CH₄ methane
CO₂ carbon dioxide
N₂O nitrous oxide
OHV Off-highway Vehicle

Activities that require fossil fuel-powered machinery, such as minerals development and motorized vehicle use, comprise the majority of greenhouse gas emissions in the Planning Area under all of the alternatives. Wildland fires, including prescribed burns, would also result in CO₂ emissions. Alternative C is projected to result in the most new oil and gas wells and locatable mineral development (the activities anticipated to result in the greatest greenhouse gas contributions during the planning cycle), resulting in the most CO₂ emissions, followed by alternatives D, A, F, B, and E.

CH₄ is more than 20 times as effective as CO₂ at trapping heat in the atmosphere and accounted for 8.2 percent of GHG emissions in 2008 (based on CO₂ equivalents) (EPA 2010). CO₂ equivalent is a measurement that allows an aggregate comparison of multiple GHGs (e.g., CH₄ and N₂O), created by multiplying the actual or anticipated emissions of each gas by its relative global warming potential. Oil,

gas, and locatable mineral development and enteric fermentation from livestock (which accounted for 25 percent of total CH₄ emissions in 2008 [EPA 2010]) are the predominant source of CH₄ emissions in the Planning Area. As a result of higher levels of mineral development, CH₄ emissions are anticipated to be highest under Alternative C, followed by alternatives A, D, F, B, and E. Animal Unit Month (AUM) projections under alternatives A, C, D, and F are similar, and therefore would result in similar CH₄ emissions. Alternatives B and E would reduce AUMs by about 50 percent, resulting in a proportional reduction in CH₄ emissions from enteric fermentation.

N₂O emissions, which like CH₄ are also more effective heat trapping agents than CO₂, would result predominantly from fuel combustion in motor vehicles in the Planning Area. These emissions are likely to be greatest under Alternative C, followed by alternatives A, D, F, B, and E.

Under all alternatives, management actions would likely affect the level of carbon sequestration in the Planning Area. Management that conserves carbon sinks or provides for research and technology to store carbon that would otherwise be released into the atmosphere would reduce overall contributions of GHGs. Alternative E would result in the greatest preservation of biological carbon sinks including vegetation and soils, followed by alternatives B, F, D, A, and C. Forest management practices and silvicultural treatments that improve forest health and reduce the risk of catastrophic wildfire may increase or maintain carbon sequestration in forests and woodlands in the short term; however, altering the natural fire regime through forest management may lead to long-term impacts on forest health (e.g., infestation) that affect carbon sequestration in forests and woodlands. Alternative C includes the greatest number of silvicultural practices and other treatments to actively manage forests and woodlands, followed by alternatives D, A, F, B, and E. Allowing carbon sequestration research and projects under Alternative C and considering carbon sequestration research and projects under alternatives D and F would increase the potential for carbon sequestration projects and management that reduces atmospheric CO₂, compared to the other alternatives.

4.1.2 Geologic Resources

Management of geologic resources primarily addresses preserving unique geologic features such as paleontological resources, fragile easily eroded geological features, or scientifically important strata. Mineral development, as well as other surface-disturbing activities, can alter existing geologic features by disturbing, or excavating soil and rock. Sections 4.5 *Heritage and Visual Resources* and 4.7 *Special Designations and Other Management Areas* in this chapter discuss associated impacts to geologic resources. Section 4.2 *Mineral Resources* discusses impacts to mineral resources.

4.1.3 Soil

Soil resources provide the foundation for a variety of other resources and resource uses in the Planning Area. Adverse impacts to soils result from management actions that compact soil, increase erosion and runoff, disrupt soil stability, or reduce soil productivity. Surface-disturbing activities, such as mineral resources development, can result in removal of vegetative cover, soil compaction, reduced water infiltration, changes in physical and biological properties, and reduction in organic matter content. Beneficial impacts to soils result from management that minimizes soil compaction or erosion and runoff, stabilizes soil, and increases soil productivity. For example, management allowing post-disturbance reseeding would stabilize the soil and limit erosion.

Direct impacts to soils result from activities that disturb the existing soils horizon through earth-moving activities or remove the vegetative cover—loosening the surface soil, compacting soil layers, and

exposing soil particles to wind and water. Indirect impacts include management actions that increase the likelihood of soil erosion. Actions that create impervious surfaces (e.g., road construction) or new water sources (e.g., surface discharge of produced water) may increase runoff and erode soils.

Short-term impacts to soils are those that result from initial surface disturbance prior to completion of reclamation and revegetation activities. Long-term impacts are those that result from actions that leave bare ground and areas not reclaimed after 5 years. Long-term impacts to soil productivity would also result from disturbance that degrades the physical and biological properties of the soil.

4.1.3.1 Methods and Assumptions

The soils analysis uses the Water Erosion Prediction Project (WEPP) soil erosion model to analyze impacts to soil resources. WEPP simulates the conditions that affect erosion, such as the amount of vegetation canopy and soil water content, to estimate erosion rates. To facilitate this analysis, the Internet-based U.S. Forest Service (USFS) WEPP interfaces were used for erosion predictions using the “Disturbed WEPP” and “WEPP Road” modules.

Erosion rates are inherently difficult to predict. The rates of erosion predicted by WEPP are within +/-50 percent. Despite this lack of precision, these rates are appropriate for comparing and analyzing impacts of the alternatives on the soil resource. Erosion rates are calculated for different resource programs using surface-disturbance acreage figures as projected in the reasonable foreseeable action table in Appendix T.

WEPP model climate parameters were developed using Worland, Wyoming precipitation data at 5,000 feet above mean sea level to represent the entire Planning Area. Both the Disturbed WEPP and WEPP Road modules are limited to four soil textures (clay loam, silt loam, sandy loam, and loam). The WEPP analysis used a loam soil texture for all erosion predictions.

Disturbed WEPP has eight vegetative treatment options available: 20-year-old forest, 5-year-old forest, shrub-dominated rangeland, tall-grass prairie, short-grass prairie, low-severity fire, high-severity fire, and skid trail. By adjusting cover parameters, these vegetative treatment options can be applied to a wide variety of vegetative communities and land uses.

All WEPP erosion analyses used a 50-year simulation to represent the return interval.

The WEPP analysis used the following parameters:

- Slopes used in Disturbed WEPP – Upper slope 0 to 25 percent; lower slope 5 to 25 percent
- Slope lengths used in Disturbed WEPP – 300 feet (standard length used for environmental analysis in the Planning Area)
- Gradients used in WEPP Road – Road gradient 4 percent; fill gradient 30 percent; buffer gradient 15 percent
- Lengths used in WEPP Road – Road length 200 feet; fill length 15 feet; buffer length 130 feet
- Width used in WEPP Road – Road width 12 feet
- Rock cover used in Disturbed WEPP and WEPP Road – 5 percent

The WEPP model calculated an initial average erosion rate of 4.165 tons per acre per year for short-term disturbances and a rate of 1.602 tons per acre per year for post-reclamation disturbances in the long term, and estimated that areas impacted by short-term surface disturbance would experience 0.34 inches of runoff per year, and in the long term, average runoff would drop to 0.19 inches per year. The WEPP model estimated that there would be only trace amounts of annual runoff from undisturbed

areas. Appendix V provides a full list of the assumptions and parameters used in the WEPP analysis, and a table of erosion rates calculated by resource area.

Other assumptions used in this impact analysis include:

- There would be little or no runoff from undisturbed rangelands and forestlands (Laufen et al. 2000; Elliot et al. 2000).
- Bare soil (without vegetation or other surface cover) with a surface layer that has been altered from its natural condition is more susceptible to accelerated wind and water erosion than undisturbed soil.
- Implementing the *Wyoming Standards for Healthy Rangelands* (Appendix N) improves vegetation health, vigor, cover, and litter, as well as minimizes erosion rates in most areas.
- Wind erosion can affect soil productivity in a similar manner as water erosion. Because current soils data is not adequate to make a realistic determination of acres susceptible to wind erosion on rangelands, and there is no wind-erosion prediction technology available for use in a rangeland setting, this analysis will be limited to impacts resulting from water erosion.
- Most soils with a moderate water erosion potential within the Planning Area correlate with steep slopes (greater than 15 percent).
- The BLM will use BMPs to reduce runoff, soil erosion, and sediment yield, and to retain water on the landscape.
- To be effective on highly erodible soils, more extensive BMPs than those in common use are required to be utilized and aggressively maintained. The risk of BMP failure is greater on highly erodible soils.
- Although some forms of surface disturbance are restricted on slopes greater than 25 percent, it is assumed disturbance on highly erosive soils is distributed across the landscape in the same proportion these soils occur on the land, unless a proposed management action specifies additional protective measures. In other words, if 5 percent of the soils in the Planning Area are highly erosive, then it is assumed that 5 percent of the projected total disturbance would occur on highly erosive soils.
- Projected surface disturbance for each alternative potentially modifies soils by disrupting soil stability, changing vegetative cover that can reduce nutrient recycling, damaging biological crusts, decreasing productivity, and increasing compaction. When these modifications occur on highly erodible soils, the potential for accelerated erosion is greater than on less erodible soils. Site-specific erosion predictions and calculations require detailed soil mapping of areas to be disturbed. Soil mapping during site-specific analysis enables the BLM to minimize disturbance of highly erodible or otherwise sensitive soils.
- Sensitive soils incur greater adverse impacts from surface-disturbing activities than nonsensitive soils. Sensitive soils are fragile and especially susceptible to adverse impacts from surface disturbance because they are highly erodible and saline, sodic, or alkaline, or have a low reclamation potential. These fragile soils have limited reclamation potential either because of the vegetative community, physical or chemical limitations, susceptibility to erosion, or steep slopes.
- Installing and maintaining erosion controls and other mitigation measures, such as BMPs, result in a substantial reduction in soil erosion, depending on site conditions. However, these measures may not reduce adverse soil compaction and productivity impacts.

- Subject to applicable laws and regulations, surface-disturbing activities on fragile soils, soils with low reclamation potential, and soils with highly erosive characteristics will be authorized on a case-by-case basis.
- Fine-textured soils are more susceptible to water erosion and compaction when wet, whereas coarse-textured soils are more susceptible to wind erosion.
- Unless constrained by a management action or other data, surface disturbance will increase throughout the Planning Area during the planning cycle.

4.1.3.2 Summary of Impacts by Alternative

Impacts to soil resources may result from surface disturbance associated with a variety of resource programs that result in vegetation removal including mineral resources development, motorized vehicle use, road construction, and recreation. Concentrated or improperly managed livestock grazing can also result in adverse impacts to soil due to herbaceous vegetation removal. The greatest impacts to soil resources are anticipated under Alternative C, which would result in the greatest surface disturbance and erosion. The erosion rate due to surface-disturbing activities under Alternative C is estimated to be 66,459 tons per year in the long term, followed by Alternative D (29,326 tons per year), Alternative F (28,297 tons per year), Alternative A (25,065 tons per year), Alternative B (17,450 tons per year), and Alternative E (17,305 tons per year). Alternative E would result in the fewest potential adverse impacts to soil resources because it includes the most restrictions on surface-disturbing activities compared to the other alternatives. Alternative E also includes the most proactive management to minimize adverse impacts to soils in disturbed areas, followed by alternatives B, F, D, C, and A.

4.1.3.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Soils on BLM-administered surface lands and federal mineral estate could be disturbed under each alternative by activities proposed across a variety of resource programs. In disturbed areas, the WEPP model predicts an erosion rate of 4.165 tons per acre per year in the short term, which, after reclamation, would decrease to 1.602 tons per acre per year in the long term. This base erosion rate remains constant under each alternative. The intensity of impacts from erosion would vary under each alternative based on the area of projected surface disturbance. The intensity of impacts to soil resources from surface-disturbing activities under all alternatives is anticipated to be similar to the reasonable foreseeable actions identified in Appendix T.

