planning area (Cervoski et al. 2004). Activities such as rock climbing and quarry operations can affect roosting bats in rock crevices and cliffs. Broad-scale insect control projects can affect the prey base of bats and other insectivores.

Trends

Population status, trends, and distribution of the spotted bat in Wyoming are not entirely known, making effective management difficult. It is an extremely difficult species to inventory and monitor.

Townsend's Big-eared Bat

Regional Context

Townsend's big-eared bat, a BLM Wyoming-listed sensitive species, is most common throughout the western half of North America and occurs south into central Mexico, although it is considered rare in Wyoming. Although Wyoming forms part of the Core Population Area of the species' main range, it is distributed sparsely throughout the state (Clark and Stromberg 1987).

Current Conditions

This species has been recorded in Converse, Goshen, Platte, Crook, Fremont, Big Horn, Hot Springs, Sweetwater, Washakie, Park, and Johnson counties. Suitable habitats in Wyoming include deciduous forests, dry coniferous forests, sagebrush and other shrublands, short-grass and mixed-grass prairies, and juniper woodlands. This species uses caves, abandoned mines, buildings, and rock outcrops for day and night roosts and hibernation sites (Orabona et al. 2012). Although no breeding has been reported, this species has been observed in the planning area (Orabona et al. 2012).

Roosting habitat has been lost in Wyoming and continues to be threatened by abandoned mine reclamation and renewed mining. Townsend's big-eared bat is extremely sensitive to disturbance at maternity roosts and hibernacula. Recreational activities (such as spelunking) can affect roosting bats in caves and abandoned mines. Broad-scale insect control projects can affect the prey base of bats and other insectivores.

Trends

Population status, trends, and distribution of the Townsend's big-eared bat in Wyoming are not known, making effective management difficult.

Reptiles and Amphibians

Columbia Spotted Frog

Regional Context

The Columbia spotted frog, a BLM Wyoming-listed sensitive species, occurs throughout much of British Columbia and in Washington, Oregon, Idaho, Montana, Nevada, Utah, and Wyoming (Stebbins 1985). Wyoming is on the eastern edge of the frog's range, where it is known from Park, Teton, Lincoln, Fremont, Sheridan, and Sublette counties. The primary population is in the northwest part of the state, where it is contiguous with populations in Idaho and Montana (BLM 2003c).

Current Conditions

There is a glacial disjunct population in the Big Horn Mountains about 100 miles east of the primary, contiguous population. It is confined to the headwaters of the South Tongue River drainage and its tributaries in Sheridan County (Garber 1994). There are no other known populations in the planning area. In Wyoming, suitable habitats are present in foothills and

montane zones, usually near permanent water such as ponds, sloughs, small streams, and beaver ponds. This species might avoid areas with warm stagnant water and dense cattails. It breeds in old oxbow ponds with no fish and with emergent sedges in wet meadows at the edge of lodgepole pine forests (Garber 1994). Adult spotted frogs typically feed on insects, invertebrates, and small vertebrates, including tadpoles and other frogs.

Trends

The Big Horn Mountain population is likely limited in its range and vulnerable to extirpation. Introduced species, such as the bullfrog, are thought to be a factor in the decline of this species. Other factors could include alterations in habitat quality. The source and extent of these alterations is not well understood.

Northern Leopard Frog

Regional Context

The Northern leopard frog, a BLM Wyoming-listed sensitive species, is found throughout much of the southern half of Canada, south through the upper mid west and central plains states, westward into Idaho, Nevada, northern Arizona, and New Mexico (Stebbins 1985). The northern leopard frog has experienced contractions in its range resulting from local extirpations of breeding populations, particularly in western North America (Wagner 1997).

Current Conditions

In Wyoming, this species is present in cattail marshes and beaver ponds from the plains to montane conditions as high as 9,000 feet (Orabona et al. 2012). Adult leopard frogs typically feed on insects, invertebrates, and small vertebrates, including tadpoles, snakes, and fish. This species is present in suitable habitats throughout the planning area.

While no single factor has been identified as the overwhelming cause for the reduction in leopard frog populations, there are several contributing factors, including disease (red-leg and chytrid), introduced species (bullfrogs, fish, and crayfish), chemicals (e.g., atrazine and rotenone), and habitat loss/alteration/fragmentation. Habitat changes and other factors could be adversely affecting this species, but lack of data precludes identification of specific problems and development of management recommendations. Population status, distribution, and habitat data are lacking for this species.

Trends

While northern leopard frogs were once very common, their populations are currently undergoing a range-wide dramatic decline.

3.4.9.4. Trends

Trend information where available was discussed by species within the *Current Conditions* section.

3.4.9.5. Key Features

Key features for special status wildlife species include: riparian corridors (see key features in the *Fish and Wildlife Resources – Fish* section) and the following:

*Chapter 3 Affected Environment
Special Status Species – Wildlife (including
Greater Sage-Grouse)*

- *Prairie Dog Colonies* – Prairie dogs have been described as a keystone species and an ecological engineer. They build prairie dog towns, which provide habitat for more than 170 species. Of species regularly associated with prairie dog colonies, six are on the BLM Wyoming sensitive species list – swift fox, mountain plover, ferruginous hawk, western burrowing owl, loggerhead shrike, and long-billed curlew. This biodiversity issue is relevant in the planning area.
- *Sagebrush Steppe Ecosystems* – Sagebrush steppe ecosystems support a variety of species. Sagebrush obligates are animals that cannot survive without sagebrush and its associated perennial grasses and forbs; that is, species that require sagebrush for some part of their life-cycle. Sagebrush obligates in the PRB, listed as sensitive species by BLM Wyoming, include Greater Sage-Grouse, Brewer's sparrow, sage thrasher, and sage sparrow.

3.5. Heritage and Visual Resources

3.5.1. Cultural Resources

Cultural resources are tangible, physical evidence or expression of past human activity in the form of material items produced by human workmanship or use, and elements of the natural environment that were altered by people's activities. Examples of cultural resources include artifact scatters, animal traps, rock art, battle sites, trails and structures. Cultural resources can possess important scientific information about the past and may be valuable to the cultural and social heritage of our citizens, locally, regionally and nationally. Archeologists, anthropologists, ethnographers, historians and other researchers study the remains of the past in an effort to identify the forces that have shaped human history, and to define how cultures originate, develop and interact with the environment. Cultural resources in the form of emigrant trails, rock art, campsites, mines, ghost towns, homesteads, or sacred sites can provide people with visible links to their past and reminders of their ancestral heritage. In turn, this can help to foster a sense of belonging and pride in our cultural and historical backgrounds.

3.5.1.1. Regional Context

The archeology of the Northwestern Plains is divided into two major timeframes. Prehistoric refers to a timeframe beginning with the arrival of humans into North American around 12,000 years ago and ends with the arrival of Euro-American into the region in the early 1800s. The term historic generally refers to the time period after the arrival of Euro-Americans and to events that typically have associated written records. Physical remains and traces of events associated with each time period can be considered archeological sites, many of which are present in the planning area. The BLM is obligated by law, regulation and policy to preserve and protect significant archeological sites.

Prehistoric Context

The Buffalo planning area is mostly within the Northwest Plains physiographic region, and partially in the Rocky Mountains. This distinction is important in a discussion of cultural prehistory, because some defined prehistoric cultural complexes theoretically occur in the mountains and not on the plains, and vice-versa. Several notable researchers have established these localized cultural complexes and the regional cultural chronology over the last several decades (Mulloy 1958; Frison 1991). Although not always corresponding in names, divisions, or

dates of complexes, these chronologies are all generally based on and recognized by projectile point typology and other stone tools as culturally diagnostic markers (Frison et al. 1996).

The Frison (1991) summary of the Northwest Plains and proposed prehistoric chronology is generally accepted as the primary narrative for the region. Furthermore, the chronological framework was partially established by work conducted on and data retrieved from significant sites within Buffalo planning area. Therefore, for the purposes of this discussion, this overview uses the Frison (1991) chronology, which ranges from the Paleoindian period to the Protohistoric period, for a span of nearly 12,000 years.

The Paleoindian period is considered the first human occupation of the New World; however, the timing and location of the first migrations is a topic of debate. Generally believed to have occurred sometime after the retreat of the Continental Glacier, the currently accepted chronology of the Paleoindian period is considered to start roughly 12,000 years before present with the Clovis culture and ending with the Late Paleoindian Lanceolate period around 7,800 years before present. However, earlier dates are not only possible but ultimately probable, considering the contemporaneous Clovis cultural materials found all across North and South America.

Paleoindian cultures are believed to have been opportunistic hunters and gatherers who relied on big game hunting and supplemented their diets with plant resources. The climate immediately after the glacial retreat is believed to have been much wetter than at present. The projectile point technology is characterized by large lanceolate spear points, thought to have been used as thrusting spears or atlatl darts, especially at the beginning of the period. By the middle of the Paleoindian period, stemmed points began to appear; by the end of the period, many different point styles are evident. The main complexes derived from these projectile points on the Northwest Plains are Clovis, Goshen, Folsom, Hell Gap-Agate Basin, Alberta-Cody and Late Paleoindian Lanceolate, with minor traditions such as the Foothill-Mountain Paleoindian.

The Early Archaic period is recognized by side notched projectile points dating from approximately 8,000 years before present to 5,500 years before present (Frison 1991) and a distinct change in subsistence strategies. A more intensive use of plant products is suggested in the Early Archaic by the increased number of stone-lined roasting pits and grinding-stone artifacts recovered from sites of this age. This change in subsistence strategy could have been due to a reduced animal population (as well as human population) from a drier climate across the Plains known as the Altithermal climatic episode, which occurred at roughly the same time (Frison 1991). It is not clear at this time if Early Archaic age sites are few in number due to low human populations or because of increased erosion during the drier climatic episode. Either way, the Early Archaic period is underrepresented on the Northwest Plains.

The Middle Archaic period of the northwest plains is usually synonymous with the McKean complex, which dates from 5,500 years before present to 3,500 years before present. Characterized by a style of projectile points, the period also sees a proliferation in the grinding stones and stylized forms of food preparation pits that made their appearance in earlier periods (Frison 1991). In addition, the earliest stone circle sites are attributed to the Middle Archaic period, which suggests a possible change in habitation structures for prehistoric cultures. This change could represent the origin of tipis with the rocks used to hold down hide covers, or for other log-structure dwellings with stones used as a foundation (Frison 1991).

The Late Archaic period of northwest plains prehistory dates from 3,500 to 1,500 years before present. The period is recognized by corner-notched dart points described as the Pelican Lake, Yonkee, and Besant cultural horizons (Frison 1991). The Pelican Lake variant is widespread in

the northern Plains and Rocky Mountains, whereas the Yonkee is less widespread and is mostly found within the PRB of Montana and Wyoming. The Besant variant appears later on the Plains at approximately 2,000 years before present (Frison 1991). The Late Archaic period also is known for large communal bison kills in arroyo traps or bison pounds.

The Late Prehistoric period of the northwest Plains prehistory dates from approximately 1,500 to 200 years before present. The period is recognized by the emergence of arrow points from the introduction of the bow and arrow (Frison 1991). Additionally, the period sees a proliferation of stone circles and diagnostic pottery of various traditions (Frison et al. 1996). Large communal bison hunts also increased during the Late Prehistoric Period.

The Protohistoric period of the Northwest Plains basically starts with the contact of Native Americans with Europeans, which occurred up to 250 years ago or more. The period can generally be dated from 250 years before present to the historic period, which started roughly 130 years ago. The Protohistoric archeological record is characterized by horses, glass beads, metal artifacts, or other European trade items (Frison et al. 1996).

The introduction of the horse brought the most significant cultural changes to Plains Indian groups (Frison 1991). Acquisition of horses increased mobility and contact with other groups, changed hunting techniques, and likely altered political structures (Aaberg et al. 2006). Regarding local area tribes, Shoshonean groups are believed to have been the first to acquire horses (in the first quarter of the 18th Century), with the Crow acquiring them shortly thereafter (Frison 1991).

Historic Context

By the early 1800s, fur trappers were exploring the Big Horn Mountains and PRB. In 1807 George Drouillard, a former member of the Lewis and Clark Expedition, explored and trapped portions of the upper Yellowstone, Bighorn, and Tongue River drainages, drafting a sketch map of the pertinent geographic features (Skarsten 1964). Another exploration party under the command of Jean Baptiste Champlain and Ezekiel Williams trapped the drainages on the eastern flanks of the Big Horn Mountains. The next major commercial expedition through the northwest plains was carried by the American Fur Company and Pacific Fur Company in 1811 (Allen 1997; Chittenden 1954; Goetzmann 1966; Swagerty 2001). An overland party under the command of Wilson Price Hunt was dispatched to the Columbia River. The group ascended the Missouri River from St. Louis and turned inland at the confluence of the Grand River. Proceeding west, Hunt's party reached the Little Missouri River and followed its course southwest into the PRB (Chittenden 1954; Goetzmann 1966). The expedition was subsequently guided by the Crow Indians and another trapper, Edward Rose, through Powder River Pass into the Wind River country in September 1811 (Chittenden 1954; Goetzmann 1966).

Rocky Mountain Fur Company trapping parties under the commands of William Ashley, Jim Bridger, John Weber, Robert Campbell, and Jedediah Smith traversed the area of present-day Wyoming between 1822 and 1825 (Allen 1997; Chittenden 1954; Dale 1917; Goetzmann 1966; Morgan 1953; Swagerty 2001). In summer 1823 Smith followed the Belle Fourche River into the Powder River valley and crossed west over the mountains via Granite Pass into the Bighorn Valley (Allen 1997; Chittenden 1954; Dale 1917; Goetzmann 1966; Morgan 1953). English fur trader Benjamin Bonneville, whose trapping forays were primarily west of the Rocky Mountains dispatched Antonio Montero to establish a trading post on the Powder River. The post, referred to as the "Portuguese Houses," was constructed in 1828 and eventually abandoned in 1836 to 1837 (Watson 1982). The demise of the fur trade by 1840 was precipitated by decreased demands for

pelts and the suspension of financing for fur trade ventures in 1837 (Watson 1982). In spite of this, the descriptions and delineation of the Rocky Mountain region by these fur traders provided the catalyst for subsequent Euroamerican settlement.

Several expeditions with varying goals travelled through the PRB in the 1840s and 1850s. Jesuit missionary Pierre-Jean DeSmet went through the basin along the east face of the Big Horns in 1849. Sir George Gore travelled throughout the Buffalo planning area in 1855 and 1856. Gore was a wealthy Scottish aristocrat who spent two years on a hunting expedition in the western US. In 1859 and 1860, the Reynolds Expedition was the first systematic military effort to map and describe the topography in the planning area. William F. Reynolds was a captain in the Corps of Topographical Engineers, a branch of the United States Army. The expedition travelled along the east face of the Big Horns, part of their route later becoming the Bozeman Trail. The Reynolds party included geologist Ferdinand V. Hayden who would later explore and document the Pumpkin Buttes.

In 1863 John Bozeman scouted a route through the PRB that would provide a direct overland route for freight traffic and immigrants to the gold fields in western Montana. The later establishment of the Bozeman Trail and the efforts of the United States Army to protect travelers along the route led to “Red Cloud’s War” between the United States Army and a combined force of Sioux, Cheyenne, and Arapaho. Although the U.S. Army established several forts along the Bozeman Trail, it never fully succeeded in protecting travelers along the trail. The Fetterman Battle, near Fort Phil Kearney, resulted in the worst defeat of the U.S. Army at the hands of the Plains Indians as Fetterman and his entire command of 80 soldiers were killed. Failing to achieve success in region, the Army eventually abandoned its efforts with the signing of the second Treaty of Fort Laramie in 1868, which closed the Bozeman Trail and ceded the majority of the Buffalo planning area to the Sioux.

What is referred to as the “Great Sioux War” began in the early 1870s as settlers and miners began to break the provisions of the 1868 Treaty of Fort Laramie and venture into land set aside for the tribes. The discovery of gold in the Black Hills resulted in hundreds of miners entering what was then Sioux territory. After a series of conflicts between the tribes and white settlers and miners in reservation lands, the U.S. Army was once again at war with the Sioux, the Cheyenne, and the Arapahoe. The climax of the war was the Battle of Little Bighorn, in which General George Custer and his entire command of 300 men were killed. The most significant events associated with the war within the planning area occurred after the Battle of Little Bighorn as the U.S. Army increased its efforts to remove the tribes from the area. Cantonment Reno was constructed as a military supply fort on the Bozeman Trail. The Dull Knife Battle in the Southern Big Horn Mountains resulted in the Northern Cheyenne Tribe losing the majority of their possessions and horses resulting in their eventual surrender. General George Crook later undertook a failed winter campaign to locate the Sioux in the PRB. By 1877 the Great Sioux War was over. The Sioux, Cheyenne, and Arapaho tribes surrendered to the U.S. Army, and were forcibly removed from the PRB, leaving it open for stock grazing and homesteading.

By the early 1880s, the open-range practice of turning cattle loose on the range in the fall and gathering them in the spring, with no supervision from cowboys, was in full swing (Larson 1978). Small land and livestock owners started to band together as early as 1871. The booming cattle industry was dominated by cattle kings, represented by the Wyoming Stock Growers Association. During the early 1880s, the cattle industry in Wyoming peaked. An estimated 175,000 cattle grazed the open range in Johnson County in 1884, and in 1886, more than 6,000 sheep also ranged in Johnson County (Bollinger and the Jim Gatchell Memorial Museum 2009).

In 1890, Wyoming became the 44th state in the Nation. The tensions between the small and large livestock growers would culminate in the early 1890s with the Johnson County War, which “ranks as the most notorious event in the history of Wyoming” (Larson 1978). The big operators began to take matters into their own hands beginning with the lynching of James Averill and Ella “Cattle Kate” Watson near Independence Rock on July 20, 1889 (Larson 1978). Eventually, approximately 50 invaders hired by large cattle operators, invaded Johnson County and killed both Nick Ray and Nate Champion at the KC Ranch house on April 9, 1892 (Bollinger and the Jim Gatchell Memorial Museum 2009). The invaders stayed the night at the TA Ranch but were surrounded the next day by a posse that had formed in Buffalo after being informed of the Ray and Champion deaths (Bollinger and the Jim Gatchell Memorial Museum 2009). The invaders barricaded themselves at the ranch and held off the Buffalo posse until April 13, at which time soldiers from Fort McKinney arrived and arrested the invaders (Bollinger and the Jim Gatchell Memorial Museum 2009). None of the invaders was convicted of a crime. The Johnson County War was a major political issue in the 1892 elections that ended with Democratic victories in the gubernatorial and the congressional races.

Economic depression was widespread in the United States throughout the 1890s, and the cattle industry shrank considerably (Larson 1978). However, the fledgling oil industry produced the first oil well in the Shannon Field of the Salt Creek oil basin in 1889 (Larson 1978). The first oil field established in the PRB, in 1887, was in the Moorcroft area (Metz 1992). The Salt Creek oil field boomed during World War I as demand for oil peaked in 1917 (Metz 1992). The Teapot Dome scandal, along with the depressed oil market and the lack of transportation, led the Wyoming oil industry into a “lull until after the Depression” (Metz 1992). Between 1900 and 1938, approximately 6,700 wells were drilled for O&G in Wyoming” (Metz 1992).

Throughout the 1890s and until 1901, the Hole-in-the-Wall Gang, a loose knit group of outlaws sometimes led by Butch Cassidy, were based out of the Red Wall or Hole-in-the-Wall southwest of Kaycee. Other famous outlaws reported as being in the PRB include Frank James, who used the pseudonym McKinney while he rode with Big Nose George Parrott’s gang in 1878 (Patterson 1982). Nate Champion, who was killed during the Johnson County War, was considered by some to be an outlaw who rustled cattle. Patterson (1982) claims, “many members of Butch Cassidy’s Wild Bunch of the 1890s got their start riding with Champion’s rustlers, including the Logan brothers, Flat Nose George Currie, and Tom O’Day.”

The expansion of the Homestead Act in 1909 brought a new wave of homesteaders to the PRB (SWCA 2006) and, in 1916, the Stock Raising Act allowed an individual to claim 640 acres for grazing, although the federal government retained the mineral rights. Many dry-land farmers “flocked to the state in the years 1909-1913” (Larson 1978). World War I brought an increased demand for agricultural goods and encouraged the growth of farms and ranches, which were becoming more mechanized, but also going into debt (Cassidy 2006). After World War I, agricultural production in the PRB remained high, never dropping to prewar levels, which led to excess products on the market and drove prices down (Cassidy 2006). In addition, a severe drought hit the area in 1919. All of these factors combined to lead to the large scale abandonment of homesteads and/or banks repossessing land (Cassidy 2006).

Agriculture, oil, and coal mining were economically very important to Wyoming, and all three industries suffered setbacks in 1920 (Larson 1978). National coal strikes in 1919 and 1922 affected the state, and petroleum production declined after 1924 (Larson 1978). In the PRB, Cassidy reports that the average farm and ranch size doubled between 1920 and 1929, due in part to larger operations expanding and buying out smaller farms and ranches as mortgages

foreclosed or they were “weakened by the tight money supply and declining prices on their products” (Cassity 2006).

By 1940, farms were no longer family businesses. Instead, large corporate farms that specialized in one crop, or cattle or sheep, were the most successful and numerous, while small landholders and farmers were not economically viable (Cassity 2006). The principal industries of Wyoming, and the PRB, including agriculture, livestock, transportation, oil, and coal prospered during World War II, effectively ending the Great Depression (Larson 1978).

Regulatory Context

NHPA requires federal agencies to consider impacts to historic properties prior to making land use decisions. Historic properties are localities that are listed on or are eligible for listing on the National Register of Historic Places (NRHP). Historic properties can include (but are not limited to) archeological sites, historic sites, or properties significant to tribes for spiritual or religious significance. NHPA compliance and NEPA compliance related to this RMP were coordinated to conserve BLM resources, reduce redundancy and make it easier for the public and tribes to understand when and how to contribute to the decision making process. The BLM consulted the Wyoming State Historic Preservation Office (SHPO), several tribes, county and state governmental representatives, industry representatives, private landowners, the public, and other interested parties through meetings with agencies, public meetings, and the public comment period. The goals, objectives and alternatives associated with this document were created in consultation with the cooperating agencies. Comments received during scoping and after issuance of the draft EIS were considered by the BLM and incorporated into the analysis of this document.

On a project specific basis federal agencies are required to consider impacts to such historic properties, although they are not required to protect them. Through consultation with SHPOs, tribes and other entities, adverse impacts to historic properties must be resolved. Mitigation is an option for the resolution of adverse effects, but it is also BLM policy to initially attempt to avoid impacts to historic properties. Federal agencies are required to protect and preserve certain types of sites that are significant to tribes.

Federal agencies are required to protect and preserve certain types of sites that are significant to tribes. The American Indian Religious Freedom Act (AIRFA) is a civil rights act requiring federal agencies to consider impacts to sites that are important to tribes for religious purposes. The Native American Graves Protection and Repatriation Act (NAGPRA) protects Native American graves on federal surface and requires federal agencies to repatriate Native American human remains and funerary objects taken from federal surface to tribes.

Following BLM policy (reference 8130), cultural resource protection plans can be drafted for significant archeological sites or regions containing numerous examples of significant sites. According to BLM Manual 8130.4 “Cultural Resource Project Plans (CRPP) are detailed design plans for implementing decisions made in regional or local land use plans.” An earlier version of the BLM cultural resource manual referred to these plans as “cultural resource management plans (CRMP).” BFO drafted three CRMPs as a result of the 1980 RMP, however these plans are now out dated and obsolete.

3.5.1.2. Indicators

The resource indicator for cultural resources is the degree of loss of characteristics that qualify a historic property for listing on the NRHP or something that diminishes the value of an area important to Native American or other traditional communities. Natural or accelerated erosion, project construction, unauthorized collection, and vandalism can remove, alter, or damage characteristics that make the resource significant. Any impact to a cultural resource is difficult to measure without baseline data, which is typically recorded on a site form. The majority of cultural resource sites in the planning area have not been recorded. Inventories are typically conducted, sites are recorded and historic properties are avoided in response to project applications which reduces or minimizes the loss of characteristics that qualify a historic property for listing on the NRHP. On a much smaller scale, sites are recorded in a proactive manner in order to gather baseline data which is used in the event of natural impacts or unauthorized collection. Any loss of the characteristics that make a historic property significant could be addressed through techniques including (but not limited to) site stabilization, repair or additional recordation.

3.5.1.3. Current Condition

Archeological investigations in the planning area started in the 1950s with the Smithsonian Institution's Missouri River Basin (MRB) surveys. Since the 1970s, however, most investigations were associated with NHPA compliance as a result of coal, oil, gas, and other minerals exploration and development. The numbers of cultural resources inventories and associated surveyed acres have increased and decreased over the decades with the boom and bust cycle of the O&G industry. Since the late 1990s, several thousand sites have been discovered during over one million acres of inventory associated with CBNG development in the PRB.

The planning area is in the Northwest Plains and Rocky Mountain physiographic regions. For analysis purposes, the area has been divided into four cultural subregions based on present-day ecological conditions (Chapman et al. 2004). These subregions are delineated based on such factors as geology, physiography, hydrology, climate, soils, wildlife, vegetation, current land use, and known cultural resource site locations. A discussion of subregions is necessary to understand how cultures adapted, subsisted, and settled in this region. As Wood (2003) states in reference to the sub-regions of the Great Plains, "These subareas, for the most part, are reflected in the cultural systems of the people who lived within them." Map 46 shows the analyzed cultural subregions for the planning area in Campbell, Johnson, and Sheridan counties. Note that this analysis excludes the higher-elevation ecoregions of the Big Horn Mountains since this subregion is managed by the USFS. Table 3.47, "Summary of Prehistoric Sites by Cultural Period and Subregion in the Planning Area" (p. 536) lists prehistoric sites chronologically by cultural period for each subregion in the planning area.

Table 3.47. Summary of Prehistoric Sites by Cultural Period and Subregion in the Planning Area

Cultural Subregion	Unknown Prehistoric	Paleoindian	Early Archaic	Middle Archaic	Late Archaic	General Archaic	Late Pre-historic	Proto-historic	Total
Grassland	2,626	44	44	136	245	52	393	21	3,561

Note: Some totals might not equal the sums of the values.

¹Derived from land status maps supplied from the Wyoming Geographic Information Science Center.

²Includes overlapping survey areas; assumes 100-foot-wide survey corridor for linear inventory.

³Number of components will not match number of sites because a site can have both historic and prehistoric components.

⁴Includes eligible sites, listed sites, National Landmarks, and National Monuments.

BLM Bureau of Land Management

NRHP National Register of Historic Places

The Southern Big Horn Subregion has a much higher density of sites than the rest of the planning area. There are also more numerous significant prehistoric sites such as rock art and rock shelters in the Southern Big Horn Subregion. The Tongue River Subregion also has a higher density of sites than other subregions, but the majority of those sites are historic. The data show that the Grassland and Powder River Subregions have been inventoried more extensively than other subregions, a result of CBNG and coal development in these areas. These subregions contain several significant sites (Carter-Kerr-McGee Site, Ruby Site, Cordero Mine Site, etc.), but at a lower density than the Southern Big Horn and Tongue River Subregions.

Historic Trails

There are numerous historic trails in the planning area, most notably the Bozeman Trail which is listed on the NRHP. Much of the trail has disappeared or has been destroyed by recent roads and, where evident, appears as sporadic “U” shaped wagon ruts or two-track roads. There are very few intact significant portions of the Bozeman Trail on BLM surface in the planning area, the most notable example being near the crossing of Crazy Woman Creek. Other historic trails in the planning area eligible for listing on the NRHP include the Deadwood Trail, Sawyers Expedition Route, Crook Scout Route, Black and Yellow Trail, and the Texas Trail.

The exact locations of most historic trails are typically not known until a specific project is analyzed by the BFO and an archeological inventory is undertaken. The general location of most historic trails are documented on historic maps, typically General Land Office maps from the late 1800s. Historic trails were often placed in the most logical locations for roads and were often continuously used through history and into recent times. In these cases historic trails can be obscured by two-track ruts or modern road upgrades. Some segments of historic trails are represented by sinuous intact trail ruts paralleling existing county roads or state highways. In some cases inventory reveals that physical remains of the trail are not evident due to erosion or deposition. In rare cases intact historic trail ruts are isolated in areas that are not near modern roads or other improvements. Although historic trails as a whole can be listed or eligible for listing on the National Register, in most cases the entire trail has not been inventoried. Inventoried segments are classified as either “contributing” or “non-contributing” to the site’s integrity. Contributing segments are considered to be intact and are worthy of preservation while non-contributing segments are portions of the trail that have typically been destroyed and do not warrant preservation. Segments of the historic trails that have not been ground-truthed are considered to be “unevaluated.” The BFO treats unevaluated historic trail segments as if they are contributing segments until they get a proper evaluation.

BFO must also consider impacts to the setting of historic trails. As defined in National Register Bulletin 15, “Setting is the physical environment of a historic property. Whereas location refers to the specific place where a property was built or an event occurred, setting refers to the character of the place in which the property played its historical role. It involves how, not just where, the property is situated and its relationship to surrounding features and open space.” In many areas in the planning area contributing trail segments do not have intact settings due to modern developments such as O&G infrastructure, roads, powerlines or other such facilities. In these cases, the setting is considered to be compromised. Areas within the setting of historic trails that do not contain modern or recent modifications or structures are generally considered to have intact settings.

Buried Cultural Resources

Alluvial and colluvial deposits have the potential to contain intact buried cultural resources, but consistently locating such resources is difficult. A geoarcheological assessment associated with the DOE's PUMP III (Eckerle et al. 2005) study examined general depositional areas throughout the planning area that have the potential to contain such resources. Relying on soil geology and archeological data, the study found that alluvial and colluvial deposits are more likely to contain buried cultural resources than others. The study also noted that due to some unique circumstances in the planning area buried cultural resources are difficult to locate in cutbanks or in soil profiles exposed by construction equipment. The PUMP III report makes a statistical assumption that, in lieu of an obvious soil horizon and estimating a typical artifact density of approximately 100 per square meter, the probability of encountering a buried site in a cutbank (or construction trench) is an astonishingly low 0.3 percent (Eckerle et al. 2005). This notion is reinforced by the fact that many significant buried archeological sites discovered in the 1970s and 1980s attracted academic investigations (Carter-Kerr-McGee Site, Sisters Hill Site, Ruby Site, etc.), but after nearly two million acres of archeological inventory no recent sites eliciting such interest have been discovered. Although the geology of planning area exhibits the preservation traits to hold numerous significant buried sites, such sites are very difficult to discover.

Traditional Cultural Properties and Sacred Sites

National Register Bulletin 38 defines Traditional Cultural Properties (TCPs) as a “kind of cultural significance a property may possess, and that may make it eligible for inclusion in the Register, is *traditional cultural significance*. “Traditional” in this context refers to those beliefs, customs, and practices of a living community of people that have been passed down through the generations, usually orally or through practice. The traditional cultural significance of a historic property, then, is significance derived from the role the property plays in a community's historically rooted beliefs, customs, and practices” (NPS 1990). TCP status can be given to sites that are significant to any culture, although the focus in the Wyoming has typically been on Native American concerns. There is one known TCP in the planning area, the Pumpkin Buttes. Sacred sites are not easily defined, but are typically discrete geographic areas that have religious or cultural significance to Native Americans tribes. Sacred sites are not necessarily archeological in nature and can be expressed by things like geographic locations or plant communities.

As mandated by the NHPA, the BLM primarily consults Native American tribes about impacts to sacred sites or TCPs, although tribal concerns can go beyond impacts to specific archeological sites. Tribal representatives indicate that archeologists are not adequately trained to identify areas important to a tribe, and suggest the use of trained tribal members to do so. Tribes also indicate sacred sites are not necessarily archeological in nature and may be more properly associated with things such as geographic features or plant communities. To date the BFO has not utilized Native American inventory before making land use decisions.

In 2006 the BLM, in consultation with the Wyoming SHPO and 15 tribes, determined that Pumpkin Buttes is a TCP. The site consists of four prominent buttes on the divide between the Belle Fourche basin and PRB. Although the buttes themselves are considered to be significant, several tribes also identified specific sacred sites and indicated that there could be numerous undocumented sacred sites, such as burials and offering sites, on the buttes. The buttes are also the origin place for a significant ceremony related to a specific tribe. Many tribes indicated a desire to utilize the buttes for ceremonial and plant-gathering activities. Tribes have informed the BLM that the setting or viewshed that can be observed from sacred sites such as the Pumpkin buttes are important aspects of those sites. For example, Pumpkin Buttes are the highest point in

the PRB and geographic features such as the Big Horn Mountains, Black Hills and the Laramie Range are visible in the distance. Tribes informed the BLM that visible modern developments between Pumpkin Buttes and such features may diminish the experience for those performing ceremonial uses.

In 2009, the BLM and the Wyoming SHPO signed a programmatic agreement related to the proposed energy projects within two miles of the Pumpkin Buttes TCP. The agreement allowed the BLM to streamline the SHPO consultation process for projects within two miles of the base of the buttes if the applicant could design their project to create a weak contrast to the setting of the TCP. The agreement did not create any type of specific protections for the buttes themselves; it is essentially a way to expedite projects that conform to a specific set of design features that are intended to preserve the setting of the TCP.

Native American burials have been located and in some cases inadvertently removed from public lands in the planning area. NAGPRA mandates that all Native American human remains and associated funerary objects on public lands be protected, and if they are removed, they are to be repatriated. The BFO is actively working to repatriate Native American human remains and associated funerary objects removed from BLM-administered lands. Occasionally, tribes request that such remains or funerary objects are re-interred on BLM-administered surface.

Consultation with tribes related to TCPs and sacred sites in the planning area is primarily performed in relation to NHPA and NEPA compliance. Consultations and information gathering related to this planning effort indicate that the Pumpkin Buttes TCP is a very significant resource to all tribes. Most tribes also indicated that all rock art sites, burials, and sites containing stone features are significant to their cultures. Tribal representatives were hesitant to pinpoint specific locations of significant areas since the places may be well known through oral traditions, but since tribes have not had a strong presence in the planning area since the late 1800s specific locations may be currently unclear to them. They identified that field visits were a good way to confirm the locations of culturally significant areas. However, they also expressed strong confidentiality concerns with public disclosure of such locations and were hesitant to have them described in this document. Most tribes expressed a strong desire to take part in project level planning effort to locate areas that are significant to their cultures, but there are significant challenges to meeting this goal.

Project specific tribal consultation has typically been reactionary in nature and there have been few opportunities for proactive planning to identify such sites. The high proportion of federal undertakings that occur on private surface in the planning area often complicates the situation. Tribes have no input on the overall management of areas that are significant to their cultures that are on private surface unless there is a federal nexus. Additionally, the BFO has established good working relationships with tribes, but there is no clearly defined process outlining the triggers for consultations or for a process to be followed once consultations are initiated. Programmatic consultation agreements between a tribe or tribes and the BLM can outline such a process. An agreement can clarify rules, give the BLM and tribes a sense of participation, and outline how each party is obligated and involved.

Rural Historic Landscapes

National Register Bulletin 30 defines a rural historic landscape as “a geographical area that historically has been used by people, or shaped or modified by human activity, occupancy, or intervention, and that possesses a significant concentration, linkage, or continuity of areas of land

use, vegetation, buildings and structures, roads and waterways, and natural features” (NPS 1989). To date there are no identified rural historic landscapes in the planning areas. BLM did consider defining the ranching community around the Pumpkin Buttes as a rural historic landscape during the process of determining that the buttes are a TCP (SWCA 2006). The buttes are a distinct geographic area, but the ranching community does not possess a significant adaptation to the area as reflected in any specific types of buildings, roads, vegetation types, etc. The presence of the Pumpkin Buttes in the area did not appear to make the local ranching community any more or less distinctive than other ranching communities in northeastern Wyoming and the BLM did not feel it warranted a special designation.

Management Challenges

There are several unique management challenges associated with cultural resources in the planning area. Consistent assessments of site conditions throughout the planning area are difficult given the recent focus on energy development projects. Areas that are developed for fluid minerals or coal are often intensively inventoried, while other areas with significant resources (such as the South Big Horns) are not. Impacts to the setting of historic properties presents a difficult management challenge in the face of energy development. Increased energy development is also leading to other unique challenges as hundreds of thousands of acres are inventoried and documented.

Large-scale block inventories can be good tools for cultural resource managers, but in the heavy APD permitting atmosphere at the BFO through the 2000s, their use for Section 106 compliance did not necessarily result in the desired outcome. Cultural resources inventory for the purpose of complying with Section 106 of the NHPA identifies archeological sites, but does not necessarily lead to advancement of archeological knowledge. Variable recordation techniques, limitations of regulation, private surface owner concerns, and other issues hinder pure scientific investigations. There is a general assumption that block inventories as a result of NHPA compliance for energy projects are beneficial for the archeological information they provide. One assumption is that identifying sites on a general scale provides good contextual information for a region. Another logical assumption is that specific site information gained from site recordation related to NHPA compliance can be used to formulate various regional hypotheses. There is also an assumption that sites that would not normally be studied are excavated as a result of heightened development, again supplying important archeological data. Although these assumptions are logical, they are not entirely accurate. The assumption that large-scale block inventories provide good contextual information is not necessarily true. One reason for this is that NHPA compliance inventories are not peer reviewed. Generally, the BLM and the SHPO are the only reviewers of Class III reports; specific site interpretations from archeological consultants are not often critiqued. In addition, most inventories in the Buffalo planning area occur on split estate, with the surface belonging to a private land owner. In many cases, the landowner requests cultural resource information from their property be considered confidential. This negates the possibility of using that information for any future scientific purpose.

Another reason for doubting the validity of contextual information provided by contracted archeological reports is that the inventory results vary greatly between consultants. The BLM is responsible for controlling the quality of contracted reports, but given an immense workload, field verification of contractors’ results is not performed for entire blocks. Field checks for block inventories are primarily performed where the ground will be disturbed, leaving the rest of the block inventory unverified. Analysis of the Wyoming Cultural Resource Office database reveals several instances where different consulting archeologists report drastically different site densities

for adjoining project areas in the same topography. There is an inaccurate assumption that data gathered from individual site forms identified during compliance inventories can be used to formulate regional hypotheses. As mentioned before, the lack of peer review in these instances is a major factor. Also, the kinds of data the BLM and the SHPO require contractors to provide are very basic. The goal of a cultural resources survey designed to comply with NHPA Section 106 is to identify historic properties. Typically, the data required to make this determination do not need to be exhaustive. Basic archeological investigation techniques such as formal excavation, radiocarbon dating, faunal analysis, and paleoethnobotanical analysis are rarely necessary for the BLM to determine site eligibility. In addition, most of the sites recorded during these inventories are surface manifestations. It is risky to assume that the presence or absence of certain types of artifacts found at surface scatters provides useful archeological information. Given the propensity for surface sites to experience both erosion and unauthorized collection, site interpretation can easily be skewed. It is inaccurate to assume that heightened development provides for more data recovery or excavation. BLM policy is to avoid historic properties. For CBNG projects, anything beyond simple shovel testing to make determinations of eligibility is exceedingly rare. Because CBNG facilities can easily avoid historic properties in the PRB, mitigation in the form of site excavation simply does not happen.

There is also a major hazard to cultural resources associated with performing large block inventories. It is possible that the BLM's intent to protect sites through identification and avoidance inadvertently leads to unauthorized collection. Identifying, recording, and mapping a site puts it at a heightened risk of unauthorized collection or vandalism. Leaving pin flags in the field, marking artifacts or site boundaries, and PVC datums highlight the location of archeological sites. Artifacts and features are documented in Class III reports; however, it is common for artifacts to be missing when field checks are performed by BLM archeologists. In a few cases, all of the artifacts appear to have been stolen.

Timely documentation of site conditions is one of the greatest management challenges for the BFO. There are numerous significant sites, such as cave sites in the Middle Fork area, the BLM has not visited since the 1970s. Some sites, such as Cantonment Reno and the Sweem-Taylor rockshelter, have associated interpretive facilities, but are not regularly patrolled to check for signs of vandalism or natural erosion. Other sensitive sites, such as burial sites or the Pumpkin Buttes TCP, do not receive adequate BLM visitation to immediately address imminent threats.