Actions such as mineral resources development, motorized vehicle use, road construction, and recreation that disturb the soil surface can increase runoff and erosion, resulting in adverse impacts. The BLM utilizes various methods to minimize impacts to soil resources under all alternatives. BMPs, watershed enhancement projects, conservation practices, Storm Water Discharge Plans, and reclamation plans are designed to reduce impacts to soil, resulting in more successful reclamation, reduction in impacts during the time that soil is bare, as well as reduced runoff, soil erosion, and sediment yield. The BLM mitigates impacts from surface-disturbing and disruptive activities through the application of the *Wyoming BLM Standard Mitigation Guidelines for Surface-Disturbing and Disruptive Activities* (Appendix H).

Motorized vehicle use can compact the soil surface and remove vegetative cover that would protect soil from runoff events. Management that limits motorized vehicle use to existing roads and trails would

prevent route proliferation and vegetation removal that may increase erosion. In addition, management actions that restore plant communities would enhance soil resources by restoring infiltration, organic matter content, productivity, and reducing erosion.

Wild horses can adversely affect soils, especially in Herd Management Areas (HMAs) where concentrated year-round grazing can occur. Studies have shown that areas with wild horses experience increased compaction of the soil surface, especially in areas with finer-textured soils (Beever 2003; Beever and Herrick 2006). Horse-occupied sites also have been shown to have a lower abundance of grass and shrub cover on rangeland compared to sites where horses have been removed (Beever and Herrick 2006). Horses tend to use only a few trails to get water, which concentrates their movement and defecations and results in a greater impact to soil resources in these areas (Beever 2003). The impacts to soils from wild horses will likely be similar across all alternatives since the initial appropriate management levels for the HMAs do not vary.

Livestock, on the other hand, unless they are near a water source, tend to distribute themselves more uniformly across the landscape when grazing, thereby distributing the impacts. The BLM utilizes the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N) to protect and improve rangeland health, which is generally effective in managing the impacts to soils from livestock grazing.

Disposal of topsoil within the Planning Area is prohibited, which would result in beneficial impacts to soil resources, because this management would prevent the removal of soil at the startup of surface-disturbing activities or the loss of soil through disposals.

Actions that restrict surface disturbance in the Planning Area occur under all alternatives and generally are considered to have a beneficial impact on soil resources. For example, withdrawals that close areas to operation of the public land laws would reduce the potential for impacts to soil from surface-disturbing activities.

Alternative A

Surface Disturbance

Projected short-term disturbance from all BLM actions under Alternative A (current management) would affect 136,253 acres, resulting in erosion rates of 567,492 tons per year. After reclamation, long-term erosion rates would average 25,065 tons per year. Standard BMPs and mitigation guidelines combined with the restrictions on development on slopes greater than 25 percent are generally effective in mitigating impacts to soil and water resources under normal conditions.

Resource Uses

Surface-disturbing activities associated with mineral development expose soils to increased erosion potential in both the short term and long term. With projected initial disturbance of 25,552 acres for mineral resource development, short-term erosion rates would average 106,424 tons per year under Alternative A (Appendix T and Appendix V). Once these sites are stabilized and reclaimed, erosion rates would drop to 20,879 tons per year. Increases in surface disturbance related to mineral development may result in a proportional increase in impacts to soils.

Alternative A designates 115,905 acres of BLM-administered surface land available for disposal. Uncontrolled surface-disturbing activity would adversely affect land transferred out of federal control. Alternative A withdraws the second most acreage from operation of the public land laws in the Planning Area. Land withdrawn from operation under the public land laws would reduce the potential for

impacts to soil from surface-disturbing activities. The greatest long-term disturbance from ROW development would be from roads and other ROW facilities (typically associated with oil and gas facilities and mineral development). The projected initial erosion rate from disturbance associated with other ROW facilities would be 875 tons per year, which would decrease to 336 tons per year after reclamation. With the projection of 1,966 acres of disturbance associated with road construction (primarily related to oil and gas development and other local demand), short-term erosion would be 5,217 tons per year (Appendix T and Appendix V). Once new roads are stabilized, long-term erosion rates would average 2,608 tons per year.

Comprehensive travel and transportation management (CTTM) under Alternative A restricts motorized vehicle use in the majority of the Planning Area to existing roads and trails. The BLM anticipates an increase in motorized vehicle use in the Planning Area over the life of the plan. Increased motorized vehicle use on more user-created trails would accelerate degradation of the soil resource by removing vegetative cover and increasing erosion in more areas. Short-term disturbance associated with the creation of new roads and trails in areas open to cross-country motorized travel is predicted to disturb 1,233 acres, with erosion rates of 5,135 tons per year. Once these areas are stabilized, long-term erosion rates would average 1,338 tons per year (Appendix V).

Most of the Planning Area would remain open to livestock grazing under this alternative. Concentrated herbivory can result in adverse impacts when adequate vegetation does not remain to protect the soil resource. Excessive vegetation removal can cause soil compaction that reduces infiltration, increases runoff, and hampers reclamation. Livestock grazing management under Alternative A provides for protection or enhancement of other resource values, which would provide beneficial impacts to soils. Alternative A prohibits the placement of salt, mineral, or forage supplements within $\frac{1}{4}$ mile of water, wetlands, riparian areas, and reclaimed or reforested areas, which would reduce vegetation removal and soil compaction from concentrated livestock grazing. Rangeland improvement projects, including spring development, pipeline development, reservoir/pit development, fence development, well development, and reservoir maintenance development, are predicted to result in an initial disturbance of 370 acres and erosion rates averaging 1,541 tons per year (Appendix T and Appendix V). Revegetation would usually occur within several growing seasons and long-term erosion rates would average 34 tons per year.

Special Designations

Alternative A places constraints and restrictions on surface-disturbing and disruptive activities in certain special designation and other management areas where surface disturbance is minimized. Such areas, including Wilderness Study Areas (WSAs) (141,068 acres), Wild and Scenic River (WSR) eligible waterways (27,317 acres), and Areas of Critical Environmental Concern (ACECs) (71,646 acres), include restrictions that limit surface disturbance, resulting in beneficial impacts to soil resources within these areas. The Carter Mountain ACEC (10,867 acres) and Upper Owl Creek ACEC (13,758 acres), designated under Alternative A, include specific management prescriptions designed to protect fragile soils.

Resources

Fire and fuels management may have an adverse impact as well as a beneficial impact on soil resources. Fire in the Planning Area can affect soils in the short term by removing vegetation and exposing soils to water and wind erosion. Under certain conditions, intense fires can create hydrophobic soil conditions (i.e., resistance to water infiltration), whereby runoff and erosion are increased. Wildfires in the Planning Area are estimated to result in 117,620 acres of surface disturbance, which is not anticipated to vary by alternative, and an average erosion rate of 489,887 tons per year. In the long term, however,

provided vegetative recovery is successful, fire can have a beneficial effect on soil resources by reducing long-term erosion and the risk of catastrophic fire.

Suppression and rehabilitation activities can also have the potential to affect the soil resource in both the short and long term. Activities such as firebreak construction, clearing vegetation, and use of heavy equipment would disturb the soil surface and increase erosion in the short term. For example, fire lines constructed during suppression efforts can channelize surface runoff, which can result in gully erosion. In the long term, however, successful stabilization efforts can increase cover with a subsequent reduction in the natural rate of erosion.

Alternative A utilizes wildland fire to restore fire-adapted ecosystems and to reduce hazardous fuels. The BLM anticipates that fire management would result in 40,000 acres of short-term disturbance from prescribed fire and 30,000 acres of short-term disturbance from mechanical fuels treatment on BLM-administered land in the Planning Area (Appendix T). This disturbance would result in an average erosion rate of 166,600 tons per year for prescribed fire and 124,950 tons per year for mechanical fuel treatments. The BLM does not anticipate long-term surface disturbance or associated erosion from prescribed fire or mechanical fuels treatments following reclamation.

Management actions under Alternative A designed to protect wildlife and special status species habitat from the impacts of surface-disturbing and disruptive activities also would protect soil resources from these activities. Management actions such as applying no surface occupancy (NSO) restrictions within big game crucial winter range and applying a controlled surface use (CSU) stipulation within ¼ mile of occupied greater sage-grouse leks would reduce the chance of erosion. Vegetation management in crucial wildlife habitat is an additional beneficial impact for soil resources.

Proactive Management

Existing management actions intended to protect soils include analyzing all surface-disturbing and disruptive activities for suitability and impact, seeding areas impacted by surface-disturbing activities, and reestablishing vegetative cover within 5 years of initial seeding. The use of native plant species under Alternative A would not have a substantial impact on runoff and erosion. Under Alternative A, the BLM considers topsoil salvage and the stabilization of heavily eroded or washed out roads on a case-by-case basis. The BLM also implements watershed improvement practices to reduce sediment loadings in streams. This includes seeding, riparian/stream restoration, travel management, head cut control and sediment capture and containment projects. This alternative requires stabilization of existing watershed improvement projects where they have failed to promote, enhance, or improve watershed stability. However, Alternative A does not require reclamation plans. Reclamation plans can improve the effectiveness of the reclamation process and reduce the risk of additional soil degradation. Due to the increase in off-road motorized vehicle use in the Planning Area, two-track trails and unimproved roads are a substantial source of runoff and sediment. The lack of mandatory action to stabilize heavily eroded or washed out roads increases the potential for degradation of watershed health.

Alternative B

Surface Disturbance

Alternative B includes less acreage subject to surface-disturbing activities through management actions for other resources than Alternative A; therefore, surface disturbance under this alternative would result in less impacts to soils than Alternative A. Under this alternative, projected short-term disturbance from all BLM actions would affect 73,940 acres. Erosion rates for short-term disturbance under Alternative B would be 307,960 tons per year. Following reclamation of disturbed sites, the

projected long-term erosion rates would average 17,450 tons per year; 7,615 tons per year less than Alternative A.

Alternative B includes greater restrictions on surface-disturbing activities than Alternative A for the protection of other resources such as special designations, crucial wildlife habitat, and recreation management areas.

Resource Uses

With the projected initial disturbance of 17,306 acres for mineral resource development, short-term erosion rates would average 72,079 tons per year under Alternative B (Appendix T and Appendix V). After these sites are stabilized and reclaimed, erosion rates would drop to 9,942 tons per year, 10,937 tons per year less than Alternative A.

Under Alternative B, the impacts of disposal and retention would be similar to those described under Alternative A. Under Alternative B, 24,042 acres are identified for disposal, which is less than under Alternative A. Disposing of potentially less land may decrease the potential for uncontrolled surface-disturbing activities and soil resource degradation. Withdrawals under Alternative B would close the most land to operation under the public land laws relative to the other alternatives. The projected initial erosion rate from disturbance associated with other ROW facilities (typically associated with oil and gas facilities and mineral development) would be 396 tons per year, which would decrease to 152 tons per year after reclamation, which is less than Alternative A. With the projection of 1,229 acres of disturbance associated with road construction (primarily related to oil and gas development and other local demand), short-term erosion would be 3,261 tons per year (Appendix T and Appendix V). Once the roads are stabilized, long-term erosion rates would be 1,632 tons per year, 976 tons per year less than Alternative A.

Alternative B designates the majority of the Planning Area as limited to designated road and trails for motorized vehicle use, reducing the potential for new route proliferation and providing more protection to soil resources than Alternative A. Compared to Alternative A, which designates the most acreage in the Planning Area as limited to existing roads and trails, and although inappropriate use of vehicles may still occur in areas limited to designated roads and trails, Alternative B would allow greater management control over motorized vehicle use and help limit the impacts to soils. Alternative B also designates a larger area as closed to motorized vehicle use compared to alternatives A, C, and D. Short-term disturbance associated with new road and trail creation in areas open to cross-country motorized travel under Alternative B is predicted to disturb 2,776 acres, with erosion rates of 11,562 tons per year (Appendix T and Appendix V). Once these areas are stabilized, long-term erosion rates would average 1,711 tons per year, which is higher than Alternative A.

Under this alternative, a large portion of the Planning Area is closed to livestock grazing (1,984,211 acres). A ½-mile buffer prohibiting the placement of salt, mineral, or forage supplements near water, wetlands, riparian areas, and reclaimed or reforested areas would provide greater protection of soil in these areas compared to Alternative A. Short-term erosion rates associated with rangeland improvement projects in the Planning Area would average 771 tons per year based on an initial disturbance of 185 acres. After reclamation, long-term erosion rates would average 17 tons per year.

Special Designations

Compared to Alternative A, Alternative B places more restrictions on surface-disturbing activity within special designations and other management areas where surface disturbance is minimized. Many of these areas designated and managed under Alternative B, including ACECs (302,490 acres), Special Recreation Management Areas (SRMAs) and Recreation Management Zones (RMZs) (933,831 acres),

Soil

WSAs (141,068 acres), WSR suitable waterways (27,317 acres), and lands with wilderness characteristics managed specifically to preserve their wilderness characteristics (476,349 acres), include restrictions such as NSO, mineral withdrawals, and prohibitions on surface-disturbing activities that would, subject to applicable laws and regulations, result in long-term beneficial impacts to soil resources within these areas. Similar to Alternative A, the Carter Mountain ACEC (16,574 acres) and Upper Owl Creek ACEC (32,733 acres) include specific management prescriptions designed to protect fragile soils. However, the beneficial impact would be greater under Alternative B because the two ACECs include a combined additional 24,681 acres more than the same two ACECs under Alternative A.

Resources

Fire and fuels management under Alternative B utilizes wildland fire and other vegetative treatments to restore fire-adapted ecosystems for natural resource systems and to reduce hazardous fuels. The BLM anticipates that management will result in 20,000 acres of short-term disturbance from prescribed fire and 5,000 acres of short-term disturbance from mechanical fuels treatment on BLM-administered land in the Planning Area (Appendix T). This would result in an average erosion rate of 83,300 tons per year for prescribed fire and 20,825 tons per year for mechanical fuel treatments, 83,300 tons per year and 104,125 tons per year less than Alternative A, respectively.

Alternative B applies greater restrictions on surface-disturbing activities designed to protect wildlife and special status species habitat than Alternative A and therefore has a greater beneficial impact on soil resources. Vegetation management in crucial wildlife habitat is an added beneficial impact for soil resources.

Proactive Management

The management prescriptions on lands administered by the BLM under Alternative B are more protective of soil resources than Alternative A. Proactive management actions under this alternative include taking inventory of erosion rates and analyzing impacts from surface-disturbing activities by mapping soils, collecting samples, and evaluating current conditions. Site-specific data would result in better project design, BMP implementation, and better reclamation.

Proactive management also includes reestablishing native plant communities in disturbed areas, requiring topsoil salvage for all surface-disturbing activities, and requiring photo point monitoring of all channel crossings and all surface disturbance greater than ½ acre. The BLM would improve watershed health through the development of watershed improvement practices including seeding, riparian/stream restoration, travel management, head cut control and sediment capture and containment projects in cooperation with local governments and by stabilizing watershed projects if they are no longer meeting source objectives to prevent the release of stored sediment. Protecting watershed health will help to reduce the incidence of runoff and erosion.

Successful reclamation efforts following surface disturbance reduce the chance of long-term impacts to soil. Under Alternative B, higher reclamation standards and greater proactive management would improve reclamation success compared to Alternative A. Requiring reclamation plans before any authorized surface-disturbing activity leads to more successful reclamation efforts, which would benefit soils. A temporary protective surface treatment (such as mulch, netting, or tackifiers) used for the reclamation of all mechanically disturbed areas would, on average, reduce erosion rates in the short term by 2.97 tons per acre per year in these areas. Alternative B requires a more stringent reclamation standard than Alternative A by requiring 50 percent pre-disturbance of desired vegetative cover within three growing seasons and 80 percent pre-disturbance vegetative cover within 5 years of initial seeding.

While providing a beneficial impact to soils by reestablishing vegetative cover, the use of native plant species in disturbed areas would not have a substantial impact on runoff and erosion.

Alternative B mitigates the impacts to soil from the increase in off-road motorized vehicle use in the Planning Area by closing and reclaiming eroded roads and trails if alternative roads and trails are available and stabilizing or relocating these roads and trails if alternative routes are not available. Applying proactive management actions under this alternative would provide the most beneficial impacts to soils of any alternative.

Alternative C

Surface Disturbance

Alternative C places the fewest restrictions on resource uses with the result that more acreage is subject to surface-disturbing activities than the other alternatives. Under this alternative, projected short-term disturbance from all BLM actions would affect 245,642 acres, the most of any alternative. Erosion rates for short-term disturbance under Alternative C would be 1,023,099 tons per year. Following reclamation of disturbed sites, the projected long-term erosion rates would average 66,459 tons per year, over twice as high as under Alternative A.

As with the other alternatives, restrictions on surface-disturbing activities for the protection of other resources (e.g., water, biological resources, and special designations) may provide additional protection for soil resources.

Resource Uses

With the projected initial disturbance of 25,912 acres for mineral resource development, short-term erosion rates would be 107,923 tons per year under Alternative C. Once these sites are stabilized and reclaimed, erosion rates would decrease to 21,114 tons per year, slightly more than under Alternative A.

Alternative C identifies the most acreage of all alternatives for disposal of BLM-administered surface lands (117,845 acres), resulting in greater uncertainty of future land uses and impacts to soil.

Alternative C designates the fewest acres for withdrawal from the operation of the public land laws than the other alternatives, which increases the potential for adverse impacts to soil. The projected erosion rates from surface disturbance associated with other ROW facilities (typically associated with oil and gas facilities) are the highest of any alternative, averaging 970 tons per year in the short term and 373 tons per year in the long term. With the projection of 4,638 acres of surface disturbance associated with road construction (primarily related to oil and gas development and other local demand), short-term erosion rates would be 12,307 tons per year (Appendix T and Appendix V). Once the roads are stabilized, long-term erosion rates would average 6,154 tons per year, the highest of all alternatives.

Alternative C limits motorized vehicle use to existing roads and trails in the majority of the Planning Area, resulting in similar impacts as those described under Alternative A. Alternative C closes the fewest number of acres to motorized vehicle use and opens more acreage to cross-country motorized travel than any other alternative, resulting in the least protection of soil resources in sensitive areas. The areas open to cross-country motorized travel, such as Basin Gardens Play Area SRMA and Lovell Lakes “Motocross” area, would have a higher probability of erosion and long-term soil degradation than areas that close or limit motorized vehicle use. Partly because more acreage is open to cross-country motorized travel, short-term disturbance associated with the creation of new roads and trails for recreational purposes (12,907 acres) is projected to be higher under Alternative C than under the other alternatives. The creation of these roads and trails would result in erosion rates of 53,758 tons per year

in the short term, the highest of all alternatives (Appendix V). Once these areas stabilize, long-term erosion rates would average 20,401 tons per year.

Under Alternative C, the majority of the Planning Area is available for livestock grazing. The BLM manages livestock grazing to optimize commodity production while meeting rangeland health standards but not specifically to enhance other resource values. Management under Alternative C also does not prohibit the placement of salt, mineral, or forage supplements, and increases the potential for adverse impacts to soil near water, wetlands, riparian areas, and reclaimed or reforested areas. This alternative focuses on rangeland improvement projects to mitigate impacts to resources. Short-term erosion rates associated with rangeland improvement projects in the Planning Area would be 3,082 tons per year based on an initial disturbance of 740 acres. After reclamation, long-term erosion rates would decrease to 74 tons per year, higher than the other alternatives.

Special Designations

Compared to other alternatives, Alternative C prescribes fewer restrictions on surface-disturbing and disruptive activities for a smaller number of special designations and other management areas where surface disturbance is minimized. Alternative C designates two ACECs (11,799 acres) which provide protection for the soil resource by limiting surface-disturbing and disruptive activities. Alternative C also manages the 10 WSAs (141,068 acres) in accordance with BLM Manual 6330, *Management of Wilderness Study Areas* to maintain the non-impairment standard, and therefore provides protections for soils within these areas. Alternative C, in contrast to Alternative B, does not include special management prescriptions for WSR eligible waterways or lands with wilderness characteristics that would provide additional protection for soils.

Resources

Fire and fuels management under Alternative C utilizes wildland fire and other vegetative treatments to restore fire-adapted ecosystems, to enhance forage for commodity production, and to reduce hazardous fuels. The BLM anticipates that management would result in 80,000 acres of short-term disturbance from prescribed fire and 60,000 acres of short-term disturbance from mechanical fuels treatment on BLM-administered land in the Planning Area (Appendix T). This would result in an average erosion rate of 333,200 tons per year for prescribed fire and 249,900 tons per year for mechanical fuel treatments, which are the highest erosion rates of all alternatives. In comparison, wildland fires in the Planning Area are estimated to result in 117,620 acres of disturbance, which is not anticipated to vary based on alternative, and an average erosion rate of 489,887 tons per year.

In contrast to the other alternatives, Alternative C applies fewer management restrictions on surface-disturbing and disruptive activity designed to protect wildlife and special status species. The absence or reduction of these restrictions results in greater potential for adverse impacts to soil resources.

Proactive Management

Proactive management under Alternative C is similar to Alternative A. However, unlike Alternative A, Alternative C reestablishes plant communities in disturbed areas to increase commodity production and requires reclamation plans on a case-by-case basis. The use of reclamation plans can increase the use of BMPs to better protect the soil resource and improve overall reclamation success. Alternative C sets a lower vegetation restoration standard than alternatives B and D. Alternative C requires 30 percent desired vegetative cover within three growing seasons compared to Alternative A, which does not specify the degree of cover to be restored. Low vegetative cover increases the chance of erosion and nutrient loss, which increases the difficulty of achieving successful final reclamation. On a case-by-case basis, watershed projects are stabilized if they are no longer meeting resource objectives, resulting in a

beneficial impact to soil and watershed health by preventing the release of stored sediment. Other management actions beneficial to soil resources under Alternative C include stabilizing heavily eroded or washed out roads and collecting site-specific data through mapping, collecting, and evaluating current erosion conditions on a case-by-case basis. Site-specific data would result in better project design, BMP implementation, and better reclamation.

Alternative D

Surface Disturbance

Impacts to soil from surface disturbance under Alternative D are projected to be greater than under alternatives A and B but less than under Alternative C. Projected short-term disturbance from all BLM actions would affect 140,175 acres (Table 4-1), resulting in an erosion rate of 583,827 tons per year. After reclamation, the long-term erosion rate would average 29,326 tons per year, which is slightly greater than Alternative A.

Resource Uses

Under Alternative D, the projected amount of surface disturbed by activities associated with minerals development (25,229 acres) is greater than under Alternative B but less than under alternatives A and C. The predicted average erosion from surface disturbance would be 105,079 tons per year in the short term, reducing to 20,398 tons per year after reclamation and stabilization. Proper reclamation in accordance with an approved reclamation plan, stipulations, or measures, which are required under Alternative D, would help improve reclamation success and reduce long-term impacts to soil.

Alternative D identifies 66,363 acres for disposal of BLM-administered surface lands, more acres than under Alternative B but fewer than under alternatives A and C. Impacts to soil resources in areas disposed from federal ownership would be similar to those described for Alternative A. The erosion rate predicted from disturbance associated with other ROW facilities and road construction would be the same as under Alternative A.

CTTM under Alternative D would protect soil from motorized vehicle use on more acreage than alternatives A and C through closures and limiting motorized vehicle use to designated roads and trails, but would also designate the second most acreage as open to cross-country motorized travel (5,885 acres). Partly because more acreage is open to cross-country motorized travel and partly due to a higher projected rate of yearly new road and trail creation under this alternative, disturbance associated with the creation of new roads and trails (5,820 acres) is projected to be higher under Alternative D than under alternatives A and B but less than under Alternative C. Creating these roads and trails would result in erosion rates of 24,240 tons per year in the short term and 6,313 tons per year in the long term (Appendix T and Appendix V).

Livestock grazing management is conducted in a similar fashion as Alternative A, resulting in similar impacts to soils. Alternative D is projected to disturb the same acreage from rangeland improvement projects as Alternative A and result in the same amount of erosion.