Hundreds of archeological sites are discovered and recorded each year as a result of inventory associated with energy development. Most of these sites are assessed for their eligibility for listing on the NRHP. Site condition is assessed as part of the eligibility determination. Site condition can change over time due to such actions as erosion, grazing, unauthorized collection, and vandalism. Because the condition of a site can readily change, monitoring is necessary. Due to the recent increased emphasis on energy development, the BFO has focused on permitting and has performed minimal monitoring.

There are nationally significant historic sites in the planning area, such as Cantonment Reno, that experience human and natural impacts. The site, on BLM surface, is a rare example of a military fort from the late 19th Century, and contains well-defined feature foundations and thousands of buried artifacts. Although there is no legal public access, there are documented cases of unauthorized excavation and collection at Cantonment Reno. The site is on a floodplain and could soon be exposed to erosion from an encroaching oxbow bend in the Powder River. Other nationally significant historic sites on or partially on BLM surface that could be experiencing

similar impacts are the Dull Knife Battlefield, Crazy Woman Battle site, and portions of the Bozeman Trail.

Archeological sites in rockshelters are typically significant because they are often stratified and tend to preserve artifacts and features more than open-air sites. There are numerous rockshelters in the Middle Fork and other similar canyons in the South Big Horn Mountains that require special consideration. Many of the known rockshelters in the planning area have not been properly recorded or patrolled in the last 30 years. Looters often target rockshelters as likely places to recover artifacts, and it is very likely that significant rockshelters on BLM surface have been vandalized.

One of the significant rockshelter sites in the planning area that has been adversely affected is the Sweem-Taylor rockshelter. Excavation by an amateur society in the 1950s removed almost all of the cultural deposits inside the shelter. Amateurs performed the work using dated excavation methods, and no peer reviewed scientific description or analysis of the finds was published. After the excavation, looters removed the remaining cultural layers inside the shelter. Although a barrier fence between an access road and the site and an interpretive sign were installed in the 1980s, most of the damage had been done. Due to the complete removal of the cultural layers, the site cannot be analyzed using modern technology and professional methods, and now contains very little important scientific information.

Rock art is a fragile resource that can be affected or altered by many natural or human-caused factors. The majority of rock art in the planning area has modern graffiti near or on top of the art. Rock art on boulders inside the Sweem-Taylor rockshelter were destroyed or removed during unauthorized excavation. Smoke from modern campfires inside the shelter also led to the destruction of some rock art. Rock art erodes due to natural weathering, especially if it is placed on soft sandstone. Site 48JO108 was recorded in 1978 as a fairly well defined pictograph on a sandstone cliff face. During a site visit in 2009, it was noted that almost half the pictograph was no longer distinguishable due to natural weathering.

Preservation of the setting of historic trails presents a unique management challenge. Setting is one of the aspects that can contribute to the integrity of a historic property. For example, if an individual on a portion the Bozeman Trail can observe the same type of landscape adjacent the trail as a traveler on the trail in the early 1860s did, the site retains its historic setting. The addition of O&G facilities to the setting of a historic trail obviously does not give an observer the impression that the historic setting is intact. With setting being a subjective term, it is a difficult concept to effectively manage. It is essential that the person assessing the setting has a thorough knowledge of both the history of the landscape and the historic property being evaluated. An observer who is not familiar with the Wyoming landscape may feel that a trail segment adjacent to a crested wheat field without visible O&G facilities or modern buildings retains its historic setting. Someone familiar with the history of the area could identify the crested wheat as a non-native species, which is only established by mechanical seeding, and determine that the historic setting has been compromised.

Preserving the setting of historic properties that are surrounded by private surface presents a major management challenge. The setting near the Pumpkin Buttes TCP is entirely on private surface. When the BLM determined that the Pumpkin Buttes was a TCP, it also determined that although there are existing modern developments such as roads, powerlines, fluid mineral wells, etc., the setting of the site was intact. BLM later signed an agreement with the Wyoming SHPO stating that it would apply certain conditions on energy development projects in order to preserve the

setting. BLM can require COAs that reduce visual impacts, but those conditions are only limited to BLM authorizations. Private land owners and proponents building projects that do not have any associated federal authorizations are not obligated to consider impacts to the setting of the Pumpkin Buttes TCP. These actions can have major impacts to the setting of the TCP and may diminish it to the point that the setting no longer contributes to the integrity of the site.

Archeological sites are fragile nonrenewable resources. Sites in the planning area have been adversely affected or destroyed through various actions. The BLM has taken measures to reduce impacts to some sites, but hundreds of significant sites do not have specific protection measures. Although monitoring is necessary to document and prevent site damage, the BFO does not have the proper planning document or resources to do so.

3.5.1.4. Trends

If the demand for production of federally owned minerals increases or remains the same, there will be an increased need to identify cultural resources. Intensive inventory is required before approval of any surface-disturbing activity associated with minerals development. In the PRB EIS, the BLM suggested that operators have their permittees perform large block inventories to better plan large projects with multiple wells and associated infrastructure, and most operators have complied with this request. The contracted reports are used to determine if archeological sites eligible for listing on the NRHP will be affected by the proposed action. Sites that not eligible for listing on the NRHP are not avoided and could be destroyed during construction. It is BLM policy (as outlined in BLM Manual 8140) that historic properties are avoided by at least 100 feet. If historic properties cannot be avoided, they must be mitigated.

The demands of recent heightened federal minerals production has created, and will continue to create, impacts to cultural resources. BLM archeologists often perform pre-approval field checks of contracted Class III inventories, but are primarily focused on the project footprint and are unable to adequately verify the accuracy of large block inventories. Therefore, it is not clear if the contracted inventories are adequately locating all cultural resources. The emphasis on report review and permitting does not allow BLM archeological personnel the time to adequately perform post-approval duties. Although post-approval site monitoring is rare in the planning area, many sites in developed areas appear to have been subject to unauthorized collection or vandalism. Protective measures are often required as COAs for federal undertakings, but it is not clear if those measures are adequately implemented.

3.5.1.5. Key Features

There are numerous archeological sites throughout the planning area that are key features. Site types range from prehistoric sites that are significant for their scientific value, historic structures or the locations of significant historic events, and sacred sites significant to Native American tribes. There are undoubtedly undiscovered significant sites throughout the planning area, but the following known sites necessitate special management considerations.

Prehistoric sites

1. Buried sites:
 - Sisters Hill Site
 - Carter-Kerr-McGee Site
 - Ruby Site

- Piney Creek Site
 - Big Goose Site
 - Cordero Mine Site
 - Mavrakis-Bentzen-Roberts Site
 - Powder River Site, Mooney Site
2. Rockshelters:
 - Schiffer Cave Site
 - Grey-Taylor Site
 - Sweem-Taylor Site

Historic Sites

1. Forts and Ranches:
 - Cantonment Reno
 - Fort Reno
 - LX Bar Ranch
 - K Ranch
2. Trails:
 - Bozeman Trail
 - Deadwood Trail
 - Sawyers Expedition Route
 - Crook Scout Route
 - Black and Yellow Trail
 - Texas Trail
3. Battle Sites:
 - Dull Knife Battle
 - Crazy Woman Battle
 - Tongue River Fight Site

Sacred Sites

1. TCPs:
 - Pumpkin Buttes
2. Rock Art
3. Stone Circle and Cairn Sites

Areas With a High Potential for Buried Cultural Resources

Areas with a high potential for buried cultural resources are key features that should be considered during the planning process. Buried archeological sites are very difficult to locate during a standard Class III inventory and during earth moving construction activities. Given the potential for significant buried sites and the difficulty in locating those sites, such areas necessitate special management considerations.

South Big Horn Mountains

The 1985 RMP necessitated the creation of the **CRMP** for the Outlaw Cave Archeological District. Limited inventory indicated a high density of significant sites (rockshelters, rock art, and stratified buried sites) near Outlaw Cave and in the drainage of the Middle Fork Powder River. The density of significant sites reported in this early inventory is undoubtedly not limited to that specific area. Recent data indicate the entire Southern Big Horn Mountain Subregion contains the

same high density of significant sites. Given the density of significant sites and the limited amount of research in the subregion, the general area necessitates special management considerations.

3.5.2. Paleontological Resources

Paleontological Resources are any fossilized remains, traces, or imprints of organisms, preserved in or on the earth's crust, that are of paleontological interest and that provide information about the history of life on earth. Scientifically significant paleontological resources (including vertebrate, invertebrate, plants, and trace fossils) are known to occur in many of the geologic formations within the Wyoming PRB. These paleontological resources are documented in the scientific literature and in museum records, and are known by paleontologists and land managers familiar with the area. It has been determined that paleontological resources on federal land shall be managed and protected using scientific principles and expertise. Appropriate plans for the inventory, monitoring, and the scientific and educational use of these resources shall be developed, in accordance with applicable agency laws, regulations, and policies. These plans shall emphasize interagency coordination and collaborative efforts where possible with non-federal partners, the scientific community, and the general public.

All paleontological resources offer scientific information, but not all fossils offer noteworthy scientific information. Fossils generally are considered to be scientifically noteworthy if they are unique, unusual, rare, diagnostically or stratigraphically important, or add to the existing body of knowledge in a specific area of science. Most paleontological resources occur in sedimentary rock formations. Although experienced paleontologists generally can predict which formations may contain fossils and what types of fossils may be found based on the age of the formation and its depositional environment, predicting the exact location where fossils may be found is not possible.

3.5.2.1. Regional Context

Geologic formations are the basic units of stratigraphy. A formation consists of a certain number of rock strata that have a comparable lithology, facies or other similar properties. Paleontological resources are closely tied to the geologic formations in which they are present; different-aged rocks contain different types of fossils. Almost all of the geologic formations in the planning area have the potential to produce significant paleontological resources. There are known fossil localities scattered throughout the planning area that have produced a variety of important fossils from the six Class 5 formations, as well as others, so there is a potential for additional significant discoveries to be made. Formations known to produce important vertebrate remains in the planning area include the Chugwater, Sundance, Morrison, Cloverly, Lance, Fort Union, Wasatch and White River formations. Many of the fossil-bearing formations within Wyoming are in the planning area, but they are not extensively distributed or substantially exposed at the surface.

Management of fossils found on BLM-administered lands is restricted to public surface. Collecting fossils is allowed with some restrictions, depending on the significance of the fossils. Hobby collecting of common invertebrate or plant fossils by the public is allowed in reasonable quantities when only hand tools are used and negligible disturbance is made. Commercial collecting of fossils is not permitted. Collection of all vertebrate and any administratively designated plant or invertebrate fossils may be done only under permits issued by the BLM to qualified researchers. All fossils collected under a permit remain public property and must be curated in an approved repository.

The BLM utilizes the Potential Fossil Yield Classification (PFYC) system to classify the potential to discover or impact significant paleontological resources. PFYC is based on the likelihood of geologic formations to contain significant paleontological resources using a scale of 1 (very low potential) to 5 (very high potential). The PFYC is intended to help determine proper management and mitigation approaches for surface-disturbing activities, disposal or acquisition actions, recreation possibilities or limitations, and other BLM-approved activities, with more intense mitigation efforts aimed at higher-potential formations. The system also can highlight areas likely to be a focus of paleontological research efforts or illegal collecting.

3.5.2.2. Indicators

The primary resource indicator for paleontological resources is the degree of loss of characteristics that make fossils or fossil localities important for scientific and educational use or public enjoyment. Damage or destruction of the fossils themselves, impacts to the natural setting of the fossils, poorly executed molding or casting, or disassociation of related fossils all can contribute to a loss of scientific information or public use of the resource. Natural or accelerated erosion, decay of the fossils, project construction, improper collection, and vandalism can remove, alter, or damage the characteristics that make the paleontological resource scientifically important or enjoyable for the public.

3.5.2.3. Current Condition

Exposure of bedrock is necessary to find fossils, and these exposures are limited in the planning area due to the generally rolling, soil-covered, and well-vegetated landscape. Although most of the formations in the planning area contain fossils, relatively few fossil localities are recorded. Documentation of fossils depends on the number of researchers and others looking for fossils. Out of 53 current BLM paleontological research permits, 12 include some type of focus on the planning area. Only two researchers are specifically focused on paleontological resources in the planning area. Even though there appears to be low academic interest at the current time, there is still a high likelihood that undocumented significant fossils are present in the planning area.

Scattered occurrences of vertebrate fossils, leaf impressions and invertebrate marine fossils are known in the planning area. The most easily identified fossil in the planning area is petrified wood from the Wasatch Formation, sometimes found as large log segments or rarely as upright stumps. The Dry Creek Petrified Tree EEA (40 acres) near Buffalo contains fossilized trees and stumps preserved in upright positions and fallen logs. The BLM has developed the location with interpretive signs and walkways to provide an educational area. An NSO stipulation has been applied to the site to restrict any surface disturbances.

Mitigation efforts aimed at identifying and protecting paleontological resources are being applied to energy development activities, major pipelines, and road and other construction actions. These efforts are focused on areas anticipated to commonly contain significant fossils. While it is likely that there is some hobby collecting of fossils the planning area, there is no data relating levels of use. Similarly, there is no documentation of illegal fossil collecting in the planning area.

The potential for impacts to scientifically significant paleontological resources are predicted to be greatest in areas where PFYC Class 4 or 5 (High or Very High) formations are present. In addition, in most cases those rock units with a PFYC of 3 (Moderate or Unknown) will require some management decision and action. Class 3 formations are fossiliferous units where fossil content varies in significance, abundance, and predictable occurrence; or of unknown fossil

potential. Surface-disturbing activities will require sufficient assessment to determine whether significant paleontological resources occur in the area of a proposed action, and whether that action could affect the paleontological resources.

The Wasatch Formation is the most geographically widespread unit exposed on the surface over most of the planning area. It is underlain by the Fort Union Formation. The fossiliferous Morrison and Lance formations crop out along the margins of the PRB and occur at depth in the vicinity of the coal mines. The highly fossiliferous White River Formation occurs only on Pumpkin Buttes in southwestern Campbell County.

In recent years, the Wasatch Formation has been downgraded to a Class 3a formation (geologic units with widely scattered scientifically significant fossils) in the PRB, but remains a Class 5 formation (highest rating) statewide. The Fort Union Formation has been proposed to be upgraded from a Class 3 (geologic units where fossil content varies in significance, abundance, and predictable occurrence; or of unknown fossil potential) to a Class 4 formation (geologic units containing a high occurrence of scientifically significant fossils) statewide.

Currently there are six geologic formations in the field office that have a PFYC rating of 5 (Table 3.49, “Formations Containing Very High Fossil Yield Classifications” (p. 549)). These formations total 230,182 acres or approximately three percent of the entire planning area. A total of 28,177 acres with a PFYC rating of 5 occur on BLM surface (3.6%). However, as the PFYCs for rock units in Wyoming are under revision, these numbers will change in the near future.

Table 3.49. Formations Containing Very High Fossil Yield Classifications

Formation	Age	Potential Fossil Yield Classification
White River Formation	Oligocene Epoch, Tertiary Period – approximately 38 to 30 million years ago	5
Moncrief and Kingsbury Conglomerate Members of the Wasatch Formation	Eocene Epoch, Tertiary Period – approximately 55 to 38 million years ago	5
Lance Formation	Cretaceous Period – approximately 70 to 65 million years ago	5
Cloverly Formation	Cretaceous Period – approximately 138 to 100 million years ago	5
Morrison Formation	Jurassic Period – approximately 142 to 138 million years ago	5
Sundance Formation	Jurassic Period – approximately 170 to 142 million years ago	5
Source: Love et al. 1993		

White River Formation

The Middle Tertiary White River Formation consists of bentonitic mudstone, sandstone, and altered or unaltered volcanic debris. Thousands of vertebrate fossils have been collected from this rock unit, including mammals, reptiles, amphibians, fish, and birds, as well as trace fossils. This formation is found throughout the Northern Great Plains and forms the landscape preserved at Badlands National Park in South Dakota. The only occurrence of this geologic formation in the planning area is the sandstone caps forming the tops of Pumpkin Buttes. Vertebrate fossils, including mammal bones from this formation have been located in the planning area.

Moncrief and Kingsbury Conglomerate Members of the Wasatch Formation

The Lower Tertiary Wasatch Formation in eastern Wyoming consists of sandstone and variegated claystone with numerous coalbeds in the lower portions (Love and Christiansen 1985). In the western PRB the Wasatch Formation includes the Moncrief Member (a conglomerate of Precambrian clasts, interbedded with sandstone and claystone) and the Kingsbury Conglomerate (a conglomerate of Paleozoic clasts, interbedded with sandstone and variegated claystone) (Love and Christiansen 1985). In southwestern Wyoming the Wasatch Formation contains numerous mammal, amphibian, bird, and reptile fossils, including trace fossils. Wasatch Formation deposits underlie the majority of the planning area, and occasionally contain fossil bones. Reptile and mammal fossils are sporadically found throughout the basin, and some very rich fossil localities are known from this unit near the towns of Sussex and Lynch. Some nearly complete large fossil mammals have been found in the upper parts of the formation. Researchers have also collected small vertebrate fossils, including mammal bones, primarily from anthills in the Wasatch Formation.

Lance Formation

The Upper Cretaceous Lance Formation is dominated by nonmarine coastal floodplain sandstones, mudstones, and marls, with marginal marine sandstones and shales in its lower parts. It reaches more than 750 meters in thickness and is found in many places throughout Wyoming. The formation can contain a diverse fauna from the end of the Mesozoic Era including tyrannosaurs and other theropods, ankylosaurs, hadrosaurs and other ornithopods, ceratopsians, and pachycephalosaurs, and pterosaurs, as well as a variety of mammals, reptiles, amphibians birds, and fish. Important track sites are also known. A relatively small portion of the formation is exposed along the margins of the planning area. There are no known fossil discoveries from the geologic unit in the planning area, although there have been numerous significant finds between Lusk and Newcastle.

Cloverly Formation

The Lower Cretaceous Cloverly Formation was deposited under floodplain and lacustrine conditions, having an average thickness of approximately 90 meters. The formation primarily has variegated claystones with channel-filling sandstones and conglomeratic sandstones. Above the zone of conglomerates and conglomeratic sandstones at the base of the Lower Cretaceous, the shales and sandstones are buff and gray with purple, maroon, and red shales in the middle. The Cloverly Formation has produced a diverse dinosaur fauna in Montana and the Bighorn Basin of Wyoming including iguanodonts and other ornithopods, sauropods, theropods, and ankylosaurs as well as lizards, turtles, fish, and early mammals. Dinosaur eggs have also been found in this unit. Small portions of the formation are exposed in the foothills of the Big Horn Mountains in the planning area, although no significant finds have been documented.

Morrison Formation

The Upper Jurassic Morrison Formation was deposited under floodplain and lacustrine conditions and can be up to 65-meters thick. It consists of green and greenish-gray shale and claystone with lenticular silty sandstones and occasional conglomerates, thin carbonaceous beds, freshwater marls, and limestone lenses characteristic of floodplain and lake deposits. The Morrison Formation is well known for producing a scientifically noteworthy and highly diverse fauna and flora. In

Wyoming this fauna includes allosaurids and other theropods, diplodocids and camarasaurids, stegosaurs, ornithopods, ankylosaurs, and pterosaurs, as well as variety of mollusks, reptiles, amphibians, fish, early mammals, and trace fossils. This formation is found throughout the Rocky Mountain area and is noted for fossil deposits at Dinosaur National Monument in Utah, Como Bluff in Wyoming, Dinosaur Ridge in Colorado, and other world-class sites. Small portions of the formation are exposed in the foothills of the Big Horn Mountains in the planning area and important discoveries have been (and continue to be) made there since the late 1800s.

Sundance Formation

The Middle-Upper Jurassic Sundance Formation consists of marine sandstones, limestones, and shales deposited in an inland sea or adjacent near-shore and beach deposits from the latter part of the Jurassic Period. The formation varies in thickness from 75 to 130 meters. It consists of greenish-gray glauconitic mudstones and shales with some interbedded sandstones and limestones containing many invertebrate fossils, including clams and oysters, crinoids (sea lilies), echinoids (sea urchins), and belemnites (squid-like animals). Marine reptiles including ichthyosaur, and plesiosaur specimens are also found this formation. A rich trace fossil record is recorded in this unit ranging from a diversity of invertebrate traces to pterosaur and theropod dinosaur footprints. Small portions of the formation are exposed in the foothills of the Big Horn Mountains in the planning area, although no significant finds have been documented.

3.5.2.4. Trends

Given the limited number of localities, monitoring data and the minimal amount of paleontological research in the planning area it is difficult to identify trends. It can be assumed that any surface-disturbing activities in areas with a PFYC of 5 have the potential to destroy significant fossils. Although, the majority of foreseeable development considered in this plan is not in these areas.

However, as most of the geologic formations in the planning area have the potential to produce significant paleontological resources and there are known fossil localities scattered throughout the planning area, there is a potential for additional significant discoveries to be made. Future research and mitigation efforts could discover significant paleontological resources, which could require special management to protect or develop them.

However, the absence of localities in the PRB does not always mean that scientifically significant fossils are not present, as much of the area within and surrounding the PRB has not been adequately explored for paleontological resources. As a result, development activities in the planning area have the potential to adversely affect scientifically significant fossils, if they are present in or adjacent to disturbance areas.

The greatest potential impact on surface and subsurface paleontological resources would result from disturbance of surface sediments and shallow bedrock during construction and/or operations, depending on the type of project. Potential subsurface disturbance of paleontological resources (e.g., during drilling operations) would not be visible or verifiable. However, as only portions of the planning area have been evaluated for the occurrence of paleontological resources, and discrete locations for development activities cannot be determined at this time, no accurate estimate can be made as to the number of paleontological sites that may be affected by cumulative development activities. Development activities which involve federally owned surface and/or minerals are subject to federal guidelines and regulations protecting paleontological resources.

Protection measures, permit COAs, and/or mitigation measures would be determined on a project specific basis at the time of permitting to minimize potential impacts on paleontological resources as a result of these activities.

3.5.2.5. Key Features

Geologic formations with a very high (Class 5) potential to produce significant paleontological resources currently include the White River Formation, the Moncrief and Kingsbury Conglomerate Members of the Wasatch Formation, and the Lance, Cloverly, Morrison, and Sundance Formations. These geologic formations amount to approximately 230,182 acres or approximately three percent of the entire planning area; on BLM surface, they total approximately 28,177 acres or approximately 3.6 percent. Due to the fact that these formations have a very high potential to contain significant fossils, they are key features.

In addition, unique examples of large intact logs and upright stumps of petrified wood fossils preserved in the Wasatch Formation are the most widespread important fossils in the planning area. The Dry Creek Petrified Tree EEA is an outstanding example of this resource and is a key feature.

3.5.3. Visual Resources

Scenic values are identified in FLPMA as one of the array of resources that the BLM must manage and protect. To meet its responsibility to maintain the scenic values of public lands, the BLM has developed a Visual Resource Management (VRM) system based on the concept that every landscape has the basic environmental design elements of form, line, color, and texture. Projects that repeat the natural environmental design elements are generally considered to be in harmony with their surroundings and result in less impact to visual resources; those that do not repeat natural environmental design elements create contrast and result in greater impacts to visual resources. Determining how an area should be managed first requires an assessment of the area's scenic values.

The VRM system provides an orderly method for observing the scenic qualities of public lands, classifying existing visual resources and determining appropriate management actions. It also provides a way to analyze potential impacts to visual resources and apply visual design techniques to ensure that surface-disturbing activities harmonize with their surroundings. The BLM VRM system consists of two stages – (1) Visual Resource Inventory (VRI) and the designation of VRM Classes during the resource management planning process; and (2) implementation of RMP decisions and analysis through the Visual Contrast Rating (VCR).

The inventory stage, performed in the planning area in July 2009 (BLM 2009b), provides a baseline assessment of the condition of visual resources and assigns them to inventory classes. The VRI is composed of three factors:

- **Scenic Quality Rating Units.** Rating units divide the landscape within the planning area into discrete units of similar natural character based on the physical design elements of form, line, color, and texture.
- **Sensitivity Level Rating Units.** Sensitivity levels (high, moderate, low) measure public concern for scenic value. Determinations include identification of visually sensitive publics (i.e., TCPs), landscape features of concern and any other corresponding scenic values identified or documented by the public.

- **Delineation of Distance Zones.** Distance zones (foreground/middleground, background, seldom seen) assist in defining areas that are visible from nearby access areas from landscapes that appear farther away. The VRI process includes identifying places where the public is most likely to view public lands.

Thus, the VRI rates the visual appeal of a defined land, measures public concern for scenic quality of the tract, and determines whether the tract of land is visible from travel routes or observation points. Units within the planning area are then placed into one of four VRI classes based on the interrelationships between the three inventoried factors. The process is described in detail in BLM Handbook H-8410-1 (BLM 1986a). VRI Class I includes the most highly valued visual landscapes while VRI Class IV are the least. The VRI serves as the baseline from which change is to be measured through NEPA analyses during the implementation phase of the land use plan.

The results of the VRI are considered throughout the RMP process in conjunction with other management actions for a given alternative. In each alternative, BLM-administered lands are assigned to management classes (VRM Class I-IV) with established objectives. For example, management of an area with high scenic value might be focused on preserving the natural character of the landscape, and management of an area with little scenic value might allow for major modifications to the landscape within a given alternative.

3.5.3.1. Regional Context

Units of BLM-administered surface within the planning area are classified as one of the four VRM classes based on management objectives in concert with the unit's identified scenic values. The degree of visual modifications allowed is specific for each VRM class (BLM 1984). The goal of VRM, however, is to minimize the visual impacts of all surface-disturbing activities regardless of the VRM Class in which they occur. The *Glossary* summarizes the objectives for VRM classes. Formerly, VRM included an additional class (Class V) that identified areas where the landscape character has been so severely impaired that landscape restoration or rehabilitation was necessary (i.e., large surface coal mines). Lands that are managed by the USFS, such as the Bighorn National Forest and Thunder Basin National Grassland, are subject to the landscape or scenery management considerations required under USFS policy and specified in the relevant Forest Plan.

3.5.3.2. Indicators

Visual resources within the planning area are influenced by a wide variety of topographic, geologic, hydrological, vegetative, and other characteristics of the region. The type of vegetation varies and is largely dependent on elevation and the amount of precipitation received in any given area. Landforms range from relatively flat land, to low mountains, low rolling or flat-topped hills, and isolated hills, to higher elevations near the Big Horn mountains containing mountain shrub vegetation and alpine forest. Cultural modification exists in various levels of concentration across the landscape, but is generally concentrated near cities and towns for residential development and infrastructure, while O&G operations are concentrated within the Powder River Breaks. Vegetation patterns, landforms and development, in conjunction with several other environmental factors, affect color, form, line, and contrast. The indicator for visual resources is the repetition of these four natural environmental design elements.

3.5.3.3. Current Condition

Visual resources in the planning area vary widely, from mountains and foothills in the western portion to low rolling prairie in the east. The large areas of undisturbed sagebrush-grasslands and mountain foothills in the planning area are unique compared to the more densely populated Great Plains regions to the east and south. While the visual resources inventory incorporates the entire visual landscape into the analysis, the BLM only assigns VRI and VRM classes to BLM-administered surface.

Almost 60 percent of the planning area is in the PRB ecoregion (EPA 2004). This region includes gently rolling to steep dissected plains and wide belts of steeply sloping badlands that border the Powder and Tongue river valleys. In places, flat-topped, steep-sided buttes rise sharply above the surrounding plains, such as Pumpkin Buttes in the southeast part of the planning area. The vegetation is primarily sagebrush and grassland, with patches of pine-juniper woodland.

The foothill shrublands and low mountains ecoregion of the Wyoming Basin is the second largest region represented on BLM-administered surface in the planning area (approximately 14%). It is in the southwest part of the planning area in the foothills of the Big Horn Mountains. The vegetation is shrub steppe, desert shrubland, and pine-juniper woodland. The Chugwater Formation, with its striking crimson color and steep vertical escarpments, is prominent in the southern foothills of the Big Horn Mountains. In addition, Powder River tributaries cut deep vertical canyons in the foothills of the Big Horn Mountains, and then break out into broad riparian zones that provide visual diversity across the grasslands of southern Johnson and Campbell counties.

Visual resources are also often associated with recreational opportunities and/or special designations. Many recreational activities, such as backpacking, geologic and nature study, photography, and hiking, are greatly influenced by the natural settings and scenic views that VRM is intended to protect. Areas managed to protect primitive recreational opportunities, such as WSAs or suitable segments of Wild and Scenic Rivers (WSRs), would have strong visual resource components.

Visual Resources Inventory within the Planning Area

The BFO produced a detailed analysis of visual resources in the planning area in the BFO VRI which is herein incorporated by reference (BLM 2009b). The entire planning area was divided into a total of 48 Scenic Quality Rating Units based on physiographic elements such as geology, vegetation, hydrology, texture, color, variety, and topography. With few exceptions, the Scenic Quality Rating Unit boundaries were also used for analysis of the sensitivity of the landscape in terms of public concern for scenic values. Finally, the analysis considered the distance of a given unit based on relative visibility from travel routes or observation points. Mineral exploration, mining activities, ranching, and recreational use have been ongoing in the BFO for several decades. Consequently, the Field Office has an extensive road and travel-route network. The result is that very few areas are not within three to five miles of travel routes, and no lands are more than five miles from an established road or trail. Even in the roughest and most topographically diverse parts of the BFO, roads and trails penetrate virtually all areas. In addition, areas that are not easily accessed are still visible. Therefore, for the purpose of determining final VRI Classes, only the Foreground-Middleground distance zone is applied to inventoried lands within the planning area. Map 48 displays the VRI Classes assigned to the planning area.

Current Visual Resource Management within the Planning Area

While the VRI documents the baseline conditions of visual resources on public lands and provides a quantifiable framework for assessing VCR during implementation, discussion of the current VRM classes (Alternative A) provide the basis for the no action/present management alternative environmental consequences documented in Section 4.5.3, “Visual Resources” (p. 1377).

The predominant VRM classes in the planning area are Classes III and IV, which comprise approximately 80 percent of the total area (Map 48). Some scenic areas are managed as VRM Class II, including lands adjacent to the Bighorn National Forest and within the foothills of the Big Horn Mountains, the Tongue River east of Interstate 90, State Highway 336 in the vicinity of Wyarno, U.S. Highway 14 and Interstate 90 in the vicinity of the Powder River, and Interstate 90 between Rozet and Wyodak. The majority of the Fortification Creek area is designated VRM Class III. Only approximately one percent of the area is rated as Class V, primarily in the vicinity of coal mines and densely populated areas. The VRM system no longer recognizes Class V management areas. As reclamation in previously designated Class V areas has yet to take place, the areas are generally managed as VRM Class IV. The 1985 RMP and subsequent amendments or updates did not formally designate areas as Class I, as shown in Table 3.50, “Visual Resource Management Classes” (p. 555). However, WSAs and the portion of the Middle Fork Powder River corridor that is suitable and eligible for WSR designation are currently managed as VRM Class I (BLM 2000b).

The three WSAs have been withdrawn from mineral entry and are closed to leasing. Under current management, any facilities or structures proposed in or near WSAs must be designed so as not to impair wilderness suitability. Outside of WSAs, no activity or occupancy is allowed within 200 feet of the edge of state and federal highways. Facilities or structures such as powerlines, oil wells, and storage tanks are required to be screened, painted, and designed to blend with the surrounding landscape except where safety dictates otherwise.

Table 3.50. Visual Resource Management Classes

VRM Class	BLM Surface Acres
Class I ¹	30,103
Class II	127,594
Class III	63,583
Class IV	559,674
Class V	702

Source: BLM 2012f

¹ The three WSAs and Middle Fork Powder River WSR were not originally designated as VRM Class I, but are managed as such. The acreage for the Fortification Creek WSA (12,419) was subtracted from VRM Class III and the acreage for the remaining WSAs and Middle Fork Powder River WSR (17,984) was subtracted from VRM Class II.

VRM Visual Resource Management

Visual Intrusions

Impacts to visual resources from human disturbance were relatively minor before mineral development under current management. O&G development, particularly CBNG, has resulted in the most widespread impacts to visual resources in the PRB. Long-term disturbance to visual

resources has occurred with the construction of well pads, access roads, overhead powerlines, water-handling facilities, central metering facilities, and compressor stations. Increased night lighting at facilities has introduced intrusive and potentially undesirable elements into the visual landscape. The scores assigned for the cultural modification factor in the scenic quality evaluation of the VRI assist in documenting a baseline for analyzing impacts from visual intrusions. Visibility has been affected by fugitive dust emissions and exhaust from vehicles and production facilities. Natural disturbances have been principally fire and drought. Coal mining has had the most intensive impact on visual resources in the portions of the planning area affected by coal mining. During the life of a coal mine, substantial changes to line, form, color and texture occur on a local level.

In VRM Class II areas along major transportation routes, facilities constructed on state and private surface that were not part of a federal action have resulted in substantial impacts to visual resources in the area and eroded the usefulness of mitigation measures implemented on federal surface. As of April, 2012, there were approximately 1,025 active O&G wells in VRM Class II areas, mainly along Interstate 90, U.S. Highway 14/16, and near the Tongue River. Of these, 645 (63%) were non-federal actions. Surface-disturbing activities associated with these facilities are easy to notice because of the amount of contrast with the representative landscapes. Additionally, across the planning area the extraction of other minerals such as bentonite, uranium, sand, and gravel often includes a substantial change in the line, color, and form of the existing landscape, which increases with the scale of the operation.

3.5.3.4. Trends

The widespread development of mineral resources in the planning area has created direct, adverse visual impacts. Mitigation of this activity has largely prevented mineral development activities from exceeding the established VRM class objectives. However, the trend toward continued expansion of natural resource development could create areas of potential conflict between resource uses and the established VRM class objectives.

The number of completed wells in the planning area has averaged more than 1,000 per year since 2004. However, the number of plugged wells has been substantially less, approximately 230 per year over the past 15 years. Exceptions for development within 200 feet of highway corridors have been granted by the Federal Highway Administration, creating notable contrasts to the existing landscape along the I-90 corridor. O&G facilities constructed on private surface that were not part of a federal action have resulted in impacts to the viewshed, despite mitigation measures implemented on federal surface. These non-BLM actions have resulted in major impacts to visual resources in Class II areas along Interstate 90 and U.S. Highway 14 near the Powder River. Extraction activities for other minerals (such as bentonite, sand, and gravel) have contributed to visual resource degradation at a site-specific level. However, many recent applications for mining of these minerals have been for areas either adjacent to, or very near, existing mining operations, and therefore tends to minimize overall degradation by concentrating it in areas already degraded.

Renewable energy projects such as solar panels or wind farms have not yet been constructed in the planning area, although at least one project has been proposed on fee surface adjacent to BLM-administered lands. Renewable energy project proposals are expected to increase as traditional energy sources are depleted and the economic and political incentives for alternative energy sources increases.

Recreational use, most specifically OHV use, has adversely affected visual resources by damaging vegetation and increasing erosion, especially in riparian areas or on hillclimbs. Enforcement of OHV regulations in the planning area was minimal before 2008, resulting in resource damage, including visual resource impairment. The presence of law enforcement personnel since 2008 has reduced or mitigated the number of OHV incidents in the planning area.

Visual intrusions normally associated with smaller projects would result in fewer impacts to visual resources. Contrasts in the basic elements are generally moderate and most of these projects remain subordinate to the representative landscape. These projects include a wide variety of range improvements, fuel-reduction projects, and two-track roads throughout the planning area.

3.5.3.5. Key Features

The following visually sensitive areas have been identified to help guide land use management decisions.

Unique Visual Landscapes

The Big Horn Mountains and foothills form the western boundary of the planning area and dominate the view from many observation points to the east. River canyons cutting through a variety of geologic formations interrupt the foothills, creating dramatic shapes along the eastern slope of the Big Horn Mountains.

The Middle Fork Powder River is in the southwest portion of the planning area. It includes steep incised canyons, ranging in elevation from 5,000 to more than 8,000 feet. It is a popular recreation area, frequented by fishermen, hikers, and history buffs. Outlaw Cave is in Middle Fork Canyon.

The Red Wall, east of the Middle Fork Powder River, is a unique geologic formation running north to south along the foothills of the Big Horn Mountains. It is characterized by its steep cliffs and red stone of the Chugwater Formation. The Middle Fork Powder River and its tributaries run in the valley between the Red Wall and the Big Horn Mountains, creating a picturesque riparian corridor. The Hole-in-the-Wall historic site is on the southern end of the Red Wall on BLM surface.

Two WSAs, Gardner Mountain and North Fork, are in the Big Horn Mountain foothills, also in the southwest part of the planning area. They are approximately 5 miles apart in a very remote portion of the mountains. The Red Fork Powder River runs through the Gardner Mountain WSA and the North Fork Powder River bisects the North Fork WSA. The scenic rugged canyons and rock outcrops have prevented much development in the region apart from isolated range facilities, small mines and historic forestry actions.

There is a third visually unique WSA in the north-central portion of the planning area. Fortification Creek WSA is east of the Powder River and is dominated by steep draws, erosive soils, and a mosaic of vegetative types. It includes juniper-ponderosa pine woodland patches that provide cover for a resident elk herd.

Primary Visual Corridors

The planning area is divided by two interstate highways – Interstate 90, which runs primarily east-west through the PRB and then north to the Montana State line, and Interstate 25, which runs north-south along the Big Horn Mountains to its intersection with Interstate 90. Interstate 90 is a

major transportation highway across the northern tier of the United States and is one of the main vacation routes between the Black Hills of South Dakota and Yellowstone National Park.

The U.S. Highway 14/16 corridor runs east-west across the northern portion of the PRB. It is an alternative route through the Big Horn Mountains, following riparian valleys for approximately half its distance across the planning area.

U.S. Highway 59 runs north-south along the eastern side of the planning area. It is a main industrial transportation route between Gillette and Douglas to the south. The northern portion of the route, between Gillette and the Montana State line, is largely undeveloped.

Several rivers offer opportunities for recreation, especially fishing, including Clear Creek, Crazy Woman Creek, the Tongue River, and all forks of the Powder River. The Tongue River in Sheridan County is also a popular destination for boaters and float trips throughout summer months. The Middle Fork Powder River is a blue ribbon trout stream and one of the most popular destinations for anglers in the planning area.

Historic properties are also particularly susceptible to visual impacts. Areas of notable concern for visual impacts to the cultural setting include the Pumpkin Buttes TCP, the Bozeman Trail and historic forts and battlefield sites. Visual intrusions in these locations can greatly affect visitor experience and the integrity of areas where viewshed is integral to historical significance.

3.6. Land Resources

3.6.1. Forest Products

3.6.1.1. Regional Context

The planning area lies on the east side of the Big Horn Mountains and extends into the PRB. The ecoregions for the forest lands are the Granite Subalpine Zone, the Dry Mid-Elevation Sedimentary Mountains, and the Pryor Bighorn Foothills. There are seven major forest management units and smaller units that are scattered tracts from the north end of the planning area west of Sheridan, Wyoming, on the Red Grade Road and larger contiguous tracts that extend from Mosier Gulch to the Hole-in-the-Wall campground in the South Big Horns. The geographical area includes the Billy Creek forest management area at the North end of Hazelton Road on the east facing slopes of the Big Horns, the Powder River Management Area, Hazelton Road Management Area, the Horn, Bear Trap Management Area, Garden Mountain Management Area, and the Graves Corral Management Area on the southern end.

There are scattered woodlands throughout the tri-county area with concentrations of woodlands in Campbell and Johnson Counties. They are concentrated in the Pine Scoria Hills, the Casper Arch, the Mesic Dissected Plains, and the PRB Ecoregions. The woodlands in Campbell County, extend from Dead Horse Creek to Bitter Creek on the Montana border, on the east side from Homestead Draw to Horse Creek, and in the southeast from Corral Creek to 7 Prong Creek. The woodlands extend on the east side of the south Big Horns to the Middle Fork Powder River in Johnson County.