Special Designations

Alternative D designates several special designations and other management areas that would minimize surface disturbance and provide a beneficial impact to soil in these areas. Management prescriptions for ACECs (105,498 acres) and WSAs (141,068 acres) can provide additional protection for soils from surface-disturbing activities. Alternative D protects a greater area in these special designations from surface-disturbing activities than alternatives A and C, but less than Alternative B. Management of

certain SRMAs would only allow surface-disturbing activities if the impacts could be avoided, minimized or mitigated, thereby reducing the impacts to soil in the long term. Similar to Alternative C, Alternative D does not include special management prescriptions for WSR eligible waterways that would provide additional protection for soils. Similar to Alternative A, the Carter Mountain ACEC (10,867 acres) and Upper Owl Creek ACEC (13,758 acres) include specific management prescriptions designed to protect fragile soils.

Resources

Fire and fuels management under Alternative D would utilize wildland fires and other vegetation treatments to restore fire-adapted ecosystems, reduce hazardous fuels, and accomplish resource management objectives. Under Alternative D, prescribed fire and mechanical fuels treatments are projected to disturb the same acreage as under Alternative A and would result in the same erosion rate and similar impacts to soils.

Management designed to protect fish and wildlife, special status species, and other biological resources would provide benefits to soil by limiting surface-disturbing activities and other actions that could degrade soil health. The beneficial impacts would be similar to those described under Alternative A except that several areas would require avoidance of surface-disturbing activities. In these areas, surface-disturbing activities would be prohibited unless the impacts could be mitigated, thereby limiting long-term adverse impacts.

Proactive Management

Overall, proactive management actions under Alternative D would provide soil resources with greater protection and improve reclamation efforts more than alternatives A and C but less than Alternative B. Stabilization of existing watershed improvement projects would prevent the release of stored sediment and the degradation of watershed health. In disturbed areas, the reestablishment of healthy native or desired plant communities (DPCs) would benefit soils by increasing vegetative cover and reducing runoff. Soil would also benefit from the reclamation standards under Alternative D, which considers final reclamation to be achieved if conditions are equal to or better than pre-disturbance site conditions. When appropriate for the site and situation, Alternative D would require temporary protective surface treatments such as weed-free mulch, matting, netting, or tackifiers to facilitate the reclamation of disturbed areas, which would result in beneficial impacts similar to those described for Alternative B.

Applying a Master Leasing Plan (MLP) to the Fifteenmile MLP Analysis Area (230,699) under Alternative D would reduce the potential for adverse impacts from oil and gas-related surface disturbance to Limited Reclamation Potential (LRP) soils. The MLP requirements include CSU restrictions, a minimum lease size of 640 acres, and allowing only one oil and gas-related facility, not exceeding 32 acres of surface disturbance at any given time, per lease. Although certain exceptions would apply, Alternative D also limits OHV use for notice of staking level casual use actions to areas within 300-feet of established roads with limited travel designations. The reduction in adverse effects from these restrictions would be limited by the generally low potential for oil and gas development within the Fifteenmile area. However, should oil and gas development occur, Alternative D management would provide less protection for LRP soils than Alternative B, which applies a NSO restriction and prohibits OHV use for notice of staking level casual use actions in the Fifteenmile MLP Analysis Area, but more protection than under alternatives A and C, which only apply case-by-case basis restrictions on surface-disturbing activities.

Alternative E

Surface Disturbance

Alternative E includes the greatest restrictions on surface-disturbing activities, compared to the other alternatives, for the protection of other resources such as special designations, crucial wildlife habitat, and recreation management areas, and would result in the fewest impacts on soils. Under Alternative E, projected short-term disturbance from all BLM actions would affect 71,829 acres (Table 4-1), resulting in a short-term erosion rate of 299,169 tons per year. Following reclamation of disturbed sites, projected long-term erosion rates would average 17,305 tons per year, which is the least among the alternatives. Management practices relating to surface disturbance would be the same as Alternative B, except for areas within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). In this ACEC, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) so they do not exceed one disturbance per 640 acres and cover less than 3 percent of the total sage-grouse habitat, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. This restrictive management over the large area of the ACEC would generally benefit soil resources by limiting the size and extent of disturbances.

Resource Uses

Under Alternative E, initial disturbance of 17,297 acres for mineral resource development is projected, and short-term erosion rates would average 72,042 tons per year under Alternative E (see Appendix T and Appendix V). Following stabilization and reclamation of disturbed areas, erosion rates are projected to drop to 9,936 tons per year, which is the same as Alternative B, and less than the other alternatives.

Alternative E identifies 24,042 acres for disposal (including disposal for specific uses), which is the same as Alternative B, decreasing the potential for surface-disturbing activities and soil resource degradation in areas removed from federal ownership. The initial erosion rate from disturbance associated with other ROW facilities would be 396 tons per year, decreasing to 152 tons per year after reclamation, which is the same as Alternative B, and less than the other alternatives (Appendix V).

Alternatives B and E include the most limitations on and closures to motorized vehicle use for resource protection. Therefore, these alternatives would minimize new route proliferation and provide more protection to soil resources than the other alternatives. Similarly, alternatives B and E close the largest area to motorized vehicle use compared to the other alternatives and include the greatest areas of seasonal closures. Under Alternative E, new road and trail creation in areas open to cross-country motorized travel would result in generally the same acreage of short- and long-term disturbance as Alternative B and erosion rates following stabilization would be the same as listed under Alternative B (Appendix T and Appendix V). Total disturbances associated with road construction under Alternative E are projected to be the same as Alternative B, resulting in less short- and long-term erosion when compared to alternatives A, C, D, and F (Appendix T and Appendix V).

Livestock grazing management under Alternative E would be the same as Alternative B, and impacts to soil would be the same as described under that alternative.

Special Designations

Special designations under Alternative E would be the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land within greater sage-grouse Key Habitat Areas that would be designated as an ACEC. The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative E would result in additional protection for soils in comparison to the other alternatives. Specifically, requirements include a full

reclamation bond to insure restoration of disturbed areas to their original condition and other habitat restoration and vegetation management requirements associated with the Greater Sage-Grouse Key Habitat Areas ACEC would reduce adverse impacts from surface-disturbing activities in greater sage-grouse Key Habitat Areas.

Resources

Fire and fuels management under Alternative E would result in the least amount of disturbance from fuels treatment and prescribed fire of any alternative, and the fewest short-term adverse impacts to soils from fire management activities. Approximately 18,000 acres of short-term disturbance from prescribed fire is projected under Alternative E (Appendix T). An average erosion rate of 74,970 tons per year for prescribed fire and 20,825 tons per year for mechanical fuel treatments is projected for Alternative E, which is the least for all alternatives (Appendix V). Post-fire reclamation requirements within the Greater Sage-Grouse Key Habitat Areas ACEC would result in additional beneficial impacts on soil retention through management practices that ensure long-term persistence of seeded and pre-treatment native plants.

Proactive Management

Soil resources management under Alternative E would generally be the same as Alternative B, and beneficial impacts to soils would be the same as Alternative B. However, areas in the Greater Sage-Grouse Key Habitat Areas ACEC would be subject to additional protective management under Alternative E; these additional protections would result in the greatest overall beneficial impacts to soil resources of any alternative.

Alternative F

Surface Disturbance

Impacts to soil resources from surface disturbance under Alternative F are projected to be greater than under alternatives A, B, and E, but less than under alternatives C and D. Short-term disturbance from all BLM actions would affect 137,065 acres (see Table 4-1 and Appendix T) under Alternative F, resulting in an erosion rate of 570,877 tons per year. Following reclamation, the long-term erosion rate would be 28,297 tons per year, which is greater than alternatives A, B, and E (Appendix V). Management practices restricting surface disturbances for the protection of other resources (such as soil, water, biological resources, and special designations) would be the same as Alternative D, except within areas of the proposed Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). In this ACEC, the BLM manages the density of disturbance to not exceed an average of one disruptive activity location per 640 acres and cover less than 3 percent of the total greater sage-grouse PHMAs, compared to a larger allowable disturbance of 5 percent under Alternative D. This restrictive management over the large area of the ACEC would generally benefit soil resources by limiting the size and extent of disturbances.

Resource Uses

The projected surface disturbance from minerals development would be 25,223 acres under Alternative F and would be greater than alternatives B and E, less than alternatives A and C, and generally the same as Alternative D (Appendix T). A predicted average erosion rate of 105,054 tons per year would result from these surface disturbances under Alternative F in the short term (Appendix V). Following reclamation and stabilization, the erosion rate is expected to decrease to 20,395 tons per year. Resource exploration, development, and extraction management under Alternative F would be the same as Alternative D, and impacts to soils would generally be the same as Alternative D. However,

in greater sage-grouse PHMAs, additional restrictions on leasable minerals under Alternative F would decrease surface disturbance impacts compared to Alternative D.

The management of lands and realty and ROWs under Alternative F would generally be the same as Alternative D, and impacts to soils would be the same as Alternative D.

Impacts from CTTM and recreation management under Alternative F would provide greater protections for soil resources than under alternatives A, C, and D, but fewer protections than under alternatives B and E. CTTM management practices for Alternative F would be the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC where motorized vehicle use would be limited to designated roads. Under Alternative F, disturbances associated with the creation of new roads and trails is projected to involve 1,343 acres and would be less than alternatives A, C, and D, but higher than under alternatives B and E (Appendix T). New road and trail construction under Alternative F would result in erosion rates of 3,564 tons per year in the short term and 1,783 tons per year in the long term (Appendix V).

Livestock grazing management under Alternative F would generally be the same as Alternative D, and impacts to soils would be the same as Alternative D. However, for areas within the Greater Sage-Grouse PHMAs ACEC, livestock grazing restrictions and vegetation management requirements under Alternative F would result in additional beneficial impacts to soil resources through increased vegetation cover and infiltration compared to Alternative D.

Special Designations

The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative F would result in greater protections for soil resources in comparison to alternatives A, C, and D, but fewer than under alternatives B and E. Special designations under Alternative F would be the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land within the Greater Sage-Grouse PHMAs ACEC. When compared to alternatives A and D, Alternative F would add additional management actions within the Greater Sage-Grouse PHMAs ACEC that would provide benefits to soil by limiting surface-disturbing activities and other actions that could degrade soil health. The beneficial impacts would be similar to Alternative A, except that more acreage would be managed to avoid and minimize surface-disturbing activities, thereby limiting short- and long-term adverse impacts.

Resources

Under Alternative F, prescribed fire and mechanical fuels treatments are projected to disturb less acreage than Alternative A and would subsequently result in decreased erosion rates. Approximately 40,000 acres of short-term disturbance from prescribed fire is projected under Alternative F (Appendix T). An average erosion rate of 166,600 tons per year for prescribed fire and 124,950 tons per year for mechanical fuel treatments is projected for Alternative F, the same as alternatives A and D, and greater than alternatives B and E (Appendix V). Disturbance from fuels treatments and prescribed fire under Alternative F would be the same as Alternative D, with the exception of additional fire management restrictions within the Greater Sage-Grouse PHMAs ACEC that would be designed to maintain or improve sagebrush habitat. The additional ACEC restrictions would decrease the potential adverse impacts to soil resources from fire management activities compared to alternatives A and D.

Proactive Management

Soil resources management that would benefit soil resources under Alternative F are the same as Alternative D for areas outside of the Greater Sage-Grouse PHMAs ACEC; management of areas inside

that ACEC would provide greater protection and improve reclamation efforts more than alternatives A, C, and D, but less than alternatives B and E.

4.1.4 Water

This section summarizes beneficial and adverse impacts to surface water quality and quantity, and groundwater quality and quantity. In addition, the section describes the differences between direct and indirect impacts and short- and long-term impacts.

Surface Water Quality

Adverse impacts to water quality are those that result in a violation of state water quality standards or degrade a designated use. Management actions that permit surface-disturbing activities that contribute to offsite erosion and sediment delivery are considered adverse impacts. Beneficial impacts to surface water quality result from management actions that improve water quality or minimize, reduce, or prevent offsite erosion or the discharge of supplemental water that is of lower quality than the ambient water quality of the receiving water. For example, management actions that stabilize watershed projects no longer meeting resource objectives or that seed degraded portions of watersheds would result in beneficial impacts to surface water quality.

Direct impacts to surface water quality are those that degrade the ambient water quality of surface waters in the Planning Area. For example, management actions that modify drainages, such as altering the number of linear water crossings or the distribution and condition of wetlands and riparian areas, would result in direct impacts to surface water quality. Indirect impacts are those that disturb soil in a watershed, especially highly erodible soil, as this leads to increased sedimentation.

Long-term impacts to surface water quality are those that result from bare soil or established point discharges that increase sediment loads or degrade water quality. Short-term impacts include exceedances of state water-quality standards mitigated within required timeframes, or surface disturbances temporarily affecting water quality that are reclaimed immediately after a temporary use.

Surface Water Quantity

Impacts to surface water quantity result from management actions that reduce or supplement streamflows and may be either beneficial or adverse, depending on the quantity and the location of the withdrawal(s) and/or discharge(s).

Direct impacts to surface water quantity result from management actions (e.g., vegetative and physical treatments, impoundments, retention and detention structures, etc.) that increase or decrease runoff, as well as from changes in the quantity of produced water discharged into the system. Direct impacts also result from adding or modifying diversions from the drainage system.

Indirect impacts to surface water quantity result from management that modifies the capacity of stream channels or result in changes to the amount of water reaching the stream system. For example, changes in the locations of roads that direct surface water runoff into drainages may increase or decrease the timing and amount of surface water flowing in the stream system. The distribution and condition of wetlands and riparian areas would indirectly result in changes to surface water quantity because they increase infiltration and delay peak flows.

Long-term impacts to surface water quantity are those that alter the amount of impervious surface in a drainage or change established discharges that alter supplemental streamflows (more than 5 years).

Short-term impacts include uses that may temporarily affect water quantity, such as temporary impoundments or detention structures.

Groundwater Quality and Quantity

Change in the number of wells drilled in a given area, including domestic or municipal water supply wells, and water disposal or injection wells, result in direct impacts to groundwater quality and quantity. Other factors include the number and location of springs developed, whether there are water conservation efforts in an area, and the amount of water infiltration and recharge. Oil- or gas-well stimulation methods also can directly affect groundwater, although proper construction, completion, and plugging/abandonment of oil, gas, water, and monitor wells would assist in protection of groundwater resources.

Indirect impacts to groundwater quality and quantity result from activities that modify recharge areas related to a groundwater system or systems. For example, activities that decrease vegetative cover, or increase runoff, can reduce infiltration of precipitation, thereby reducing recharge to groundwater aquifers.

Short-term impacts to groundwater are those resulting from any temporary or short-term use of groundwater—for example, temporary use of a well to supply water for drilling an exploratory gas well or for supplementing the water supply in a grazing allotment. Long-term impacts to groundwater quality and quantity can result from permanent oil and gas fields and production facilities constructed in recharge areas, or from landscape alterations that modify groundwater recharge. Such impacts can include wells that deplete an aquifer through extraction of water, paved surfaces and compacted soils that decrease water infiltration, or wells used to inject water of similar quality (disposal wells) into the aquifer.

4.1.4.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Surface disturbance can affect surface water quality by increasing sediment transport, which can ultimately be transported to streams or other surface waters and by reducing infiltration, which affects surface water and groundwater quality, quantity, and timing.
- Surface disturbance can affect surface water quality by concentrating flow and increasing flow energy resulting in increased erosion. Most activities that result in 1 or more acres of surface disturbance require coverage under a Wyoming Pollutant Discharge Elimination System (WYPDES) storm water permit, and require a storm water pollution prevention plan that identifies specific BMPs to prevent or reduce erosion and pollution, periodic inspection and monitoring, and cannot result in a violation of water quality standards in the receiving stream.
- Actions that provide protection for the soil and vegetation resources will generally mitigate impacts on the water resource as well.
- Soils that are the most susceptible to erosion are the most likely to adversely affect surface water quality if disturbed. The amount of sedimentation is determined by many factors, including the amount of disturbed surface, the type of soil, the amount and timing of water sufficient to create overland flow, the proximity to established channels, the density and vigor of the vegetative community, the buffering capacity of land over which the water would flow, and the effectiveness of erosion-control measures, such as BMPs.

- The extent of two-tracks and unsurfaced roads (i.e., those without gravel or any other added surface material) is an indicator of the quantity of erosion and sediment delivery that may impact surface water quality within each watershed (Furniss et al. 2000).
- Produced water generated from oil and gas development adds to surface water flows and can supplement streamflows. It is assumed legal water rights are established according to the requirements of the state engineer if livestock producers or other land users choose to utilize this water.
- The impacts of produced water from coalbed natural gas (CBNG) wells have not been studied to the same extent as those of produced waters from conventional oil and gas wells, and may vary considerably based on the specific characteristics of the produced water and its receiving environment (Veil et al. 2004). For the purposes of this analysis, water produced from future CBNG wells in the Planning Area is assumed to be of essentially the same quality and quantity as produced water from conventional or deep oil and gas wells. Specific impacts from the disposal and treatment of produced water are regulated through the Wyoming DEQ WYPDES permitting program.
- Produced water discharged from oil and gas operations generally has a higher temperature than the naturally occurring surface water. However, most produced water discharges first enter a naturally ephemeral drainage that would otherwise not contain surface water. By the time the produced water does reach a perennial water, the temperature has cooled dramatically and there is little if any impact on the temperature of perennial water. Wyoming DEQ oversees the water from the point of discharge to assure that Wyoming rules and regulations are implemented so as to not change the ambient water temperature to levels that result in harmful acute or chronic effects to aquatic life, or that would not fully support existing and designated uses (Wyoming DEQ 2013d).
- Surface-disturbance associated with mineral development is one of many human activities that in addition to natural events have the potential to impact shallow groundwater quality and quantity. Locations in the Planning Area with depths to groundwater of less than 100 feet are considered the most likely to be impacted by mineral development or natural events. The shallower the depth to water, the more sensitive an aquifer is to contamination (Wyoming Geographic Information Science Center 1998).
- The state of Wyoming has primacy regarding water. This includes water quality standards and water rights. The BLM may use water as an indicator or management tool, but it does not directly manage water.
- The principal sources of surface disturbance from mineral development are roads and well pads for oil and gas and the disturbance created by solid mineral mining.
- Livestock usually affect soil less than other developments, but the tendency for livestock to concentrate in riparian areas and in the proximity of open water while simultaneously affecting riparian vegetation may increase loading of fecal bacteria and nitrate (NO₃) to surface waters, and may increase erosion and sedimentation. In cooperation, consultation, and coordination with permittees/lessees, cooperators, and other stakeholders, the BLM would develop and implement appropriate livestock grazing management actions to enhance rangeland health, improve forage for livestock, and meet other multiple use objectives by using the *Wyoming Guidelines for Livestock Grazing Management*, other appropriate BMPs, and development of appropriate range improvements.
- Herbivory use is typically disproportionately higher in riparian/wetland communities than in upland communities. Improper or unmanaged herbivory can adversely impact these areas

throughout the year, but surface impacts (due to hoof action) are generally greater in the spring and early summer, when soils are wet and, therefore, more vulnerable to compaction and stream banks are more vulnerable to sloughing. Because herbivores tend to congregate in these communities during the hot season (mid to late summer), the utilization levels in riparian/wetland areas can be high.

- Substantial disturbance to soil, including compaction of soil or changes in vegetative cover, would increase water runoff and downstream sediment loads and would lower soil productivity, thereby degrading water quality, channel structure, and overall watershed health. Several factors influence the degree of impacts attributed to any one disturbance or series of disturbances, including location within the watershed, time and degree of disturbance, existing vegetation, and precipitation.
- Changes in channel geomorphology due to activities may be detrimental to current designated uses. Sediment in channels is necessary for maintaining channel geomorphology and building riparian systems. Most channel systems achieve a channel form in equilibrium to the water and sediment being naturally supplied to it and generally respond to changes in sediment loads or streamflows by changing the channel form.
- Changes in flow frequency, volume, duration and/or energy, sediment loading, and bank degradation may degrade aquatic habitat and may affect other designated uses (e.g., stock-watering, irrigation, and drinking water supplies). Changes in water quality for surface waters, such as increases in pollutants, may also degrade aquatic habitat or affect other designated uses.
- The BLM policy prohibiting the mixing of chemicals within 500 feet of open water (BLM Handbook H-9011) would reduce the likelihood of chemical spills from federal actions contaminating surface waters.
- Because the state of Wyoming must comply with federal laws, compliance with state laws includes compliance with federal rules and regulations, including the Clean Water Act, Safe Drinking Water Act, and others. Therefore, it is assumed that any discharged water would meet water quality limits at the point of discharge.
- As populations expand in the area, disturbances that affect water in the Planning Area will most likely continue to expand.
- This analysis uses the WEPP model to calculate the runoff amounts and erosion rates used throughout this section. WEPP simulates the conditions that affect runoff and erosion, such as the amount of vegetation canopy and soil water content, to estimate runoff averages and erosion rates. For a more detailed description of the WEPP model and a list of the assumptions and parameters used in the analysis, see Section 4.1.3 *Soil* and Appendix V. All erosion rates and runoff amounts calculated using the WEPP model for this section were calculated using the same assumptions and input parameters that were used for Section 4.1.3 *Soil* and as described in Appendix V.

4.1.4.2 Summary of Impacts by Alternative

Adverse impacts to surface and groundwater quality and quantity include increased erosion and sediment loading in streams and may result from a variety of resource programs including soils management, minerals development, management of fish and wildlife, motorized vehicle use, and improper livestock grazing management. Reclamation and other management activities that increase vegetative cover result in beneficial impacts to water resources. Alternatives that result in more long-

term surface disturbances and stipulate fewer restrictions on resource uses that might affect water resources are anticipated to result in the greatest overall impact to water resources. Alternative C would result in the greatest adverse impacts to water resources due to the greatest projected surface disturbance and the fewest resource use restrictions. Although it would allow more long-term disturbance than Alternative A, Alternative D may result in fewer long-term adverse impacts to water resources due to increased reclamation standards and requirements for mitigation under this alternative. Alternative E would result in the fewest adverse impacts to water resources due to the comparatively smaller amount of projected surface disturbance and greater number of resource use restrictions under this alternative. Impacts to groundwater quality may result from produced water discharge where oil and gas wells are in areas with shallow groundwater. Alternative C is projected to result in the greatest number of new federal oil and gas wells, followed by alternatives A, D, F, B, and E (Appendix T).

4.1.4.3 Detailed Analysis of Alternatives

The following analysis focuses on potential short-term and long-term impacts to surface water and groundwater quality and quantity as a result of allowable uses and management actions proposed under each alternative. The proposed management of the following resource programs has the highest potential to beneficially or adversely affect water resources: locatable minerals, oil and gas (including, but not limited to the handling of produced water), soils (including restoration of healthy plant communities), fish and wildlife, CTTM, livestock grazing, and ACECs and other special designations. Other resource programs that have the potential to affect water resources include recreation (particularly the recreational use of OHVs), ROW improvements, watershed enhancement, invasive species, and forests, woodlands, and forest products (though these activities are usually small scale and do not totally denude the surface or alter root masses). Emphasis on the *Wyoming Standards for Healthy Rangelands* (Appendix N) would moderate impacts to water resources.

The principal factors used to differentiate between alternatives are the acres of projected surface disturbance for each alternative and the limitations of allowable uses and management actions. Alternatives with higher projected disturbance areas may lead to greater potential impacts to surface and groundwater (as described below under *Impacts Common to All Alternatives*). Similarly, greater or fewer allowable uses under an alternative would lead to a similar change in the potential for impacts to surface and groundwater. Due to the programmatic nature of the RMP alternatives, the timing and specific location of project actions that may affect resources are not defined. Alternative A is the primary point of comparison for all other alternatives.