The forest products industry within the planning area has also undergone a substantial reduction in infrastructure because of the recession in the area. This includes the closure of the primary saw

mill in Sheridan, Wyoming and the intermittent closing of two smaller mills in Buffalo. Due to this fact, sales for saw logs have been minimal and post and pole sales have increased in demand and value; however, these post and pole products are being delivered to South Dakota, which is a greater than 450 mile round trip. The nearest saw mill is located in Livingston, Montana, which also presents an extremely high fuel cost, with a distance of 650 miles. Personal use has averaged 220 cords per year between 2009-2013 (BLM TimberSale Information System). Multiple other products including Christmas tree sales have been utilized to thin sapling stands and implement meadow restoration processes.

According to the BLM Economic Analysis for 2012, Public Domain Forestry returns between \$10–\$15 to the community for every dollar expended by the forestry program.

3.6.1.2. Indicators

The fundamental indicators are those that recognize a connection between the forest and the people. The only way to achieve sustainability of the forest and therefore the forest products is to have understanding and support of the people.

Forest product sales (commercial and personal use) are an important part of maintaining and restoring forest health by removing dead and dying trees, and effectively managing the density of the forests.

- To ensure the productivity of the forest and woodlands for forest products they need to be available for timber production and management.
- The forest and woodlands need to be managed for ecosystem health.
- The production and removal of the forest products should compare to sustainable harvest levels.
- The resources that play a role in the forest and woodland health, such as soil and water and wildlife habitat, should be conserved and maintained.
- Representation of multiple tree species and genetic variation within the species, and multiple age classes, to support diversity and a multitude of products, concentrating on commercially desirable tree species.
- Support and maintenance of the socioeconomics, including demand, of the community and society.
- The political framework and support for the forest industry.

3.6.1.3. Current Condition

The BFO administers 77,229 acres of forests and woodlands. Forests and woodlands are distinguished by type (species composition) and the physical environment in which they grow. Approximately 95 percent of the volume removed was utilized for forest products, with posts and poles being the largest components of removal from the growing stock, followed by sawlogs and fuelwood. The remaining 5 percent was left in the woods.

Worldwide, fuelwood has taken the lead in forest uses with over 1.8 percent of the wood being utilized in this capacity. The forest products removed in this area have followed suit, as the mills that once utilized and dispensed the forest products have declined.

Forest lands commercially available for production and harvest average approximately, 5 to 10 mbf per acre. These volumes increase or decrease with the economy, opportunities, and natural occurrences.

Active timber sales within the area will continue, primarily in lodgepole and Douglas fir. The areas harvested in the past have successful natural regeneration in the openings and provide species and age class diversity. These future stands will require thinning and other silvicultural manipulations to reduce the density and promote healthy stands. The sale and removal of forest products have been focused on salvage harvest for the sawlogs and Timber Stand Improvement, especially for the posts and poles, to create healthy and resistant forest.

3.6.1.4. Trends

Timber processing capacity has steadily declined over the past two decades within the planning area, as well as in the west. In the interior west, the restricted availability of timber is the result of several restrictions such as appeals and litigation, Threatened and Endangered species protection, changing environmental laws, and the changing expectations of the public.

The integration of the timber industry into the global markets has introduced substantial competition worldwide and has driven down the prices of forest products. The recent recession is the worst in 25 years for the forest products industry.

The development of new forest products such as wood pellets, biofuels, and biomass has not gained substantial traction within the region; most of the new development of these alternative products has been concentrated in the southeast and the northwest portions of the U.S.

As a result of fire suppression and the reduction in harvesting activities, forests with commercial potential are in need of active management to increase their economic suitability, economic viability, and health conditions. However, the increased utilization of fuelwood aids in manipulating the increased amount of fuels in the forest and reducing the density of forest and woodland stands to support the diversity of age and species distribution.

The public demand for fuelwood, posts and piles and other special forest products, such as Christmas trees has remained strong and is anticipated to increase as the population of the planning area increases. The continuing recovery from the recession and the concern about forest health issues have provided opportunities for increased commercial activity to improve forest health.

3.6.1.5. Key Features

The key feature of the forest products program is the flexibility that the forest presents in providing the desirable products to the communities and the ability to manipulate the forest/woodlands in producing these products while providing for all the other resources including watersheds, wildlife, and recreation. The products are allocated in response to the economics of the communities.

A unique characteristic of forest and woodlands is that they are renewable resources. Therefore, products utilized by society and, in particular, this community are able to be replaced. Successful regeneration of the forest is and has been a valuable asset in replacing vegetation and replenishing the watersheds of the Big Horn Mountains.

The other type of product provided by the forest and woodlands, is a product that cannot be measured. This is the value offered for educational opportunities, conservation benefits, and recreational activities.

3.6.2. Lands and Realty

Lands and realty management supports all resources and resource management programs. The primary focus activities of the program are land use authorizations for ROW and corridor management associated with O&G development. Secondary activities include land tenure adjustments such as sales, exchanges, donations, acquisitions (including easements); leases and sales under the Recreation & Public Purposes Act; withdrawals; classifications and other segregations, various land use authorizations; and trespass identification and abatement.

3.6.2.1. Regional Context

FLPMA is the primary statute governing public land management and is the primary authority for activities within the lands program. Specific BLM Wyoming objectives include the following:

- Avoid trespass and improve access and manageability of public lands
- Support multiple-use management goals among the various resource programs
- Respond to public requests for land use authorizations, sales and exchanges, and to acquire access to serve administrative and public needs
- Consideration of Recreation and Public Purposes (R&PP) applications that do not exhibit conflicting uses
- Support management of other resource programs and other federal agencies regarding withdrawals

3.6.2.2. Indicators

Indicators for management for success in the Lands and Realty program would include the number of actions and acreage size of land use authorizations such as leases, permits, easements, land tenure adjustments, withdrawals, classifications, and segregations. For example, the number and acreage of access easements acquired and the total acreage that becomes legal public access from the acquired easements.

3.6.2.3. Current Condition

The BLM currently manages approximately 10 percent of the surface in the planning area. The general land ownership pattern in the planning area consists of some large blocks of BLM-administered public lands interspersed with many isolated, small-acreage parcels, which are difficult or impossible to access or manage.

The BFO identifies approximately 108,243 acres as more difficult or less economic to manage than most of the BLM-administered public lands in the planning area. These lands have priority consideration for disposal through exchange, public sale, or transfer of jurisdiction to another agency.

Leases, Permits, and Easements

Land use authorizations under FLPMA section 302 (b) authorizes the BLM to use, occupy, and develop public lands through leases, permits, and easements of those public lands. CFR Title 43 Part 2920 provides the appropriate regulations and guidance for these authorizations. Easement acquisitions are an integral part of management.

Since 1985, the BFO has acquired 24 easements on non-federal lands for improved access and public land management. The BFO acquired easements in the Poison Creek, Dry Creek Petrified Tree, and Outlaw Cave areas. These lands involve a total of approximately 96 acres.

Land Tenure Adjustments

The land ownership pattern in the planning area is diverse, with a large portion of scattered parcels that are isolated by large private landholdings. This scattered isolated ownership pattern makes these lands difficult and economically inefficient to manage as part of the public land system. The small size of many scattered parcels and their isolation from other parcels of public land make them of marginal utility to the public. Lack of legal public access diminishes their public utility. The existing plan prioritizes exchanges and acquisitions on lands adjacent to large blocks of public lands. Some area of exceptions occur north of Gillette (Cow Creek Breaks area), the eastern flank, and south to southwest Johnson county areas, where larger parcels are present.

Land ownership (or land tenure) adjustment refers to those actions that result in the retention of public land, disposal of public land, or the acquisition by the BLM of non-federal lands or interest in land. Land tenure adjustment is used to increase access and manageability of public lands, particularly those with high-value resources. Special legislation often governs land program activities in a particular management area, or directs acquisition or disposal of specific lands. Private legislation can also direct land tenure adjustments.

Management recognizes the potential retention of lands where there are archeological, historic, wildlife, or other values. Conversely, small parcels included in a large federal grazing allotment are generally efficient to manage and should be retained. Lands identified for disposal are typically small, isolated tracts that are difficult and economically inefficient to manage. Lands designated in the BLM land use plan as potentially available for disposal are more likely to be conveyed out of federal ownership through an exchange rather than a sale. This preference toward exchange over sale is established in BLM's policy.

Retaining isolated land parcels in public ownership remains a management liability because they are difficult to access and uneconomical to manage with the potential for trespass, resulting in unnecessary management costs to abate and mitigate. In most cases, these lands provide little or no utility to the public because of limited or lack of legal access, and the average size of individual parcels is too small to afford a viable recreation or other outdoor experience.

Historically, many isolated public land parcels were difficult to access and manage appropriately. Although the BFO acquired approximately 24 easements for access and range management, the overall condition remains – small isolated parcels with limited or no access are difficult to manage due to increased potential for conflicts with adjacent landowners, inadvertent and willful trespass, and other uses difficult to monitor and control.

Land Sales (FLPMA Section 203)

Conducting land sales requires either offering a direct sale to relevant landowners, which could include the state in which the lands are located, the local government entity in the state, adjoining landowners, individuals, or any other person. FLPMA states that, “the United States receives fair market value of the use of public lands and their resources unless otherwise provided for by statute” (FLPMA section 102(9)). Competitive sale of lands is required unless the Secretary of

the Interior determines a necessity to dispose of lands through modified competitive bidding or without competitive bidding.

To be considered for disposal, lands must, at a minimum, meet the following criteria as outlined in Section 203 of the FLPMA: (1) They are difficult and uneconomical to manage, and are not suitable for management by another federal department or agency; (2) The tract was acquired for specific purposes and is no longer required for that purpose or any other federal purpose; (3) Disposal would serve important public objectives, including but not limited to, community expansion or economic development, that could not be achieved prudently or feasibly on land other than public lands and that outweigh other public objectives or values.

The BLM gives priority consideration for identified disposal lands and lands meeting disposal criteria for exchange or public sale identified in the land use plan (Appendix L (p. 2211)). The BFO identifies priority lands in areas adjacent to major blocks of public land, areas with high recreational potential, and areas where easements will improve access.

One 40-acre sale under Revised Statute 2455, which sets forth provisions related to public land sales under the Isolated Tracts Act, occurs in the BFO. There have been 15 FLPMA land sales that occurred since 1985 on approximately 1,304 acres.

Mineral (FLPMA Section 209)

FLPMA specifies that all minerals underlying public lands disposed of by sale shall be reserved to the United States, unless all mineral interests in the lands, except where there are no known mineral values, or where the reservation of the mineral rights is interfering with or precluding a more beneficial use of the land. FLPMA section 209 also specifies the conditions under which the mineral rights will be conveyed, a mineral report must be prepared to assess fair market value of the minerals, payment of the administrative costs of the sale, payment of fair market value for the mineral rights, and possibly having to perform an exploratory program and preparing a mineral report. The Surface Mining Control and Reclamation Act defines criteria for minerals in environmentally sensitive areas like steep slopes, timber lands, and prime farmland, including minerals underlying alluvial valley floors. The BLM will provide opportunities for such exchanges while meeting fair market value requirements.

Land Acquisitions (FLPMA Section 205)

The BFO gives priority to lands adjacent to major blocks of BLM-administered public lands. Acquisition is used to acquire key natural resources or acquire legal ownership of lands that enhance the management of existing lands and resources, such as in areas with high recreational or natural resource values. Acquisition of land by purchase is used sparingly given the limited funds available through appropriations. The preferred method for acquisition will be through exchange.

Exchanges (FLPMA Sections 205 and 206)

Exchange is the process of trading lands or interest in lands. BLM-administered public lands may be exchanged for lands or interests in non-federal lands owned by corporations, individuals, or government entities and located in the same state. Exchanges are the primary means by which land acquisition and disposal are carried out. Except for those exchanges that are congressionally mandated or judicially required, exchanges are voluntary and discretionary transactions with willing landowners. Exchanges must be of approximately equal monetary value and located

within the same state, be in the public's best interest and conform to applicable BLM land use plans and National BLM policy in BLM Manual 2200–1 Land Exchange Handbook, and meet the requirements of BLM Manual H-2104 Preacquisition Environmental Site Assessment.

Land exchanges are used to improve public lands and interests in land with high public resource management capabilities. Protecting resources and/or implementing management actions on acquired public lands or disposing of public lands that are difficult or expensive to manage, consolidating land and mineral ownership patterns to achieve more efficient management of resources and BLM programs, and disposing of land parcels identified for disposal through the planning process. Recent exchanges resulted in the acquisition of 9,906 acres of private land in the Cow Creek Breaks area and 1,600 acres adjacent to the Tongue River.

Federal law prohibits exchange of public lands in one state for private land in another unless authorized by an Act of Congress. Exchanges are to be of equal value, based on a fair market appraisal, and do not have to be of equal acreage. In other words, exchanges are made on a value-for-value basis rather than an acre-for-acre basis. Furthermore, land exchanges are a discretionary BLM action. The BLM is not obligated to process every proposal it receives, even if the proposal has some merit. The BLM evaluates exchange proposals in light of existing workloads, funding, and other program priorities when deciding to pursue a land exchange proposal.

Since 1985, the BFO has processed 17 land exchange cases under FLPMA section 206 involving approximately 55,000 acres of non-federal and federal lands. BLM acquired 15,321 acres. There are two exchanges pending. Land exchanges take considerable resource time and generally multiple years to complete. However, little focus on land exchanges in the planning area perpetuates the ongoing fractionated land ownership pattern and limited access to public lands. This creates higher costs for resource planning and administration, and provides little legal authority to obtain access from disinterested land owners.

Recreation and Public Purposes Act Leases and Conveyances

This act of June 14, 1926, as amended in 1988 (43 U.S.C. 869 et seq.), commonly known as the Recreation and Public Purposes Act, authorizes the Secretary of the Interior to lease or convey public lands for recreational and public purposes. The act also authorizes direct conveyance of public lands for solid waste disposal or any other purpose that could result in or include the disposal, placement, or release of any hazardous substance to state and local governments and to qualified non profit organizations. The BLM periodically reviews areas leased or conveyed under the act to ensure continued compliance with the associated terms and conditions. A lease can be terminated or a title to patented land can revert to the United States if the authorized entity is not complying with those terms.

To date, the BFO has issued R&PP patents for the Buffalo Housing Authority on one acre, the Buffalo Rifle Range on five acres, the Sheridan Recreation Complex on 560 acres, and the City of Buffalo Green Belt consisting of 260 acres. The BLM is considering one conveyance from the town of Kaycee for an R&PP sale for a shooting range.

Trespassing and Illegal Dumping

Trespass actions are uses of public land that occur or are ongoing without specific authorization, or that exceed the established thresholds of an authorization or of casual use. Casual use is defined by the regulations at 43 CFR 2920.0-5(k) as follows:

“Casual use means any short term noncommercial activity which does not cause appreciable damage or disturbance to the public lands, their resources or improvements, and which is not prohibited by closure of the lands to such activities.”

Trespass actions can cause damage to public lands and natural resources. The cost to resolve trespass and to clean up and reclaim the public land affected by trespass is often passed on to the general public. Trespass resolution involves cessation of the unauthorized use, and could require removal of the unauthorized facilities or appropriate authorization of that use. Three considerations are included in trespass abatement, as follows:

- Payment of the administrative costs to resolve the trespass
- Payment of fair market value for the period of unauthorized use
- Rehabilitation and restoration of the affected public lands

To date, there are approximately 49 identified cases of unauthorized use, occupancy, and development. Several unauthorized uses were informally identified in 2011 and the number is expected to increase substantially in the wake of the intense O&G development activities in the area.

Donations and Condemnations

The BLM occasionally receives gifts or donations of lands or interests in land where an entity elects not to receive the market value for the interests being conveyed. Donations are infrequent and cannot be planned for. They are sometimes used in conjunction with other acquisition tools to complete larger transactions. The BLM has not used condemnation in the Buffalo planning area. From the 1960s to 1972, the BFO received nine land donations totaling approximately 80 acres.

Withdrawals and Classifications

A withdrawal is a formal action that sets aside, withholds, or reserves federal lands for public purposes. Table 3.51, “Existing Withdrawals and Classifications in the Planning Area” (p. 565) displays the existing withdrawals and classifications in the planning area. Withdrawals accomplish one or more of the following:

- Transfer total or partial jurisdiction of federal land between federal agencies
- Segregate (close) federal land from operation of some or all of the public land laws and or mineral laws
- Dedicate federal land to a specific purpose

Table 3.51. Existing Withdrawals and Classifications in the Planning Area

Name	Acreage
Resource Protection	
Stock driveways	18,391
Winter Game Ranges	4,583
Classifications	
R&PP Classifications	0
Other Federal Agency Withdrawals	

Name	Acreage
Bureau of Land Management miscellaneous	968
U.S. Forest Service national recreation sites	3,823
U.S. Forest Service national forests	20,167
U.S. Department of Defense	3,733
Veteran's Administration	61
U.S. Bureau of Recreation Power Site Classification	6,831
Source: BLM 2010 	
Note: Due to overlapping resources, numbers are not additive.	
R&PP Recreation and Public Purpose	

Withdrawals are established for a wide range of public purposes, including military reservations, administrative sites, national parks and national forests, reclamation projects, recreation sites, stock driveways, and power and water site reserves. There are three major types of withdrawals, as follows: (1) Administrative withdrawals – those made by the President, the Secretary of the Interior, or some other authorized officer of the executive branch of the federal government; (2) Congressional withdrawals – withdrawals legislated by Congress; and (3) Federal Power Act (16 U.S.C. 791 et seq.) or Federal Energy Regulatory Commission withdrawals – power project withdrawals established under the authority of the Federal Power Act.

The BLM is responsible for reviewing all proposed administrative withdrawals and restorations; for making recommendations concerning those actions to the Assistant Secretary of the Interior; and for assisting other bureaus and agencies with their withdrawal and revocation programs.

The withdrawal review program is primarily aimed at existing administrative withdrawals and making recommendations concerning the extension, modification, or revocation of the withdrawals. Requirements of national laws and concerns about scarce resources or species in key areas with mineral potential, could justify withdrawal of the land from operation of the mining laws. Land uses can change when withdrawals are revoked. In part this is the result of opening the land to operation under the mining laws. Part of the review process for land withdrawals must include anticipation of any such land use changes.

Management decisions for withdrawals for surface and minerals are considered on a case-by-case basis. Withdrawals are used to segregate or reserve lands for a specific purpose or use. A withdrawal can also transfer jurisdiction of a tract of land under BLM jurisdiction to another federal agency. Withdrawals in the planning area also serve to protect public lands from operation of the public land laws, including the mining laws, but not including mineral leasing laws.

There are several withdrawals in the planning area serving various interests including several stock driveway withdrawals encompassing almost 18,391 acres. There are three crucial winter game ranges for big game in the planning area that the WGFD manages as a wildlife protective area through a cooperative agreement with the BLM. The Amsden Creek (approximately 3,905 acres) and Kerns (approximately 4,949 acres) winter game ranges, located west to northwest of Dayton, Wyoming, managed as a wildlife refuge area withdrawal and the Ed O. Taylor winter game range, formerly Middle Fork recreational withdrawal, (approximately 10,224 acres) is west of Kaycee, Wyoming. The withdrawal protects the Middle Fork area from mineral entry because this area has unique visual qualities, wildlife habitat, fisheries, and general outdoor recreational qualities.

Because the acquisition program is envisioned to be an ongoing effort, acquisitions through these tools would continue to improve management opportunities, to enhance recreation opportunities,

and to further resource preservation. Only very high priority exchanges and acquisitions will be possible. Furthermore, the existing plan contains a maintenance action that establishes criteria for evaluating acquisitions and sales. These criteria are reevaluated and modified in this plan revision.

3.6.2.4. Trends

Currently, there is a substantial need to consolidate land ownership patterns and access routes through sales, exchanges, and acquisitions. The BFO anticipates the land and realty program to be slightly more active during the period of the next plan than during the last 20 years in order to achieve an improved land ownership pattern across the planning area.

Land tenure adjustments (which include sale, acquisitions, and exchanges) in the planning area are rare due to the priority for O&G ROW activities over the last several years. However, addressing land tenure adjustments is necessary to improve access and management. Achieving an improved land ownership pattern will reduce management costs, reduce owner conflicts associated with multiple uses on public lands, reduce trespass, and improve a greater overall range of multiple-use opportunities.

Current land disposal consists of two pending land exchanges in the planning area. Current management challenges are primarily related to the focus on O&G authorizations and compliance monitoring. Improved public land tenure boundaries and access opportunities across private lands would facilitate a more efficient management framework. An active land tenure program would provide opportunities to consolidate land ownership patterns, and strengthen the BFO's ability to access these lands and efficiently manage resources for the protection, conservation, and multiple uses of public lands.

Trespass is an ongoing and increasing problem in the Buffalo planning area. Some types of known illegal activities include, but are not limited to, indiscriminate dumping of trash, debris, and household wastes; farming and irrigation of public land; corrals; fences; buildings and construction of roads and other utility-related features.

3.6.2.5. Key Features

The primary key feature is the land tenure pattern (ownership). Key areas in the planning area include:

- The southern region of the planning area, commonly known as the South Big Horns, encompasses resource values including cultural and historical properties, cave and karst sites, wildlife and livestock habitat, and recreation opportunities.
- The eastern region of the planning area is the most likely area for wind-energy development. The BFO manages many small, isolated, and difficult to access parcels in this area. Authorizations for uses on these parcels will likely result from continued O&G development and wind-energy development.
- The Powder River and Powder River Breaks, and the northern region of the planning area, encompass a variety of natural formations, include considerable wildlife and livestock habitats, contain considerable O&G resources (both federally and privately owned), and offer multiple recreation opportunities.
- Pumpkin Buttes is a natural feature in the center of the planning area that can be seen for miles around. This unique, culturally sensitive site is used for communications sites.

3.6.3. Renewable Energy

Information in this section includes a brief summary of the types of renewable energy (wind, solar, biomass, and geothermal), the demand for renewable energy, and federal direction for renewable energy (i.e., the National Energy Policy Act of 2005).

3.6.3.1. Regional Context

Renewable energy comes from replenishing sources like wind, sun, water, and heat generated from the earth. Wyoming is considered one of the most viable places in the country for energy development. The planning area has experienced intense O&G development activity. These activities are likely to continue into the foreseeable future. There is potential for energy development under new technologies, particularly using renewable energy sources. This will likely affect management actions in the planning area. According to the National Renewable Energy Laboratory (NREL), there is fair to good potential for wind-energy development, and fair potential for solar development. Conversely, there is very little potential for biomass or geothermal development in this area.

The Energy Policy Act of 2005, sections 221 through 237, addresses geothermal development; section 367 addresses ROW fees based on fair market value data. Other potential renewable energy sources not yet identified also would be supported in the planning area considering the use and its relation to other resource objectives and goals.

Section 211 of the Energy Policy Act of 2005 addresses wind-energy activities; implementation of EO 13212 (May 18, 2001) requires the BLM “to expedite projects that will increase the production, transmission, or conservation of energy.” IM 2009-043 is currently being updated and will provide guidance on implementing a ROD for the programmatic EIS on wind-energy development and guidance on processing ROW applications for wind-energy projects on BLM-administered lands and will be finalized by the time the final resource plan revision is in place.

3.6.3.2. Indicators

Indicators of the success of the renewable energy program would be the number of renewable energy ROW authorizations and the acreages involved.

3.6.3.3. Current Condition

Current management and development challenges are unknown because there have been no formal inquiries associated with renewable energy development in the planning area. Given that the area is considered to have moderate potential for wind- and solar-energy development, the BFO is open to these types of uses across the planning area into the foreseeable future. The planning area has not seen any solar renewable energy development, except for some individual solar panels that supplement electricity to individual O&G or water wells. This activity is minor compared to the potential within the planning area.

3.6.3.4. Trends

Considering nationwide and statewide trends to pursue clean energy resources, it is reasonable to expect that the BFO will see increased interest in renewable energy development in the future. Recent wind-energy development on private surface in the planning area suggests there will be interest in wind-energy development on public lands in the future. There is moderate potential for wind-energy development in the southern and southeastern regions of the Buffalo planning area.

3.6.3.5. Key Features

The most notable areas identified for wind-energy development are the southern region of the planning area and the southern Big Horn Mountains.

3.6.4. Rights-of-Way and Corridors

A ROW grant is an authorization to use portions of public land for specific facilities, utilities, or transportation for a specified period. The ROW program consists of the evaluation, authorization, and management of ROWs for a variety of uses on public land. Most authorizations extend over a 30 year period. ROWs are removed and reclaimed upon termination of the grant.

3.6.4.1. Regional Context

Revised Statute 2477 is a contentious issue with those attempting to utilize this statute to cross private lands for recreational purposes. The statute was passed to facilitate early western settlement. Its entire text is stated in one sentence: “the right-of-way for the construction of highways across public lands not otherwise reserved for public uses is hereby granted.” The FLPMA repealed Revised Statute 2477 and regulates ROW grants within the BLM.

3.6.4.2. Indicators

The number of ROWs issued, the types of ROWs, and the acreage involved will be the indicators for the success of the ROW program.

3.6.4.3. Current Condition

Most ROWs on BLM-administered lands in the planning area are associated with O&G development, electrical transmission, irrigation ditches, and communications. At present, the primary ROWs issued are for site facilities, reservoirs, O&G, water, electricity, and roads. The number of communication site ROWs continues to grow. Increasing populations and continued mineral development require utility ROWs to support those infrastructures. Also, changing telecommunications technology is increasing the need for more communication sites and fiber-optic routes. Access roads and utilities associated with development of private lands have become increasingly important. Authorizations must consider all other resource values and their locations.

See Table 3.52, “Existing ROWs in the Buffalo Field Office Planning Area” (p. 570) for a list of existing ROWs in the planning area.

Table 3.52. Existing ROWs in the Buffalo Field Office Planning Area

Existing Authorization	Number of Sites	Acres ¹
Roads ²	569	15,786
Pipelines/sites (mostly oil and gas related)	441	4,522
Powerlines/sites	435	2,740
Telephone/fiber-optic cables	55	173
Water facility ditches and reservoirs	120	1,077
Communication sites: concentration area south Middle Butte of Pumpkin Buttes	24	17
U.S. Forest Service easements/grants	14	3,289
Other	15	130
Total	1,673	27,734
Source: BLM 2010e		
¹ Right-of-way miles were not calculated because there are substantial numbers of existing supplemental uses in the grant information. LR2000 totals do not reflect these supplemental uses and therefore would not be accurate. As a result, the acres were calculated to provide an accurate calculation of actual surface disturbances. Numbers are current as of 2011.		
² Includes railroads and stations, federal highways, and material sites.		
ROW Right-of-Way		

The BFO authorizes most ROW disturbances within corridors by placing linear roads, pipelines, and electric lines alongside one another to the extent practical. Generally, the existing identified major corridor routes are localized to major traffic routes. The BFO will continue to coordinate disturbances among operators or development entities to keep disturbance corridors to a minimum. Achieving this will reduce fragmentation of wildlife habitat and surface disturbance.

Since fiscal year 1985, the BFO has processed more than 1,800 ROWs across almost 28,000 acres of public land. The 2001 RMP amendment identified 850 ROWs issued since 1985, a span of 16 years. The remaining 950 grants were processed after 2001. At present, there are approximately 1,673 authorized ROWs in the planning area.

3.6.4.4. Trends

The BFO historically managed ROWs related to livestock grazing and some O&G development. In recent years, CBNG development has dominated ROW activities, and this is likely to continue during the planning period.

The BFO will continue to coordinate disturbances among operators or development entities to keep disturbance corridors to a minimum. Achieving this will reduce fragmentation of wildlife habitat.

Current BLM policy is that using public lands for CCS purposes, which is the long-term isolation and storage of carbon (usually in the form of liquefied CO₂) underground, will be authorized as a Land Use Application and Permit (WO IM-2012-035). Interest suggests that the BFO may receive applications to inject CO₂ into pore spaces in the rocks below the surface. See Chapter 3 *Geological Resources* for more information regarding CCS, and the likely trend for these projects in the planning area. Land use authorizations would require rent on the entire subsurface space used and could encompass thousands of acres.

3.6.4.5. Key Features

Key features are the ROW Exclusion and Avoidance Areas within the planning area which have been specifically identified for the protection of other resources. Individual resource sections in Chapters 2 and 4 identify and address the protected areas.

3.6.5. Travel and Transportation Management

Travel management planning is the proactive management of public access in compliance with travel-related regulations and according to the best land use management principles. Travel management planning involves the following (Graves et al. 2006):

- A comprehensive approach that considers various aspects of road and trail system planning and management; natural resource management; road and trail design and maintenance; and recreation and non-recreation uses of roads and trails
- Route inventory and evaluation, innovative partnerships, user education, mapping, monitoring, signage, field presence, and law enforcement
- All resource aspects (recreational, traditional, casual, agricultural, industrial, educational, and cultural) and accompanying modes and conditions of travel on the public lands, including motorized, mechanized, and nonmotorized/mechanized uses

3.6.5.1. Regional Context

Travel and transportation decisions include allowable types of travel (over land, water, and snow, and by air), and modes and conditions of travel on public lands. Pivotal to the BLM strategy for managing public lands is maintaining and improving the BLM transportation system, which includes roads, bridges, trails, and related facilities in a manner that enhances accessibility, connectivity, and safety, while addressing public needs, preserving ecological functions, and fostering economic development (BLM 2001b). Map 60 illustrates the preliminary transportation network for the BFO. Maps 61 to 64 identify the transportation features in the Sheridan, Gillette, Wright, and Kaycee areas, respectively.

A well-functioning transportation system is essential for resource extraction, energy production, and recreational activities on BLM-administered lands. In addition to allowing the BLM to achieve its agency goals – sustaining the health, diversity, and economic vitality of our public lands – transportation enables ongoing contributions to the regional and national economies.

In BLM-administered areas where there are unique circumstances, high levels of controversy, or complex resource considerations, a Travel Management Area (TMA) may be delineated to address particular concerns and prescribe specific management actions for a defined geographic area. TMAs are areas where a rational approach has been taken to classify the area as Open, Closed, or Limited. An individual Special Recreation Management Area (SRMA) is often also a TMA.

3.6.5.2. Indicators

The indicator for the program is the increase or decrease in transportation routes or access opportunities to and on BLM-administered lands. TMAs are usually identified where travel and transportation management (either motorized or nonmotorized) require particular focus or increased intensity of management. While OHV-area designations are land use plan allocations, TMAs are planning-tool delineations (BLM 2007k). TMAs may be established during the

planning process or during the development of a Recreation Area Management Plan. All designated travel routes in TMAs should have a clearly identified and documented need and purpose, and clearly defined activity types, modes of travel, and seasons or timeframes for allowable access or other limitations.

3.6.5.3. Current Condition

County roads providing critical access to larger parcels of BLM-administered lands include Hazelton Road, Barnum Road, Mayoworth/Slip Road, Trabing Road, Tipperary Road, Sussex Road, Upper and Lower Powder River Road, Irigary Road, Schoonover Road, Napier Road, Bishop Road, and Elk Creek Road. Most county roads are also designated as stock driveways. The transportation infrastructure, traffic volume, and accident rates in the planning area are relatively low due to small populations in the counties.

At present, the BFO maintains 16.5 miles of roadways in the planning area. However, the much larger network of unimproved, two-track and industrial roads are not included in this figure. According to the 2003 PRB Final EIS, approximately 7,135 miles of new improved and 10,619 miles of two-track roads are being developed in conjunction with CBNG facilities, both on public and private lands. Some of these roads have not been constructed or maintained to BLM standards. In an effort to minimize road footprints and accommodate use, the BLM has previously issued decisions to allow roads that do not meet BLM standards. Over time, these roads have become a safety and resource concern. The potential for maintaining these roads to provide public access to public lands is uncertain at this time.

Travel Management and Off-Highway Vehicles

OHV use continues to increase in popularity and includes four-wheel-drive, sport utility, and all-terrain vehicles (ATVs). Typical recreational OHV activities in the planning area include exploring, ATV and motorcycle trail riding, and OHV use related to hunting. In addition, OHV use can provide access over long distances for hunters and subsequent nonmotorized recreational purposes such as fishing, hiking, mountain biking, horseback riding, and primitive camping opportunities. People with disabilities may be allowed to travel on OHVs in otherwise closed areas on a case-by-case basis with a permit from the WGFD and authorization from the BLM authorized officer. Table 3.53, “2010 Motorized and Nonmotorized Activities and Number of Participants in the Buffalo Planning Area, Wyoming” (p. 573) lists the numbers of participants in motorized and nonmotorized recreational activities.

Table 3.53. 2010 Motorized and Nonmotorized Activities and Number of Participants in the Buffalo Planning Area, Wyoming

Motorized Activities	Number of Participants
Driving for pleasure	2,682
Hunting – Big Game (assumes use of four-wheel-drive vehicles and ATVs)	10,150
OHV – ATV	3,105
OHV – cars, trucks, and sport utility vehicles	1,778
Nonmotorized Activities Requiring Vehicle Access	Number of Participants
Bicycling (Mountain & Road)	666
Fishing	3,104
Hiking, walking, and running	5,646
Horseback riding	1,048
Hunting – Small game, Upland Bird, Waterfowl, Other	1,765
Picnicking	2,984
Camping	2,720
Source: BLM 2011h	
ATV All terrain vehicle	
OHV Off-highway vehicle	

The road network in the planning area is comprised of a series of county roads, BLM-maintained roads, existing two-track roads, and snowmobile trails. The maintenance and use of these travel routes has become an integral part of public land management because these roads are used for both recreational and non-recreational purposes. Motorized off-road travel to perform necessary tasks and casual use, which includes activities such as retrieving big game kills, livestock management, and energy-related exploration, is currently allowed. Non-recreational OHV use in the planning area is predominately related to rangeland management and energy development and is usually managed under an authorization or permit. The BLM uses OHVs under administrative use for inspections, vegetative treatments, surveying, mapping, inventories, monitoring, fire suppression, and project construction and maintenance.

Travel Management Designations

The BLM must designate all public lands as Open, Closed, or Limited for OHV use. Area and trail designations are completed during the planning process and are limited to the following three management categories:

- *Open*: Areas used for intensive OHV use where there are no compelling resource needs, user conflicts, or public safety issues to warrant limiting cross-country travel. Areas where all types of vehicle use are permitted at all times anywhere in the area.
- *Limited*: Areas or trails where the BLM restricts OHV use to meet specific resource management objectives. These limitations can include limiting the time or numbers and types of vehicles; limiting the time or season of use; permitted, licensed use only; limiting to existing roads and trails; and limiting use to designated roads and trails. The BLM may place other limitations, as necessary, to protect other resources, particularly in areas that OHV enthusiasts use intensively or where they participate in competitive events.
- *Closed*: Areas where the BLM enforces a closure to all OHV use when it is necessary to protect resources, ensure visitor safety, or reduce conflicts, including units in the National Wilderness Preservation System. Access by means other than OHV (i.e., foot, horseback, and bicycle) is generally allowed.

Table 3.54, “OHV-Use Designations in the Planning Area” (p. 574) identifies the acreages of OHV-use designations in the planning area as identified in the existing plan.

Table 3.54. OHV-Use Designations in the Planning Area

Designation	Acreage
<i>Open areas:</i> Vehicle travel is permitted both on and off roads if the vehicle is operated responsibly in a manner unlikely to cause substantial undue damage to the environment.	20,386
<i>Closed areas:</i> Travel by vehicles, including snowmobiles, is prohibited.	3,650
<i>Limited areas A:</i> Use is limited to existing roads and vehicle routes in existence as of 1985.	566,184
<i>Limited areas B:</i> Use is limited to designated roads and vehicle routes in these areas. (Until signs are posted, vehicle travel is limited to existing roads and vehicle routes.)	170,982
<i>Limited areas C:</i> Vehicle travel is closed to all OHVs, including snowmobiles, from December 1 to April 15.	37,646
Total	798,848
Sources: BLM 2001a; BLM 2012f	
OHV Off-highway Vehicle	

Area designations are completed during the Land Use Planning process (this document) whereas trail designations are implementation level decisions complete through a variety of site specific decision making processes, including Travel Management Plans.

OHV Use and Environmental Concern

It is reasonable to expect impacts from OHV use to accumulate over time as visitation increases and new roads and trails develop. Dispersal of OHV use is directly related to the size and percentage of federal parcels in a given area and the ease of public access. Unregulated use can heavily impact popular areas (e.g., Weston Hills and Middle Fork Powder River area) with high concentrations of OHV use. Adverse impacts include habitat fragmentation, increased soil erosion, stream sedimentation, physical damage to vegetation, and damage to vegetative communities due to the spread of invasive plant species. Environments that are more susceptible to OHV-related damage include crucial winter ranges, wildlife breeding areas, riparian habitats, and areas with steep slopes, wetlands, and riparian areas or sensitive soils.

Current OHV management allows off-road and trail travel to perform necessary tasks and for casual use, which includes activities such as retrieving big game kills, livestock management, and energy-related exploration. Impacts related to necessary tasks and casual use are increased soil erosion, habitat fragmentation, route proliferation, visual degradation, and degradation of recreational settings.

The BLM objective is to improve a selective public lands transportation system that will contribute to a safe and adequate network of roads and trails to improve public access while protecting sensitive resources and reducing environmental impacts. Meeting current OHV management challenges will require the BLM to continue to gather data for needs analyses, coordinate with adjacent agencies and partners to improve consistency in transportation planning procedures and the designation and data needs, and to continue to provide updated and current transportation information and an improved road and trail system.

3.6.5.4. Trends

Prominent among the travel management issues the BLM faces is the complex challenge of managing motorized activities on public lands. The combined effect of population increases in the west, growth in the use of OHVs in the planning area over the last 10 years, and technological advances has generated increased social conflicts and resource impacts on public lands related to motorized recreation, and impacts to other recreation activities and resource uses.

Indiscriminate use of OHVs continues to increase, creating unauthorized pioneered trails. These trails can scar landscapes, dissect vital wildlife habitats, increase the degradation of cultural and paleontological resources, and cause increased erosion to fragile soils. The environmental impacts of OHV use are becoming apparent in the planning area, most notably in the Weston Hills Recreation Area and on BLM-administered lands in the southern Big Horn Mountains. The Powder River Breaks south of Interstate 90 also experience heavy vehicle traffic because the area is designated as Open for OHV use. OHV users often adopt routes created by necessary tasks and casual use and perceive them as existing routes. This trend creates an increase in roads and trails. In areas where vehicle use is limited to existing roads and trails, issues arise on user created routes because subsequent users can legally operate on non-designated routes.

3.6.5.5. Key Features

Open Areas

Both the 1985 RMP and 2001 Update designated 20,386 acres as Open, where vehicle travel is allowed both on and off roads if the vehicle is operated responsibly in a manner unlikely to cause substantial undue damage to the environment. These areas include all stock driveways and rests, and approximately 3,460 acres south of Interstate 90 at its junction with the Powder River.

Limited Areas

Approximately 97 percent (774,184 acres) of the planning area is designated as “limited to existing” or “limited to designated” roads and trails (Map 65). Although there are approximately 800,000 acres of BLM-administered land in the planning area, public access via motorized routes is only available to approximately 400,000 acres. The limited use designations were originally intended to allow OHV use without increasing the number of acres disturbed. Additionally, the designation of routes will assist in reducing physical impacts and conflicts between various uses. Recreational users within “limited” areas cannot travel off roads and trails except during the performance of “necessary tasks,” such as for game retrieval. Since the 1985 RMP and the 2001 Amendment, OHV use in the planning area has increased dramatically. OHV users are creating new trails every year, especially during the hunting season.

Closed Areas

Areas closed to all OHV use include 40 acres in the Dry Creek Petrified Tree EEA, 572 acres in Cantonment Reno, and 3,038 acres in Middle Fork Canyon. These areas have special resource concerns and were closed to OHVs as a protective measure. This management action has proven an effective way to protect cultural and natural resources from unnecessary degradation.

3.6.6. Recreation

As one of the DOI's four primary missions, recreation is an important BLM program. The primary mission of the outdoor recreation program is to provide a broad spectrum of resource-dependent recreational opportunities to meet the needs and demands of visitors to public lands. The Recreation and Visitor Services (R&VS) program also seeks to maintain high-quality recreation facilities that meet public needs and enhance the image of the agency, as well as to improve understanding of public land resources and foster support of the BLM by effectively communicating the agency's multiple-use management programs to the recreation visitor. *BLM's Priorities for Recreation and Visitor Services* (BLM 2007b) identifies seven objectives for the R&VS program. These include:

- Manage public lands for recreation experience and quality of life outcomes.
- Encourage sustainable travel and tourism development with gateway communities and provide community-based conservation support for visitor services.
- Provide fair value and return for recreation through fees and commercial services.
- Establish a comprehensive approach to travel management and planning.
- Ensure public health and safety, and improve the condition and accessibility of recreation sites and facilities.
- Enhance and expand visitor services, including interpretation, information and education.
- Encourage and sustain collaborative partnerships, volunteers and citizen-centered public service.

3.6.6.1. Regional Context

Recreation planning produces opportunities for visitors to experience desired physical and social outcomes. Recreational values are considered in management through the understanding that settings provide opportunities for experiences created by visitors and that a diversity of settings provides the basis for quality recreation experiences. The responsibility for managing for various types of settings lies with the land management agency. Settings are comprised of a variety of attributes such as biophysical (human-induced and natural environment), social (visitor type and density), and managerial (regulations and facilities). Each of these attributes differs, thus facilitating some experiences and hindering others. By providing a diversity of settings with varying attributes over space, and making visitors aware of those opportunities, public land managers ensure that visitors are capable of producing quality experiences (McCool et al. 2007). Decisions for the recreation program should be responsive to past changes and adaptive to future changes in technology, sources of information, demographics, and population dynamics.

Visitors come to the planning area from all over the United States and from international locations. The location of the planning area in relation to other natural areas (Yellowstone National Park and the Bighorn National Forest to the west, Montana to the north, the Black Hills to the east, and the Front Range to the south), the accessibility of the planning area via major interstate corridors, and the abundant natural and cultural resources of northeastern Wyoming drive visitation. Historically, the summer months of June through August receive the heaviest use related to non-consumptive recreation. Hunting season (September through November) also brings high visitation to the planning area, with the highest use occurring on large tracts of BLM-administered lands with public access. However, research predicts that as the retirement population in the United States increases, many public lands will experience more consistent year-round use as retired visitors exercise the ability to travel and recreate year-round (McCool et al. 2007). According to the Wyoming Office of Tourism, key activities that motivate people to

choose Wyoming include scenery and natural experiences. More than half of the visitors in the 2012 Visitor Profile Report participated in hiking or backpacking and more than a third reported engaging in wildlife watching (Wyoming Office of Tourism 2012).

Recreation on public lands provides regional economic benefits. Recreation service providers (e.g., hotels, outfitters, equipment manufacturers and dealers, and restaurants) depend in part on public lands for their livelihoods. The Bureau of Labor Statistics predicts a 19 percent increase in recreation-related jobs between 2010 and 2020 (Bureau of Labor Statistics 2012c). Many recreation-related jobs depend on public lands, including BLM-administered lands. Protecting recreation resources could benefit the future of the recreation and tourism industry. One study (Sonoran Institute 2006) showed that annual expenditures from hunting and fishing in Wyoming exceeded \$335 million and that hunters spent 74 percent of their hunting days (960,000 days) on public lands. A 2009 Wyoming Travel Impact Report estimates that travel and tourism to Wyoming generated more than \$3.1 billion in direct spending and resulted in \$128 million in state and local tax revenues and supported approximately 30,500 jobs (with earnings of \$761 million) for Wyoming residents (Dean Runyan Associates 2013).

Recreational opportunities are offered to the public on BLM-administered lands in the planning area where there is legal access. The BLM provides opportunities for outdoor recreation and nature-based tourism using the concept of multiple-use management. Research and regional scoping meetings have identified that the public values natural landscapes, the freedom to choose a particular activity in which to participate, the opportunity to test skills, time spent with family and friends, and the opportunity for discovery. In addition, Johnson and Sheridan counties were identified as non-metropolitan counties with “significant concentrations of recreational activity” and recreation-driven economic growth (Johnson and Beale 2002).

3.6.6.2. Indicators

The indicator for the recreation program is the ability to provide a spectrum of recreation opportunities (i.e., primitive, developed, extractive and non-extractive) on BLM-administered lands. Visitor satisfaction can often identify when and where additional opportunities are necessary.

3.6.6.3. Current Condition

The approximately 800,000 acres of BLM surface in the planning area receive in excess of an estimated 30,000 recreation visits per year since 2010 (BLM 2013l). The towns of Sheridan, Buffalo, Gillette, Arvada and Kaycee are adjacent to public lands used by local residents as community recreation areas. Visitation to Mosier Gulch, Welch Ranch, Dry Creek Petrified Tree, Weston Hills and Burnt Hollow predominately consists of local residents. Middle Fork and Hole-in-the-Wall draw visitation from a much broader region; it is not uncommon to find visitors from Colorado, Nebraska and Montana at Outlaw Cave. Both the southern Big Horns and the PRB attract many out-of-state hunters to BLM recreation sites and tracts with public access. Hunting associated with commercial guides also occurs on public lands without public access.

The BFO recreation program is responsible for maintaining developed recreation sites ranging from minor access route improvements to trailheads, primitive campgrounds, and day-use areas. The BLM posts public and private land boundaries, interprets resources, and provides regulatory and informational kiosks in high-use areas. Detailed information is available to the public via informational pamphlets, land ownership maps, and online websites. BLM personnel encourage

the principles of programs such as Leave No Trace and TREAD Lightly! through public outreach. Law enforcement is also an integral part of the recreation program.

Several developed recreation sites in the planning area are closed to livestock grazing (Mosier Gulch, Dry Creek Petrified Tree EEA). Additionally, the discharge or use of firearms, weapons, and fireworks within developed recreation sites is prohibited per 43 CFR 8365.2-5(a). Prohibiting the discharge of projectiles and weapons at developed recreation sites not only prevents damage to facilities (signs, picnic tables, etc.), but it also reduces the possibility of accidental injury to other visiting recreationists.

Monitoring and enforcement of dispersed recreation is severely limited, especially in areas with a small percentage of public lands and limited access. The BLM depends on cooperation from public land users and other federal and state agencies for successful management of these areas. Cooperation from public land users is received through voluntary compliance with regulations and contributions of noncompliance information. The WGFD and local law enforcement agencies help provide an official presence that would otherwise not be available. Management prescriptions emphasize monitoring, education, and enforcement to reduce user conflicts and provide resource protection.

Most of the complaints the BLM has received involves illegal posting or otherwise restricting public access to federal lands, trespass onto private lands, vandalism to vegetation and soils, illegal dumping and failure to maintain roads. In addition, the BLM has received complaints about unpermitted outfitters and guides, and the careless discharge of weapons near infrastructure associated with various developments. All complaints are investigated or handled on a case-by-case basis.

Special Recreation Permits

The BFO issues an assortment of special recreation permits (SRPs) for commercial, competitive, or organized recreational uses of public lands. The BFO currently manages 46 SRPs; the majority are for commercial outfitting and guide services. Fees collected from SRPs average between \$10,000 and \$12,000 per year and are used to improve facilities or support programs within the planning area.

Undeveloped/Dispersed Recreation

Dispersed recreation occurs throughout the planning area over a wide range of ecosystem types. Occurring in combination with other resource activities, dispersed recreation includes but is not limited to hunting, camping, hiking, sightseeing, OHV use, vehicle touring, backpacking, horseback riding, photography, wildlife viewing, geo-caching, and fishing, boating, and other water-related activities.

Hunting, camping, fishing, and vehicle touring are among the most common recreational activities on BLM-administered public lands in the Buffalo planning area. All BLM-administered lands allow for hunting and many areas are open to target shooting unless posted otherwise. Restrictions on gun use include a prohibition on shooting within developed recreation sites and areas and upon, along or across roadways. Vehicle touring is generally in conjunction with hunting, fishing, rock hounding, equestrian use, camping, or hiking. During hunting season, there is an increase in use of motorized vehicles throughout the planning area.

By definition, dispersed recreation is comprised of small events distributed over large areas. Impacts such as minor disturbances to soil and vegetation are negligible and the environment tends to recover quickly. However, long-term cumulative impacts could occur in association with dispersed recreational activities. They are normally, but not exclusively, linked to heavily used areas and could include soil compaction and erosion, dispersal of invasive plant species, the creation of unauthorized two-track roads and trails, and the purposeful vandalism of natural and cultural resources. Over time, recreational activities could adversely impact sensitive soils, wildlife habitat, riparian areas, and important cultural and historical sites.

Recreation Management Areas

A recreation management area (RMA) is a land unit where R&VS objectives are recognized as a primary resource management consideration and specific management is required to protect the recreation opportunities. The RMA designation is based on: recreation demand and issues, recreation setting characteristics, resolving use/user conflicts, compatibility with other resource uses, and resource protection needs. A RMA is designated as either a SRMA or an extensive recreation management area (ERMA). SRMAs recognize unique and distinctive recreation values and are managed to enhance a targeted set of activities, experiences, benefits, and recreation setting characteristics, which become the priority management focus. ERMAs recognize existing recreation use, demand, or R&VS program investments and are managed to sustain principal recreation activities and associated qualities and conditions of the ERMA, commensurate management with other resources and resource uses.

Both SRMAs and ERMAs must have measurable objectives. SRMAs are recognized as the predominant land use plans focus for R&VS, where specific recreation opportunities and recreation setting characteristics are managed and protected on a long-term basis. Therefore, in SRMAs, the identification of recreation as the “predominant use” could constrain other uses and resources. ERMAs, in contrast, are managed commensurate with the management of other resources and resource uses. Thus, the essential difference between SRMAs and ERMAs is not necessarily the level of visitor use or necessary investment on the part of the BLM, but whether the area is to be managed with recreation as the predominant use (i.e., SRMA) or recreation is to be managed as a commensurate use with other resources or resource uses (i.e., ERMA).

Special Recreation Management Areas

SRMAs are an administrative unit where the existing or proposed recreation opportunities and recreation setting characteristics are recognized for their unique value, importance and/or distinctiveness, especially as compared to other areas used for recreation. These areas are identified during the resource management planning process and are traditionally areas that experience higher recreation use, require extra recreation investment, or need more intensive recreation management. The 1985 Buffalo RMP and the 2001 RMP Update did not designate any SRMAs. However, the 1985 RMP did designate the following two parcels as recreation areas:

- Weston Hills Recreation Area – Parts of this area are managed as undeveloped and developed recreation areas. Weston Hills is open to motorized vehicle use, and common activities include mountain biking, camping, hiking, horseback riding, big game hunting, and OHV use (ATVs and four-wheel-drive vehicles).
- Mosier Gulch Recreation Area – This area is managed as a developed recreation area. Mosier Gulch is open to motorized vehicle use, and common activities include fishing, hiking, mountain biking, picnicking, and wildlife viewing.

The 2001 RMP Update also prioritized recreation and prescribed management objectives in the Middle Fork, Dry Creek Petrified Tree, Weston Hills, and Mosier Gulch management areas and for the Gardner Mountain Trail. Management of recreation values or interpretive materials was also specifically addressed for Fortification Creek, Cantonment Reno and Crazy Woman Battle Site.

Two recreation sites, Burnt Hollow and Welch Ranch, were acquired after the RMP was last updated or amended. Recreation management was prioritized for both of these sites in site-specific management plans.

Based on visitor use, recreation setting, and desired future conditions identified in land use plans, there are seven areas in the planning area equivalent to SRMAs (Table 3.55, “Special Recreation Management Area Equivalents in the Planning Area” (p. 580)).

Table 3.55. Special Recreation Management Area Equivalents in the Planning Area

Recreation Management Area
Burnt Hollow
Dry Creek Petrified Tree
Middle Fork Powder River
Mosier Gulch
Welch Ranch
Weston Hills

Extensive Recreation Management Areas

ERMAs are an administrative unit that requires specific management consideration in order to address recreation use, demand, or R&VS program investments. ERMAs are managed to support and sustain the principal recreation activities and the associated qualities and conditions of the ERMA. Management in all ERMAs is focused on custodial implementation actions that address visitor health and safety, user conflicts, resource protection issues, and maintaining access or appropriate activity participation. The BLM often designates multiple ERMAs in a planning area based on homogenous land type or recreational opportunity factors across a large area. Lands with public access are available for dispersed recreational use by the general public. Actions proposed under other resource management programs will generally affect the recreation resource more substantially in areas with legal public access.

Public Lands Not Designated as Recreation Management Areas

Public lands that are not designated as SRMAs or ERMAs are managed to meet basic R&VS and resource stewardship needs. Recreation is not emphasized, however recreation activities may occur (except on any lands closed to public use). Currently, there are no lands identified as closed to public entry or use in the planning area. The R&VS for lands outside of RMAs are managed to allow recreation uses that are not in conflict with the primary uses of these lands. In general, these lands in the planning area will include BLM-administered parcels without legal public access. Recreation can and often does occur on lands without public access; these parcels are primarily used for recreation by adjacent private landowners or commercial outfitters and guides operating under a SRP.

3.6.6.4. Trends

Management practices change over time as social priorities shift and new scientific knowledge enhances the ability to responsibly manage differing land uses. Visitor use estimates for the planning area indicate a recent substantial increase in the number of visits to public lands in the planning area, from an estimated 20,500 visits per year in 2005 to nearly 38,700 visits per year in 2012 (BLM 2011h; BLM 2013l). Over the past 20 years, there has been a major shift in the way land management agencies view outdoor recreation. Public lands have always provided recreation opportunities. However, outdoor recreation is now recognized as an important land use providing social and economic benefits on national, regional, and local levels.

Recreation demands are expected to increase in conjunction with population. Increased public demand for the services provided by commercial, competitive, and organized activities on public lands is also anticipated. Recent studies indicate that Americans are participating in increasing numbers in recreational pursuits that natural areas and public lands provide. Both the total number of Americans and the total number of days annually in which we participate in nature-based recreation have grown substantially in the past 20 years (Cordell 2012). In particular, non-consumptive wildlife-based recreation (such as nature viewing and photography), have grown strongly, as have the number of days Americans spend primitive camping and backpacking. Participation in motorized recreational opportunities such as four-wheeling and off-road driving have also increased (Cordell 2012).

3.6.6.5. Key Features

The following paragraphs describe several features of particular importance to recreation on BLM-administered lands in the planning area. The BLM will use these key areas to shape management allocations and recreation management decisions during the planning process.

BLM-Administered Lands Adjacent to Walk-In Hunting or Fishing Areas

WGFD manages the Private Lands Public Wildlife Access program to improve public access for hunting and fishing opportunities. Walk-in agreements are negotiated between WGFD and private landowners for a specific period of time, usually several years, and thus the status of an access areas can change during the life of this plan. BLM-administered lands adjacent to Walk-In Areas provide additional access and hunting and fishing opportunities for recreationists. While the WGFD and the adjacent private landowner have authority over any lands enrolled in the program, the BLM can support the objectives of the Private Lands Public Wildlife Access program through collaborative management.

Burnt Hollow

Burnt Hollow Management Area (BHMA) consists of approximately 18,000 acres of public land accessible via State Highway 59 North approximately 20 miles northeast of Gillette, Wyoming. The management area includes Cow Creek Breaks. Highway 59 borders approximately 2.4 miles of the area, providing public access. There are two developed parking areas along this route. There is an undeveloped parking area on state land at the northeast end of the area. This parking area is accessed via Cow Creek Road, which runs for 1.9 miles along the Burnt Hollow boundary.

The area offers varied topography, including rolling sagebrush-grasslands, steep precipitous drainages, scoria buttes, and clayey outcrops with juniper and ponderosa pine uplands. Several intermittent drainages contain plains cottonwood and junipers. Springs and small wetlands are scattered throughout the BHMA. Livestock grazing, wildlife habitat, and limited mineral development are the historic land uses.

The few existing two-track roads in the BHMA were created for mineral exploration and livestock management and are only open for motorized use under administrative and permitted actions. The BHMA features opportunities for nonmotorized dispersed recreation, including camping, mountain bicycling, environmental education, hiking, horseback riding, small- and big-game hunting, picnicking, and wildlife viewing. Overnight camping and campfires are prohibited in the developed parking areas. The management area is closed to target shooting.

Cabin Canyon

The Cabin Canyon area is located off of Bishop Road approximately 22 miles southeast of Gillette, and is a 1,369 acre parcel with public lands surrounded by approximately 2,460 acres of adjacent state lands. The area has experienced increased motorized use, both on and off designated routes. Current uses are predominately mineral extraction and grazing, but motorized recreational use is slowly increasing. Recent complaints from the public regarding the proliferation of user created routes, litter, recreational shooting, established campsites, and other activities have increased education and enforcement efforts in this area.

Dry Creek Petrified Tree Environmental Education Area

The Dry Creek Petrified Tree management area is a 2,567 acre environmental education site primarily used by tourists and students. The area highlights 60 million year old remnants of petrified Metasequoia trees within red sage hills and sagebrush country. The area is approximately 8 miles east of Buffalo, Wyoming, and access is via Johnson County's Tipperary Road. The area includes a developed parking area with an outdoor toilet accessible to people with physical disabilities. The Dry Creek Petrified Tree EEA has an 0.75 mile interpretive trail; signs identifying the area and its unique values are posted on the site. The area is open to nonmotorized recreation opportunities, including cycling, hiking, and small- and big-game hunting. Open fires and discharge or use of fireworks, firearms or weapons are not allowed in the developed parking area or the interpretive site (43 CFR 8365.2). Vehicle access into the area is allowed for administrative purposes and livestock operations along existing primitive resource roads; these roads are open to nonmotorized use by the public. Vehicle use beyond the parking area is prohibited.

Hole-in-the-Wall

The Hole-In-The-Wall is part of a colorful and scenic red sandstone escarpment known as the Red Wall. The area is a historic site on BLM-administered land approximately 16 miles southwest of Kaycee, Wyoming. The area is accessible via trailheads along Natrona County 105/Bufalo Creek Road; however, vehicle access to Hole-In-The-Wall proper is limited due to land ownership patterns. The location is best known for legends of outlaw activity in the late 1800s, most notably involving Butch Cassidy and the Wild Bunch Gang. The area includes a public viewing and parking area and trailhead, with interpretive signs. More than 2.5 miles of trails are open to nonmotorized use. The surrounding area is open to motorized dispersed recreation where designated, including driving for pleasure along Johnson County roads.

Kaycee Stockrest

The BLM administers approximately 2,685 acres just northwest of the city of Kaycee. Public access is available via Highway 191 or a public easement issued to Johnson County. Approximately 200 acres is a designated stockrest. This unit has historically been used for recreational target shooting and OHV riding by local residents. The BLM received a proposal for consideration of the development of a shooting range at the site in 2009. An additional 2,485 acre parcel provides some hunting opportunities during the fall.

Middle Fork Recreation Area and Outlaw Cave

The Middle Fork Recreation Area is a spectacularly scenic part of the Old West encompassing approximately 10,083 acres. The Middle Fork area is topographically diverse, ranging in elevation from 5,000 to 8,000 feet, with numerous steep incised canyons, a red sandstone escarpment known as the Red Wall, and open grassland parks interspersed with ponderosa pine, Douglas fir, and limber pine forests. The wildlife found here are just as varied – elk, mule deer, pronghorn, mountain lions, eagles, and other small mammals and rodents. The Middle Fork Powder River is a blue ribbon trout stream containing brown and rainbow trout. The area includes the Ed O. Taylor Wildlife Habitat Area managed by the WGFD.

The Middle Fork area is approximately 20 miles southwest of Kaycee, Wyoming, and is accessible via State Highway 190 and Barnum Road. Multiple named roads provide approximately 50 miles of access routes to the area, including Barnum Mountain Road, Outlaw Cave Road, South Slope Road, Bachus Pasture Road, Buffalo Creek Road, Hazelton Road, and Bar C Road. There are another 18 miles of primitive access roads in the SRMA; however, vehicle and OHV use is allowed only on designated trails. The area is open to motorized and nonmotorized recreation opportunities such as camping, freshwater fishing, cycling, hiking, big-game hunting, and OHV (ATV and four-wheel-drive vehicles) use on designated routes.

Outlaw Cave is in the Middle Fork Recreation Area and has 0.5 mile of access road to a developed campground. There is approximately 1 mile of hiking trails to access the Middle Fork Powder River via the Middle Fork Canyon trail. An outhouse is provided; however there is no potable water at the campground. The site includes picnic tables and fire rings. A fire swept through the area in 2006, taking many of the mature trees. The area also contains archeological sites dating back to the prehistoric period, including stone circles, quarry sites, rock art, and curious petroglyphs.

Mosier Gulch

The Mosier Gulch Recreation Area is an approximately 1,026-acre parcel accessed via State Highway 16 West approximately 3 miles west of Buffalo, Wyoming. Approximately 0.5 mile of improved resource road provides access into the area's two developed parking areas. An outdoor toilet is available and is accessible to people with physical disabilities. A hand-pumping water well and four picnic sites with tables and grills provide opportunities for picnicking. There are two undeveloped parking areas. An interpretive sign that identifies the area and its facilities is posted on the site. Overnight camping, open fires, and the discharge of fire arms are prohibited in the parking or picnic areas. The area is closed to motorized use beyond the improved access road. The area is open to nonmotorized recreation opportunities including picnicking, freshwater fishing, hiking, and small- and big-game hunting.

North Bighorns Parcels

The BLM manages approximately 2,926 acres 13 parcels ranging from 40 acres to 650 acres adjacent to the Bighorn National Forest in Sheridan County, and one 40 acre parcel along Keystone Road. Public access to these parcels includes Highway 14, Smith Creek Road, Red Grade Road, Keystone Road, Little Goose Creek Road, and walk-in access from the national forest. Recreational use, including staging and riding of OHVs on parcels adjacent to public roads is known to occur.

Trails

In addition to designated OHV trails (see the *Travel and Transportation Management* section above), there are several trails for nonmotorized use in the planning area. Developed hiking trails in the planning area include Gardner Mountain Foot and Horse Trail, Hole-in-the-Wall Trail, Outlaw Cave Fishing Access Trails, the interpretive trail at the Dry Creek Petrified Tree EEA, and Poison Creek Trail.

Welch Ranch

The Welch Ranch Management Area is a 1,748-acre parcel approximately 10 miles north of Sheridan, Wyoming. Welch Ranch is in the PRB, a part of the Northern Great Plains, which includes most of northeastern Wyoming and a portion of southeastern Montana. The Big Horn Mountains are within sight of Welch Ranch to the west. The Welch Ranch area is accessible from Sheridan via Wyoming State Highway 338 (Decker Road). There are two developed parking areas at the junction of Highway 338 and the Tongue River, with directional signs identifying the area. The few existing two-track roads in the Welch Ranch area were originally created for mineral development and livestock management and are currently only open for motorized use under administrative and permitted actions.

Welch Ranch occupies a portion of the Tongue River valley floor and the adjacent dissected uplands between Ash Creek and Hidden Water Creek. Approximately 1.5 miles of the Tongue River run through the eastern portion of the Welch Ranch area. There is a coal seam fire on a ridge in the southwestern corner of Welch Ranch. Evidence of historic wildland fire is apparent from several fire events in the past few decades.

The area offers nonmotorized dispersed recreation, including camping, mountain bicycling, fishing, hiking, horseback riding, small- and big-game hunting, upland bird hunting, picnicking, wildlife viewing, bird watching, and float trips. Motorized use and target shooting are prohibited in the management area. Overnight camping, open fires, and discharge or use of fireworks, firearms, or weapons are prohibited in the developed parking area (43 CFR 8365.2).

Weston Hills

The Weston Hills area consists of approximately 9,500 acres of BLM surface lands adjoining the Thunder Basin National Grassland. The USFS jointly manages Weston Hills. The area is 25 miles northeast of Gillette, Wyoming, and accessible via State Highway 59 North.

Elevations in the Weston Hills Recreation Area range from 3,800 feet to more than 4,500 feet. The lower elevations are grasslands with some juniper, while the upper elevations are ponderosa

pine-covered hills and steep drainages interspersed with meadows and scoria outcrops. From vantage points in Weston Hills Recreation Area, one can see the Big Horn Mountains to the west and Devil's Tower to the east.

There are 5.9 miles of improved resource roads into the SRMA with two parking areas, both on USFS surface. One parking area is unimproved; the other is improved with an outdoor toilet accessible by people with physical disabilities. There also is a warm-water fishing pond at the site. The area is open to motorized and nonmotorized recreation opportunities, including mountain biking, hiking, horseback riding, small- and big-game hunting, fishing, and OHV use. Target shooting is prohibited on the Thunder Basin National Grassland and a temporary shooting closure was implemented on BLM-administered lands at Weston Hills in 2008. There are approximately 10 miles of primitive roads and OHV trails with use restricted to marked routes only. There are another 6.4 miles of trails open to nonmotorized use.

3.6.7. Lands with Wilderness Characteristics

Managing the wilderness resource is part of the BLM's multiple use mission. Lands with wilderness characteristics are parcels that meet a size requirement of 5,000 acres (or exception criteria) and contain naturalness and either outstanding opportunities for solitude or primitive and unconfined recreation. In addition, they may also possess supplemental values (e.g., ecological, geological, or other features of scientific, educational, scenic, or historical value). They are identified through a process described in BLM Manual 6310 – Conducting Wilderness Characteristics Inventory on BLM Lands and considered in the land use planning process under BLM Manual 6320 – Considering Lands with Wilderness Characteristics in the BLM Land Use Planning Process (BLM 2012b).

Under FLPMA section 201, the BLM keeps an updated inventory of the lands with wilderness characteristics resource and considers new information related to wilderness characteristics when preparing land use plans. Lands with wilderness characteristics may be managed to protect and preserve some or all of those characteristics through a land use planning process. Citizens' Wilderness Proposals (CWPs), new acquisitions, and contiguous areas of BLM surface with at least 5,000 roadless acres are considered for their potential wilderness character.

The Buffalo planning area contains three WSAs that have been previously inventoried and determined to possess wilderness characteristics (see the *Wilderness Study Areas* section of this chapter). The *Lands with Wilderness Characteristics* resource analysis is limited to areas outside of designated WSAs.

3.6.7.1. Regional Context

Initial inventories for lands potentially containing wilderness characteristics in the planning area were completed in 1978. Lands that clearly and obviously did not contain wilderness characteristics were then released from further consideration, and lands potentially containing wilderness characteristics underwent an intensive inventory. In 1979, intensive inventories were completed for three units in the BFO: Fortification Creek, Gardner Mountain, and North Fork. In the BFO, portions of these three areas were determined to meet the size and naturalness criterion and were submitted to Congress as WSAs. All other parcels were determined to lack wilderness characteristics according to the 1979 report.

3.6.7.2. Indicators

A wilderness inventory evaluates wilderness characteristics as defined in Section 2(c) of the Wilderness Act of 1964, and incorporated in FLPMA. Guidelines for producing an inventory of wilderness characteristics are specified in BLM Manual 6310 – Conducting Wilderness Characteristics Inventory on BLM Lands. In order for an area to be classified as **lands with wilderness characteristics**, it must possess sufficient size (or meet size exception criteria), naturalness, and outstanding opportunities for either solitude or primitive and unconfined recreation. In addition, it may also possess supplemental values. While the BLM is precluded from establishing any new WSAs or modifying existing WSAs during the planning process (BLM 2012c), the agency is required to consider wilderness characteristics in the planning process. When such lands are present, the BLM examines options for managing these lands and determines the most appropriate land use allocations for them. Thus, **lands with wilderness characteristics** are managed under administrative prescriptions analyzed in a land use plan, and, **in contrast to WSAs**, are not Congressionally mandated.

3.6.7.3. Current Condition

In February 2004, the BLM received a document entitled *Wilderness at Risk-The Citizens' Wilderness Proposal for Wyoming BLM Lands* (Updated Version) submitted by a consortium of organizations led by the Wyoming Wilderness Association (Howell 2004), an updated version of a previous document known as the *Citizens' Wilderness Proposal* (Wyoming Wilderness Coalition 1994). The proposal requests additional acres surrounding each of the three existing WSAs be protected as wilderness.

The Wyoming Wilderness Coalition proposes:

- **Approximately** 7,133 acres be added to the existing Fortification Creek WSA
- **Approximately** 10,181 acres be added to the existing Gardner Mountain WSA
- **Approximately** 3,388 acres be added to the existing North Fork WSA

For each of the above proposals, the document summarizes the highlights, location and access, wilderness qualities, resource analysis, and proposes boundaries and management recommendations. In summary, the CWP recommends additional acres in the Fortification Creek area for its “unique topography and truly western scenery;” additional acres in the Gardner Mountain area because of its “impressive historical legacy and terrific wildlife habitat;” and additional acres in the North Fork Powder River area for its “unsurpassed delicate beauty, impressive environment, and outstanding fishery” (Howell 2004).

Lands with Wilderness Characteristics Inventory Summaries

All contiguous blocks of BLM-administered lands greater than 5,000 acres or potentially meeting exception criteria were assessed through interdisciplinary review. Those parcels containing extensive O&G development, public roads, or having documentation of multiple constructed and maintained roads were eliminated from further consideration. Remaining parcels were inventoried for wilderness characteristics. A summary of the findings is presented below; detailed information is contained within the permanent documentation file for each wilderness characteristics inventory (BLM 2013f).

Gardner Mountain Citizens' Wilderness Proposal and Adjacent BLM-Administered Lands (WY-060-201)

The Gardner Mountain CWP (10,181 acres) and additional contiguous BLM-administered lands (~13,000 acres) were inventoried in 2011 and 2012 (BLM 2013f). The unit consists of BLM-administered lands south of the Slip Road and north of Barnum and Brock roads. In total, the 23,380 acres inventoried in the Gardner Mountain region did not meet the naturalness criteria. It was therefore determined that the Gardner Mountain inventory unit does not contain wilderness characteristics, and will not be carried forward in the alternative process.

North Fork Citizens' Wilderness Proposal (WY-060-202)

The North Fork CWP and additional contiguous BLM-administered lands were inventoried in 2011 and 2012 (BLM 2013f). The CWP totals approximately 3,470 acres as well as the WSA. Contiguous BLM-administered lands outside of the CWP, including the Horn encompass approximately 3,100 acres. In total, the 6,548 acres inventoried in the North Fork region did not meet the naturalness criteria. It was therefore determined that the North Fork inventory unit does not contain wilderness characteristics, and will not be carried forward in the alternative process.

Face of the Bighorns (WY-060-203)

The BLM documented consideration of a portion of the Face of the Bighorns in 1979 and decided against completion of an intensive inventory of the area at that time. The BLM determined that the area did not have potential for wilderness, but the rationale for the initial determinations were inconsistent with current guidance. The Face of the Bighorns was inventoried in 2011 and determined to meet the size and naturalness criteria and possess outstanding opportunities for both solitude and primitive and unconfined recreation.

Fortification Creek Citizens' Wilderness Proposal (WY-060-204)

The Fortification Creek CWP was inventoried in the summer and fall of 2010 (BLM 2011c; BLM 2013f). The CWP was separated into two sub-units for inventory purposes based on maintained roads and the configuration of the CWP in relation to the WSA. The Southeastern sub-unit totals approximately 1,705 acres and did not meet the size requirements or exceptions. Due to O&G activities and existing roads, the area did not appear to be natural. The Western sub-unit totals approximately 5,420 acres and meets the size requirements for consideration. The Fortification Creek Western sub-unit did not meet the naturalness criteria; when mechanically constructed and maintained roads are considered the unit does not contain 5,000 roadless acres. It was therefore determined that the Fortification Creek CWP does not contain wilderness characteristics, and will not be carried forward in the alternative process.

New Acquisitions

The BLM has made several acquisitions since the 1985 RMP. The Welch Ranch (1,747 acres) does not meet the size or exception criteria and was not analyzed further. The BLM has acquired two parcels (Collins Land Exchange at Weston Hills and 60 Bar Exchange at BHMA) in northern Campbell County that resulted in BLM parcels meeting the size requirement and were considered for potential wilderness characteristics. However, the levels of historic O&G development coupled with the presence of nearby state highways and county roads, extensive route networks and the current levels of motorized use at these two parcels led our interdisciplinary team to determine that further analysis was not necessary. The new acquisitions did not contain wilderness characteristics and therefore will not be carried forward in the alternative process.

3.6.7.4. Trends

Lands with wilderness characteristics are considered to be a diminishing resource nationwide. The planning area has experienced an increase in visitation since 2006 (BLM 2011h). The region has also experienced an increase in development and other multiple uses with an emphasis on mineral extraction, agricultural use, and both motorized and nonmotorized recreation opportunities.

3.6.7.5. Key Features

The one lands with wilderness characteristics unit (WY-060-203) determined to possess wilderness characteristics is located along the ridgeline of the southern Big Horn Mountains in Johnson County, Wyoming (BLM 2013f). The area was proposed as the Face of the Bighorns Area of Critical Environmental Concern (ACEC) by citizen's groups, but did not meet the relevance and importance criteria for ACEC designation (BLM 2003c). The area does meet the lands with wilderness characteristics criteria for size, naturalness and outstanding opportunities for both solitude and primitive and unconfined recreation. The vegetation and topography include forests, meadows, rock-outcroppings, and steep mountain slopes. Elevations within the unit range from approximately 5,250 feet to 7,580 feet. Slopes exceed 30 percent in much of the area, reducing the potential for issuing ROWs, constructing roads or permitting the associated economic recovery of timber. Portions of this unit are designated as important to various wildlife, particularly elk. The area does not contain any existing O&G leases, is outside of the assessment area for CBNG (very low potential), and has no conventional O&G potential.

Manageability of portions of the lands with wilderness characteristics unit may be difficult, particularly in the extreme northern portion of the unit along Billy Creek Road. The northern portion of the unit is adjacent to numerous summer homes and cabins, creating a wildland-urban interface that may require mechanical thinning to prevent wildfire. The Billy Creek Road is a cherry-stemmed route in the northwestern portion of the unit. The BLM manages a nonmotorized trail, the Poison Creek Trail, to provide hiking opportunities and access for anglers off of the Billy Creek Road. The unit is about 3.5 miles across at its widest point and approximately 0.25 mile wide at its narrowest sections in the southern portion. The unit consists of 12,237 acres of BLM surface with wilderness characteristics (Map 73).

3.6.8. Livestock Grazing Management

The livestock and agricultural industry has a long and rich heritage in Wyoming. The precipitation levels, soils types and limitations, and topography make northeast Wyoming better suited to livestock grazing on the grasslands and shrublands than to cultivated agriculture (farming). Grazing on public lands represents a vital economic value to agricultural producers and to local communities. In addition, livestock grazing represents irreplaceable environmental and social values. Livestock have grazed on these allotments for more than 100 years. These values and traditions contribute important and irreplaceable wildlife habitat, open spaces, ranchland buffers between federal lands and developments, scenic vistas, visual beauty, and the traditional image and heritage of the historic rural landscapes of Wyoming and the U.S. West.

Livestock grazing can impact soil, plants, biological crusts, streams, and springs. Soils can be affected by hoof action that breaks up soil clumps and "plants" seeds in the soil. Grazing also can compact soils if livestock are confined. Impacts to plants is primarily through removal of vegetative mass (leaves); this can invigorate plants to produce more and remove any old growth

that if allowed to build up can stunt and inhibit plant growth. A healthy stand of vegetation holds and protects soils from wind and water erosion. This reduces soil sediments from entering streams and affecting water quality. Vegetation also helps hold banks of streams and spring areas to keep soil in place and reduce water erosion. Plants also help filter sediments, and such filtration improves water quality in streams and springs. Grazing management is designed to increase plant productivity and reduce soil erosion by controlling grazing through fencing and water projects and by balancing forage demands with the land's productivity.

3.6.8.1. Regional Context

The BLM is responsible for administering livestock grazing on public land across the planning area. Livestock grazing includes the grazing of domestic animals (e.g., cattle, sheep, horses, yaks, and bison). All public land in the planning area is designated for grazing unless otherwise prohibited and is governed under Taylor Grazing Act Section 15, which regulates issuing grazing leases on public lands outside the original grazing district boundaries established by the Taylor Grazing Act of 1934. Base property is defined in 43 CFR 4100.0–5 as (1) Land that has the capability to produce crops of forage that can be used to support authorized livestock for a specified period of the year, or (2) water that is suitable for consumption by livestock and is available and accessible to the authorized livestock when the public lands are used for livestock grazing. In accordance with 43 CFR 4110.2–1, the authorized officer shall find land or water owned or controlled by an applicant to be base property if: (1) it is capable of serving as a base of operation for livestock use of public lands within a grazing district, or (2) it is contiguous land, or when no applicant owns or controls contiguous land, noncontiguous land that is capable of being used in conjunction with a livestock operation which would utilize public lands outside a grazing district. In most cases, the base property for a Section 15 lease adjoins, surrounds, or is intermingled with the leased public lands authorized for grazing under this document. Water does not serve as base property in Wyoming. Public lands comprise approximately 10 percent of the surface acres; the remaining 90 percent is a combination of private and state lands. The majority of lands with live water (streams and springs) were homesteaded and are private lands. Therefore, except for drilled water wells and associated stock water pipelines and constructed reservoirs, most of the water available for livestock and wildlife comes from private lands.

From 1949 through 1954, the BLM conducted a classification of public lands within the BFO as part of a regional effort generally referred to as the “Missouri River Basin Survey”. A large portion of the BFO was resurveyed in 1968. Through the MRB effort the PRB (Area 3) was inventoried for vegetation, capability, erosion and carrying capacity. The MRB survey determined ecological range condition for each range site on the basis of a comparison between the existing site vegetation versus what the site was originally (potentially) capable of producing. The process to estimate the available forage for livestock grazing was conducted by trained individuals and involved intensive vegetation sampling (clipping, weighing, and ocular estimation). The stocking rates for the majority of the grazing leases within the BFO are based on this inventory.

Most professional Rangeland Management Specialists that have worked in the BFO have felt that the authorized grazing use (animal unit month [AUM]) generated from the MRB was conservative. In the years since the MRB survey, the BLM has conducted supplemental Ecological Site Inventories and updated the authorized use on a few grazing allotments. In each of these cases, it was determined that the carrying capacity was higher than those resulting from the MRB. Forage produced from the public lands within the BFO area contribute approximately 110,000 AUMs or about 4 percent of the feed requirements for the livestock for all land

ownerships. The Buffalo RMP approved October 4, 1985, and the 2001 update, state that “any permanent increases in the amount of forage produced are considered for wildlife and watershed protection before additional livestock use is authorized.”

3.6.8.2. Indicators

The indicators for the livestock grazing program are an increase or decrease in available forage and/or an increase or decrease in AUMs on BLM-administered lands.

Also, the BLM recognizes that AUM production on its rangelands can be sustained only with proper management of livestock grazing activities. To evaluate land health and keep AUM production sustainable, the BLM utilizes the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for Public Lands Administered by the Bureau of Land Management in the State of Wyoming* (BLM 1997).

In 1998 the BFO began assessing and evaluating whether public lands in their allotments were achieving these standards in accordance with the change in 1995 to the 43 CFR 4100 grazing regulations. Management decisions and actions are made in accordance with the *Standards for Healthy Rangelands*. The BLM in Wyoming uses these standards to allow sustainable livestock grazing to continue while protecting watersheds, riparian and upland ecosystems, and wildlife habitat.

Standards address the health, productivity, and sustainability of BLM-administered public rangelands and represent the minimum acceptable health for public rangelands. The standards apply to all resource uses on public lands. Their application will be determined as resource-specific guidelines are developed. Standards are synonymous with goals and are observed on a landscape scale. They describe healthy rangelands rather than important rangeland by-products. The achievement of a standard is determined by observing, measuring, and monitoring appropriate indicators. An indicator is a component of a system for which the characteristics (e.g., presence, absence, quantity, and distribution) can be observed, measured, or monitored based on sound scientific principles.