Impacts Common to All Alternatives

Surface Water Quality Impacts

Actions that remove vegetation and loosen surface soil may cause surface runoff, resulting in soil erosion and sedimentation in the surface water system. Activities that compact soils can result in even greater runoff and erosion. Eroded soil that reaches surface water channels is a principal source of impaired surface water quality. The amount of sediment delivered to a stream depends on many factors (e.g., slope length and gradient, vegetative cover and type, and density of the drainage network), all of which may result in deposition of the sediment before it reaches a drainage (also called buffering). For example, large runoff events can lead to gully erosion, which can deliver large amounts of sediment in a small period.

Analysts used the WEPP analysis model, described in Section 4.1.3 *Soil* of this chapter, to estimate average runoff as a result of surface disturbances in the Planning Area. Analysts used the same assumptions they used to estimate soil erosion (see Section 4.1.3 *Soil* and Appendix V) to calculate the mean annual average runoff. The WEPP model estimates that areas affected by short-term surface disturbance would experience 0.34 inches of runoff per year. Once these areas are stabilized and reclaimed, the average runoff would drop to 0.19 inches per year in the long term. In comparison, the WEPP model estimates that with no disturbance there would be only trace amounts of annual runoff. The scale of impacts from runoff is anticipated to vary by alternative based on the amount of surface disturbance anticipated under each alternative. Therefore, if there is more acreage of surface disturbance, there is more impact to water resources in the Planning Area.

The highest potential for long-term surface disturbance under all alternatives would result from the development of minerals, fire and fuels management, forest management, ROW development (roads, pipelines, and powerlines), motorized vehicle use, and recreational site development. Soil disturbance may also result from invasive species and pest management, motorized vehicle use, livestock and wildlife grazing, and the reclamation of disturbed areas. Alternatives with greater projected surface disturbance would result in increased sedimentation. Livestock and wildlife also may introduce fecal coliform, NO₃, and sediment to surface waters, which would contribute to water quality impairment.

Roads intercept surface water runoff on the landscape and often direct flows to drainages through ditches and culverts. If roads are unsurfaced, runoff flowing down a road often picks up sediment that is then deposited in the surface water system at stream crossings or at culverts and water bars. Alternatives that increase the density of roads in a watershed, especially unsurfaced roads, may increase sedimentation. Roads may also act as conduits for directing contaminants from vehicles and resource management activities (e.g., pesticide applications) into the surface water system (Furniss et al. 2000). The aerial application of fire suppressant chemicals within 300 feet of perennial waters is avoided under all alternatives, which would reduce the potential for chemical contamination of surface waters.

Short-term and long-term surface disturbance (e.g., from oil and gas and other minerals development, or travel and transportation management) and herbivory within the Planning Area also may affect surface water quality. Those watersheds with the greatest proportion of highly erodible soils have the most potential for contributing sediment to the surface water system with the presence of surface-disturbing activities. Under all alternatives, implementation, inspection, and maintenance of BMPs and the development and implementation of Stormwater Pollution Prevention Plans, as required under the WYPDES Stormwater Program would minimize sedimentation within watersheds. Water management plans for surface discharges of produced water would include reclamation strategies, mitigation, and monitoring to track changes in receiving channels and to minimize adverse impacts to watershed health. The BLM monitors rangeland health to determine livestock grazing management actions necessary to control erosion and other water-quality issues, such as contamination by fecal coliform bacteria that affect surface waters. Proper management of livestock grazing can mitigate sediment delivery from erosion. WYPDES permits required by the state of Wyoming would regulate water quality changes associated with point source discharges (Wyoming DEQ 2004). In the case of WYPDES permits on public land, the BLM consults with Wyoming DEQ-Water Quality Division (WQD) during the permitting process and follows-up if issues associated with permitted discharges are discovered.

Management that reduces the production of sediment (e.g., through the enhancement of vegetative ground cover, proper livestock grazing management, or watershed improvement projects that reduce sediment transport into waterways) would have a beneficial impact on efforts to reduce sedimentation of Bighorn Lake. A 2009 study by the Bureau of Reclamation (BOR) and U.S. Army Corps of Engineers states that implementing BMPs in the Bighorn Basin could reduce the total sediment load entering this

reservoir. The study notes, however, that such an approach might not be a practical way to achieve substantial sediment reductions given conditions in the area, noting that it would require considerable time to achieve results noticeable in the northern portion of Bighorn Lake that are important for recreational access (USACE and BOR 2009).

The Wyoming DEQ WQD permits surface discharges of produced water from oil and gas wells through a WYPDES permit that requires compliance with specific water-quality standards. The quality of produced water discharged on the surface must be suitable for designated uses, such as agriculture and livestock, and cannot result in a violation of water-quality standards in the receiving stream. Due to prolonged contact with the formations that contain oil and gas and contamination from chemical additives used in well drilling and production, this water may be more saline and contain higher concentrations of organic compounds (e.g., oil and other hydrocarbons) and various inorganic compounds than the receiving surface waters (Veil et al. 2004). Adverse impacts on surface water quality from the introduction of these components of produced water would be minimized, but not eliminated, under all alternatives by following standard practices, BMPs, and guidelines for surface-disturbing activities. The properties of produced water can vary depending on the location of the producing well and the oil and gas formation, which will influence the application of BMPs and other measures intended to safeguard water quality.

Surface Water Quantity Impacts

When watersheds lack vegetation, surface infiltration into the soil decreases, causing more runoff to reach stream systems. As surface disturbance increases, so does the amount of bare soil, compacted soils, and possibly less-pervious areas in a watershed. As a result, more surface water runoff reaches streams in a shorter period of time, which increases the potential for sedimentation and the frequency of flooding or erosive velocities from high flows in channels. Conversely, activities such as reclamation would improve vegetative cover and would have a beneficial impact. Healthy vegetative cover increases infiltration of surface water flows, filters out sediment before it reaches drainages, reduces runoff, and lowers peak flows in the surface water system. Prescribed fire would reduce vegetation cover and increase sedimentation in the short term, but restoring fire-adapted ecosystems would increase vegetation cover and decrease the potential for large catastrophic fires in the long term. Concentrated grazing by livestock, wild horses in HMAs, and wildlife may contribute to soil compaction and damage to the vegetative cover and soil crust, thus increasing surface water runoff, erosion, and sedimentation.

Produced water from oil and gas wells sometimes is discharged to surface waters, thereby contributing to surface water flows. Beneficial impacts from produced water discharges include increased availability of surface water. Under conditions where produced water discharges enable the establishment of riparian vegetation, channel erosion and resulting impacts on water quality could decrease. Potential adverse impacts from produced water discharges include erosion, changes in stream morphology and increased loading of sediment, chlorine, selenium, and arsenic. This would be the case under all alternatives, including Alternative B, under which the BLM would prohibit new surface discharge of produced water on public lands. Surface discharges previously authorized by the state of Wyoming would be allowed to continue.

Groundwater Quality and Quantity Impacts

Potential sources of groundwater contamination may come from point sources, such as chemical spills, chemical storage tanks (aboveground and underground), industrial sites, landfills, household septic tanks, oil and gas well sites, oil and gas detention and retention ponds, well stimulation and hydraulic fracturing, and mining activities. Other possible sources of groundwater contamination may come from nonpoint sources, such as roadways and agricultural activities. Groundwater quality is most susceptible to pollution where the aquifer is shallow (within 100 feet of the surface), very permeable, or connected

directly to a surface water system, such as river gravels. Shallow aquifers are more vulnerable to contamination from activities that disturb the surface or subsurface in a given area. Produced water from oil and gas wells and, potentially, CBNG would have the greatest potential to affect groundwater quality and quantity where the wells or produced water discharge points are in areas with shallow depth to groundwater.

Potential impacts on groundwater resources from fluid mineral extraction activities could include the five following scenarios:

- Contamination of aquifers through the introduction of drilling fluids during drilling.
- Extended fracture growth allowing hydraulic fracturing fluid migration into source water zones or drinking water supplies.
- Cross-contamination of aquifers from the introduction of drilling fluids into one aquifer that travels upward into shallower units due to improperly sealed well casings.
- Localized depletion of unconfined groundwater availability.
- Progressive contamination of deep confined, shallow confined, and unconfined aquifers if the deep confined aquifers are not completely cased off from deeper units.

The BLM considers the application of BMPs as Required Design Features during site-specific permitting and compliance with federal rules and regulations to be adequate, to a reasonable level of certainty, in preventing groundwater contamination from fluid mineral extraction activities. In addition, proper construction, completion, and plugging/abandonment of oil, gas, water, and monitor wells, as well as the implementation of a groundwater monitoring program for oil and gas wells, in accordance with the rules of the Wyoming Oil and Gas Conservation Commission would assist in protection of ground water resources.

Proactive Management Actions

Management actions that would protect or enhance water resources, regardless of the alternative, include, but are not limited to: applying BMPs for oil and gas and water well drilling operations, mining, and other activities that could affect groundwater resources; using watershed improvement and conservation practices, and Stormwater Discharge Plans to reduce impacts; restoring healthy plant communities and vegetative cover after surface disturbance in a timely fashion; meeting Wyoming DEQ water quality standards; and participating in the development and implementation of local watershed management plans and/or total maximum daily loads (TMDLs) with interested stakeholders and the Wyoming DEQ WQD. The BLM designates the Spanish Point Karst ACEC under all alternatives, which would protect important groundwater recharge areas from surface-disturbing activities and other resource uses that may affect water quality.

Alternative A

Surface Disturbance

The BLM projects approximately 15,646 acres of long-term surface disturbance from BLM-authorized actions and approximately 136,253 acres of short-term surface disturbance (Table 4-1). Surface-disturbing activities would result in adverse impacts to water quality due to erosion, runoff, sedimentation, and potential changes in the chemical characteristics of water resources. Erosion rates, calculated using the WEPP model (Appendix V), are estimated to be 567,492 tons per year in the short term. After reclamation, long-term erosion rates would average 25,065 tons per year. The BLM analyzes all surface-disturbing activities for suitability and potential impact, which may reduce adverse

impacts from surface disturbances by allowing the BLM to impose additional mitigation to reduce erosion on some projects.

Resource Uses

Resource uses such as locatable minerals operations, oil and gas operations, travel and transportation management, and livestock grazing may result in both direct and indirect adverse impacts to water resources. Direct adverse impacts resulting from such activities include accidental chemical releases. Under Alternative A, the BLM allows the aerial application of pesticides near water on a case-by-case basis subject to label requirements, which would result in potential but limited direct adverse impacts to water quality. Indirect adverse impacts may result from surface disturbance, soil erosion, and resultant sedimentation. Alternative A would result in new roads from ROW development and user pioneered roads in areas open to cross-country motorized travel (Appendix T). The amount of new roads would result in proportional adverse impacts to soils, described under *Impacts Common to All Alternatives*. The BLM conducts the least extensive monitoring of grazing allotments under this alternative, which may result in less documentation of impacts to water quality, compared to the other alternatives. Alternative A prohibits the placement of salt, mineral, or forage supplements within ¼ mile of water, which would reduce the potential for soil compaction and vegetation removal adjacent to waterways from concentrated livestock grazing.

Under Alternative A, the BLM authorizes new activities resulting in the surface discharge of produced water if it meets State of Wyoming water quality standards. Such discharges could increase in-stream flow, thereby benefitting surface water quantity.

Special Designations

Special designations, such as ACECs, would restrict surface-disturbing activities and resource uses that may adversely impact water quality and quantity, which generally would result in beneficial impacts to water resources. Under Alternative A, ACECs and WSAs would encompass 44 and 19 miles of streams, respectively. Due to their size and management, special designations under Alternative A would result in the third-greatest beneficial impact to water resources, compared to the other alternatives.