3.6.8.3. Current Condition

In the planning area, public lands comprise approximately 10 percent of the surface acres; the remaining 90 percent is a combination of private and state lands. Due to this scattered land pattern, livestock operations and management are run as seamless units regardless of surface ownership. To separate public lands to be managed as special units would not be feasible for the grazing lessee or the BLM. The BLM manages livestock grazing on 782,102 acres in the planning area. This acreage incorporates 427 grazing leases (Table 3.56, “Summary of Livestock Type and Authorizations in the Buffalo Planning Area” (p. 591)) authorizing approximately 106,078 AUMs of livestock forage in 477 grazing allotments. Four hundred livestock operators use public lands in the planning area in Johnson, Campbell, and Sheridan Counties; most of these lands are in Johnson County. The BFO also administers grazing use for public lands within the boundaries of adjacent BLM Field Office planning areas through cooperative management agreements. Over the last 20 years (1989–2008), the lowest AUM allocation was in 2006 with a total of 89,297 AUMs authorized, the highest was in 1997 with 108,607 AUMs, and the AUM annual authorization average is 98,278.

Table 3.56. Summary of Livestock Type and Authorizations in the Buffalo Planning Area

Livestock Type	Number of Leases
Cattle only	362
Sheep only	18
Cattle and sheep	24
Horses only	5
Bison only	2
Yak only	1
Cattle and horses	11
Cattle, sheep, and horses	4
Total	427
Source: BLM 2009a	

Livestock grazing on allotments is authorized during various times during the year depending on management objectives. Grazing periods vary with elevation and geographical change, resource needs, and user preference. The higher-elevation allotments are generally grazed during summer and fall. The lower-elevation areas can be grazed during any season. Most of the allotments in the planning area are operating with prescribed use levels that provide for plant recovery to enhance land health. When rangelands are not meeting resource objectives, the BLM implements changes in grazing management.

In 1985, all allotments were placed in categories established by BLM range management policies, as follows: “I” (Improve), “M” (Maintenance), and “C” (Custodial). The BLM categorizes allotments according to the greatest potential for resource improvement and the greatest economic return for applied management. Factors in the categorization process include public land acreage, estimated range health and trend, resource conflict or concerns, existing grazing systems, range suitability, production potential, wildlife habitat values, land patterns and acreages, and range improvement needs. Allotments with larger tracts of public land and the highest potential were placed in the I and M categories; allotments with smaller tracts of public land were placed in the C category. The BLM gave priority to the I category allotments, followed by the M category allotments and then the C category allotments. Map 72 shows how the planning area has been categorized.

At present, 18 allotments in the planning area are operated under allotment management plans (AMPs) or management agreements (Table 3.57, “Activity Plans – Allotment Management Plans and Management Agreements” (p. 591)). AMP and grazing agreements usually incorporate a deferred rotation grazing system to allow periodic rest during the critical growing season for vegetation from initial spring green-up through seedset (March 1 to July 10).

Table 3.57. Activity Plans – Allotment Management Plans and Management Agreements

Allotment Number	Allotment Name	Type of Plan	Public Acres
22213	Tongue River	AMP	1,767
22214	Schooner Ranch	AMP	12,482
32014	North Windmill	AMP	2,074
02275	Remington Creek	AMP	2,676
02310	Little Willow	AMP	6,080
02344	Dry Vee	Agreement	4,442
02371	Slope/Mountain/Stubbs Draw/Poker Creek	AMP	16,540

Allotment Number	Allotment Name	Type of Plan	Public Acres
02380	Wormwood Ranch/Beaver Creek	AMP	12,917
02390	Olmstead	AMP	832
02426	Crooked Creek	AMP	20,367
02430	Powder River	AMP	4,526

AMP Allotment management plan			

The BFO assesses/evaluates approximately 10 percent of the grazing allotments in the planning area annually. Where existing grazing management practices or levels of grazing use on public lands are significant factors in failing to achieve the standards and conform with guidelines, appropriate actions are being taken that will result in significant progress toward fulfillment of the standards and significant progress toward conformance with the guidelines. The BLM monitors to ensure proper grazing on allotments and uses the monitoring results to help determine if the present management is adequate for achieving land health standards or if a change in management is needed. Changes in management that have been applied include the construction or implementations of range improvements to aid in livestock management. Range improvement projects can include construction of fences, water delivery systems, and water holding facilities; prescribed burning; and ensuring reliable water sources. It can also include cultural changes such as a change in livestock type, deferment of a portion or all of an allotment, change or limitation of the season of use, or leasing additional lands. The goal is to continue sustainable livestock use on public lands while maintaining healthy watersheds and providing habitat for wildlife.

At the end of fiscal year 2008, the BFO had completed land health evaluations on 125 allotments comprising 588,581 acres of public land. The BLM determined that one or more rangeland health standards were not being met in three allotments (a total of 9,601 acres). Only a portion of those acres within the allotments did not meet rangeland health standards.

The BLM implements range improvement projects to help achieve management goals. Range improvement projects implemented before the 1960s were financed by the grazing lessees. Later, the BLM contributed funds to projects and in some cases fully financed them. In recent years the BLM has sought and participated in cost-shared projects with other agencies and private organizations to achieve mutual goals on public and private lands.

The BFO uses set criteria to prioritize new projects for funding. Highest priority is given to reconstruction of existing projects and new projects needed to achieve the standards for healthy rangelands and conform with guidelines for livestock grazing management. Criteria used to rank other projects include implementation of activity plans; cooperatively funded projects; allotment category (I, stock driveway, M, and C); number of allotments benefited; project cost; number of AUMs of forage authorized on an allotment; and wildlife habitat enhancement. Current BLM policy is to assign all maintenance responsibilities to the benefiting user, usually the grazing lessee.

Before 1997, an average of 6 to 10 range improvement projects were completed annually. Since 1998, an average of four to six range improvement projects have been completed annually. These projects consist primarily of fences, stock-water pipelines, spring developments, water wells, and vegetative treatments (Table 3.58, “Range Improvement Projects Implemented in the Buffalo Planning Area, Wyoming Since 1998” (p. 593)).

Table 3.58. Range Improvement Projects Implemented in the Buffalo Planning Area, Wyoming Since 1998

Type of Project	Number Projects Projected	Projects Completed Since 1998
Fences (miles)	3.3	21
Reservoirs (number)	1	0
Springs (number)	2	7
Wells (number)	3	2
Pipelines (number)	5	10
Source: BLM 2008a		

3.6.8.4. Trends

Livestock grazing will continue in the planning area in response to public demand. Many livestock operators in the planning area depend on the forage public lands provide. A predicted increase in development of mineral resources in the planning area will increase the presence of energy development-related infrastructure and machinery (e.g., roads, pipelines, well pads, processing facilities, and a variety of vehicular traffic). Construction of new facilities and related infrastructure necessary to extract mineral resources will require removal of existing vegetation. Further indirect loss of available forage could occur as increased infrastructure and traffic constrain livestock movements. As reclamation practices are applied to the public lands, the BLM could adjust livestock numbers and locations to ensure the success of those applications.

Evaluation of land health will continue, with a focus at the allotment level. The emphasis will change somewhat from focusing only on high-priority allotments to focusing on all public lands, especially those with potential Greater Sage-Grouse habitat and habitat for other species at risk. The BLM would still adjust grazing use at the allotment level. Table 3.59, “Animal Unit Months Billed in the Planning Area” (p. 593) lists AUMs billed in the Buffalo planning area.

Table 3.59. Animal Unit Months Billed in the Planning Area

Year	Campbell County	Johnson County	Sheridan County	Field Office Total
1989	34,096	52,862	5,103	92,061
1990	34,505	55,024	5,359	90,068
1991	33,234	59,281	4,796	97,311
1992	32,860	61,078	5,145	99,083
1993	34,170	60,733	5,292	100,195
1994	35,075	66,601	5,601	107,277
1995	35,698	58,825	5,423	99,946
1996	36,368	59,865	5,107	101,340

Recent agricultural land sales suggest that there is general stability in agricultural land uses and the ownership of agricultural properties. Future demand for agricultural land in Johnson, Sheridan, and Campbell Counties and the State of Wyoming can be expected from persons seeking a rural lifestyle in either part- or full-time agricultural activities. Some existing agricultural operations might choose to expand by acquiring additional lands. Agricultural property sizes will vary, depending on the buyers' financial resources, lifestyles, and preferences and their intended uses of the property.

Developers often are attracted to better agricultural land because its topography makes it more economical to develop. This also can result in the reduction of agricultural land and the decline of the quality of life in northeast Wyoming.

3.6.8.5. Key Features

Key features for livestock grazing include I and M category allotments and crucial habitat areas for wildlife and special status species, and recreational sites.

3.7. Special Designations

The planning area contains proposed ACECs, proposed Scenic and Back Country Byways, a waterway that is suitable and eligible for WSR designation and three WSAs, discussed below. The planning area does not contain designated or proposed National Scenic and Historic Trails, National Recreation Trails or National Water Trails and these designations will not be discussed further.

3.7.1. Areas of Critical Environmental Concern

3.7.1.1. Regional Context

FLPMA section 103(a) defines an ACEC as an area within public lands where special management attention is required to protect and prevent irreparable damage to important historical, cultural, and scenic values, fish and wildlife, and natural systems or processes, and to protect human life and safety from natural hazards. ACEC implementation regulations are 43 CFR 1610.7-2(b).

The land use planning process may officially designate an area found to meet ACEC criteria and would specify the special management direction needed to protect the relevant and important resource values. While the BFO does not currently have any designated ACECs, there are several areas that meet the relevant and important criteria.

3.7.1.2. Indicators

Before an area is nominated for ACEC designation, it must meet both the relevance and importance criteria (43 CFR 1610.7-2 and BLM Manual 1613) to become eligible for further consideration. An area would meet the relevance criteria if it contains one or more of the following: a significant historic, cultural, or scenic value; a fish or wildlife resource; a natural process or system; or natural hazards. An area would meet the importance criteria if it is characterized by one or more of the following: qualities or circumstances that make it fragile, sensitive, irreplaceable, rare, unique, etc.; more than locally significant qualities; warrants protection to satisfy national priority concerns or to carry out FLPMA mandates; qualities that warrant concern for safety and public welfare; or poses a significant threat to human life and safety or to property.

3.7.1.3. Current Condition

The public nominated seven areas for ACEC designation in 2002 (Koepsel 2002). The Notice of Intent for BLM's national Greater Sage-Grouse Planning Strategy (WO IM-2012-044) invited the public to nominate or recommend areas on public lands for Greater Sage-Grouse and their habitat to be considered as ACECs. Several nominations were received. Through the scoping process, numerous nominations were presented. It is also BLM policy to evaluate newly acquired lands, such as Burnt Hollow and the Welch Ranch to determine if they meet the ACEC criteria.

Potential Areas for Consideration as ACECs

Seven public nominated ACECs and the Cow Creek Breaks (Burnt Hollow) acquisition were initially analyzed in the PRB Final EIS (BLM 2003c). Six of the nominations were determined to meet the ACEC criteria. BLM also concluded that current management was sufficient to protect the relevant and important criteria but deferred any designation decisions until such time an amendment specific to their designation or revision of the Buffalo RMP is conducted (BLM 2003c). The areas evaluated in the PRB Final EIS include Cantonment Reno, Burnt Hollow, Dry Creek Petrified Tree, Face of the Bighorns, Fortification Creek Elk Area, Hell's Half Acre, Hole-In-The-Wall, and Pumpkin Buttes. Of these, the Face of the Bighorns and Hell's Half Acre were determined not to meet the criteria and were eliminated from further consideration. In addition to the areas identified in the 2003 PRB Final EIS, the Welch Ranch parcel, acquired in 2003, also merits consideration for designation as an ACEC. Finally, an ACEC to conserve the fragile sagebrush ecosystem is also being evaluated. Table 3.60, "Evaluation of ACEC Relevance and Importance Criteria" (p. 596) lists the citizen's ACEC proposals meeting BLM criteria, new acquisitions, and areas internally identified for further review, and the BLM determinations regarding relevance and importance.

Table 3.60. Evaluation of ACEC Relevance and Importance Criteria

Proposed ACECs	Relevance Criteria	Importance Criteria
Cantonment Reno	Significant historic values (Pioneer history and associated with Bozeman Trail).	Regional and national significance (one of few forts from the time period on public land); vulnerable to adverse change (unauthorized excavation).
Burnt Hollow	Scenic values; geologic features and natural hazards (steep erosive soils prone to flooding).	Public and management concerns for safety (flood potential).
Dry Creek Petrified Tree	Rare geologic features (excellent paleontological specimens on a site with public access).	Regional significance; fragile and irreplaceable qualities (paleontological specimens) which are vulnerable to adverse change.
Fortification Creek Elk Area	Scenic values and wildlife resources (yearlong, calving and crucial winter range of plains-based elk herd).	Rare qualities (plains-based elk herd) which are vulnerable to adverse change (high mineral potential); warrants protection to meet national priority concerns.
Hole-In-The-Wall	Significant historic (western lore associated with Butch Cassidy) and scenic values (panoramic views of the Red Wall/South Big Horns).	Distinctive historical and interpretive qualities; public concerns for management.
Pumpkin Buttes	Significant cultural and historic values (religious and cultural importance to Native Americans; used by early pioneers as a landmark destination); scenic values and unique geologic features (erosional remnants forming high buttes east of the Powder River).	Regional and national significance (Native American religious and cultural values) which are vulnerable to adverse change (wind and uranium potential; communication site).
Sagebrush Ecosystem	Significant wildlife values (Greater Sage-Grouse and other rare or special status sagebrush obligates) and natural systems (sagebrush ecosystem).	Sagebrush ecosystems are fragile and sensitive systems that provide essential habitat for several special status and rare species. Greater Sage-Grouse conservation is a national priority, and the proposed ACEC has been recognized as appropriate to maintaining sustainable Greater Sage-Grouse populations.
Welch Ranch	Important scenic value, important fish and wildlife resource, and presence of a natural hazard (active coal seam fire).	More than locally important qualities that give it special worth; coal seam fire creates management concerns about safety and public welfare.
ACEC Area of Critical Environmental Concern		

3.7.1.4. Trends

The PRB Final EIS (BLM 2003c) analyzed all of the potential ACECs with the exception of the Sagebrush Ecosystem and Welch Ranch. The PRB Final EIS concluded that present management was sufficient to protect the relevant and important ACEC values. The PRB Final EIS was an O&G project and therefore did not analyze all potential land use activities affecting ACEC values. Land uses such as renewable energy development, ROWs, and other mineral development could adversely affect ACEC values.

3.7.1.5. Key Features

Burnt Hollow (Cow Creek Breaks)

The BHMA is a recently acquired parcel totaling nearly 18,000 acres of BLM-administered lands

in northern Campbell County. The varied topography and diversity of vegetative communities is unique and provide habitat for numerous wildlife species including trophy class mule deer. A few of the ephemeral drainages support ecologically important cottonwood riparian communities. The area is comprised of gently rolling sagebrush-grasslands, ponderosa pine and juniper woodlands, scoria buttes, and clayey escarpments. Portions are roadless due to steep terrain and unstable soils. The lands are presently used for livestock grazing and wildlife habitat; mineral development is limited to a few abandoned drill holes. Cultural resources are also present in the area. Twenty-three cultural properties have been recorded in the vicinity. One occupation site has been determined eligible for listing on the NRHP; another is of unknown eligibility. Other prehistoric and historic era sites are known to exist in the area, but have not yet been recorded. The area is approximately 20 miles north of Gillette on Wyoming Highway 59. Most importantly, the area is one of the largest blocks of contiguous public land in Campbell County, and one of the only parcels in the county that possesses the size and naturalness to accommodate primitive and unconfined nonmotorized recreational opportunities.

The area meets the relevance criteria for scenic value and presence of a natural hazard due to steep erosive soils and flooding potential. Burnt Hollow meets the importance criteria because of public and management concerns about safety and public welfare (flooding potential) (BLM 2003c, Appendix R).

Cantonment Reno

Cantonment Reno is a 523 acre parcel on BLM surface on the site of a historic military supply fort established in 1876 on the Bozeman Trail. The fort had the capacity to house more than 350 soldiers and contained quarters, kitchens, mess houses, a hospital, storage buildings, and specialized facilities for cavalry. It was used as a supply depot for military campaigns, primarily against the Northern Cheyenne during the winter of 1876 to 1877. The U.S. Army abandoned the cantonment in 1878. The site retains well-defined features (foundations), contains numerous buried artifacts, and is noteworthy for the large amount of intact archeological information it contains. Hundreds of documents relating to the fort are on file at the National Archives, presenting numerous opportunities to answer research questions through site excavation.

Although there is no public access, there has been unauthorized excavation and collection at the site. The location is on a floodplain of the Powder River and might soon be exposed to erosion from an encroaching oxbow bend. The fluid minerals under the site have been leased, but there is a NSO stipulation for the entire proposed ACEC. There is extensive CBNG development a few miles to the east.

Cantonment Reno is the only military fort from the period of the Great Sioux War on BLM surface in the United States. The site meets relevance criteria because it is a rare and sensitive archeological resource. The site also meets importance criteria because it is directly associated with nationally significant historic events (the Great Sioux War), has qualities that give it significant special worth and distinctiveness, and has qualities that make it fragile and vulnerable to adverse change (BLM 2003c, Appendix R).

Dry Creek Petrified Tree

The Dry Creek Petrified Tree area is a 2,567-acre parcel that includes exposed specimens of petrified trees within a 40-acre environmental education site approximately 8 miles east of Buffalo. The site has public access, an interpretive trail, an outhouse, and a picnic shelter with tables. Tourists, local schools, and hunters use the area. The area is a PFYC Class 5 Area and contains excellent paleontological specimens.

The area meets relevance criteria for unique geologic feature and importance criteria for regional significance (used as an educational and tourist attraction) and fragile and irreplaceable qualities (paleontological specimens) which are vulnerable to adverse change (unauthorized removal of specimens) (BLM 2003c, Appendix R).

Fortification Creek Elk Area

The Fortification Creek area meets relevance criteria for scenic value and as a wildlife resource. It also meets the importance criteria for rare qualities (plains-based elk herd) which are vulnerable to adverse change (high mineral potential). The BLM deferred a decision on the citizen nomination within the PRB Final EIS (BLM 2003c) concluding that management was sufficient to protect the relevant and importance criteria. The Decision Record for the 2011 Fortification Creek RMPA/EA (BLM 2011c) made a final determination on the citizen nomination, again concluding that management was sufficient to protect the relevant and importance criteria. The Decision Record also identified that the citizen proposed boundary did not adequately represent the resources for which the ACEC was nominated. To better represent the relevant and important resource values, the boundary evaluated in the RMP revision is the BLM-administered lands within the crucial seasonal ranges (calving areas and crucial winter range).

The Fortification Creek area is comprised of rough prairie break topography bisected by several drainages. Typical vegetation is sagebrush-grassland intermixed with juniper. Elk were historically present in the area but were extirpated in the late 1800s. Today, a herd of approximately 200 elk resides year-round in the area as a result of reintroductions in the 1950s. The elk herd and its habitat have been affected by and encroached upon by CBNG development (BLM 2011c; BLM 2007g). The Fortification Creek area also contains a WSA, scenic values, steep slopes, highly erodible soils, and fragile watersheds (BLM 2003c, Appendix R).

Hole-In-The-Wall

Hole-in-the-Wall is approximately 20 miles southwest of Kaycee, Wyoming. It is a colorful and scenic red sandstone escarpment rich in legend of outlaw activity in the late 1800s, most notably Butch Cassidy and the Wild Bunch Gang. The "hole" is a gap in the Red Wall that, legend has it, outlaws secretly used to move horses and cattle from the area. The BLM has not identified or documented any historic sites on BLM surface in the area. Many of the historic features are on private lands and several key artifacts have been removed and placed in regional museums. However, the area remains a popular destination for travelers from outside the region and for commercial tours due to the recognizable name, notoriety, and relevance in western lore. The area is primitive in nature, with few visitor services. The BLM recently implemented several actions (creating a public viewing and parking area and trail head and installing interpretive signs) to protect the site and allow for public access.

Hole-in-the-Wall meets the relevance criteria for significant historical or cultural values and scenic value. The site meets the importance criteria for having distinctive historical and interpretive qualities; public concerns for management (BLM 2003c, Appendix R).

Pumpkin Buttes

Pumpkin Buttes is approximately 45 miles southwest of Gillette, rising approximately 800 feet above the surrounding landscape. The buttes consist of five flat-topped mesas referred to as North Butte, North Middle Butte, South Middle Butte, South Butte, and Indian Butte. The BLM administers most of the mineral estate under the buttes. All of South Middle Butte and half of North Middle Butte are BLM surface. There is no public access to the BLM surface on either butte, although the BLM purchased an administrative easement to South Middle Butte. South

Middle Butte is currently used as a communications site and includes six transmission towers. There are numerous mining claims for uranium or other minerals on and near the buttes, with one proposed uranium mining operation on BLM surface on North Middle Butte. There is extensive CBNG development around the buttes, and an existing oil field within 3 miles. A 200 turbine wind-energy development has been proposed on fee surface within 2 miles of the east side of the buttes.

Recent consultations with Native American tribes revealed that the buttes were utilized for many types of traditional, religious and ceremonial purposes. Indications of traditional and religious uses (e.g., stone circles, eagle traps, and cairns) remain on most of the buttes. In 2007, the BLM determined in consultation with 15 tribes that the Pumpkin Buttes has an ongoing connection to traditional beliefs and practices of several Native American tribes and designated the buttes as a TCP. During the consultation process, the tribes expressed a continued interest in using the buttes for ceremonial or educational purposes.

Pumpkin Buttes is also a prominent landmark associated with several historic events. All of the explorers of the PRB in the early and mid 19th Century mention the buttes in their journals. Jim Bridger is credited with naming Pumpkin Buttes in the 1850s. The buttes also are mentioned as a landmark in several emigrant diaries from travelers on the Bozeman Trail in the 1860s. The buttes had a role in Red Cloud's War and the Great Sioux War, as a lookout for the U.S. Army and Native American tribes.

The site meets the relevance criteria because it contains several rare and sensitive archeological resources, and is a significant religious and cultural resource important to several Native American tribes. The site meets the importance criteria because it has qualities that give it significant special worth and distinctiveness. The area also has qualities that make it fragile, sensitive, irreplaceable, and vulnerable to adverse change. The area also meets the importance criteria because it warrants protection to carry out FLPMA mandates (BLM 2003c, Appendix R).

Sagebrush Ecosystem

The Notice of Intent for BLM's national Greater Sage-Grouse Planning Strategy (WO IM-2012-044) invited the public to nominate or recommend areas on public lands for Greater Sage-Grouse and their habitat to be considered as ACECs. Numerous nominations were received. Greater Sage-Grouse are a management indicator species for sagebrush ecosystem health, meaning that they are dependent upon sagebrush ecosystems at a landscape scale for their survival and managing Greater Sage-Grouse habitat would conserve other rare and special status sagebrush dependent species. Greater Sage-Grouse populations have the greatest chance of persisting when landscapes are dominated by sagebrush and natural or human disturbances are minimal (Aldridge et al. 2008; Knick and Hanser 2011; Wisdom et al. 2011). The BFO is evaluating the public lands within 4.0 miles of Greater Sage-Grouse leks and winter concentration areas, an area of 467,897 acres or 60 percent of the BLM surface within the planning area. Management within 4 miles of critical habitat features is consistent with the National Technical Team recommendations (Taylor et al. 2012) for Greater Sage-Grouse conservation.

A sagebrush ecosystem ACEC meets relevance characteristics for conserving wildlife resource values and natural systems. Sagebrush ecosystems provide essential habitat that support several BLM special status species including the Greater Sage-Grouse, an ESA Candidate species. Additional BLM sensitive species dependent upon sagebrush ecosystems, and present within the planning area, include: Brewer's sparrow, sage sparrow, and sage thrasher. Sagebrush ecosystems are terrestrial plant communities that support multiple resources (soil, water, native vegetation,

biodiversity, rare and sensitive species, etc.) and land uses (recreation, livestock grazing, etc.) for which the BLM is responsible for sustainable management.

A sagebrush ecosystem ACEC meets importance characteristics for protecting a natural system and for meeting national priorities. Sagebrush ecosystems are fragile and sensitive systems that provide essential habitat for several special status or rare species. Sagebrush ecosystems and the rare and sensitive species that they support are vulnerable to adverse change. Sagebrush ecosystems have been fragmented in the planning area by energy development particularly CBNG. Greater Sage-Grouse conservation is a national priority, and the proposed ACEC has been recognized as appropriate to maintaining sustainable Greater Sage-Grouse populations. The PRB provides important genetic linkage between population strong holds in Montana (MZ I) and the Wyoming basins (MZ II).

Welch Ranch

The Welch Ranch Management Area is a 1,748-acre parcel approximately 10 miles north of Sheridan, Wyoming, along State Highway 338. The BLM acquired Welch Ranch in 2004 as part of a land exchange (BLM 2005f). The BLM administers all of the coal estate under the surface acreage of Welch Ranch and a portion of the O&G mineral estate. As a new acquisition, the BLM must evaluate the area as a potential ACEC. At least two homesteads (the Tryor homestead and the Evans homestead) were present on the property, which also historically included a post office. There also is evidence of prehistoric use, including lithic scatters and quarries. Current and historic uses include grazing; current management provides grazing from November through April. Approximately 1.5 miles of the Tongue River runs through the Welch Ranch. The riparian corridor is important migratory bird habitat and boasts excellent habitat for mule deer and other big game. The Tongue River is a red ribbon fishery, meaning it has regional importance. A free-flowing prairie river with easy public access from a major population center in Wyoming is extremely rare. Without special designation and management, public recreation visitation will degrade the importance and relevance criteria. Increased public awareness of riparian health will assist to improve the habitat through cooperative efforts and increase the species diversity and numbers of birds to the point that the area will be acknowledged as an Important Bird Area.

There is an active coal seam fire on a ridge in the southwestern corner of Welch Ranch. Historic records indicate that the coal seam fire began before 1940 (BLM 2003b), and while the origin is unclear, the fire is now considered to be part of the natural process. The OSM and specialists within the BLM have voiced concerns regarding human health and safety in relation to the coal seam fire and has suggested that special management might be necessary to prevent unsafe exposure to this hazard. Proposed abatement would have resulted in undue and unnecessary environmental degradation and was not expected to completely extinguish the fire.

The area meets the relevance criteria for scenic value, a fish and wildlife resource, and presence of a natural hazard (coal seam fire). The coal seam fire on the north side of the river is an important resource because it represents a threat to health and safety, influences plant and animal distribution and form, and represents historical mining operations. There are no known injuries from public interaction with the fire vents. Welch Ranch meets the importance criteria because it has more than locally important qualities that give it special worth and there are management concerns about safety and public welfare. Prairie riparian habitats represent less than one percent of the planning area. The Welch Ranch constitutes one of very few BLM-administered riparian areas and one of the few areas in Sheridan County with public access for fishing and boating. The combination of the rarity of the riparian habitat type, the accessibility of the location in near a population center, and high recreational use underscore the importance of Welch Ranch.

3.7.2. Scenic or Back Country Byways

3.7.2.1. Regional Context

The BLM began a National Back Country Byway Program in 1989 to focus on enhancing recreational opportunities. A National Scenic Byway System was subsequently created under Section 1047 of the Intermodal Surface Transportation Efficiency Act of 1991. This act recognized the BLM National Back Country Byway Program as a component of the National Scenic Byway System (section 1032, eligible projects). The objectives of the byway program include the following:

- Enhance opportunities for the American public to see and enjoy the unique scenic and historical opportunities on public lands.
- Foster partnerships at local, state, and national levels.
- Contribute to local economies.
- Enhance the visitor's recreation experience and communicate the multiuse management message through effective interpretative programs.
- Manage visitor use along the byway to minimize impacts to the environment and to protect visitors.
- Contribute to the National Scenic Byway System in a way that is uniquely suited to BLM-administered national public lands.

Transportation corridors with high scenic, historic, archeological, or other public-interest values are eligible for inclusion in the National Scenic Byway System. Byways are nominated through a collaborative process and are usually designated through RMPs. Proposed byways must have attractions important on a state and national basis. Many have recreational, historical, wildlife, educational, scientific, or cultural features. The entire route must have legal access. All state, federal, and local agencies with jurisdiction over road segments of the byway must agree to the designation.

While there are no BLM-administered National Byways within the planning area, there is one BLM-administered Back Country Byway, and another byway being evaluated just outside the planning area boundaries. The South Big Horns/Red Wall National Back Country Byway, administered by the Casper Field Office, traverses the South Big Horn Mountains in northwest Natrona County. The Worland Field Office is currently evaluating the Hazelton Road within Washakie County as a potential Back Country Byway in their RMP revision. Within the planning area there are three Scenic Byways administered by the Bighorn National Forest: Bighorn Scenic Byway (US 14), Cloud Peak Scenic Byway (US 16), and Medicine Wheel Passage Scenic Byway (US 14A).

3.7.2.2. Indicators

Management indicators would be the ability to meet the objectives for which the individual byways were designated.

3.7.2.3. Current Condition

At present, there are no BLM-administered National Byways in the planning area; six routes will be evaluated.

- **Hazelton Road** – This route traverses the spine of the Big Horn Mountains in western Johnson County from US 16 south to the Washakie County line (33 miles). If designated within the Buffalo and Worland Field Offices, the Hazelton byway would connect the Cloud Peak Scenic Byway to the South Big Horns/Red Wall National Back Country Byway. The route has a mixed land tenure including private (64%), BLM (18%), Bighorn National Forest (16%), and lands managed by the State of Wyoming (2%).
- **Slip Road** – A 15 mile route providing access to the southern Big Horn Mountains from Mayoworth northwest of Kaycee. The route is a stock driveway, and with the exception of 0.5 mile of state land the entire route is on BLM surface. The western terminus is the proposed Hazelton Back Country Byway.
- **Trabing and Sussex Roads** – These two routes follow 44 miles of the Bozeman Trail through southern Johnson County connecting Interstate 25 in the north to WY 192 in the south. There are several interpretive displays related to the Bozeman Trail along the route. The route has a mixed ownership including private (83%), BLM (11%), and lands managed by the State of Wyoming (6%).
- **Powder River Road** – This route parallels the Powder River for 73 miles from Interstate 90 to the Montana State line. The route has a mixed land tenure including private (88%), BLM (11%), and lands managed by the State of Wyoming (1%).
- **Rome Hill** – This is a short (3 miles) route in southwestern Johnson County running west from the proposed Hazelton Back Country Byway to the Washakie County line. The route has a mixed land tenure including private (82%), BLM (15%), and lands managed by the State of Wyoming (3%). Rome Hill Road is not being evaluated as a potential Back Country Byway in the Worland RMP revision.
- **Tipperary and Thompson Creek Roads** – This 37 mile route passes through mixed prairie and break landforms in eastern Johnson and Sheridan Counties connecting Interstate 90 with US 14/16. The route provides access to the Dry Creek Petrified Tree EEA and parallels a portion of lower Crazy Woman Creek. The route has a mixed land tenure including private (94%), BLM (3%), and lands managed by the State of Wyoming (3%).

All routes are natural surfaced well maintained routes passable to passenger vehicles.

3.7.2.4. Trends

National Byways were a popular program at the time of their creation. Funding has substantially decreased in recent years, popularity of the program has waned with the decreased funding. Byways appeal to the increasing segment of the public engaging in vehicle touring that prefers less traveled scenic back country routes to highway travel.

3.7.2.5. Key Features

The six routes exhibit the potential for designation as National Back Country or Scenic Byways. Public support and cooperation with the appropriate counties would be essential to designate any routes.

3.7.3. Wild and Scenic Rivers

3.7.3.1. Regional Context

In 1968, Congress passed the Wild and Scenic Rivers Act, thereby establishing the National WSR System for the purpose of preserving rivers with outstandingly remarkable values in a free-flowing condition for the benefit of present and future generations. The BLM was subsequently directed to evaluate waterways and provide recommendations of which public waterways under its administration meet the criteria for designation as WSRs (BLM 2012d). The WSR System is a system of congressionally designated rivers and their immediate environments that have outstanding scenic, recreational, geologic, fish and wildlife, historic, cultural, and other similar values and are preserved in a free-flowing condition. The system consists of three types of rivers, as follows:

- Recreation – Rivers or sections of rivers that are readily accessible by road or railroad and that might have some development along their shorelines and might have undergone some impoundments or diversion in the past
- Scenic – Rivers or sections of rivers free of impoundments, with shorelines or watersheds still largely undeveloped but accessible in places by roads
- Wild – Rivers or sections of rivers free of impoundments and generally inaccessible except by trails, with watersheds or shorelines essentially primitive and waters unpolluted

The BLM is responsible for evaluating all rivers on BLM-administered land to determine if they are appropriate for addition to the System and, as appropriate, making recommendations for legislative actions to accomplish such additions. River or stream segments must be found eligible and suitable to be considered for designation as WSRs, and only Congress can designate segments.

3.7.3.2. Indicators

WSRs must meet certain eligibility and suitability criteria. According to BLM Manual 6400 – Wild and Scenic Rivers, to be eligible for designation as a WSR, a waterway must be free-flowing and it must possess one or more of the following outstandingly remarkable values: scenery, recreation, geology, fish, wildlife, historical, cultural, or other similar values. To be further considered for designation, a waterway must meet suitability requirements related to manageability, land tenure status, reasonably foreseeable potential uses of the river corridor, and considerations of cost of management.

3.7.3.3. Current Condition

The BFO completed an assessment of all waterways within the planning area in 1993 and 1994 (BLM 2001a) and documented the findings in Appendix G of the 2001 RMP Update. A WSR Final Review Report was completed for the planning area in 2003 (BLM 2003d). The WSR eligibility review report (BLM 2003d) is available on the BFO website (<http://www.blm.gov/wy/st/en/programs/Planning/rmps/buffalo/docs.html>). Four waterways were determined to be eligible for WSR designation: Beartrap Creek, Middle Fork Powder River, North Fork Powder River, and Powder River (Cantonment Reno). However, only the Middle Fork Powder River was determined to be eligible and suitable for WSR designation (BLM 2003d) (Table 3.61, “Middle Fork Powder River Wild and Scenic River Values” (p. 604)).

Table 3.61. Middle Fork Powder River Wild and Scenic River Values

Suitable for Wild and Scenic River status (miles)	Tentative Classification	Outstandingly Remarkable Values	Current management	Mineral potential, leasable	Mineral potential, locatable	Mineral potential, salable
11.25 miles in Buffalo Field Office **Note: an additional ~1.2 miles of suitable and eligible waterway extends into the Worland Field Office	Wild	Scenic, Recreational, Historic Cultural, Fish and Wildlife (Class I fishery)	BLM manages the free-flowing condition, water quality, tentative classification, and any outstandingly remarkable values of suitable rivers in a manner that protects and/or enhances these conditions and values until congress designates the river or releases it for other uses per BLM Manual 6400	Low	Low; the portion within the Ed O. Taylor has been withdrawn from mineral entry	Very low
Source: BLM 2012f BLM Bureau of Land Management						

3.7.3.4. Trends

A site-specific interim management plan is in place to maintain the wild and scenic characteristics of the Middle Fork Powder River. Proposals to dam the Middle Fork Powder River have been submitted in the past, but have not been pursued and are not currently reasonably foreseeable.

3.7.3.5. Key Features

The BLM has determined that a portion of the Middle Fork Powder River (11.25 miles; 2,664 acres) meets the WSR suitability factors and should be managed to maintain or enhance their outstandingly remarkable values (BLM 2001a). The interim management prescriptions for suitable waterways in the Buffalo RMP planning area apply only to the waterway corridor of 11.25 miles of the Middle Fork Powder River and includes the waterway area, its immediate environment, and an average of no more than one quarter mile (1,320 feet) from the ordinary high water mark on both sides of the waterway. This boundary is preliminary and, by Section 3(b) of the WSRA, may vary on either side of the waterway and be narrower or wider as long as the total corridor width averages no more than 320 acres (half of a mile or 2,640 feet wide) per river mile, and can be delineated by legally identifiable lines (e.g., survey or property lines) or some form of on-the-ground physical feature (e.g., canyon rims, roads, etc.) which provide the basis for protecting the waterway's outstandingly remarkable values. Since the suitable waterway within the Buffalo RMP planning area (i.e., Middle Fork Powder River) is located within a deep canyon

that is capable of both supporting and protecting the identified outstandingly remarkable values, corridor boundaries for the Middle Fork Powder River are delineated by the canyon rims, except in cases where “rim-to-rim” exceeds an average of a half mile. Final boundary delineation would be made if and when Congress decides to designate the waterway segments under review.

The public lands along all 11.25 miles are tentatively classified as wild. Interim management practices for the BLM-administered parcels along the Middle Fork Powder River meeting the wild classification will focus on maintaining or enhancing the outstandingly remarkable scenic, recreational, cultural, historic, fishery, and wildlife values and maintaining the relatively primitive, pristine, rugged, and unaltered character of the area.

3.7.4. Wilderness Study Areas

3.7.4.1. Regional Context

In 1964, Congress passed the Wilderness Act, thereby establishing the National Wilderness Preservation System for the purpose of preserving lands in a natural condition for the benefit of present and future generations. Through FLPMA (Section 603), Congress directed the BLM to inventory, study, and recommend which public lands under its administration should be designated as Wilderness.

WSAs are areas determined to meet Wilderness eligibility requirements but for which Congress has not acted on the managing agency’s recommendation. WSAs often have special qualities, such as ecological, geological, educational, historic, scientific, and scenic values. They are managed in accordance with BLM Manual 6330 – Management of Wilderness Study Areas to prevent impairment of wilderness characteristics until Congress acts to designate such areas as Wilderness or release the areas from further study.

3.7.4.2. Indicators

WSAs must be managed in such a manner as to preserve unimpaired their wilderness characteristics as discussed in Section 2(c) of the Wilderness Act of 1964, and incorporated in FLPMA (Section 603), which states: “A wilderness, in contrast with those areas where man and his own works dominate the landscape, is hereby recognized as an area where the earth and its community of life are untrammelled by man, where man himself is a visitor who does not remain. An area of wilderness is further defined to mean in this Act an area of undeveloped federal land retaining its primeval character and influence, without permanent improvements or human habitation, which is protected and managed so as to preserve its natural conditions and which (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; (3) has at least five thousand acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and (4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.”

The BLM performed inventories of roadless areas in the planning area in 1979 and made recommendations to Congress of areas potentially suitable for designation as Wilderness. These recommendations are based on factors such as the manageability of the area, how well it meets the characteristics of wilderness, conflicts or potential for conflicts with other users and uses, and other relevant factors.

3.7.4.3. Current Condition

While there are no congressionally designated Wilderness areas in the planning area, the BFO does manage three WSAs. The three BLM-administered WSAs in the planning area include Gardner Mountain, North Fork Powder River, and Fortification Creek (Map 75).

The BLM completed the Wyoming Statewide Wilderness Study Report in 1991 (BLM 1991b). In this study, the BLM inventoried and documented the features of all WSAs in Wyoming. In addition, each WSA was recommended or not recommended for designation as Wilderness. Regardless of the BLM recommendation, all WSAs included in the 1991 report continue to be managed as WSAs and must be addressed as WSAs in RMP revisions.

The BLM recommendations were incorporated in the 1985 Buffalo RMP. As of October 1, 2012, Congress had not acted on these recommendations. Congress requires the BLM to manage WSAs to preserve the wilderness characteristics under the non-impairment standard until Congress designates the lands under wilderness review as Wilderness, or releases the lands to uses other than Wilderness.

3.7.4.4. Trends

Congress has not taken action on the WSAs within the planning area since 1979. Given the historic, regional and political context of wilderness, Congress is not expected to take action regarding the WSAs during the life of this plan. BLM management continues to manage the WSAs within the Buffalo planning area to the non-impairment standard.

3.7.4.5. Key Features

Gardner Mountain WSA (WY-060-201)

The Gardner Mountain WSA, which encompasses approximately 6,423 acres with no state or private inholdings, is in Johnson County 40 miles southwest of Buffalo. The area is characterized by the rugged terrain of the southern Big Horn Mountains and dominated by ponderosa pine, Douglas fir, limber pine, scattered mountain mahogany, and meadows. Deep, steep-walled canyons of Beartrap Creek and the North Fork of the Red Fork Powder River are the dominant perennial water sources. The area provides winter habitat for elk and mule deer and other wildlife resources including mountain lions, black bears, turkeys, blue grouse, golden eagles, and red-tailed hawks, among others. Solitude, excellent fishing opportunities, wildlife-based recreation, historic landscapes, and naturalness are some of the wilderness opportunities in this WSA.

North Fork Powder River WSA (WY-060-202)

The North Fork Powder River WSA, which encompasses approximately 10,089 acres with no state or private in holdings, is in Johnson County 30 miles southwest of Buffalo. The area is dominated by two deep, rugged and scenic canyons – Pass Creek and North Fork Powder River. Vegetation in the steep terrain is dominated by ponderosa pine, Douglas fir, and limber pine, while mixed with open, native-grass covered areas. The area provides winter range for elk, is a pronghorn migration route, and provides habitat for black bear and a variety of other species and raptors. Solitude, excellent fishing opportunities, primitive and unconfined recreation, and naturalness are some of the wilderness opportunities in this WSA.

Fortification Creek WSA (WY-060-204)

The Fortification Creek WSA, which encompasses approximately 12,419 acres of public lands and one state-owned in holding of 640 acres, is 36 miles northeast of Buffalo in northeastern Johnson County and northwestern Campbell County. The area is representative of the Sagebrush Steppe ecosystem/Great Plains Shortgrass Prairie province. The landscape is steeply sloping, highly dissected, and gullied terrain. The main drainages are Bull Creek, Little Bull Creek, and Deer Creek. Vegetation consists of juniper, sagebrush, and grasses. Most of the WSA is considered crucial for elk, which use the area for winter and calving range because of the available forage and cover. Solitude, primitive and unconfined recreation, naturalness and unique landscapes are some of the wilderness opportunities in this WSA.

3.8. Socioeconomic Resources

3.8.1. Social Conditions

Social conditions concern the human communities in the planning area, including towns, cities, and rural areas; the customs, culture, and history of the area as it relates to human settlement; and current social values. Although BLM management actions in the planning area can affect counties outside the planning area through social interactions among those who live, work or have social connections with nearby counties, BLM expects effects of its management actions to primarily impact counties in the planning area. Counties outside the planning area were not included in this analysis.

This section describes population and demographics, customs, culture, and social trends.

3.8.1.1. Indicators

Social conditions are best described by a combination of quantifiable indicators and qualitative descriptions that, in combination, characterize the various social aspects of the planning area. Quantifiable social indicators used below include resident population, population change, and other demographic indicators. Qualitative descriptions include those of communities and infrastructure in the planning area, local governments and occupational and interest groups. Poverty indicators are presented in the *Environmental Justice* section.

3.8.1.2. Current Condition

Population and Demographics

Table 3.62, “Population Change by County, 2010” (p. 608) summarizes population information for the planning area counties in 2010; Table 3.63, “Populations of Towns in the Planning Area in 2010” (p. 608) lists populations for towns in the planning area in 2010. The most populous county in the planning area is Campbell County, with more than 46,000 residents in 2010. Sheridan County had approximately 29,000 residents, and Johnson County had approximately 8,500. The most populous cities in the planning area, in order of decreasing size, are Gillette (Campbell County), Sheridan (Sheridan County), and Buffalo (Johnson County).

Table 3.62. Population Change by County, 2010

Area	Population in 2010
Campbell County	46,133
Johnson County	8,569
Sheridan County	29,116
Wyoming	563,626
United States	308,745,538
Sources: U.S. Census Bureau 2012	

Table 3.63. Populations of Towns in the Planning Area in 2010

Town	Population in 2010
Arvada	43
Big Horn	490
Buffalo	4585
Clearmont	142
Dayton	757
Gillette	29,087
Kaycee	263
Parkman	151
Ranchester	855
Sheridan	17,444
Story	828
Wright	1,807
Sources: U.S. Census Bureau 2010b	

Gillette, Sheridan and Buffalo are located along the I-90 highway, which connects Buffalo to Gillette along a roughly west-east direction, and Sheridan to Buffalo along a northwest-southeast direction. A few other towns are less than ten miles off I-90 (e.g., Story, Big Horn and Ranchester in Sheridan County). US Highways 14/16 also connect Sheridan to Gillette on a slightly more northern route and a few other communities are located along this highway (e.g., Arvada, and Clearmont in Sheridan County). The two largest communities in the south of the planning area are Kaycee (along Wyoming State Highway 196, running south from Buffalo, in Johnson County), and Wright (along Wyoming Highway 59, running south from Gillette, in Campbell County). These two communities are connected by 74 miles of Wyoming routes 192 and 387, running roughly in the west-east direction.

Table 3.64, “Age Distribution by County, 2010” (p. 608) lists information about the population distribution by various age groups in 2010. Johnson and Sheridan counties had a slightly older age distribution than Campbell County, Wyoming, or the United States, as reflected in a higher median age; a lower proportion of residents in the younger age categories; and a greater proportion in the older age categories.

Table 3.64. Age Distribution by County, 2010

Area	Median Age	Percent of People by Age Category				
		Under 18	18 to 24	25 to 44	45 to 64	65 and Over
Campbell County	31.9	28	10	30	27	6
Johnson County	44.8	22	6	22	31	19
Sheridan County	41.9	22	8	23	31	16

Area	Median Age	Percent of People by Age Category				
		Under 18	18 to 24	25 to 44	45 to 64	65 and Over
Wyoming	36.8	24	10	26	28	12
United States	37.2	24	10	27	26	13

Source: U.S. Census Bureau 2012

Table 3.65, “Educational Attainment in 2010” (p. 609) summarizes educational attainment in each county in 2010. Compared to the United States, people in counties in the planning area are more likely to have a high school diploma, but less likely to have a 4-year college degree. Johnson County has the highest percentage of high school graduates and the highest percentage of 4-year college graduates. Among the three counties, Campbell County has the lowest percentage of 4-year college graduates.

Table 3.65. Educational Attainment in 2010

Area	Percent of People Age 25 and Over	
	High School Diploma	4-year College Degree
Campbell County	91.0	17.6
Johnson County	94.6	25.3
Sheridan County	92.7	23.1
Wyoming	91.3	23.6
United States	85.0	27.9

Source: U.S. Census Bureau 2010a

3.8.1.3. Trends

Customs, Culture, and Social Trends

This section describes the social development, culture, and history of the planning area to provide insight into how changes in the planning area might affect the livelihood and quality of residential life.

The first people to live in the planning area were Native American Tribes, including the Crow, Lakota/Dakota, Arapaho, Kiowa, Comanche, Blackfeet, Cheyenne, and Shoshone. The first European-American or white people in the area arrived in the early 1800s and included fur trappers, traders, and explorers (Johnson County 2005). Fur trapping became more prevalent in the 1820s and 1830s, but no large or permanent settlements had been built by the mid-1800s. Clashes between the United States military and the Native Americans increased in frequency and intensity in the 1860s and 1870s, due in part to the increased number of European-American migrants and settlers traversing the area (Johnson County 2005). A series of treaties in the late 1860s provided that the Lakota (Sioux) would be allowed to live on all of the land that is now Campbell County, along with the Powder River country and the Black Hills (Johnson County 2005; Campbell County 2007b). However, less than 10 years later the U.S. government decided to restrict the Lakota and other northern Plains tribes to smaller reservations so that the land could be opened for non-native settlers. After the U.S. military defeated and evicted the northern Plains Indians, white settlement began in the vicinity of the planning area in the late 1870s and early 1880s.

Johnson County was created in 1879, and included all of the land that is now Johnson County and Sheridan County and parts of present-day Big Horn and Washakie counties. Sheridan County was split off in 1887. Campbell County was created in 1911 from Weston and Crook counties. Homesteaders and ranchers comprised most of the first settlers. In 1892, Johnson County was the location of the “Johnson County War,” when a group of armed men were sent by powerful

cattlemen to confront small ranchers who were competing with them for the use of public grazing lands (Davis No Date). Farming remains an important aspect of the livelihoods of the local population. Table 3.66, “Farming in 2012” (p. 610) shows that there are over 1,500 farms in the three counties. These farms work with cattle, sheep, winter wheat, and alfalfa hay, among other products. Sheridan and Campbell counties rank among the top nine farming counties in the state in value of production (among 23).

Table 3.66. Farming in 2012

Area	Number of Farms ¹	Value of Livestock and Crop Production (\$ million)	Rank Among Wyoming Counties
Campbell County	633	113.6	9
Johnson County	319	76.3	18
Sheridan County	599	125.1	8
Source: National Agricultural Statistics Service 2013			
¹ Number of farms is for 2007.			

Oil exploration and production activities began in the planning area in the late 1880s, primarily in parts of Campbell County and in the Salt Creek Basin of Johnson County. Increased exploration activities by various companies in the Salt Creek Basin eventually led to the development of oil camps in neighboring Natrona County (Johnson County 2005). As settlement increased through the early 20th Century, mining, railroading, and agriculture formed the basis of the economy.

In 1923, Carter Oil Company developed some commercial quantities of natural gas in the Billy Creek field southwest of Buffalo, and from 1948 to 1956 several additional fields in Johnson County came into production (Johnson County 2005). However, oil production in Campbell County started relatively late, and in 1954 there was only one producing well in the entire county. Therefore, in Campbell County, agriculture continued as the largest employer until oil drillers discovered the vast PRB resources in the 1960s (Campbell County 2007b). Campbell County experienced a boom in oil development and production during the late 1960s and early 1970s; coal development followed almost on the heels of the oil boom. The late 1980s and early 1990s saw the beginning of CBNG development, which continues today (Johnson County 2005; Campbell County 2007b). Other minerals, including uranium and bentonite, have been important contributors to the economic development of the planning area. One of Wyoming’s three major production areas of swelling bentonite is along the flanks of the Big Horn Mountains (Johnson County 2005).

The use of natural resources on private, state, and federal lands provides the basis for continued social and economic stability in all three counties in the planning area. Agriculture, mining, mineral development and production, and tourism are directly related to the ability to use federal and state lands. Therefore, management decisions for federal lands and natural resources will have a ripple effect throughout the social and economic climate of the planning area (Campbell County 2007b). Quality of life is often associated with outdoor activities, recreation and western values, and outdoor recreation areas such as the Big Horn Mountains (Sheridan County Chamber of Commerce 2012; Campbell County No Date).

Occupation and interest groups present in the area include community development organizations, health and educational organizations, youth and senior citizen organizations, recreation organizations and business associations (National Center for Charitable Statistics 2012). Among the main industries represented in the Sheridan County, Buffalo and Campbell County Chambers

of Commerce are the O&G, coal, other mining, construction and retail industries (Sheridan County Chamber of Commerce 2013; Buffalo Chamber of Commerce 2013; Campbell County Chamber of Commerce 2011).

All three counties in the planning area have comprehensive land use plans that address existing and planned or hoped-for future conditions of transportation infrastructure and other elements. The Campbell County plan does not identify any issues associated with transportation infrastructure, although it does make clear that the county government will work to preserve ROWs for private property owners (Campbell County 2007b). The Johnson County plan notes that all county roads are functioning at acceptable levels of service, but also notes that one road (French Creek Road) extending northwest from Buffalo carries substantial traffic due to numerous subdivisions along that route. The plan predicts that due to new subdivisions planned along this corridor, maintenance and improvements of this road are expected to be issues of concern (Johnson County 2005). The Sheridan County plan identifies several new roadways proposed for the future, primarily around the towns of Big Horn and Sheridan, and an extensive network of bicycle trails and paths (Sheridan County 2008).

For other types of community infrastructure, including law enforcement, schools, and medical care, the Johnson County plan identifies a need for additional county government office space and a new law enforcement center (Johnson County 2005). The Sheridan County plan notes that rural areas in the county typically lack physical infrastructure such as sewer and water lines, and states that future development will occur only in areas that have the physical infrastructure to support it (Sheridan County 2008). It does not identify specific areas of deficient services in urban areas. The Campbell County plan does not address these types of community infrastructure.

Population

Table 3.67, “Population Change by County, 1970–2010” (p. 611) shows population growth in the counties of the planning area by decade, between 1970 and 2010. The data show how population growth in the planning area declined strongly from the 1970s to the 1980s, with negative growth in Johnson and Sheridan counties. Population growth picked up again in the next two decades, although at a slower pace.

Table 3.67. Population Change by County, 1970–2010

Area	Annual Percent Change				Percent Change 1970–2010	Annual Percent Change 1970–2010
	1970–1980	1980–1990	1990–2000	2000–2010		
Campbell County	6.5%	1.9%	1.4%	3.2%	256.0%	3.2%
Johnson County	1.8%	-0.9%	1.4%	1.9%	53.4%	1.1%
Sheridan County	3.4%	-0.6%	1.2%	0.9%	63.1%	1.2%
Wyoming	3.5%	-0.3%	0.9%	1.3%	69.6%	1.3%
United States	1.1%	0.9%	1.2%	0.9%	51.9%	1.1%

Source: Wyoming Department of Administration and Information 2013; U.S. Census Bureau 2012

Table 3.68, “Population Change of Towns in the Planning Area, 2000–2010” (p. 612) shows population growth in towns in the planning area between 2000 and 2010. The table shows towns grew at considerably different paces during that decade.

Table 3.68. Population Change of Towns in the Planning Area, 2000–2010

Town	Percent Change 2000–2010	Annual Percent Change 2000–2010
Arvada	30.3%	2.7%
Big Horn	147.5%	9.5%
Buffalo	17.6%	1.6%
Clearmont	23.5%	2.1%
Dayton	11.7%	1.1%
Gillette	48.1%	4.0%
Kaycee	5.6%	0.5%
Parkman	10.2%	1.0%
Ranchester	22.0%	2.0%
Sheridan	10.4%	1.0%
Story	-6.7%	-0.7%
Wright	34.1%	3.0%
Sources: U.S. Census Bureau 2000; U.S. Census Bureau 2010b		

The Wyoming Economic Analysis Division (2010a; 2010b) provides forecasts of population for planning area counties and some towns. Table 3.69, “Population Forecasts through 2030” (p. 612) summarizes available information from this source. The data suggest that Campbell County will grow fastest, with a growth rate double that of the state. Johnson County will also grow above the rate of the state as a whole, with Buffalo and Kaycee growing about as fast as the rest of the county. Sheridan County will continue to grow at a rate below that of the state as a whole.

Table 3.69. Population Forecasts through 2030

Area	Population (Actual or Forecasted)				Percent Change 2010-2030	
	2000	2010	2020	2030	Overall	Average Annual
Campbell County	33,698	46,133	56,890	66,060	43	1.8
Gillette	19,646	29,087	35,869	41,651	43	1.8
Wright	1,347	1,807	2,228	2,588	43	1.8
Johnson County	7,075	8,569	9,450	10,450	22	1.0
Buffalo	3,900	4,585	5,056	5,591	22	1.0
Kaycee	249	263	290	321	22	1.0
Sheridan County	26,560	29,116	31,380	33,520	15	0.7
Clearmont	115	142	153	163	15	0.7
Dayton	678	757	816	872	15	0.7
Ranchester	701	855	921	984	15	0.7
Sheridan	15,804	17,444	18,800	20,083	15	0.7
Wyoming	493,782	563,626	622,360	668,830	19	0.9
Sources: Wyoming Economic Analysis Division 2010a; Wyoming Economic Analysis Division 2010b						

The Johnson, Campbell, and Sheridan comprehensive plans discuss forecasted conditions and planned coordination to varying degrees. The most important element for BLM purpose in this analysis is that all three counties emphasize the importance of coordination with the BLM and other federal land management agencies. For example, the Sheridan County plan states that the county will cooperate with and provide guidance to federal and state agencies that manage land and resources regarding regional issues of concern, including social and economic issues (e.g., substantial natural resource development) and others (e.g., water quality from CBNG development) (Sheridan County 2009). The Johnson County plan identifies three key concerns

related to BLM-administered land and resources, all related to the continued availability of public lands for livestock grazing and the policies that affect the management of federal grazing allotments (Johnson County 2005). The Campbell County plan calls on federal and state land managers to recognize the customs, culture, economic viability, social structure, and quality of life of the citizens of Campbell County in their planning actions (Campbell County 2007b).

Note that federal law (43 CFR 1610.3) requires the BLM to prepare plans that are consistent with officially adopted local land use plans, identify inconsistencies with proposed BLM plans and local plans to the Governor, and take practical steps to resolve conflicts between federal and local plans. These requirements apply only if local governments notify the BLM that a local land use plan has been adopted (Johnson County 2005).

3.8.2. Economic Conditions

Economic analysis is concerned with the production, distribution, and consumption of goods and services. This section summarizes economic information, including trends and current conditions, for the planning area. It also identifies and describes major economic sectors in the planning area that can be affected by BLM management actions.

Economic conditions in individual communities in the planning area are integrally linked to those of other communities, both inside and outside the planning area. For example, businesses in some cities outside the planning area, such as Billings and Casper, provide services and labor to CBNG developers in the planning area. Similarly, some of the people who recreate in the Big Horn Mountains and other areas come from outside the planning area. Therefore, economic conditions outside the planning area indirectly affect the economy in the planning area, and BLM management actions in the planning area can affect economic conditions outside the planning area. However, because economic effects of BLM management actions would primarily impact the planning area, the AMS for economic conditions focuses on three counties in the planning area.

3.8.2.1. Indicators

As in the case of social conditions, economic conditions are also best described by a combination of quantifiable indicators and qualitative descriptions. Quantifiable economic indicators used below include income and labor earnings, employment and unemployment, housing availability and prices and tax collections. Earnings and employment are presented by industrial sector, when possible. Additional quantitative indicators, as well as qualitative aspects, are used to further describe important industrial sectors on BLM-administered lands and/or for the planning area (e.g., O&G, travel and tourism, livestock farming). Interrelationships among producing sectors are captured in the Chapter 4 impacts analysis by the use of the IMPLAN model. For an additional description of this model, see Appendix U (p. 2589). A qualitative description of non-market values associated with BLM-administered lands is also included.

3.8.2.2. Current Conditions and Trends

Mining, Including Oil and Gas

Mining and mineral production constitutes most of the economic activity in the planning area. Table 3.70, “Estimated Mineral Production and Value by County in the Buffalo Planning Area in 2010” (p. 614) summarizes the quantity and value of mining production in counties in the planning

area, and for the state as a whole, in 2010. Economically, the largest contributors to mining activity are oil and coal in Campbell County, and gas in all three counties. Most coal produced in Wyoming in 2010 was from Campbell County, and almost one-third of the sand and gravel produced in the state was from the three planning area counties. The *Mineral Resources* section of this chapter provides additional information about mineral resources in the planning area.

Because the BLM administers subsurface mineral resources in excess of the surface lands it administers, its decisions impact mining in the planning area (see the *Mineral Resources* section for more detail). From an economic perspective, mining is a key contributor to the economic wellbeing of the planning area; therefore, BLM management decisions in this area could impact economic conditions.

Table 3.70. Estimated Mineral Production and Value by County in the Buffalo Planning Area in 2010

Mineral	Campbell County	Johnson County	Sheridan County	Wyoming
Production or Sales (units)				
Oil (barrels sold)	6,395,812	539,283	6,103	37,410,583
Gas (thousand cubic feet sold)	137,140,505	349,220,009	52,323,923	2,429,249,686
Coal (tons)	401,618,421	0	0	438,751,440
Uranium (pounds produced)	0	0	0	1,711,712
Sand and gravel (tons)	2,630,827	728,238	245,755	11,993,124
Bentonite (tons)	0	412,654	0	4,453,282
Decorative stone (tons)	0	67	0	5,959
Taxable Valuation (\$ millions)				
Oil	397	33	0	2,332
Gas	432	1,023	172	7,601
Coal	3,528		0	4,020
Uranium	0	0	0	33
Sand and gravel	4	1	0	23
Bentonite	0	3	0	64
Decorative stone	0	0	0	0

Source: Wyoming Department of Revenue 2011. Data are for year 2010.

Travel, Tourism, and Recreation

Federal lands in the planning area provide a broad spectrum of outdoor opportunities for planning area residents and visitors. Recreation on public lands also provides economic benefits. Recreation service providers (e.g., hotels, outfitters, equipment manufacturers and dealers, and restaurants) depend on public lands, in part, for their livelihood. The approximately 800,000 acres of BLM surface in the planning area receive approximately 31,400 visits per year (BLM 2008a). Most recreational users of BLM surface are Wyoming residents. The towns of Sheridan, Buffalo, Gillette, Wright, and Kaycee all have public lands bordering them that are used as “backyard” recreation areas by local residents. However, visitors from outside Wyoming come to the planning area from all over the United States and from international locations. Visitors to the planning area come because of the central location (with Yellowstone National Park and the Bighorn National Forest to the west, Montana to the north, the Black Hills to the east, and Colorado to the south) and the historic and cultural resources. Hunting, fishing, target shooting, and vehicle touring are among the most common recreational activities on BLM-administered lands in the planning area. Therefore, BLM-administered lands contribute to economic values in the planning area, albeit

mainly for local residents and those traveling through to use recreational areas administered by the USFS, the National Park Service, or other agencies.

Figure 3.25, “Travel and Tourism Spending in the Planning Area” (p. 615) shows travel and tourism spending in the planning area. In real terms, travel and tourism spending was steady from 2000 to 2004 and increased slightly from 2004 to 2006, with some decline after 2006, more pronounced in Sheridan County. The figure does not distinguish travel for business from travel for pleasure; however, a recent study by the Wyoming Office of Travel and Tourism indicates that statewide in recent years, most trips (e.g., 98% in 2006) are due to tourism for pleasure (Wyoming Travel and Tourism 2007).

Figure 3.25. Travel and Tourism Spending in the Planning Area

Livestock Grazing

The BLM is responsible for administering livestock grazing on public land surface across the planning area. Livestock grazing includes the grazing of domestic animals (e.g., cattle, sheep, horses, yaks, and bison). The BFO manages livestock grazing on 782,102 acres. This acreage incorporates 427 grazing leases, authorizing approximately 106,078 AUMs of livestock forage in 477 grazing allotments. Four hundred livestock operators use public lands in the planning area in Campbell, Johnson, and Sheridan counties; most of the public lands are in Johnson County. The BFO also administers grazing use for public lands within the boundaries of adjacent BLM Field Offices through cooperative management agreements.

Livestock grazing on allotments is authorized during various times throughout the year depending on management objectives. In addition to the allotments, the BFO manages two major stock

driveway systems – Kaycee (28.5 miles) and Hazelton Road (51.2 miles). These two stock driveways include segments of other trails, which for administrative purposes are considered part of the main stock driveway. The stock driveways are mostly fenced lanes.

BLM-administered grazing allotment fees are lower on average than state or private lands. The federal grazing fee has been kept at \$1.35 per AUM from 2007 to 2012 (Vincent 2012). For comparison, grazing fees on state land were \$4.78 per AUM in 2006, \$5.17 per AUM in 2007, and \$5.21 in 2008 (Pannell 2008). The average grazing rate on privately owned non-irrigated land in Wyoming was \$16.00 per AUM in 2009, \$16.64 in 2010, and \$15.70 in 2008 (National Agricultural Statistics 2011).

However, the lower lease fees correspond to potentially greater use restrictions and responsibilities for the lessee. For example, federal grazing leases typically restrict the number and species of animals that may be grazed, while on private leases, there is normally no penalty for grazing more than the agreed-upon numbers of animals (USFS and BLM 1992). However, if running more animals on a private lease results in overgrazing, the landowner might not be willing to renew the lease, because if the lessee fails to maintain the condition of the property the agreement can be terminated (USFS and BLM 1992). Federal leases also tend to be less flexible than private leases regarding adjusting turnout and roundup dates (USFS and BLM 1992). In addition, there are differences in relation to construction and maintenance of rangeland improvements such as fences and water developments, although a perfect comparison is not possible because there are different specifications that vary for specific private leases. On federal leases, construction of improvements can be done in a variety of ways, and expenses other than materials could be the responsibility of the lessee; the lessee also is generally responsible for maintaining the improvements. On private leases, the landowner typically bears a substantial part of the cost of major range improvements and typically pays for revegetation (USFS and BLM 1992).

In addition, lessees on privately held land may have more influence in negotiating agreements related to access and land development. For instance, in some cases lessees have the ability to help negotiate any agreements regarding a Plan of Development for oil or gas exploration or production, and depending on the agreement may receive surface damage payments from an O&G operator. Lessees of private land may also have more ability to negotiate over public access to the land they lease.

Taylor et al. (2004) analyzed the importance of BLM-administered land for livestock grazing in nearby Fremont County using a simulated enterprise-level ranch budget. Taylor et al. (2004) stated that most ranches typically depend only partially on federal land grazing for forage, but this forage source is a critical part of their livestock operations because of the seasonal dependency, even when the proportion of acres of AUMs contributed by federal land grazing is relatively small for the operation. Much of a ranch's private land is used as hay ground to produce hay for winter feeding. Using hay acreage to feed cattle during the summer means a ranch has to purchase hay for the winter. The rigidity of seasonal forage availability means that the optimal use of other forages and resources are affected when federal AUMs are not available (Taylor et al. 2004). These authors and many others in studies they reviewed from 1975 through 2002 found that potential reductions in income and net ranch returns are greater than the direct economic loss from reductions in federal grazing.

Table 3.71, "Farm Income in 2011" (p. 617) summarizes farm income in the planning area counties. In all three counties, livestock and livestock products contribute the most of the gross farm income (at least 74%). Government payments contribute a very small amount. Although

gross income in the three counties together amounted to \$152 million in 2011, net income after expenses was negative in all three counties (and marginally positive in Campbell County if the variation in the value of inventories is considered). This fact highlights the marginal profitability of farm and ranch operations in the planning area counties, and suggests that even apparently small changes in BLM forage, other resources available to farms and ranches, or prices for inputs or products could adversely impact their viability.

Table 3.71. Farm Income in 2011

Farm Income (2011 \$ thousands)	Campbell County	Johnson County	Sheridan County
Gross income (\$)	51,877	38,540	61,996

Personal Income

This section describes personal income in the planning area. Table 3.72, “Personal Income and Earnings by Place of Work, 2011” (p. 618) summarizes the sources of personal income by place of work and county in the planning area. The table highlights county-level differences in the importance of various economic sectors, and the contribution of non-wage income, specifically dividends, interest, and rent, to personal income. In Campbell County, mining contributes almost two-fifths of total earnings by place of work, which is almost three times the contribution of any other sector. The next largest sectors are government (14%) and construction (9%). Campbell County also has a relatively low contribution from non-wage income and half of that of Johnson and Sheridan counties. Johnson and Sheridan counties have a relatively large share of income from mining; it is the third largest sector in both counties, with government employment contributing the largest share in each county followed by construction.

In all three counties, farm income contributes a very small share of earnings; in 2011, net farm income was negative in all three counties owing to expenses that exceeded gross income (Table 3.71, “Farm Income in 2011” (p. 617)). Agricultural services, such as custom tillage, may contribute as well, but the amount is no more than 2 percent in each of the three planning area counties.

The Bureau of Economic Analysis (BEA) data used to create Table 3.72, “Personal Income and Earnings by Place of Work, 2011” (p. 618) do not readily distinguish recreation earnings because these earnings can occur in a variety of sectors, including retail trade, accommodation and food services, and hunting, fishing, and trapping (included in the same row as logging and agricultural services). Subsequent tables and text provide available information on expenditures and sales tax receipts from activities related to travel and tourism, which serve as the closest approximation for recreation.

Table 3.72. Personal Income and Earnings by Place of Work, 2011

Table 3.73, “Earnings and Employment for Mining Activities (2010)” (p. 620) provides a summary of mining-related earnings and employment for the planning area counties for 2010. As the table shows, coal mining accounts for the majority of mining employment in Campbell County, while mining support activities are important in all three counties. O&G extraction and related support activities contribute some employment and earnings in all three counties, principally Campbell and Sheridan.

Table 3.73. Earnings and Employment for Mining Activities (2010)

Employment

Table 3.74, “Employment by Sector, 2011” (p. 622) summarizes employment by sector for the counties in the planning area. The breakout is comparable to the earnings table above, with substantial portions of employment derived from mining, construction, and government.

However, the differences between the two tables highlight the divergence in earnings per job in different sectors. For example, whereas mining contributes 38 percent of earnings in Campbell County, it contributes proportionally fewer jobs (27%), which illustrates the relatively high wages per job in the mining sector in that county. Similarly, retail trade accounts for 9 percent of jobs in Johnson County and 11 percent of jobs in Sheridan County, but contributes just 6 percent of earnings in Johnson County and 8 percent in Sheridan County. This divergence indicates that wages per job in this sector are relatively low, either because of lower wages per hour or because some jobs in the sector are seasonal or part-time.

Table 3.75, “Average and Median Income; Average Earnings Per Job” (p. 623) shows three different measures of earnings and income for the planning area counties using the most recent available data. Average earnings per job are highest in Campbell County, as is median household income; in Johnson and Sheridan counties, both of these measures are lower than in Wyoming, and average earnings per job are lower than in the United States. Per capita income, however, is higher in all three counties than the national figure, and is highest in Sheridan County. The relative difference between average earnings per job (which measures employment income only) and per capita income (which also includes dividends, interest, rent, and transfer payments such as Social Security) in Johnson and Sheridan counties underscores the importance of non-wage income in these counties, which is also identified above in the earnings data.

Table 3.75. Average and Median Income; Average Earnings Per Job

Area	Per Capita Income (2011) (\$)	Average Earnings Per Job (2011) (\$)	Median Household Income (2011) (\$)

Table 3.76, “Unemployment Rate in 2008 through April 2011 (Percent)” (p. 623) lists the unemployment rate for counties in the planning area compared to state and national levels. As the table shows, unemployment in the planning area counties from 2008 through April 2011 was lower than in the United States and comparable to the statewide rate (slightly higher in Johnson, and lower in Campbell and Sheridan counties). Unemployment in Campbell County has remained lower than the statewide rate by approximately one percentage point. The unemployment rate was highest in 2010 in the planning area, Wyoming, and in the country as a whole, and fell slightly in 2011.

Table 3.76. Unemployment Rate in 2008 through April 2011 (Percent)

Area	2008 (annual average)	2009 (annual average)	2010 (annual average)	2011 (annual average)
Campbell County	2.0	5.4	6.0	4.6
Johnson County	3.3	7.5	8.2	7.1
Sheridan County	3.1	6.8	7.7	6.9

United States	5.8	9.3	9.6	8.9
Sources: Bureau of Labor Statistics 2012a; Bureau of Labor Statistics 2012b				

Cost of Living

One factor that affects economic and social trends in communities is the cost of living. The Wyoming Economic Analysis Division calculates relative changes in cost of living over time by estimating the cost of a set of goods and services that represents the average consumer’s purchases for housing, food, health care, travel costs, and other items. If the cost of living for a particular area increases faster than average income, that could mean that longtime residents, especially those on fixed incomes, could find their lifestyles less affordable over time. Over the long term,

a higher cost of living could encourage people to move out of a community and discourage people from moving into the community in conjunction with employment opportunities. Overall migration into the area will likely decrease, and the demographic and socioeconomic characteristics of those who move in will be determined partially by the cost of living in the area.

The Wyoming Economic Analysis Division (2012a) calculates the change in the cost of living over time for a five-county region in northeast Wyoming, consisting of Campbell, Crook, Johnson, Sheridan, and Weston counties. Figure 3.26, “Cost-of-Living Trends in Northeast Wyoming, the State of Wyoming, and the United States” (p. 624) shows how the cost of living in northeast Wyoming has changed in relation to the cost of living in Wyoming generally and in the United States. Starting in about 2000, the cost of living in the northeast region and Wyoming as a whole began to increase at a greater rate than the cost of living in the United States. The cost of living in the northeast region has risen slightly faster than the cost of living in the state as a whole, but only slightly.

Source: Wyoming Economic Analysis Division 2012a

Figure 3.26. Cost-of-Living Trends in Northeast Wyoming, the State of Wyoming, and the United States

Housing

Table 3.77, “Average Housing Price, 1998-2011” (p. 625) lists average housing prices for the planning area counties from 1998 to 2011 based on sales of existing, detached single family homes on 10 acres or less sold during the previous calendar year (WHDP 2009; WHDP 2012). Figure 3.27, “Average Housing Price, 1998 through 2011” (p. 625) shows the same information graphically. The table and figure show that housing prices in the planning area counties have increased or decreased generally at the same rate, and at approximately the same rate as statewide.

From about 2004 through 2007, housing prices increased at a faster rate than from 1998 through 2003, but then declined slightly with the recent economic downturn.

Table 3.77. Average Housing Price, 1998-2011

Year	Campbell County	Johnson County	Sheridan County	Wyoming
1998 (\$)	105,356	102,678	101,160	96,906

Table 3.78, “Rental Housing Availability (Percent)” (p. 627) lists information about rental housing availability (i.e., rental vacancy rates) since 2001. Vacancy rates in Campbell County were generally quite low from 2001 through 2007, while vacancy rates in Sheridan and Johnson counties were somewhat variable. In 2007, vacancy rates were low – less than two percent for all three counties – but in 2008 they increased, particularly in Campbell County, and remained relatively high since then.

Table 3.78. Rental Housing Availability (Percent)

Table 3.79, “Poor-Rich Ratio, Employment Specialization, and Residential Adjustment” (p. 628) lists information about some additional economic variables of interest. The ratio of relatively low-income households to relatively high-income households, which provides an indication of the proportion of low-income households relative to high-income households, is lower in Campbell County and higher in Johnson and Sheridan counties, compared to the same statistic for the United States. The index of employment specialization is highest in Campbell County, reflecting primarily the relative concentration in the mining industry that was also seen in the earnings and employment statistics above. The index of employment specialization is higher in all three counties than the median for United States counties, which indicates that employment in all three of counties is relatively concentrated in a small number of industry sectors. This lack of diversification can mean that boom and bust cycles that affect particular industries can have a particularly acute impact in the planning area. Finally, the net residential adjustment shows the degree to which commuting across county borders affects earnings by place of work. Johnson and Sheridan counties had a positive residential adjustment in 2011, indicating that more earnings are received by people commuting out of these counties to work (the counties are “bedroom communities”). Campbell County had a relative large negative residential adjustment, indicating that considerable income is received by people commuting into the county to work (accounting for approximately 9.5% of the total personal income in the county).

Table 3.79. Poor-Rich Ratio, Employment Specialization, and Residential Adjustment

Area	Poor-Rich Ratio (2010) ¹	Employment Specialization Index (2005) ²	Net Residential Adjustment (%) (2011) ³
Campbell County	3.7	640	-9.5
Johnson County	7.2	369	3.7
Sheridan County	10.1	185	4.0
United States ⁴	5.6	155	n/a

Sources: U.S. Census Bureau 2010c; Headwaters Economics 2007a; Headwaters Economics 2007b; Headwaters Economics 2007c; Bureau of Economic Analysis 2012a

¹Measures the ratio of households with income less than \$25,000 to those with income exceeding \$200,000 (in the 2006–2010 period). For example, a ratio of 10 indicates there are 10 households with income less than \$25,000 for every household with income more than \$200,000.

²A relative measure of the diversity of the employment base of a county compared to the employment base of the United States as a whole. A lower index indicates a more diverse employment base; a higher index indicates greater specialization (employment is more concentrated in a few economic sectors).

³A positive residential adjustment indicates that more earnings are received by people who commute out of the county to work; a negative adjustment indicates that more earnings are received by people who commute into the county to work. The numeric value is the net proportion of total personal income earned across county lines.

⁴In the case of the Employment Specialization Index, represents the median for all counties in the United States (not the median value for the United States as a whole).

% percent

Tax Revenues

Economic activities on BLM-administered land and mineral estate contribute to the fiscal wellbeing of local, state, and federal governments. BLM management actions have the potential to affect tax revenues from mining and mineral production; travel, tourism, and recreation; and livestock grazing and ranching. Other BLM fiscal contributions would likely not be impacted by the choice of BLM management alternative (Payments in Lieu of Taxes) and are not discussed further.

Mineral Severance Taxes

The mining industry contributes substantially to state and local tax revenues. For example, the Wyoming State Auditor (2012) reported that state mineral severance taxes and federal mineral royalties returned to the state represented 31 percent of total state revenues in Fiscal Year 2012 – a total of \$877 million. Table 3.80, “Estimated State Severance Tax Collections in the Planning Area Counties for Production Year 2010” (p. 629) lists estimated state severance tax collections for the planning area counties and Wyoming for production year 2010.

Property Tax and Sales Tax Base (Tax Revenues)

Another way to look at the contributions of different industries in the planning area is to consider how different economic sectors contribute to local and state property values for the purpose of property tax levies, and to local and state sales taxes. Table 3.81, “Local and State Assessed Property Valuation, 2011” (p. 629) lists local and state assessed property valuation in 2011 for the planning area counties and Wyoming. Table 3.82, “State and Local Sales Tax Collections by Sector, 2011” (p. 630) lists local and state sales tax revenues by sector for each of the counties.

Table 3.80. Estimated State Severance Tax Collections in the Planning Area Counties for Production Year 2010

Together, the data on sales tax collections and property tax assessed valuations by sector provide insight into the economic base of the counties. The fiscal stability of local and state government depends on the viability and stability of local industries. Consistent with other data in this section, the mining sector is fundamental for property tax revenue, especially in Campbell and Johnson counties. In Sheridan County, mining-related property provides an important portion of locally assessed valuation, but in a lower proportion than average for the state. Residential property also provides important contributions to local assessed valuation. Agricultural, commercial, and industrial property contribute smaller amounts to local and state assessed valuation.

Mining and retail trade are the most important contributors to sales tax collections in the planning area counties. The wholesale trade sector in Campbell County, utilities in Johnson County, and the leisure and hospitality sector in Sheridan County also contribute with important shares of sales taxes. Separate data on sales tax revenues from retail trade, accommodation, and food sales (Table 3.83, “Retail, Accommodation, and Food Sales: State and Local Sales Tax Collections, 2011” (p. 631)) provide some additional insight into the contribution from elements that could be related to travel and tourism specifically – eating and drinking places and lodging. (A sizable portion of tax collections from eating and drinking places also accrue from local residents, and a portion of gasoline station tax collections would also accrue from tourists and business travelers.) These data suggest that travel and tourism is an important contributor to sales tax collections in the planning area counties, but do not dominate collections or make an overwhelming contribution.

The Wyoming Office of Travel and Tourism, estimated that in 2011 travel and tourism from business and recreational visitors accounted for \$68.4 million in state sales, use, and lodging tax revenues and \$42.0 million in local sales, use, and lodging tax revenues, not including property tax collections related to recreation infrastructure (Dean Runyan Associates 2006). These estimates are based on the data above, and additional survey data from a variety of sources. Table 3.84, “Local and State Tax Receipts Due to Travel and Tourism in Wyoming, 2011 (\$ millions)” (p. 631) shows tax receipts for the counties in the planning area.

Table 3.84. Local and State Tax Receipts Due to Travel and Tourism in Wyoming, 2011 (\$ millions)

Non-Market Values of BLM-Administered Lands

BLM-administered lands have non-market value to residents, communities, and occupation and interest groups in the planning area. Non-market values are those not reflected in market transactions and for which there is no well-defined market price. They include values associated with the use of lands but that are not captured (or fully captured) in market transactions (e.g., recreation on BLM-administered lands, the value of the viewshed) and values associated with the simple existence of natural resources on BLM-administered lands (e.g., the value biodiversity and protection of natural habitats).