Resources

Reclamation requirements to manage soil resources would result in beneficial impacts to water quality in the short term by reducing erosion and associated sedimentation, and water quality and quantity in the long term by reestablishing vegetation to reduce runoff. Under Alternative A, the BLM routinely seeds, or requires permittees and operators to seed, disturbed areas with native plant species or approved seed mixtures and reestablishes vegetative cover over disturbed areas within 5 years of initial seeding, but does not require temporary protective surface treatments for mechanically disturbed areas. The BLM considers stabilization of heavily eroded or washed-out roads as well as trail stabilization on a case-by-case basis. These management actions would result in beneficial impacts to soils and ultimately water quality under Alternative A.

Alternative A would result in disturbance from fuels treatments and prescribed fire that would result in adverse impacts to surface water quality and quantity, but the small area of these treatments and the use of BMPs would minimize these impacts. Alternative A would also result in long-term beneficial impacts from restoring fire-adapted ecosystems by reducing the potential for catastrophic fires that may cause greater adverse impacts to water resources.

Forests, woodlands, and forest products may result in adverse impacts to water quantity and quality under Alternative A. The BLM allows clear cuts of up to 300 yards in any direction under this alternative.

Clear cuts would increase sedimentation from increased erosion and runoff in clear-cut areas and result in adverse impacts to water resources. Spur roads generally are closed after completion of timber management, allowing vegetation to return, which would minimize long-term impacts to water resources from erosion in these areas.

To protect fish habitat, the BLM applies an NSO restriction and prohibits unnecessary and unmitigated surface-disturbing activities within 500 feet of surface water and riparian areas. This management would reduce adverse impacts to water quality from oil and gas development and other surface-disturbing activities.

Proactive Management

Proactive management actions under Alternative A that would result in beneficial impacts to surface water quality and quantity include implementing watershed improvement practices in Wyoming's Bighorn Basin water quality plans, encouraging the maintenance of natural flow regimes in streams supporting fisheries, and fencing streams and reservoirs as necessary. This alternative also benefits surface water quality and quantity by stabilizing existing failed watershed improvement projects to benefit watershed stability and by assessing erosion and soil stability during rangeland health evaluations.

Alternative B

Surface Disturbance

Over the long term, it is projected that BLM actions under Alternative B would disturb approximately 10,893 acres, 4,839 fewer acres than Alternative A, and would result in 17,450 tons per year of soil erosion. Projected short-term surface disturbance would affect approximately 73,940 acres (Table 4-1), resulting in an average of 307,960 tons of erosion per year. Alternative B requires additional analysis of soils for erosion potential, and therefore more information to prevent erosion than Alternative A, by requiring mapping of the soils in areas to be disturbed and elsewhere on BLM-administered lands to a series level, collecting soil samples, and evaluating current erosion conditions. Unlike Alternative A, Alternative B requires reclamation plans prior to surface-disturbing activities, increasing the chances for successful reclamation and reducing the chances for watershed decline. Surface-disturbing activities under Alternative B would also reduce the potential for erosion and sedimentation in surface waterbodies compared to Alternative A, resulting in less impervious surface to diminish groundwater recharge.

Resource Uses

Conservation measures under this alternative would improve water quality and quantity compared to Alternative A by reducing erosion and sedimentation, and increasing infiltration. Under Alternative B, the BLM prohibits the aerial application of pesticides within ½ mile of aquatic habitats, which would result in less potential for adverse water quality impacts compared to Alternative A. Alternative B would also result in fewer acres of new roads from ROW development and user pioneered roads in areas open to cross-country motorized travel (Appendix T), with proportional adverse impacts to water quality described under *Impacts Common to All Alternatives*.

The BLM conducts extensive monitoring of grazing allotments under Alternative B that do not meet the *Wyoming Standards for Healthy Rangelands* (Appendix N), which would result in more beneficial impacts to water quality than Alternative A by monitoring erosion. Alternative B prohibits the placement of salt, mineral, or forage supplements within ½ mile of water. The additional grazing

constraints under Alternative B may reduce the potential for fecal coliform and NO₃ reaching surface waters when compared to Alternative A. In addition, reduced grazing in riparian areas under Alternative B would reduce erosion and sedimentation in surface waters, and reduced well development would reduce groundwater withdrawals when compared to Alternative A.

Alternative B places more restrictions on motorized vehicle use in the Planning Area than Alternative A, which would result in less potential for vegetation removal and soil compaction, and fewer water crossings and associated adverse impacts to water resources.

Additionally, new surface discharge of produced water on public lands is prohibited, which would result in less potential adverse impacts to surface water quality and groundwater quality and quantity, and less beneficial impacts to surface water quantity than Alternative A.

Special Designations

Alternative B designates an additional eight ACECs, the Absaroka Front Management Area and manages all lands with wilderness characteristics specifically to preserve their wilderness characteristics. Under this alternative, ACECs, WSAs, the Absaroka Front Management Area, and lands with wilderness characteristics would encompass 78, 19, 15, and 90 miles of streams, respectively. The relative size and additional restrictions on surface-disturbing activities and resource uses in these areas would result in additional protection for surface and groundwater compared to Alternative A.

Resources

Alternative B would result in less adverse impacts to water resources from short-term surface disturbance than Alternative A because it applies the most stringent requirements to minimize erosion. The BLM reestablishes native plant communities in disturbed areas; requires temporary protective surface treatments of disturbed areas, such as mulch, matting, netting, or tackifiers; requires interim and final reclamation of disturbed areas at the earliest feasible time; and closes or relocates heavily eroded or washed out roads and trails. Specifically, Alternative B requires the reestablishment of 50 percent of pre-disturbance levels of desired vegetative cover within three growing seasons following surface disturbance and 80 percent within 5 years of initial seeding to prevent erosion.

Alternative B would create less disturbance from fuels treatments and prescribed fire than Alternative A, which would therefore result in less short-term adverse impacts to surface water quality and quantity, but also less long-term beneficial impacts from restoring fire-adapted ecosystems to reduce the potential for catastrophic fires.

Forests, woodlands, and forest products management practices under Alternative B would result in less adverse impact to water resources than Alternative A. The BLM prohibits clear cuts and closes timber access and haul roads not required for existing uses, which would result in less potential for erosion and sedimentation than Alternative A.

To protect fisheries and riparian/wetland areas, the BLM applies an NSO restriction on wetland areas greater than 40 acres and prohibits surface-disturbing activities within ¼ mile of riparian/wetland areas, any Wyoming Game and Fish Department (WGFD)-Blue and Red Ribbon rated waters, and many major rivers in the Planning Area. The BLM allows sediment reduction structures on a case-by-case basis. These management practices under Alternative B would reduce adverse impacts to water quality from oil and gas development more than Alternative A.

Proactive Management

Under Alternative B, the BLM manages water resources with an emphasis on conservation. Proactive management actions under Alternative B that would result in beneficial impacts to surface water quality

and quantity include completing a greater number of watershed enhancement projects; maintaining natural flow regimes in priority streams; cooperating with adjacent landowners and managers to address impaired waterbodies on the state of Wyoming 303d list; and prohibiting activities that could affect water resources within a ¼ mile area around public water supply wells, rivers, streams, and other water bodies within 10 miles upstream of public water supply intakes. Watershed improvement projects are stabilized to prevent release of stored sediment if the project no longer meets resource objectives. Proactive management actions under Alternative B would result in the more beneficial impacts to water resources than Alternative A.

Alternative C

Surface Disturbance

Long-term (41,485 acres) and short-term (245,642 acres) surface disturbance under Alternative C constitute more acreage than under the other alternatives (Table 4-1). Similarly, erosion rates under Alternative C are the highest among the alternatives. Erosion rates would average 1,023,099 tons per year in the short term and 66,459 tons per year in the long term, over twice as high as the long-term erosion rate under Alternative A. Additional analysis of soils for erosion potential, which is required under Alternative B, is performed only on a case-by-case basis under Alternative C, reducing the relative potential benefits to soils. The BLM requires reclamation plans only on a case-by-case basis, which may reduce the beneficial impacts of this action compared to Alternative B. Overall, Alternative C would have the greatest potential for erosion and sedimentation in surface waterbodies and result in the most impervious surface to diminish groundwater recharge.

Resource Uses

Alternative C would have the most acreage available for surface disturbance when compared to the other alternatives, and, therefore, the greatest potential for adverse impacts to water resources among the alternatives. Alternative C prohibits the aerial application of pesticides within 100 feet of aquatic habitats, which would result in less potential water quality impact from the associated chemicals than alternatives A and D, but more than Alternative B. Alternative C would result in the most acreage of new roads from ROW development and user pioneered roads in areas open to cross-country motorized travel (Appendix T) with proportional adverse impacts to water quality described under *Impacts Common to All Alternatives*.

Potential impacts from grazing allotment monitoring would be similar to those under Alternative A. Alternative C allows the placement of salt, mineral, or forage supplements to maximize livestock use. This management action would result in the greatest potential impact to surface water from soil compaction and vegetation removal in riparian/wetland areas and from potential fecal coliform and NO₃ introduction, compared to all other alternatives.

Alternative C would allow the most motorized vehicle use in the Planning Area, including the most acreage open to cross-country motorized travel, which would result in the greatest potential vegetation removal, soil compaction, and water crossings and the associate impacts to water resources.

Alternative C would result in the same types of adverse and beneficial impacts from produced water disposals as described under *Impacts Common to All Alternatives* and Alternative A. However, expanded oil- and gas-well development projected under this alternative would result in the greatest intensity of these impacts, because groundwater withdrawals would increase compared to the other alternatives.

Special Designations

Except for travel restrictions, Alternative C proposes no specific management for the Absaroka Front Management Area, and also designates fewer ACECs than alternatives A, B or D, manages all WSR eligible waterway segments as unsuitable for inclusion in the National Wild and Scenic Rivers System (NWSRS), and does not manage any lands with wilderness characteristics to protect their wilderness characteristics. Under Alternative C, ACECs and WSAs encompass 9 and 19 miles of streams, respectively. Generally, Alternative C would protect fewer areas from surface-disturbing activities than the other alternatives and therefore would be the least beneficial to surface and groundwater.

Resources

To prevent erosion, Alternative C requires 30 percent of pre-disturbance vegetation cover within three growing seasons of initial seeding. However, unlike Alternative B, Alternative C does not institute long-term vegetation cover requirements. Alternative C would result in the greatest adverse impact to water resources from short-term surface disturbance due to the greater acreage disturbed under this alternative and because it applies the second-least stringent requirements to minimize erosion. Alternative C does require reclamation plans on a case-by-case basis and stabilizes heavily eroded or washed out trails, which are a major source of runoff and sediment.

Alternative C would result in the greatest disturbance from fuels treatments and prescribed fire. This disturbance would result in the greatest short-term adverse impacts to surface water quality and quantity, but would have the greatest long-term beneficial impact of restoring fire-adapted ecosystems to reduce the potential for catastrophic fires.

Forests, woodlands, and forest products management practices under Alternative C would result in similar impacts to water resources as under Alternative A. The BLM allows clear cuts of up to 100 acres (more area than under Alternative A) and permits timber access and haul roads to remain open to meet other resource goals and objectives, maintaining impervious surfaces in these areas.

Alternative C applies similar NSO restrictions as Alternative A, but allows surface-disturbing activities in flood plains or riparian/wetland areas on a case-by-case basis. These management practices under Alternative C would result in the greatest potential adverse impacts to water quality from oil and gas development, compared to the other alternatives.

Proactive Management

Under Alternative C, the BLM manages resources with an emphasis on resource uses. This alternative manages for the stabilization of watersheds through maintenance of existing watershed improvement projects. Under Alternative C, the BLM does not implement or develop new watershed improvement practices and only fences springs and their associated wetlands. Overall, proactive management actions under Alternative C would result in the fewest beneficial impacts to water resources, compared to the other alternatives.