Although the BLM was unable to identify studies of non-market values for the planning area, there are non-market values that are typically associated with the types of use of BLM-administered lands in the planning area and with some of the occupation and interest groups present in the planning area. There is evidence of non-market values associated with a variety of recreational activities present on BLM-administered lands, such as hunting, fishing and off-road vehicle driving (Loomis 2005). There is also evidence of non-market values associated with the protection of rare and endangered species similar to species present in the planning area such as the Greater Sage-Grouse (Richardson and Loomis 2009). Particular occupation and interest groups are likely to attribute non-market values to specific aspects of BLM-administered lands such as the protection of natural environments (environmental groups), benefits for activities associated with specific lifestyles (e.g., ranching), or the natural scenery.

3.8.3. Health and Safety

3.8.3.1. Regional Context

The BLM Hazard Management and Resource Restoration Program addresses a variety of hazards on public surface to reduce risks to visitors and employees. Hazards can include hazardous materials; abandoned mine shafts and adits; abandoned equipment and structures; explosives and munitions; toxic gases; and spills from pipelines, tankers, and storage tanks, among others.

Activities directed toward health and safety concerns in the planning area primarily encompass the following:

- AMLs
- O&G facilities
- Hazardous wastes and materials
- Physical hazards

3.8.3.2. Indicators

Management indicators include: AMLs, coal seam fires, hazardous materials and waste, and physical hazards.

3.8.3.3. Current Condition

Abandoned Mine Lands

At present, there are there are 72 known AML sites in the planning area. These sites include sand, gravel, bentonite, coal, and other mineral mining sites. New AML sites typically are found every year; therefore, current database records might not include every AML site in the planning area (BLM 2009g).

Physical hazards are common at abandoned mine sites and these hazards are not always apparent to visitors. Abandoned mine sites have proven to be a luring and sometimes life-threatening attraction for both children and adults. Serious injury or death can occur at these sites. Common hazards include open vertical shafts; unstable overhead rock and decayed support structures; deadly gases and lack of oxygen; remnant explosives and toxic chemicals; high walls, open pits, and open drill holes; and becoming lost and disoriented while underground. Subsidence at abandoned coal mines and coal seam fires pose additional hazards. The BLM Wyoming State Office has a prioritized list of AML sites that pose the greatest risk to people and the environment.

AML sites that impact water quality are addressed using the watershed approach. Using this approach accomplishes the following objectives:

- Allows mitigation to be risk based by identifying priority sites
- Fosters collaborative efforts across federal, state, and private administrative boundaries
- Considers all issues important to water resource protection
- Reduces the cost of mitigation
- Provides the most efficient method of remediating AML sites by utilizing a wide range of available resources

The BLM and the Wyoming DEQ, AML Division, have a cooperative agreement that facilitates the reclamation of AML sites on BLM-administered lands. The state program, as required by the Surface Mining Control and Reclamation Act of 1977, focuses on public safety hazards. In addition, the BLM has received some funding from its AML Program to address environmental hazards and watershed concerns associated with abandoned mines on a site-specific basis. By combining available funding, safety hazards and environmental impacts to water quality and watershed function can continue to be addressed in a more comprehensive fashion at priority AML sites. In this collaborative partnership approach, the BLM and the Wyoming DEQ, AML Division, are undertaking several AML reclamation projects on public lands in the planning area.

Coal Seam Fires

The burning of coal seams is not an uncommon occurrence and can be started either naturally or by human activity. With the right conditions, spontaneous combustion can occur, particularly when oxygen is present. Coal seams can also ignite from lightning strikes, wildfires, or other ignition sources.

In the western United States, research has shown that numerous coal seam fires have occurred over the last several million years. The most extensive burning of coal seams has taken place in the PRB in northeastern Wyoming and southeastern Montana, resulting in the formation of large amounts of clinker (see *Mineral Resources — Salable Minerals*) (Heidel 2007). There are 43 known active and historic coal seam fires in the planning area, with the majority of these occurring on privately-owned lands (BLM 2011g).

Threats to public health and safety include gas emissions and physical hazards. Emissions from coal seam fires can include CO₂, CO, NO_x, SO₂, and trace elements such as arsenic, mercury, and selenium (Finkelman 2004). In limited testing in the PRB, elevated levels of CO and CH₄ have been detected (Coates and Heffern 1999). As a coal seam burns, the space that the coal took up is now partially empty. The rocks and soils over them are left without proper support, and they can subside, creating fissures that can reach the surface. These fissures can be several to tens of feet deep, creating a direct hazard to humans and wildlife.

Hazardous Materials and Waste

Hazardous materials in the planning area are associated with activities performed by industry and the public, and by illegal dumping of commercial or household waste. There are no approved hazardous waste dumps or repositories in the planning area. Table 3.85, “Activities and Associated Hazardous Materials” (p. 634) lists and describes potential sources of hazardous materials.

Table 3.85. Activities and Associated Hazardous Materials

Activity	Associated Hazardous Material
Hazardous materials associated with historic and ongoing mining operations	<ul style="list-style-type: none"> • Acid rock drainage • Chemicals associated with processing rock or ore, or used in laboratories • Explosives • Heavy metals • Asbestos
Illegal dumping	<ul style="list-style-type: none"> • Unauthorized landfills • Dumping of barrels or other containers with hazardous substances
Illegal activities	<ul style="list-style-type: none"> • Drug laboratory waste • Wire burns • Abandoned property
Hazardous material spills	<ul style="list-style-type: none"> • Spills from vehicle accidents • Industrial accidents
Oil and gas activities	<ul style="list-style-type: none"> • Hydrogen sulfide gas • Petroleum and chemical spills • Pipeline releases • Leaking tanks • Asbestos • Industrial accidents
Source: BLM 2009e	

Physical Hazards

In addition to hazardous materials, there is a variety of other hazards that could pose a risk to the public and the environment. These could include physical hazards such as abandoned structures or equipment, mine shafts, explosives and munitions, and solid waste dumps. Environmental hazards include petroleum or other chemical releases from pipelines, commercial vehicles, and storage facilities that are not regulated for hazardous materials.

Program Objectives

To protect human health and the environment and comply with applicable laws and regulations, the BLM Hazard Management and Resource Restoration Program has the following objectives:

1. Identify and control imminent hazards or threats to human health and the environment from hazardous substance releases on public lands.
2. Promote working partnerships with states, counties, communities, other federal agencies, and the private sector to prevent pollution and minimize hazardous waste on public lands.
3. Provide hazardous materials management training to BLM employees and educate public land users concerning laws, rules, and standards.
4. Require potentially responsible parties to undertake response actions and to pay their fair share or face cost recovery.
5. Encourage public collaboration in environmental decision making.
6. Inventory, assess, and manage the cleanup of hazardous substance release sites on public lands that present a potential risk to human health and the environment and promote healthy ecosystems.

7. Ensure that solid and hazardous waste treatment, storage, and disposal facilities that might affect public lands are properly located, designed, and constructed, consistent with the law.
8. Reduce hazardous waste produced by BLM activities and from authorized uses of public lands through waste minimization programs that include recycling, reuse, substitution, and other innovative, safe, and cost-effective methods to prevent pollution.
9. Ensure that authorized activities on public lands comply with applicable federal, state, and local laws, regulations, policies, guidance, and procedures.
10. Ensure appropriate review of authorized activities and application of effective management controls to correct weaknesses.

Management Challenges

Continued O&G development, particularly the transition from CBNG development to more conventional natural gas development, has the potential to increase hazardous materials spills from well drilling and development; pipelines; compressor stations; service vehicles and trucks; and other associated activities. Like many industries, O&G operators use specific chemicals in their drilling, recovery, and manufacturing processes. Unfortunately, “green” alternative products are not available for all chemicals used for drilling and development of oil and natural gas wells. Therefore, the focus is for the operators to minimize potential environmental impacts by properly storing, transporting, using, and disposing of hazardous materials.

With the increase in population related to energy development, increased recreational use of public land can lead to additional opportunities for illegal dumping of solid and hazardous wastes.

3.8.3.4. Trends

As the demand for oil, gas, and minerals increase, so does the potential for hazardous materials spills. Although industrial operations are regulated to minimize any potential spills, accidents can never be completely eliminated. Increased recreational activities on BLM-administered lands will put visitors at a greater risk of encountering a variety of hazards, such as chemical and physical hazards left over from past industrial operations; illegal waste dumping; and illegal drug manufacturing wastes. Although the workload could increase, the Hazard Management and Resource Restoration Program will continue to manage and respond to foreseeable hazards on BLM-administered lands the same as it does now. The program will continue to emphasize protection of public health, safety, and the environment; waste minimization; and compliance with all laws, policies, and regulations.

3.8.3.5. Key Features

There are no key features for the health and safety program.

3.8.4. Environmental Justice

Minority Populations

BLM IM 2002-164, *Guidance to Address Environmental Justice in Land Use Plans and Related NEPA Documents*, provides policy and guidance for addressing environmental justice in BLM land use planning (BLM 2002). IM 2002-164 defines minority persons as “Black/African American, Hispanic, Asian and Pacific Islander, American Indian, Eskimo, Aleut, and other non-white persons.” In addition, IM 2002-164 states that an area should be considered to contain a

minority population where either the minority population of the affected area exceeds 50 percent, or the percentage of minority population in the affected area is meaningfully greater than the percentage in the general population.

Populations of the three counties in the planning area are predominantly white and non-Hispanic. Although minority populations have increased slightly from 2000 to 2011, all counties have a larger proportion of non-Hispanic white residents than do the state or the country. Table 3.86, “Minority and Low-Income Populations in Planning Area Counties, Wyoming, and the United States in 2000 and 2011” (p. 636) lists the percent of minority population and population in poverty in the counties in the planning area in 2000 and 2010.

Table 3.87, “Minority and Low-Income Populations in Planning Area Towns, Wyoming, and the United States in 2000 and 2011” (p. 636) lists population by race, ethnicity, and percent in poverty by town in the planning area in 2000 and 2011. The town of Clearmont has the highest percent minority among the towns listed in Table 3.87, “Minority and Low-Income Populations in Planning Area Towns, Wyoming, and the United States in 2000 and 2011” (p. 636), approximately twice the percent minority in the State of Wyoming.

Table 3.88, “Racial and Ethnic Groups in Buffalo Planning Area Counties and Wyoming, 2011” (p. 637) lists population by race and ethnicity in the planning area. The largest ethnic or racial group other than non-Hispanic whites in any of the counties is Hispanic or Latino (of any race); however, in all three counties the percent of people in this ethnic group is lower than that for Wyoming as a whole. Most ethnic and racial groups comprise a very small portion of populations in the planning area counties.

Source: U.S. Census Bureau 2011a; percentages may not add up to 100 percent due to rounding

In addition to the minority populations within the planning area, nearby reservations for Native American populations constitute an important part of the regional economy and social framework in the planning area. The Crow Indian Reservation, which is located in Bighorn, Yellowstone, and Treasure Counties in Montana, is adjacent to the northern border of the planning area, and the Northern Cheyenne Indian Reservation is 25 miles north of the northern border of the planning area. Many tribal members travel to Sheridan for shopping and to obtain services.

Low-Income Populations

BLM IM 2002-164 states that low-income populations can be identified according to poverty thresholds published by the U.S. Census Bureau. In addition, the IM notes, “when considering these definitions, it is important to recognize that some low-income and minority populations may comprise transitory users of the public lands and thus not associated with a particular geographic area.”

The Council on Environmental Quality (CEQ) guidance for environmental justice analysis under NEPA defines a low-income population as “either a group of individuals living in geographic proximity to one another, or a set of individuals (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect (CEQ 1997).” Although CEQ guidance does not provide a quantitative threshold (e.g., a limit on the percent of persons in poverty) for determining whether a population should be considered low income, typically the percent of persons in poverty in the planning area is compared to that in a comparison area such as the state. Quantitative criteria for what constitutes a low-income population are not specified in BLM or CEQ guidance.

As Table 3.86, “Minority and Low-Income Populations in Planning Area Counties, Wyoming, and the United States in 2000 and 2011” (p. 636) shows, the percentage of people with income

below the poverty level was less than 10 for all counties in the planning area in 2011, and all three counties saw a reduction in poverty from 2000 to 2011. The percentage of people in poverty was slightly higher in Wyoming and the United States in 2011. However, the town-level data in Table 3.87, “Minority and Low-Income Populations in Planning Area Towns, Wyoming, and the United States in 2000 and 2011” (p. 636) suggest that from 2000 to 2011, most counties with larger concentrations of persons living in poverty in the planning area saw reductions in their poverty rate.

3.8.5. Tribal Treaty Rights

A treaty is a formal agreement between the U.S. Government and a Native American Tribe or Tribes that cedes land or reserves rights to the tribe(s). Impacts to tribal treaty rights can include limitations on tribal hunting, fishing, or resource collection areas that were reserved by certain treaties. EO 13084, *Consultation with Indian Tribal Governments* (May 14, 1998), and EO 13007, *Indian Sacred Sites*, provide the framework for involving Native American Tribes in the BLM planning process. Additional guidance is provided in BLM Manual 8120, *Tribal Consultation*.

BLM land use plans must address the protection of any treaty rights within the planning area. The Wind River Reservation is the only reservation in Wyoming and is over 50 miles from the planning area. There are several reservations in states bordering Wyoming with tribes that historically had treaty rights in the PRB. Tribes may retain certain rights that were not specifically ceded when treaties were abrogated.

Impacts to tribal treaty rights can include limitations on tribal hunting, fishing, or resource collection areas that were reserved by certain treaties. Native Americans inhabited the planning area for thousands of years before European contact. The first treaty within the planning area was the Fort Laramie Treaty of 1851. The treaty defined the territory within the planning area west of the Powder River for the Crow Nation and the area east of the river for the Sioux Nation. The Fort Laramie Treaty of 1868 later proclaimed that Sioux Nation agreed to "relinquish all right to occupy permanently the territory outside their reservations" with their designated reservations being well outside of the planning area. The treaty also redefined the entire planning area as "unceded Indian Territory." However, the Sioux Nation did "reserve the right to hunt... ..so long as the buffalo may range thereon in such numbers as to justify the chase." within the unceded territory. The Treaty with the Crows, 1868 reduced the original territory of the Crow and also relinquished their territorial claims within the planning area. However, the tribe did retain "the right to hunt on the unoccupied lands of the United States so long as game may be found thereon, and as long as peace subsists among the whites and Indians on the borders of the hunting districts." The Treaty with the Northern Cheyenne and Northern Arapaho May 10, 1868 allowed both tribes to "...roam and hunt while game shall be found in sufficient quantities to justify the chase." within the planning area. Off reservation tribal hunting rights were debated in the courts for years, but the Supreme court decided in *Minnesota v. Mille Lacs Band of Chippewa Indians*, 526 U.S. 172 (1999) that any rights tribes did not relinquish still exist. It appears that minimally the Crow, Northern Cheyenne and Northern Arapaho still have treaty rights related to hunting within the planning area, however, these rights will not be part of BLMs planning effort since WGFD regulates hunting in Wyoming.

There are currently no trust lands, reservation lands, or tribally owned properties in the planning area as far as the BLM is aware. However, over the thousands of years of human occupation numerous other tribes have ties to the area as their ancestral territories or some tribes may have been associated with significant events that occurred within the planning area. Based on

these concerns the BFO may consult with the Cheyenne River Sioux Tribe, Oglala Lakota Nation, Rosebud Sioux Tribe, Fort Peck Sioux Tribe, Standing Rock Sioux Tribe, Lower Brule Sioux Tribe, Yankton Sioux Tribe, The Sisseton-Wahpeton Oyate, Crow Creek Sioux Tribe, Santee Sioux Tribe of Nebraska, Northern Cheyenne Tribe, Northern Arapaho Tribe, Crow Tribe, Eastern Shoshone Tribe, or the Three Affiliated Tribes regarding any Native American issues and concerns.

Proposed Resource Management Plan and Final Environmental Impact Statement for the Buffalo Field Office Planning Area

Volume 2 of 3 Chapter 4 (up to and including Section 4.4.8)

May 2015

Buffalo Field Office

The BLM's multiple-use mission is to sustain the health and productivity of the public lands for the use and enjoyment of present and future generations. The Bureau accomplishes this by managing such activities as outdoor recreation, livestock grazing, mineral development, and energy production, and by conserving natural, historical, cultural, and other resources on public lands.

Chapter 4. Environmental Consequences

This page intentionally
left blank

Introduction

This chapter describes potential effects on the existing natural and social environmental conditions in the Bureau of Land Management (BLM) Buffalo, Wyoming, planning area (see Chapter 3) under the alternatives described in Chapter 2. BLM planning regulations and Council on Environmental Quality (CEQ) National Environmental Policy Act (NEPA) implementing regulations at 40 Code of Federal Regulations (CFR) 1500–1508 require an analysis of these effects. This chapter describes potential effects under each alternative using the same order for resource topics as Chapters 2 and 3. Identical organization for the chapters allows readers to compare management actions (Chapter 2), existing environmental conditions (Chapter 3), and potential effects (Chapter 4) for the same resources.

The analysis of environmental consequences focuses on key planning issues (see Chapter 1) raised during the scoping process.

This chapter has 10 main sections:

- Physical Resources
- Mineral Resources
- Fire and Fuels Management
- Biological Resources
- Heritage and Visual Resources
- Land Resources
- Special Designations
- Socioeconomic Resources
- Irreversible or Irretrievable Commitment of Resources
- Unavoidable Adverse Impacts

The individual resource sections provide detailed analyses of effects under each alternative. The presentation order of these sections does not reflect their level of importance.

The subsection under each resource heading entitled *Impacts Common to All Alternatives* describes potential effects from management actions common to all alternatives. Effects included in this section are not repeated for individual alternatives. When effects would vary by alternative, they are addressed by alternative, and only potential effects under that alternative are described. If there would be no effects on given resource, that is stated within *Impacts Common to All Alternatives* section and there are no additional headings or discussion for that subject. Where potential effects from more than one management program would be very similar, they might be grouped under a single subheading (e.g., air quality and soil and water resources in the physical resources section).

During the effects analyses, each resource specialist considered management actions for other resources and programs areas. If no potential effects were identified by the resource specialist or by the public during scoping, the resources and programs are not further addressed. When management of a resource or program could affect the subject resource, those potential effects are described in detail.

Under all alternatives, the BLM would continue to comply with standard operating procedures resulting from federal laws, regulations, and policies. These standard operating procedures constitute day-to-day implementation of policy and management, and could result in certain projects being redesigned or eliminated from consideration, or could require mitigation measures

for potential adverse effects. Associated limitations or complications (e.g., increased processing times or costs) are not considered effects and are not further addressed in this chapter.

Sections at the end of this chapter describe irreversible or irretrievable commitments of resources and unavoidable adverse impacts.

Methods and Assumptions

This section describes methods and assumptions employed during the analyses, defines the types of effects projected throughout the impact sections, defines significance, categorizes effect levels, discusses the availability of data, and identifies several themes that relate to multiple resource classes.

Impact analyses and conclusions are based on interdisciplinary team knowledge of the resources and the planning area, information provided by BLM experts or experts from other agencies, and information in pertinent existing literature. Spatial analysis was performed using the Environmental Systems Research Institute, Inc. ArcGIS Desktop 10.0 computer software. The baseline used to determine potential effects is existing conditions as described in Chapter 3, Affected Environment. Analysis assumptions were developed to help guide the determination of effects. The Resource Management Plan (RMP) and Environmental Impact Statement (EIS) provides a broad management framework; the analyses described in this chapter represent the best estimates of effects because exact locations of development or management often are not known. Effects are quantified to the extent practical based on available data. In the absence of quantitative data, best professional judgment was the basis for the analysis. Effects are sometimes described using ranges of potential effects or in qualitative terms, if appropriate.

Analysis Assumptions

Several assumptions were made to facilitate the analysis of potential effects. These assumptions set guidelines and provide reasonably foreseeable projected levels of development in the planning area during the planning period. These assumptions should not be interpreted as constraining or redefining the management objectives and actions proposed under each alternative and described in Chapter 2. If there were no assumptions for a particular resource or program, the heading is not included in the resource section.

General Assumptions

- Key planning issues identified in Chapter 1 provide the focus for the scope of effects analyses in this chapter.
- Existing state and federal environmental legislation and regulatory programs would remain relatively unchanged and in effect (i.e., analyses are based on current, rather than projected future regulations).
- To the extent possible and within legal and regulatory parameters, BLM management and planning decisions will be consistent with the planning and management decisions of other agencies, state and local governments, and Native American tribes with jurisdictions intermingled with the Buffalo planning area.
- The life of the RMP (planning period) is 20 years.
- Reasonably foreseeable action (RFA) or activity scenarios for all land and resource uses (including minerals) have been developed and presented based on historical, existing, and projected activity levels for all programs.

- The alternative ultimately implemented will comply with standard practices, best management practices (BMPs), guidelines for surface-disturbing activities, and mitigation guidelines (see Appendix J (p. 2155) and Appendix D (p. 1863)). In other words, the practices and guidelines included identified in Appendix J (p. 2155) and Appendix D (p. 1863) are considered a component of each alternative. Appendix J (p. 2155) lists standard practices used in the planning area to mitigate the adverse effects of surface-disturbing activities (the Wyoming BLM mitigation guidelines for surface-disturbing and disruptive activities).
- The analysis of effects focuses on the anticipated effects of management actions and allowable uses proposed under each alternative. The effects of past and present actions are encompassed in the description of existing conditions (Chapter 3, Affected Environment).
- Discussions of effects are based on best available data. Knowledge of the planning area and professional judgment, based on observations and analyses of conditions and responses in similar areas, are used to infer environmental effects when data are limited.
- Acreage figures and other numbers used in the analyses are approximate projections for comparison and analytical purposes only. Readers should not assume numbers reflect exact measurements or precise calculations.
- Climate change is occurring and could affect surface resources in the planning area.
- The exact locations of future surface-disturbing activities cannot be predicted at the RMP level. For analysis purposes, surface-disturbing activities are assumed to occur in vegetation types in proportion to their availability in the planning area. Affected acreages for vegetation types are not absolute, but provide a basis for relative comparison among alternatives.
- Measures to mitigate adverse effects will be applied as described in Chapter 2 and applicable appendices.
- Sufficient funding and personnel would be available to implement the alternatives described in Chapter 2.
- Appropriate maintenance would be performed to maintain the functional capability of all developments.
- Monitoring will be completed as indicated, along with any needed adjustments or revisions.
- The comparison of effects among resources is intended to provide an impartial assessment to inform the decision maker and the public.

Types of Effects

The analyses consider direct, indirect, and cumulative effects, consistent with direction at 40 CFR 1502.16.

- *Direct effects* are caused by an action or by implementation of an alternative and occur at the same time and place as that action or implementation. For example, for the action of building a road, a direct adverse effect is surface disturbance. Surface disturbance is the effect of heavy equipment (the cause) removing existing vegetation, wildlife habitat, and topsoil as it grades the road location.
- *Indirect effects* also result from an action or implementation of an alternative, but usually occur later in time or removed in distance from the action or implementation. For the action of building a road, an indirect effect could occur days after the surface is disturbed and some distance from the disturbance. Heavy precipitation following the removal of vegetation and disturbance of the ground surface could erode soil and transport sediment into streams. This effect on stream-water quality would be considered indirect.
- *Cumulative effects* result from individually minor but collectively significant actions over time. A cumulative effect is the effect on the environment that results from the incremental effect

of the federal action when added to other past, present, and reasonably foreseeable future actions, federal and non-federal.

Actions anticipated during the planning period on all lands in the planning area, including private, State of Wyoming, and federal (U.S. [United States] Department of Defense and U.S. Department of Agriculture [USDA] U.S. Forest Service [USFS]) lands, have been considered in the analyses to the extent reasonable and practicable. Many public and private entities could make decisions about other actions in the planning area, although the locations, timing, and magnitude of these actions cannot be accurately predicted. Assumptions about actions outside of BLM jurisdiction considered in the cumulative effects analyses include:

- Mineral exploration and development will continue on state and private lands.
- Mineral exploration and development will remain minimal in the Bighorn National Forest.
- Use of communications sites will increase.

Irreversible commitments of resources result from actions that permanently change resources. Irretrievable commitments of resources result from actions that cause the permanent loss of resources. Residual effects are those that remain following the implementation of mitigation measures, and include effects for which there are no mitigation measures. Short-term uses versus long-term productivity refers to the relationship between short-term uses of the human environment and the maintenance and enhancement of long-term productivity of environmental resources.

Determination of Significance

Any type (e.g., direct, indirect, or cumulative) or combination of effects can be determined “significant.” A determination of significant requires consideration of the context and intensity of the effect. This means that an action must be analyzed in several contexts—such as the immediate vicinity, affected interests, and locality. Both short-term and long-term effects are relevant. Intensity refers to the severity of the effect. This environmental analysis uses the terms “negligible,” “minor,” “moderate,” and “major” to describe the significance of effects.

Determining significance is a complex process. The significance of an effect is dynamic and therefore could change during the planning period. Significance can be “actual” and supportable by fact, or “perceived” and perhaps not fully supportable even with rigorous study. For this environmental analysis, the approach to establishing significance was based on, but not limited to, legal requirements, public perception, monitoring data, and professional judgment.

Specific significance criteria are presented for each resource topic. The criteria provide thresholds beyond which effects would be considered significant. The discussion of each resource ends with a summary regarding the significance of effects.

Scale of Impacts

The following terms are used to define the extent of environmental consequences:

- Negligible – The effect on the resource would be barely detectable; less than one percent of the resource would be affected. This level of effect is considered to be not significant.
- Minor – The effect on the resource would be slight but detectable; there would be a small change in the resource. This could include effects on 1 percent to 5 percent of the resource. This level of effect is considered to be not significant.

- Moderate – The effect on the resource would be readily apparent; there would be a measurable change in the resource. This could include effects on between 5 percent and 10 percent of the resource. This level of effect is considered to be potentially significant.
- Major – The effect on the resource would be great; there would be a highly noticeable, long-term, or permanent measurable change in the resource. This could include effects on more than 10 percent of the resource. This level of effect is considered to be significant.

Availability of Data and Incomplete Information

The BLM used the best information available and pertinent to the decisions to be made through this RMP, and has expended considerable effort to acquire and convert resource data into a digital format for use in the plan. Data have been acquired from BLM sources and outside sources, such as the state.

Some information was not available for use in developing this plan, usually because there have been no inventories or inventories are not complete. Specific data not available include:

- Inventory and assessment of roads and trails
- Invasive plant species occurrence
- Definitive SSS occurrence (plant and animal)
- Certain wildlife data (definitive occurrence for many species)

Because these data are not available, effects cannot be appropriately quantified given the proposed management of certain resources. In these cases, potential effects are described in qualitative terms or, in some cases, stated as unknown. Subsequent project-level analyses will provide the opportunity to collect and examine site-specific inventory data necessary to determine the appropriate application of the RMP-level guidance. In addition, inventory efforts identified in Chapter 2 will continue to update and refine the information used to implement this plan.

Themes Relating to Multiple Resources

Split Estate

In split estate situations, different parties own the surface rights and subsurface rights (such as the rights to develop minerals) for a parcel of land. In these situations, mineral rights are considered the dominant estate, meaning they take precedence over other rights associated with the property, including those associated with owning the surface. However, the owner of the mineral estate must consider the interests of the surface estate owner. The fluid mineral rights lessee has the right to “use so much of the leased lands as is necessary to explore for, drill for, mine, extract, remove and dispose of all the leased resource” (43 CFR 3101.1-2).

During the early homesteading days, the federal government did not retain rights to the minerals or retained only the rights to coal (i.e., the Homestead Act or the Enlarged Homestead Act). However, concern grew regarding the need for strategic minerals to fuel the national economy. Later homestead acts, such as the Stockraising Homestead Act of 1916, granted land patents to private parties, but reserved the mineral rights to the federal government. The BLM must comply with the provisions of the laws under which the surface was patented. However, many of those laws do not identify the rights of the surface owner in split estate mineral development situations.

BLM involvement in split estate applies primarily to situations where the surface rights are in non-federal ownership and the rights to development of the mineral resources are publicly held and managed by the federal government. BLM authority in regards to split estate management varies by mineral type. For example with coal, Section 714 of Surface Mining Control and

Reclamation Act gives qualified surface owners veto power over surface coal leasing on their property (43 CFR 3427). The remainder of this section is specific to fluid minerals as it is the predominant use within the planning area. The Energy Policy Act requires that the BLM consult with affected property owners, representatives of the oil and gas industry, and other interested parties as it performs permit reviews (BLM 2006e). BLM policy requires that the minerals operator to engage the surface owner in negotiations for the purpose of obtaining a surface use agreement. The surface owner is invited to attend all meetings the BLM has with the minerals operator and invited to identify their concerns.

During a permit review, the BLM recommends the same level of resource protection to the surface owner's lands that would be provided on federally owned surface (BLM 2007n). The BLM carefully considers the surface owner's views and the effects on the surface owner's uses of the land before determining mitigation requirements and approving operations. The BLM must fulfill the requirements of NEPA, the National Historic Preservation Act (NHPA), the Endangered Species Act (ESA), the Clean Water Act (CWA), and other applicable laws, policies, and decisions regarding surface resources. If the surface owner's wishes are contrary to the BLM recommendations, the BLM will generally adopt the surface owner's request unless the request is contrary to the BLM's planning decisions, non-discretionary laws, current policy, or would result in avoidable significant impacts.

Split estate is a common occurrence in the planning area; the BLM manages 782,102 acres of surface estate and 4,803,277 acres of mineral estate. Table 4.1, "Surface Estate and Associated BLM-Administered Fluid Mineral Estate in the Buffalo Field Office Planning Area" (p. 648) lists surface ownership in the planning area and the number of acres of corresponding BLM-administered mineral estate.

Table 4.1. Surface Estate and Associated BLM-Administered Fluid Mineral Estate in the Buffalo Field Office Planning Area

Surface Owner	Surface Land (acres)	BLM Fluid Mineral Estate (acres)
BLM	782,102	781,013
Department of Defense	4,166	4,166
Private	5,167,265	3,963,663
State of Wyoming	538,606	54,435

BLM Bureau of Land Management		

Surface Disturbance

Surface disturbance is the result of any action or activity that alters vegetation, surface and near-surface soil resources, or surface geologic features beyond natural site conditions and on a scale that affects the value of other public lands (BLM 2007j). Examples of surface-disturbing activities include operation of heavy equipment to construct well pads, roads, pits and reservoirs; installation of pipelines and powerlines; and the performance of several types of vegetative treatments (e.g., prescribed fire). Surface-disturbing activities can be authorized or prohibited.

Most land and resource uses (e.g., mineral development, fire, forest products sales, rights-of-way (ROW) actions, and renewable-energy development) can result in surface disturbance and have the potential to affect multiple resources (e.g., soils, water, vegetation, wildlife, cultural and

paleontology resources, and recreation). Surface disturbance is defined here to avoid redundancy in the individual resource sections. Table 4.2, “Total Projected Surface Disturbance from Reasonable Foreseeable Actions in the Buffalo Planning Area” (p. 649) summarizes the projected surface disturbance under each alternative during the anticipated duration of the planning period.

Table 4.2. Total Projected Surface Disturbance from Reasonable Foreseeable Actions in the Buffalo Planning Area

Type of Disturbance	Alternative A	Alternative B	Alternative C	Alternative D
Total acres disturbed from BLM actions	322,026	422,903	422,544	486,957
Total acres reclaimed from BLM actions	221,888	344,752	291,923	358,871
Total acres of long-term disturbance from BLM actions	100,138	78,152	130,621	128,086
Total acres disturbed from non-BLM actions	2,123,460	1,890,239	2,531,611	2,168,799
Total acres reclaimed from non-BLM actions	1,943,463	1,766,623	2,174,564	1,965,851
Total acres of long-term disturbance from non-BLM actions	179,998	123,617	357,048	202,949

Note: BLM Actions are those actions authorized by BLM.				
BLM Bureau of Land Management				

Disruptive Activities

Disruptive activities are uses of and activities on public land likely to alter the behavior of, displace, or cause excessive stress to existing animal or human populations, and that occur at a specific location or time. In this context, disruptive activity(ies) refers to actions that alter behavior or cause the displacement of individuals such that reproductive success is adversely affected, or an individual's physiological ability to cope with environmental stress is compromised. The term disruptive activities does not apply to the physical disturbance of the land surface, vegetation, or features. Examples of disruptive activities include noise, human foot or vehicle traffic, domestic livestock roundups, or other human presence, regardless of the activity. When the BLM restricts disruptive activities, sound above ambient levels, light greater than background levels, and the presence of people and their activities could be prohibited or limited. The term is commonly used in conjunction with protecting wildlife during crucial life stages (e.g., breeding, nesting, and birthing), although it can apply to any resource value on the public lands. This land use restriction is not intended to prohibit all activity or authorized uses.

4.1. Physical Resources

4.1.1. Air Quality

For the Buffalo planning area, air resources were evaluated to examine how potential BLM initiatives, decisions, and alternatives would affect air quality in the region (“region” includes the planning area and federal Class I areas within 100 miles). The actions associated with each alternative may affect future air quality within this region. Impacts to air quality include changes of pollutants, visibility and atmospheric deposition. Beneficial impacts are those that decrease emissions, either from control measures or a reduction in activities that generate emissions. Direct impacts are the result of the proposed action and occur at the same time. Indirect impacts may also result from the proposed action, but would occur later in time and/or are further removed from the planning area. Indirect impacts may be assessed with the application of air quality modeling tools to help identify the impacts of emissions on regional air quality and may result in the identification and implementation of BMPs or other technologies that would reduce emissions. This section evaluates the potential impacts on air quality from specific activities authorized or performed by the BLM in the Buffalo planning area for each alternative by examining the expected levels of emissions associated with various activities in the planning area. No air quality modeling was performed as part of this analysis.

4.1.1.1. Methods and Assumptions

The air quality impact analysis for the Buffalo planning area used an emissions comparison approach that included the following:

- Identify actions and activities that generate air pollutant emissions.
- Prepare current base year (2005) equipment, production, and activity data.
- Estimate future equipment and activity for the selected future years (2015 and 2024).
- Calculate base year and future emissions associated with expected activity for each alternative based on equipment, emission factors, and activity data.
- Compare future year totals with base year for each of the alternatives to evaluate changes from the baseline and among the alternatives.

The Buffalo RMP presents a qualitative description of potential impacts, and includes emission inventories of BLM actions in the Buffalo planning area. Appendix M (p. 2239) provides a detailed description of the assumptions, activity data, emission factors, and general approach followed in estimating emissions for the various resource sectors and pollutants.

The following air pollutants were identified as being pollutants that could potentially be emitted directly (or in the case of ozone produced in the atmosphere by photochemical processes), by management activities authorized, permitted, allowed or performed under this RMP. Emissions of each of these pollutants (except ozone) were estimated for each identified activity and addressed for each alternative in this analysis:

- Criteria pollutants (Carbon Monoxide [CO], Nitrogen Oxide [NO_x], Particulate Matter less than 2.5 microns in diameter [PM_{2.5}], Particulate Matter less than 10 microns in diameter [PM₁₀], Sulfur Dioxide [SO₂])
- Organics and toxics (Hazardous Air Pollutants [HAPs] and Volatile Organic Compounds [VOCs])
- Greenhouse gases (GHGs) (Carbon Dioxide [CO₂], Methane [CH₄], Nitrous Oxide [N₂O])

Components of air quality that may be impacted include visibility, air pollutant concentrations, atmospheric deposition, and lake chemistry. Impacts on these components are affected by the magnitude and spatial and temporal distribution of the primary and precursor emissions and their interaction with local and regional meteorological conditions and topographic features. For this analysis, the changes in emissions for each of the alternatives were assessed to qualitatively determine if the resulting impacts would be significant enough to potentially violate the National Ambient Air Quality Standards (NAAQS) or the Wyoming Ambient Air Quality Standards (WAAQS), or possibly exceed screening levels of concern for visibility and atmospheric deposition. Air quality modeling can be used to simulate expected future air quality concentrations and the effects on visibility and deposition, but at this stage of the planning process, sufficient project-specific data were not available for such an assessment. Future mineral development projects will be required to conduct a full NEPA analysis of the impacts of proposed projects including air quality. Because of the level of coal mining activity in the Powder River Basin (PRB), air quality modeling studies have been conducted to assess impacts for the region. The Chapter 3 *Air Quality* section provides a summary of air quality modeling projects that have been conducted in the last several years, or are ongoing.

The following list of emission generating activities were identified as those management activities authorized, permitted, allowed or performed under this RMP that could potentially emit identified air pollutants and could potentially cause impacts to air quality within the planning area and Class I areas within 100 miles (150 kilometers) of the planning area. Emissions of air pollutants were estimated for the baseline year (2005) and projected for two future years (2015 and 2024) for each identified resource activity and addressed for each alternative in this analysis.

- Leasable Fluid Minerals – Conventional Natural Gas Development
- Leasable Fluid Minerals – Coalbed Natural Gas Development
- Leasable Fluid Minerals – Oil Development
- Leasable Solid Minerals – Coal Mining
- Locatable Minerals – Bentonite Mining
- Locatable Minerals – Uranium Mining
- Salable Minerals – Sand, Gravel, and other Mineral Development
- Fire and Fuels Management – Prescribed Fire
- Forest Products
- Land Resources – Rights-of-Way and Corridors and Renewable Energy Projects
- Land Resources – Travel and Transportation Management
- Land Resources – Livestock Grazing Management

The Buffalo Field Office (BFO) resource specialists provided the construction, operations, developed acreage, and production activity data used to estimate emissions for resource emission sources. Other activity data were derived from the surface disturbance and RFA tables (Appendix G (p. 1937)). For conventional natural gas, coalbed natural gas (CBNG), and oil development, emissions were prepared for activities on federal mineral estate in the planning area. The estimation of emissions from coal mining activity relied on information contained in the Environmental Protection Agency's (EPA's) National Emission Inventory (NEI) (EPA 2011a) and the Final Mineral Occurrence and Development Potential Report (BLM 2009c) for the planning area. Because of this, the emission estimates for coal mining activities do not vary amongst the alternatives.

Emission factors used to estimate proposed emissions were obtained from (1) the EPA NONROAD2008a Emissions Model (EPA 2008); (2) the Wyoming Department of Environmental Quality (DEQ) best available control technology (BACT) standards for natural gas-fired internal

combustion engines (Wyoming DEQ 2013c); (3) the EPA MOBILE6.2.03 mobile emissions factor model for on-road motor vehicles (EPA 2003); (4) EPA AP-42 Compilation of Air Pollutant Emissions Factors (EPA 1995); (5) the American Petroleum Institute (API) Compendium of Greenhouse Gas Emissions Estimation Methodologies for Oil and Natural Gas Industry (American Petroleum Institute 2009); (6) EPA State Inventory Tool Module (EPA 2011c); (7) the Western Governors Association Western Regional Air Partnership (WRAP) (Western Regional Air Partnership 2005); (8) 40 CFR Part 98 — Subpart W; (9) Wyoming DEQ Guidance on Oil and Gas Production Facilities (Wyoming DEQ 2013a); and (10) EPA's NEI (EPA 2013b). The Technical Support Document (TSD) for Air Quality (Appendix M (p. 2239)) includes detailed information regarding the data and assumptions used to estimate emissions for each project alternative and the emission totals for each activity per year.

Methods and assumptions used in this impact analysis include the following:

- Air pollutant emissions presented in this analysis are useful for comparing the relative amounts of emissions for each alternative and may not represent actual future emissions. Emissions estimates are based on predictions of future mineral resource development scenarios rather than actual development projects.
- Stationary sources associated with oil and gas development will operate in accordance with Wyoming DEQ's *Oil and Gas Production Facilities Permitting Guidance, Chapter 6, Section 2* revised March 2010 (U.S. Secretary of the Interior 2010).
- Emissions from the following management actions were not estimated because the potential for development was considered low: phosphate mining, oil shale development, geothermal development, gemstones and other lapidary materials development.
- Emissions from the following management actions were not included because (1) the level of activity is not expected to change between alternatives, *and* (2) the magnitude of emissions from the activity is considered to be very small in comparison to other management activities, or (3) sufficient operational or production data were not available to quantify emissions: wild (unplanned) fires, invasive species and pest management, grassland and shrubland management, and activities related to heritage and visual resources, cultural resources, paleontology, recreation, socioeconomic resources, and fish and wildlife resources.
- Activity factors (or the quantification of activity for each resource provided by the BFO) are appropriate for the base year and future timeframes.
- EPA off-road emission standards were used to estimate emissions for non-road sources in project years 2005, 2015, 2024. This approach simulates the replacement of existing sources by new lower-emitting equipment with future EPA off-road emission standards.

The purpose of the Buffalo Air RMP is to further clarify air quality goals, objectives, and management actions set forth in the Buffalo RMP and EIS. The Air RMP (Appendix N (p. 2479)) was developed in cooperation with EPA Region 8, the Wyoming DEQ-Air Quality Division (AQD), and the USFS to address how the BLM will manage air resources in the planning area. The Wyoming DEQ-AQD is the state regulatory authority responsible for ensuring compliance with the NAAQS and WAAQS, and the Air RMP is not intended to circumvent that authority. The Air RMP outlines specific requirements for proponents of projects that have the potential to generate air emissions and impact air resources within the planning area. Where applicable, the Air RMP refers to the goals and objectives found in the Buffalo RMP and EIS. Table 4.3, "State of Wyoming Presumptive BACT Requirements" (p. 653) provides an overview of activities/sources and control requirements mandated by the State of Wyoming Presumptive BACT regulations. The Air RMP outlines the control requirements in greater detail. The Air RMP is a "living

document” and may be modified to comply with law, regulation, and policy to address new information and changing circumstances.

Table 4.3. State of Wyoming Presumptive BACT Requirements

Activity/Source	Minimum Control Percentage	Minimum Potential VOC Emissions (tons/year)	Notes
Flashing/Storage Tanks and Separation Vessels	98%	10	Control devices may be removed after one year if flashing emissions have decreased to below 8 tons/year.
Dehydrations Units	98%	8	Control devices may be removed after one year if flashing emissions have decreased to below 8 tons/year and all units are equipped with flash separators and still vent condensers.
Pneumatic Pumps	98%	None	
Pneumatic Controllers	None	None	Control achieved by use of low or no-bleed controllers or by the controller discharge steams being routed to a closed loop system.
VOCs volatile organic compounds			

In June 2011, the USDA, Department of the Interior (DOI), and the EPA signed the *Memorandum of Understanding (MOU) among the U.S. Department of Agriculture, U.S. Department of Interior, and U.S. Environmental Protection Agency Regarding Air Quality Analyses and Mitigation for Federal Oil and Gas Decisions Through the National Environmental Policy Act Process*. This MOU outlines an approach to the analysis of impacts to air quality and Air Quality Related Values (AQRVs), such as visibility in Class I and sensitive Class II areas, in connection with oil and gas development on federal lands, and identifies a path to protect air quality while allowing for oil and gas development on federally managed lands. This MOU specifically addresses oil and natural gas development projects, but not other projects or resources that contribute to air quality impacts in the planning area. Because the RMP is a broad level planning document that defines allocations and projects levels of development and other land uses in a general sense, it lacks much of the specificity of future emission sources and levels that are necessary to accurately simulate future air quality impacts. Air quality impact modeling is more appropriately analyzed in the implementation level (i.e., for specific oil and gas field development projects) NEPA documents, and this type of modeling would be conducted under the guidelines of the MOU. In lieu of air quality modeling, the BLM developed the Air RMP (Appendix N (p. 2479)) which includes requirements (Section N.2.4, “Modeling” (p. 2488)) for when modeling will required.

For this analysis a base year emission inventory was developed for 2005 based on available historical equipment counts, records of production and activity, and other information. In addition to the base inventory, two future-year inventories (2015 and 2024) were prepared based on various alternative levels of activity, operations, and equipment usage for all of the activities associated with each of the managed resources. For all of the alternatives examined for the base and future years, coal mining and oil and natural gas (conventional and coalbed) development are the largest contributors to total air emissions compared to other managed activities in the

planning area. For coal mining, the emissions were estimated based on emissions prepared by the State of Wyoming as contained in EPA NEI (EPA 2011a) and production rate data and forecasts included in the Final Mineral Occurrence and Development Potential Report (BLM 2009c) for the Buffalo planning area. For oil and natural gas development, the emission estimates are based on reasonable foreseeable estimates of well counts, production and development rates, and existing technologies used in the field.

For the Buffalo planning area, activities associated with oil and natural gas development and coal mining result in the largest emissions for the majority of pollutants. Table 4.4, “Estimated Annual Emissions (tons/year) for Activities in the Buffalo Planning Area – Base Year 2005” (p. 654) presents a summary of estimated emissions (tons/year) for all resource activities for each pollutant for the base year 2005. The table presents emission estimates for oil and natural gas development sources on federal land and combined cumulative totals for these activities on federal and non-federal land within the planning area.

Table 4.4. Estimated Annual Emissions (tons/year) for Activities in the Buffalo Planning Area – Base Year 2005

4.1.1.2. Impacts Common to All Alternatives

The Wyoming DEQ has the authority to implement emission controls for sources requiring air permits under Wyoming Air Quality Standards and Regulations and to ensure that these sources do not contribute to an exceedance of an ambient air quality standard. To facilitate this process, the BLM currently implements a program to share emission source information with the Wyoming DEQ and other government agencies. This program would continue under all alternatives. In addition, the BLM would require **mitigation** to minimize impacts, such as fugitive dust emissions in proximity to high use roadways, populated areas, and resource-sensitive areas.

Because of the amount of existing and planned resource development activity, emissions of NO_x, VOCs, and CO from coal mining and oil and natural gas development could impact air quality under each of the alternatives. These emissions are precursors to **ozone** and fine particulates (PM_{2.5}) which are both secondary pollutants and ambient concentrations could increase and also affect visibility and atmospheric deposition. Emissions of primary coarse (PM₁₀) and fine (PM_{2.5}) particulates from these activities could also affect local and regional air quality by decreasing visibility and increasing deposition. Emissions for SO₂ from managed activities in the planning area are relatively small and are not expected to result in any major impacts. Except for the NO_x emissions from sand and gravel sources and the CO and VOC emissions from Travel and Transportation Management (TTM) which could contribute to impacts on ambient **ozone** and particulate concentrations, the emissions from all other resource emission source categories are relatively small and are not expected to contribute to any major adverse impacts on air quality in the planning area.

Management actions and resource uses under each of the alternatives may impact AQRVs in the nearby federal Class I area of Wind Cave National Park and the Northern Cheyenne Indian Reservation, with potentially smaller impacts at the more distant Badlands Wilderness Area. Although minerals development and production (primarily coal mining), and oil and gas production would be the primary sources of emissions, other resource management actions that would produce combustive and/or fugitive dust emissions include sand and gravel development, and uranium and bentonite mining.

Prior to project approval, the BLM would conduct environmental analyses in compliance with NEPA. Appendix N (p. 2479) includes additional information on potential BMPs and mitigation measures that may be applied in the planning area. For major projects, such as the development of a large natural gas field or mineral development project (or any project that is likely to have an impact on air quality), the BLM may require proponents to demonstrate compliance with ambient air quality standards and other federal, state, and local air quality regulations. This demonstration

may include air dispersion modeling, photochemical grid modeling, and the application of mitigation measures and control technologies prior to project authorization by the BLM.

4.1.1.3. Alternative A

Under Alternative A, resources would be managed under the existing RMP (BLM 1985c). Table 4.5, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative A – 2015” (p. 658) and Table 4.6, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative A – 2024” (p. 660) present the emission estimates for planned activities associated with the No Action Alternative (Alternative A) for 2015 and 2024, respectively. These tables provide emission estimates for the activities listed above and provide totals for activities on federal land and cumulative totals for all activities under the current management scenario. The tables also present percent difference changes in the emission totals compared to the 2005 base year totals. Figure 4.1, “Contributions of Each Category to PM₁₀ Emissions under Alternative A for 2015” (p. 662) through Figure 4.7, “Contributions of Each Category to HAP Emissions under Alternative A for 2015” (p. 665) present the relative contributions of the various activities to total emissions for Alternative A for 2015 for PM₁₀, PM_{2.5}, NO_x, SO₂, CO, VOCs, and HAPs, respectively. The figures provide relative contributions from the major activity sectors: leasable fluid minerals (oil and natural gas), leasable solid minerals (coal), locatable minerals (bentonite & uranium), and salable minerals (sand & gravel), fire and fuels management, forest products, ROWs, TTM, and livestock grazing management. Because the relative contributions of emissions do not change significantly in 2024 or amongst the other alternatives, emission pie charts for 2024 and for all other alternatives are not shown.

As noted above, the major contributor to emissions of PM₁₀ and PM_{2.5} are from coal and bentonite mining. For NO_x and SO₂, the largest contributors are from coal mining and oil development. For the planning area sources, equipment, and activities associated with the non-oil and natural gas mineral development include coal, bentonite, and uranium mining and sand and gravel operations. For CO, similar relative contributions are provided from coal mining, fire and fuels management, and TTM. For VOC emissions, contributions are primarily from the travel transportation management sector reflecting emissions from off-road engines and off-road vehicles (all-terrain vehicles [ATVs], motorcycles, snowmobiles, etc.), followed by contributions from the oil and gas development sector. For HAP emissions, similar contributions are provided from the oil and gas, non-oil and gas, and TTM sectors/activities. Of all the activity sectors examined, emissions from livestock grazing management are the lowest and these activities are the minimus contributors to emissions in the planning area.

The current management scenario includes actions that either increase or decrease the development or use of certain resources and associated activities in 2015 and 2024 compared to the base year 2005, and this results in either increases and decreases in emissions for certain categories and pollutants. Specific increases in resource use include the number of federal and non-federal natural gas and oil wells in 2015 and 2024, compared to 2005. For example, there is a planned increase of nearly 40 natural gas wells and 168 oil wells under Alternative A. Specific decreases for Alternative A include a fewer number of CBNG wells developed and a slight reduction in the total acreage used for forest products. For some resources, although there are slight increases in resource development numbers (e.g., number of wells, acreage, etc.) and activities, the emission factors for equipment expected to be used in the future are lower, reflecting cleaner engine and fuel technology, resulting in a net decrease in emissions.

Overall, compared to the 2005 base year, except for VOCs and HAPs, emissions for all other pollutants are estimated to increase for Alternative A in 2015. Except for VOC and HAP emissions, emissions for all pollutants are expected to be relatively the same or slightly increase further in 2024. VOC and HAP emissions show a decrease in 2015 and further in 2024, likely reflecting the expected introduction of cleaner engine technology for off-road construction and maintenance engines and other equipment.

It is possible that increases in NO_x and PM_{2.5} emissions could lead to increases in ambient ozone concentrations and total fine particulates and may possibly contribute to violations of the current NAAQS and WAAQS.

4.1.1.4. Alternative B

Alternative B represents the most restrictive use of resources reflecting the highest degree of conservation for physical, biological, heritage, and visual resources. This alternative limits the amount of resource growth and development activities, including the number of oil and natural gas wells, and the acreage developed and used in mining and other surface disturbing activities. Because of this, the emissions for this alternative are the lowest of all alternatives. Table 4.7, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative B – 2015” (p. 666) and Table 4.8, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative B – 2024” (p. 668) present the emission estimates for planned activities associated with Alternative B for 2015 and 2024, respectively. Although the overall emissions for Alternative B are lower than Alternative A, the relative contributions of the various activities to total emissions for Alternative B for 2015 and 2024 for PM₁₀, PM_{2.5}, NO_x, SO₂, CO, VOCs, and HAPs are similar to those presented for Alternative A in Figure 4.1, “Contributions of Each Category to PM₁₀ Emissions under Alternative A for 2015” (p. 662) through Figure 4.7, “Contributions of Each Category to HAP Emissions under Alternative A for 2015” (p. 665) above.

Compared to the 2005 base year, 2015 emissions are estimated to be similar or increase slightly for PM₁₀, PM_{2.5}, SO₂, and CO, and are expected to be relatively the same or slightly increase further in 2024. Emissions of NO_x, VOCs, and HAPs are expected to decrease in both 2015 and 2024 compared to 2005, likely reflecting restrictions on oil and gas development and the expected introduction of cleaner engine technology for off-road construction and maintenance engines and other equipment. Compared to 2005, emissions under this alternative are likely to contribute less to ambient ozone concentrations and total fine particulates, and overall impacts on air quality are expected to be the least of all of the alternatives.

4.1.1.5. Alternative C

Alternative C is the least restrictive alternative in terms of planned growth and development, number of wells/projects, etc. and the emissions for this alternative are the highest of all alternatives. Table 4.9, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative C – 2015” (p. 671) and Table 4.10, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative C – 2024” (p. 673) present the emission estimates for planned activities associated with Alternative C for 2015 and 2024, respectively. The relative contributions of the various activities to total emissions for Alternative C for 2015 and 2024 for PM₁₀, PM_{2.5}, NO_x, SO₂, CO, VOCs, and HAPs are similar to those presented for Alternative A in Figure 4.1, “Contributions of Each Category to PM₁₀ Emissions under Alternative A for 2015” (p. 662) through Figure 4.7, “Contributions of Each Category to HAP Emissions under Alternative A for 2015” (p. 665) above.

Reflecting the least amount of constraint on the development and use of physical resources, Alternative C includes the allowance for additional oil and natural gas wells to be developed, increased activity in fire, fuel, and vegetation management activities, and overall increases in mining activity for leasable minerals. For example, resource development activities would be restricted in WSAs, but would be allowed in special recreation management areas (SRMAs). Compared to the 2005 base year, emissions are estimated to increase substantially in 2015 and 2024 for all pollutants except VOCs and HAPs. For 2024, emissions of VOCs and HAPs are expected to decrease compared to 2005. VOC emissions increase slightly in 2015 and then decrease in 2024 compared to 2005. HAP emissions show a decrease in 2015 and further in 2024. The longer term decreases in VOCs and HAPs likely reflect the expected introduction of cleaner engine technology for off-road construction and maintenance engines and other equipment. Compared to 2005, emissions under this alternative are likely to contribute to ambient ozone concentrations and total fine particulates, and overall impacts on air quality are expected to be the most of all of the alternatives. The increases in NO_x and PM_{2.5} emissions could lead to increases in ambient ozone concentrations and total fine particulates, including degraded visibility and increased deposition, and may possibly contribute to violations of the current WAAQS and NAAQS.

4.1.1.6. Alternative D

Alternative D represents a balance between resource use and resource conservation and the level of planned activities associated with Alternative D lies between the least amount of activity in Alternative B and the greatest amount of activity associated with Alternative C. Table 4.11, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative D – 2015” (p. 676) and Table 4.12, “Estimated Annual Emissions (tons/year) for Activities within the Buffalo Planning Area – Alternative D – 2024” (p. 678) present the emission estimates for planned activities associated with Alternative D (Proposed RMP) for 2015 and 2024, respectively. The relative contributions of the various activities to total emissions for Alternative D for 2015 and 2024 for PM₁₀, PM_{2.5}, NO_x, SO₂, CO, VOCs, and HAPs are similar to those presented for Alternative A in Figure 4.1, “Contributions of Each Category to PM₁₀ Emissions under Alternative A for 2015” (p. 662) through Figure 4.7, “Contributions of Each Category to HAP Emissions under Alternative A for 2015” (p. 665) above.

Compared to the 2005 base year, emissions are estimated to increase in 2015 and 2024 for all pollutants except VOCs and HAPs, which are expected to decrease slightly in 2015 and decrease further in 2024. As seen in the other alternatives, the longer term decreases in VOCs and HAPs likely reflect the expected introduction of cleaner engine and fuel technology for off-road construction and maintenance engines and other equipment.

Compared to 2005, emissions under this alternative are likely to contribute to ambient ozone concentrations and total fine particulates, affecting visibility and atmospheric deposition, with the

magnitude of impacts between those of Alternative B and Alternative C. The expected level of impacts may possibly contribute to violations of the current 8-hour average **ozone** standard.

4.1.1.7. Cumulative Impacts

Analysis of Cumulative Impacts

Because no air quality modeling was conducted as part of this analysis, cumulative impacts to air quality over the life of the plan were analyzed for each alternative by comparing cumulative emissions with statewide emission totals. The 2005 Wyoming DEQ statewide emissions inventory for 42 different source categories was obtained from the EPA National Emissions Inventory (EPA 2013c). Emissions from various resources reflecting BLM actions and activities, non-BLM activities (for oil, natural gas, and CBNG development), and the cumulative totals for the planning area are compared to Wyoming statewide emissions for all anthropogenic sources in Table 4.13, “Comparison of Emissions from BLM and Non-BLM Activities in the Buffalo Planning Area to Cumulative Annual Statewide Emissions for 2005” (p. 681) for 2005 and for each of the 2015 alternatives. Due to the uncertainty inherent in estimating emissions beyond 10 years or so in the future, comparisons are not made with the 2024 emission estimates. The totals for 2005 and each of the alternatives show that emissions from BLM-managed activities in the Buffalo planning area are 3 percent or less of statewide totals.

Emissions for BLM and non-BLM activities for natural gas, oil, and CBNG development were computed based on information provided by BLM. Information on non-federal activities was not provided for any of the other resources. Also, because of the way the emissions were calculated for TTM (e.g., for public use of snowmobiles and ATVs, etc.), these activities were assumed to take place on federal and non-federal lands. As such, the emissions included under the non-BLM actions in Table 4.13, “Comparison of Emissions from BLM and Non-BLM Activities in the Buffalo Planning Area to Cumulative Annual Statewide Emissions for 2005” (p. 681) represent those activities from non-federal oil, natural gas, and CBNG development only.

In examining the emission totals, it is evident that the concentrations of CO, NO_x, and SO₂ (and to a lesser extent PM_{2.5} and PM₁₀) in the planning area could potentially increase slightly in certain areas, but would not likely contribute to exceedances of the air quality standards. Through 2011, the peak ozone concentration in the planning area was 82 percent of the 8-hour

ozone standard, while peak 24-hour and annual PM_{2.5} and peak 24-hour PM₁₀ concentrations were less than 70 percent of the applicable standards. If the existing NAAQS for ozone is lowered in the near future by EPA, this may become an important issue in the planning area. Because the emissions from BLM activities in the planning area are relatively small compared to state totals, the potential cumulative impacts on atmospheric deposition and lake acidification would likely not change significantly over the course of the plan. Likewise, total nitrogen and sulfur deposition would likely be the same and would not exceed levels of concern, and impacts on visibility would likely be minimal over the life of the plan.

For specific future proposed large-scale development projects (i.e., development of a new natural gas field) in the planning area, the BLM will likely require a more refined assessment of incremental and cumulative impacts using appropriate air quality modeling tools. These tools are able to simulate both incremental and cumulative impacts of emissions from a variety of anthropogenic and biogenic sources contributing to observed air quality in the planning area including impacts on concentrations, deposition, and visibility. The BLM will continue to work with the EPA and the State of Wyoming to ensure that emissions from activities on BLM-administered land do not contribute to any violations of the applicable NAAQS or WAAQS.

4.1.1.8. Analysis of Greenhouse Gases

Concentrations of certain gases in the earth's atmosphere have been identified as being effective at trapping heat reflected off the earth's surface thereby creating a "greenhouse effect." As concentrations of these GHGs increase, the atmosphere warms, the composition of the atmosphere changes and global climate is affected. Concentrations of GHG have increased dramatically in the earth's atmosphere in the past century. Anthropogenic (man-made) sources and other human activities have been attributed by the EPA and others to these increases particularly for CO₂, CH₄, N₂O, and fluorinated gases (DOI 2010a).

The EPA has determined that six GHGs are air pollutants and subject to regulation under the Clean Air Act (CAA): CO₂, CH₄, N₂O, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride. Of these GHGs, CO₂, CH₄, N₂O are commonly emitted by the types of activities included in this analysis, while the remaining three GHGs are emitted in extremely small quantities or are not emitted at all. GHG emissions from management actions and activities were estimated for each alternative in this analysis for CO₂, CH₄, and N₂O.

As the major component of natural gas, CH₄ emissions from and oil and gas exploration, production, and transportation can be considerable. Emissions of CH₄ from the extraction of coal from surface mines can also be significant. Emissions of CO₂ and N₂O from fossil fuel combustion and fire can also be of concern. This analysis quantified emissions of CO₂, CH₄, and N₂O from the management actions and activities for each alternative for all of the resources listed above.

Each GHG component has been given a Global Warming Potential (GWP) number that takes into account the intensity of the substance's heat trapping effect and its longevity in the atmosphere as compared to CO₂. This analysis used the EPA GWPs of 21 for CH₄, and 310 for N₂O. The estimated quantity emitted for each GHG was multiplied by its GWP and summed with the other

GHG to obtain total GHG emitted in CO₂ equivalents in short tons. CO₂ equivalents were then converted to million metric tons (MMt), the typical reporting unit for GHG emissions. Table 4.14, “Estimated Annual Greenhouse Gas Emissions (tons per year) Summary for Activities within the Buffalo Planning Area” (p.)” shows the estimated annual emissions of the GHG for each alternative. Appendix M (p. 2239) includes additional details on the GHG emissions calculations.

Table 4.14. Estimated Annual Greenhouse Gas Emissions (tons per year) Summary for Activities within the Buffalo Planning Area

Source: Appendix M (p. 2239)					
CH ₄ methane CO ₂ carbon dioxide N ₂ O nitrous oxide					

Alternative C shows the highest increases in GHG emissions due primarily to the higher projected oil and gas production activities. The total GHG emissions for all of the alternatives are fairly comparable because they are dominated by CH₄ emissions from surface coal mining operations in the PRB, which is the largest contributor compared to other activities in the planning area. Oil and gas production is the second major contributor to GHG emissions for all alternatives. The largest sources of GHG emissions within the oil and gas sector include CO₂ emissions from natural gas compressors and drill rig engines, and fugitive CH₄ emissions from wellhead equipment, pneumatic devices and tanks. The estimated GHG emissions are based on “worst case” estimates of production rates and operational characteristics and likely result in overestimated total GHG emissions. Considerable reductions in these estimated emissions may be realized at the time of actual development through control technologies such as electric compressor engines, “green completions,” low or no bleed pneumatic devices, and capture and control of leaks and vents.

Table 4.15, “Buffalo Planning Area GHG Emissions as Percentage of Wyoming Statewide GHG Emissions” (p. 684) shows the comparison of project related GHG emissions for each of the alternatives to a statewide inventory of GHG emissions that was completed in 2007. The inventory was compiled for the Wyoming DEQ by the Center for Climate Strategies and was based on actual emissions for 2005 and projected emissions for 2010 and 2020. GHG emissions estimated for each of the alternatives comprise approximately 13 percent of statewide GHG emissions. This is driven mainly by CH₄ emissions associated with surface coal mining in the PRB. The total estimated GHG emissions for 2015 for Alternative D (Proposed RMP) of 9.17 MMt are approximately equal to 0.13 percent of the total U.S. 2008 GHG emissions of 6,956 MMt (EPA

2010). Assessing the impacts of GHG emissions on global climate change requires modeling on a global scale which is beyond the scope of this analysis. Potential impacts on climate change are influenced by GHG emission sources from around the globe and it is not possible to distinguish the impacts to global climate change from GHG emissions originating from the planning area.

Table 4.15. Buffalo Planning Area GHG Emissions as Percentage of Wyoming Statewide GHG Emissions

Buffalo Planning Area		Wyoming Statewide Inventory		Percent Contribution
Scenario	Estimated GHG Emissions (MMt CO ₂ equivalents)	Year	Estimated GHG Emissions (MMt CO ₂ equivalents)	BFO GHGs to Wyoming GHGs

Table 4.16, “Estimated Annual Emissions (tons/year) for Activities in the Buffalo Planning Area – Base Year 2005” (p. 684) presents GHG emission estimations for the 2005 base year for all resource activities, and Table 4.17, “Estimated Annual Emissions (tons/year) for Activities in the Buffalo Planning Area – Alternative A – 2015” (p. 685) through Table 4.24, “Estimated Annual Emissions (tons/year) for Activities in the Buffalo Planning Area – Alternative D – 2024” (p. 694) present this information for each of the alternatives for 2015 and 2024. As noted above, the largest sources of CO₂ emissions are from activities associated with the development of leasable fluid minerals while the largest source of CH₄ emissions is from coal mining operations in the PRB.

4.1.1.9. Summary and Comparisons

Table 4.25, “Estimated Annual Emissions Summary (tons/year) for Activities within the Buffalo Planning Area ” (p. 696) presents emission totals by pollutant species for each of the alternatives. This information is displayed graphically in Figure 4.8, “Emission Estimates for 2015 from Activities within the Buffalo Planning Area” (p. 697) and Figure 4.9, “Emission Estimates for 2024 from Activities within the Buffalo Planning Area” (p. 697). A consistent methodology was followed to estimate emissions from BLM-managed activities within the planning area for a base year (2005) and two future years. As detailed in Appendix M (p. 2239), the emissions were estimated using available equipment counts and activity information for the base year (2005) and reasonable further development activity forecast information for the future years, by alternative, so that direct comparisons could be made with the base year emissions and among the alternatives. There likely exist inherent inaccuracies in the 2005 base year inventory, especially regarding information on equipment and activity levels within the planning area. Nevertheless, this inventory was developed and used for comparison with the future year inventories, which are based on best estimate future development, equipment usage and activity levels, so that inferences could be made on the potential impacts resulting from the expected changes in emissions and resulting air quality within the planning area.

Over the past several years, other agencies have developed both base year and future year emission estimates for the three counties (Campbell, Sheridan, and Johnson Counties) that make up the planning area. For example, the State of Wyoming has compiled state-wide emissions for all major anthropogenic source categories (electric generation units, other major point sources, area sources, non-road sources, and on-road sources) that have been provided to the EPA for inclusion in the NEI. The inventory is updated every three years, with the latest update compiled for 2011. Table 4.26, “Annual Total Emissions Summary (tons/year) for Campbell, Johnson and Sheridan Counties, WY from the National Emission Inventory” (p. 698) presents emission estimates for all source categories for the years 2005, 2008, and 2011. This table shows some wide variations in emissions totals between 2005 and 2011, possibly reflecting major changes or differences in the year-to-year level of resource development (e.g., coal mining, natural gas extraction, etc.), that were possibly affected by the national recession. It should also be recognized that the latest year (2011) emission inventory is likely more accurate due to better information (e.g., activity levels, equipment counts, etc.) or different methodologies that were followed in compiling the inventory, compared to the 2005 inventory. The emissions in this table cannot be compared directly to the emissions for BLM activities, because they include emissions from all source categories. However, one item to note is that the BLM VOC emissions for 2005 are much larger than the NEI emissions. This is possibly due to a more accurate estimate of VOC emissions from evaporation ponds for the various natural gas and oil development fields in the planning area in the BLM inventory.

Because coal mining is a major source of emissions in Campbell County, Table 4.27, “Annual Coal Mine Emissions Summary (tons/year) for Campbell County, WY from the National Emission Inventory” (p. 699) presents criteria pollutant emissions for the year 2005, 2008, and 2011 from the NEI. The emissions for coal mining for 2005 are quite different in this inventory than those estimated in the BLM analysis as presented in Table 4.4, “Estimated Annual Emissions (tons/year) for Activities in the Buffalo Planning Area – Base Year 2005” (p. 654). Again, this likely reflects differences in the quantity and quality of equipment and activity data, and differences in emission estimation methodologies (e.g., emission factors for various vehicles, engines, and other equipment) used in developing each of the inventories.

In addition to coal mining, oil and natural gas development are also major sources of criteria pollutant emissions in the planning area. As noted above, other regulatory agencies have compiled both base and future-year emission inventories for Wyoming and the Mountain West supporting various air quality planning and management activities. The WRAP, a multi-state planning group responsible for addressing regional haze and other regional air quality issues, has developed updated oil and gas development emission inventories for various basins in the Mountain West, including the PRB. Table 4.28, “Annual Oil and Gas Emissions Summary (tons/year) for Campbell, Johnson, and Sheridan Counties, Wyoming from the Western Regional Air Partnership Inventory” (p. 699), presents criteria pollutant emissions for 2006, 2009, and 2015 (projected). The 2006 and 2009 emissions are based on actual equipment and activity data for these years, while the 2015 emissions are projected from the 2006 emissions based on future development forecasts for the area.

For some species (e.g., NO_x), the WRAP emissions are significantly larger than those in the BLM inventory, but similar to the emissions for coal mines, the emissions from the WRAP inventory are not directly comparable to the BLM inventory, because of the likely differences in assumed equipment counts, activity levels, emission factors, and emission estimation methodologies used/followed in compiling the inventories. Like the BLM inventory presented in Table 4.25, “Estimated Annual Emissions Summary (tons/year) for Activities within the Buffalo Planning Area ” (p. 696), the WRAP inventory forecasts an increase of emissions between 2006 and 2015 from the oil and gas sector, which may contribute to air quality impacts in the future. However, the 2009 emission totals show larger increases for certain species (PM₁₀, PM_{2.5}, NO_x, and VOCs), but it is difficult to determine whether this is the result of better information and updated emission estimation methodologies, or reflects true increases solely due to increased development activity within the planning area.

4.1.1.10. Conclusion

For this analysis, emissions were estimated for the proposed management actions in each alternative for seven criteria pollutants (PM₁₀, PM_{2.5}, NO_x, SO₂, CO, VOCs, HAPs, and the following GHGs: CO₂, CH₄, and N₂O. Emissions were estimated for the base year (2005) while emissions for all alternatives were estimated for 2015 and 2024, the latter two years reflecting short-term and long-term estimates, respectively.

Estimated emissions for the years 2015 and 2024 were compared to base year emissions to determine the expected future change in emission levels for each alternative. Except for VOC emissions, for the majority of the pollutants examined, emissions are estimated to increase slightly compared to base year levels for all alternatives except Alternative B, which shows either similar values in the future years or decreases in emissions compared to 2005. The increases in emissions for all other alternatives reflect expected projected increases primarily in oil and natural gas development and other mineral development activity in the area. The large decrease in VOC emissions in the future years reflects a decrease in the number of evaporation ponds expected to be used in oil and gas development.

An examination of emissions from all activities shows that the Alternative B estimates would be the lowest of the alternatives because this alternative includes the greatest constraints on resource development and use, especially for oil, natural gas, and mineral development. Because of this, Alternative B would result in the least amount of impacts to air quality resources. Compared to 2005 totals, Alternative B shows increases in PM₁₀, PM_{2.5}, NO_x, CO, and SO₂ emissions in both future years, and a major decrease in VOC and HAP emissions. The largest estimated increases in emissions are expected from Alternative C (except for VOCs and HAPs) because this alternative reflects the least amount of constraints on natural resource development and the greatest amount of development and resource use. As such, Alternative C is expected to result in the highest impacts on air quality resources in the planning area.

As presented above, other air quality management agencies have developed both base and future year emission estimates that support air quality management analyses in Wyoming and throughout the Mountain West. The emission inventories developed by the State of Wyoming, the WRAP, and the EPA likely differ in the quality and quantity of the equipment and activity level data used, and the methodologies followed in developing the inventories. Therefore, because of these differences, the emission inventories developed by these other agencies are useful to review and examine but cannot be directly compared to the BLM emission inventories. Nevertheless, the inventories are somewhat consistent in showing increases in criteria pollutant emissions in

the future years, which could result in impacts on air quality including ambient concentrations, visibility, and atmospheric deposition within the planning area.

As noted above, energy development activities of leasable fluid and solid minerals include sources and equipment that contribute the majority of emissions in the planning area, while a number of other resources have negligible or no impacts on Air Quality within the area.

4.1.2. Geological Resources

As discussed in Chapter 3, none of the geological features occurring on public lands in the planning area are considered unique enough to warrant special management or conservation measures. Therefore, the geological resources of the planning area consist of mineral resources. See the *Mineral Resources* section, and the subsections under that for information regarding anticipated impacts to the three federal mineral classifications (Locatables, Leasables, and Salables). See the *Paleontological Resources* section for anticipated impacts to the Dry Creek Petrified Tree Environmental Education Area (EEA) (containing public lands with exposed portions of petrified trees), and the *Cave and Karst Resources* section for anticipated impacts to cave and karst resources. See the *Health and Safety* section for anticipated impacts to various geological and natural hazards occurring in the planning area.

4.1.3. Soil

This section describes potential effects on soils in the planning area from BLM management of resources and resource uses under the alternatives. The *Soil* section of Chapter 3 describes existing soil conditions. Stable and productive soil in the planning area provides the foundation for other resources (e.g., biological resources) and for resource uses (e.g., livestock grazing). Actions that disturb or compact soil, disrupt soil stability, or reduce soil productivity are considered adverse. Conversely, actions that avoid or minimize soil compaction or erosion, stabilize soil, or increase soil productivity are considered beneficial.

4.1.3.1. Methods and Assumptions

For purposes of this broad-scale analysis, the primary indicator of adverse effects on soil resources is the amount of surface disturbance from management decisions for soils and other resources, particularly surface disturbance on soils with a severe erosion hazard, soils with Limited Reclamation Potential (LRP), soils with low reclamation suitability, and steep slopes. This chapter cumulatively refers to these areas as sensitive soils. The analysis of effects on soil resources is based on the factors contributing to site degradation and their inherent risks. The types of projected effects on soils under the alternatives are similar; however, the potential amount of acres disturbed is anticipated to vary by specific allowable uses and management actions associated with individual alternatives, as described below. The projected amount of surface disturbance in the planning area is identified in the *Reasonable Foreseeable Development and Reasonable Foreseeable Action Scenarios* (see Appendix G (p. 1937)).

Short-term adverse effects on soils would result during initial surface disturbance before revegetation is completed, or before practices are implemented or structures installed to minimize erosion. There would be long-term adverse effects due to accelerated erosion in locations where bare soils were allowed to remain exposed to water and wind. Other long-term adverse effects would be due in part to changes in vegetative communities, and the loss of productivity

in areas where facilities and structures remove or greatly alter the soil profile, restricting the reestablishment of vegetation.

Assumptions

- Spatial analysis was conducted using the Natural Resources Conservation Service (NRCS) Soil Data Viewer ArcGIS Extension and the Environmental Systems Research Institute, Inc., ArcGIS Desktop 9.3 computer software using the NRCS Soil Survey Geographic Database (SSURGO) datasets. Effects are described qualitatively and, where possible quantitatively.
- The BLM would use published and preliminary (NRCS 2011c) county soil survey information to predict soil behavior, limitations, or suitability for a given activity or action. NRCS SSURGO soils data, properties, suitabilities, limitations, and local, regional and national interpretations are used for analysis.
- For analysis purposes with the geographic information systems (GIS) tools described above, if the dominant hazard condition (%) within a Soil Map Unit (SMU) has a severe management hazard rating, the entire (SMU) is rated severe. However, there could be areas in the (SMU) that could have a rating of slight or moderate.
- Any disturbance proposed on a soil identified as a “sensitive soil” has the potential to have a major impact to the soil resource, since soil erosion affects an area larger than the physical disturbance. Reclamation in these areas is challenging. Extra steps are necessary to conserve the soil resource.
- Surface disturbance on sensitive soils is distributed across the landscape in the same proportion the soils occur on the land. In other words, if five percent of the soils in the planning area are highly erosive, it is assumed that five percent of the projected total disturbance would occur on highly erosive soils. In general on BLM-administered surface in the planning area, 28 percent of the soils have high erosion potential. This assumption applies only to Alternative C, which allows for unrestricted surface disturbance throughout the planning area.
- For analysis purposes, water erosion is the primary mechanism for loss of soil productivity.
- Using the GIS tools described above, SMUs containing miscellaneous areas such as badlands, rock outcrops, and areas susceptible to mass movement were chosen from the data sets (referred to above) for the planning area. For the analysis, the areas consisting of the miscellaneous areas could be substantially less due to generalization in the applicable GIS shape file polygons.
- The BLM will use soil survey data and interpretations to predict soil behavior, limitation, or suitability for a given activity or action. Soil interpretations are developed by the cooperators in the National Cooperative Soil Survey (NCSS) and maintained by the NRCS. Soil interpretations (see Glossary) are ever evolving; therefore, as new or updated soil interpretations become available they may supersede prior interpretations. Soil interpretations do not preclude activities or actions, rather, they provide a reasonable guide to the risks, limitations, and probable outcomes of a particular use or practice. The information is not site-specific and does not eliminate the need for onsite investigation of the soil.
- Roads and trails would be properly designed and built in accordance with BLM Manual 9113 (BLM 1985b).
- Linear disturbances such as pipelines, utility corridors, and transmission lines will be managed consistent with other resource requirements and BMP’s including but not limited to corridors and collocating disturbances.

Significance Criteria

In addition to the scale of effects identified in Methods and Assumptions, an adverse effect on soil resources would potentially be substantial if erosion were to result in soil losses to the extent that a site could no longer support the native vegetative community composition and cover.

4.1.3.2. Impacts Common to All Alternatives

Soil

Using soils surveys and onsite investigations would ensure proper use of soil resources. Applying appropriate mitigation (including project relocation or denial) and requiring an approved reclamation plan would ensure all disturbances were effectively remediated to BLM standards. The soils management actions common to all alternatives would have a major beneficial effect on soil resources.

BFO has described the existing environment for erosion potential in acres and percent of the field office and displayed as specific SMU polygons in Map 3. Erosion rates are inherently difficult to predict. The BFO chose to describe the existing environment and place restrictions on the sensitive areas. Depending upon a host of soil and site variables and disturbance type, BLM may recommend avoiding these sensitive areas or mitigating the disturbances on a site-specific basis. BLM policy is to minimize any soil loss from permitted disturbances. All proposed disturbances will have a site-specific NEPA analysis and are required to have a construction, stabilization, and reclamation plan that specifically addresses erosion based on the existing soil and site conditions. The Wyoming DEQ also requires erosion control measures in their Storm Water Pollutant Prevention Plan (SWPPP) permitting process to help prevent erosion and sediment transport.

The BFO used the Revised Universal Soil-Loss Equation model to predict the average soil loss in tons per acre per year. The Revised Universal Soil-Loss Equation model (<http://www.ars.usda.gov/Research/docs.htm?docid=5974>) is an erosion model designed to predict the longtime average annual soil loss carried from runoff from specific slopes in specified management conditions. Table 4.29, "Soil Loss by Percent Slope" (p. 703) displays the soil loss in tons per acre per year relative to slope, with the other values remaining the same. Model assumptions are bare soil conditions before the addition of BMPs.

Table 4.29. Soil Loss by Percent Slope

Slope percent	Soil Loss (Tons/Acre/Year)
0.2	0.4
0.5	0.7
1	1.2
2	2.2
3	3.1
4	4.2
5	5.2
6	6.3
8	8.4
10	11.2
12	14.4
14	17.7
16	21.0
20	27.4
25	35.3
30	42.9
40	57.1

Slope percent	Soil Loss (Tons/Acre/Year)
50	70.1
60	81.6

The Revised Universal Soil-Loss Equation model uses environmental and site features including: (R) rainfall-runoff erosivity, (K) soil erodibility, (L) length of slope and (S) slope steepness, and (C) cover management and (P) erosion control practice factor to determine predicted soil loss in tons per acre per year. The factors used in the table above include: an R of (20), K of (.32), L (100 feet), S (variable), C of (1 no cover), and P of (1.2 no BMPs). Soil loss is calculated as $\text{Soil loss} = R * K * L * S * C * P$.

Physical Resources

Management actions common to all alternatives for **Cave and Karst Resources** would not affect soil resources because the actions are procedural (inventories).

Air Quality

Air quality management actions common to all alternatives include implementation of measures to mitigate effects to air quality, such as dust suppression and cooperative efforts to reduce dust emissions. These actions would help keep soil in place, and would have a moderate beneficial effect on soil resources because the actions would reduce soil loss, but not prevent it.

Water Resources

Water management actions common to all alternatives include managing surface-disturbing activities to prevent degradation of water quality, including reducing channel and bank erosion, and managing water to meet *Wyoming Standards for Healthy Rangelands*. These actions are designed to reduce or prevent soil erosion and would be applied across the entire planning area. Therefore, water management actions would have a beneficial effect on soil resources.

Mineral Resources