Alternative D

Surface Disturbance

Under Alternative D, short- and long-term surface disturbance from BLM-authorized actions would disturb more acreage than alternatives A and B but less than Alternative C. Short-term surface disturbance of approximately 140,175 acres (Table 4-1) would result in an erosion rate of 583,827 tons per year. After reclamation, long-term surface disturbance (18,306 acres) would result in an erosion

rate of 29,326 tons per year. Impacts from surface disturbance and erosion would be similar to those described under Alternative A although to a slightly higher degree due to more acreage of surface disturbance and greater erosion potential. However, more stringent reclamation standards and a requirement for reclamation plans, stipulations, or measures would provide a greater beneficial impact to surface water than both alternatives A and C by increasing the potential for successful reclamation and reducing the potential for long-term erosion. Soil and erosion evaluations are conducted in a similar manner as under Alternative A, although a slightly greater benefit may occur by conducting soil surveys as funds become available.

Resource Uses

Alternative D allows more resource use that would result in greater surface disturbance than alternatives A and B, creating a greater potential for watershed health degradation than those two alternatives. However, for certain resource programs, such as minerals development, Alternative D is projected to result in less disturbance than alternatives A and C. The BLM allows the aerial application of pesticides near water on a case-by-case basis, which would result in the same impacts as Alternative A. Alternative D is estimated to result in more new roads from ROW development and user-pioneered roads than alternatives A and B, resulting in proportional impacts.

Potential impacts from grazing allotment monitoring would be similar to Alternative A. Alternative D prohibits the placement of salt, mineral, or forage supplements within ¼ mile of water, reducing the potential for adverse impacts from concentrated livestock grazing similarly to Alternative A.

Alternative D opens more area to cross-country motorized travel than alternatives A and B, creating more areas that could be adversely affected by concentrated motorized vehicle use through increased runoff and erosion.

The surface discharge of produced water under Alternative D would be authorized for new activities where compatible with other resource objectives and in consultation with stakeholders. The impacts, both adverse and beneficial, from produced water disposals would be similar to those described under *Impacts Common to All Alternatives* and Alternative A. However, because the number of new federal wells projected under Alternative D would be less than under alternatives A and C, adverse impacts to water may be reduced overall. In addition, Alternative D would require water-monitoring plans for new activities resulting in surface discharges of water to track changes in receiving channels and to minimize adverse impacts to watershed health. If adverse impacts to receiving channels or watershed health occur, the development and implementation of water management plans, which include reclamation strategies and mitigation to address impacts, would be required.

Special Designations

Alternative D designates more acreage as ACECs than alternatives A and C and designates the Absaroka Front Management Area, which would limit surface disturbance and adverse impacts to water in these areas. However, like Alternative C, Alternative D manages all WSR eligible waterway segments as unsuitable for inclusion in the NWSRS. Under this alternative, ACECs, WSAs, and the Absaroka Front Management Area would encompass 48, 19, and 43 miles of streams, respectively, which would provide greater beneficial impacts to water resources than alternatives A and C but less than Alternative B.

Resources

Alternative D would help to reduce erosion and subsequent sediment loading in streams by reestablishing native or desired plant communities in disturbed areas; requiring temporary protective surface treatments of disturbed areas when appropriate; requiring interim and final reclamation of

disturbed areas at the earliest feasible time; and closing and reclaiming heavily eroded roads and trails if other stable roads and trails are available. While Alternative D does not specify timing requirements for achieving vegetative cover after surface disturbance, a potential adverse impact, it also does not consider successful final reclamation of vegetative cover to be achieved until conditions are equal to or better than pre-disturbance site conditions, a potential beneficial impact. Overall, measures to prevent erosion under Alternative D would result in a greater beneficial impact to surface water than under alternatives A and C, but less than under Alternative B.

Disturbance from fuels treatments and prescribed fire is projected to be the same as Alternative A with similar impacts.

In general, impacts from forests, woodlands, and forest products management would be similar to Alternative A. Spur roads would be assessed for closure on a case-by-case basis while clear cuts would be limited to 100 yards, potentially resulting in greater adverse impacts to surface water than under Alternative A by increasing runoff and erosion.

To protect riparian/wetland areas, the BLM applies a NSO restriction on wetland areas greater than 20 acres and on designated 100-year flood plains. Alternative D also prohibits surface disturbing activities within 500 feet and avoids surface-disturbing activities within ¼ mile of perennial surface water and riparian/wetland areas and WGFD rated Blue or Red Ribbon fisheries, which would provide a similar beneficial impact to water as Alternative A, but with additional protections outside of the 500-foot buffer.

Proactive Management

Proactive management actions that would benefit surface water quality and quantity include developing watershed improvement practices; applying BMPs to reduce sediment loading; avoiding activities that could affect water resources within a ¼ mile area around public water supply wells, rivers, streams, and other water bodies within 10 miles upstream of public water supply intakes; and fencing streams, wetlands, reservoirs, and riparian areas as necessary. The BLM conducts the same amount of watershed enhancement projects as under Alternative A while also stabilizing existing watershed improvement projects to prevent the release of stored sediment and protect watershed health. Similar to Alternative A, Alternative D would encourage the maintenance of natural flow regimes in priority streams supporting fisheries.

Alternative D would avoid, minimize and/or compensate BLM-authorized activities and infrastructure, such as unlined impoundment ponds/pits, reserve pits, and evaporation ponds, that could result in the contamination of sensitive water resources, including Source Water Protection Areas and “High” and “Moderately High” sensitivity aquifer systems on a case-by-case basis. This management would reduce the potential for adverse impacts to water resources.

Alternative E

Surface Disturbance

Alternative E would result in 10,676 acres of long-term and 71,829 acres of short-term surface disturbance (see Table 4-1 and Appendix T), the smallest acreage of disturbance of any alternative. Projected short-term surface disturbance would result in an initial 299,169 tons of soil erosion, followed by an estimated rate of 17,305 tons per year for the long term (Appendix V). Management practices relating to surface disturbance would be the same as Alternative B, except for areas within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). In this ACEC, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) so that they do not exceed one disturbance

per 640 acres and cover less than 3 percent of the total sage-grouse habitat, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. When compared to the other alternatives, the potential for erosion and sedimentation in surface waterbodies would be the least for the surface-disturbing activities of Alternative E, resulting in less impervious surfaces to diminish groundwater recharge. Surface-disturbing activities under Alternative E would provide the best chances for successful reclamation while also reducing the chances for watershed deterioration.

Resource Uses

Compared to the other alternatives, the restrictions on surface disturbance and conservation measures of Alternative E would provide the most improvement to water quality and quantity by increasing infiltration rates and reducing existing and future erosion and sedimentation sources. Management for resource uses would be the same as Alternative B, except for areas within the Greater Sage-Grouse Key Habitat Areas ACEC. Livestock grazing management under Alternative E would be the same as Alternative B, and impacts to water would be the same as Alternative B.

Alternative E would result in a similar number of new roads from ROW authorizations and new roads in locales open to cross-country motorized travel or from BLM road and trail creation as anticipated under Alternative B (Appendix T). Also similar to Alternative B, travel during the wettest months of the year would be restricted under Alternative E through a seasonal closure of routes within greater sage-grouse Key Habitat Areas from March 15 through June 30. However, unlike Alternative B, Alternative E includes additional restrictions on new road and trail development in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). Management in this ACEC limits the allowable surface disturbance, prohibits construction within 4 miles of leks, and restricts the types of routes that can be constructed. These restrictions would result in the least potential vegetation removal, soil compaction, and fewest water crossings and associated adverse impacts to water resources. Outside of the Greater Sage-Grouse Key Habitat Areas ACEC, management of ROWs and CTTM under Alternative E would be the same as Alternative B.

Management of new surface discharges of produced water under Alternative E would be the same as Alternative B, but would also restrict the development of infrastructure, such as reserve pits and evaporation ponds and other uses that could result in the contamination of sensitive water resources. As a result, Alternative E would limit the potential for adverse impacts from produced water discharges and other activities generally associated with oil and gas development to a greater extent than Alternative B.

Special Designations

Special designations under Alternative E would be the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land in the Greater Sage-Grouse Key Habitat Areas ACEC. Under this alternative, ACECs, WSAs, the Absaroka Front Management Area, and lands with wilderness characteristics would encompass 193, 19, 15, and 90 miles of streams, respectively.

The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative E would result in additional protection for surface and groundwater in comparison to the other alternatives. Specifically, requirements to include a full reclamation bond to insure restoration of disturbed areas to their original condition and other habitat restoration and vegetation management requirements associated with the Greater Sage-Grouse Key Habitat Areas ACEC would reduce adverse impacts from surface-disturbing activities in greater sage-grouse Key Habitat Areas.

Resources

The erosion control requirements and habitat restoration and vegetation management under Alternative E would result in the fewest adverse impacts to water resources through restricting surface disturbances. Management and impacts under Alternative E would be the same as Alternative B except in the Greater Sage-Grouse Key Habitat Areas ACEC, with additional management regarding re-establishment of sagebrush cover and understory vegetation.

Fire and fuels management under Alternative E would be the same as Alternative B, except in the Greater Sage-Grouse Key Habitat Areas ACEC, which includes additional restrictions on the use of prescribed fire and post-fire reclamation requirements compared to Alternative B. Alternative E would result in the fewest short-term adverse impacts to surface water quality and quantity from soil erosion related to fuels treatments and prescribed fire. However, fuels management under Alternative E could result in the largest adverse impacts to water quality from catastrophic fires.

Forests, woodlands, and forest products management practices under Alternative E would be the same as Alternative B, and impacts to water would be the same as Alternative B.

Proactive Management

Proactive management to protect and enhance water resources under Alternative E would be the same as Alternative B; however, Alternative E would restrict or prohibit BLM-authorized activities and infrastructure (such as unlined impoundment ponds/pits, reserve pits, and evaporation ponds) to protect sensitive water resources (Surface and Groundwater Zones 1-3 and sensitive aquifer systems), resulting in greater beneficial impacts to water resources than alternatives A or B and similar, but more beneficial impacts than Alternative D due to the more prohibitive nature of the restrictions under Alternative E.

Alternative F

Surface Disturbance

Alternative F would result in 137,064 acres of short-term and 17,663 acres of long-term surface disturbance (see Table 4-1 and Appendix T); this projected disturbance is more acreage than alternatives A, B and E, but less than alternatives C and D. Short-term surface disturbance under Alternative F would result in an initial 570,877 tons of soil erosion, followed by an estimated rate of 28,297 tons per year for the long term (Appendix V). Management practices restricting surface disturbances for the protection of other resources (such as soil, water, biological resources, and special designations) would be the same as Alternative D, except within areas of the proposed Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). In this ACEC, the BLM manages the density of disturbance to not exceed an average of one disruptive activity location per 640 acres and cover less than 3 percent of the total greater sage-grouse PHMAs, compared to a larger allowable disturbance of 5 percent in greater sage-grouse Key Habitat Areas (1,232,583 acres) under Alternative D.

Resource Uses

Alternative F would allow fewer surface-disturbing resource uses and subsequent adverse impacts to water resources than alternatives A, C, and D, but more than alternatives B and E. As a result of additional restrictions in the Greater Sage-Grouse PHMAs ACEC, the number of new roads from ROW development and user-pioneered roads would be greater under Alternative F than alternatives A, B, and E, but less than alternatives C and D. In the Greater Sage-Grouse PHMAs ACEC, Alternative F would result in fewer mineral development-related surface disturbances than alternatives A, C, and D. In areas

outside the Greater Sage-Grouse PHMAs ACEC, management for mineral resources, CTTM, and ROWs would be similar to Alternative D, and impacts to water resources would generally be the same as described for that alternative.

Livestock grazing management under Alternative F is similar to management under Alternative D, and impacts to water would be similar to Alternative D. However, management for the Greater Sage-Grouse PHMAs ACEC includes additional livestock grazing management restrictions to promote vegetative cover compared to management under Alternative D, which could reduce adverse impacts to water quality and quantity from surface runoff compared to alternatives A, C, and D.

The areas open to cross-country motorized travel under Alternative F would be the same as Alternative D, and impacts from runoff and erosion would be the same as described under Alternative D; however, Alternative F also limits travel in the Greater Sage-Grouse PHMAs ACEC to designated roads and trails, resulting in greater beneficial impacts than alternatives A, C, and D, but fewer than alternatives B and E.

Management of new surface discharges of produced water under Alternative F would be the same as Alternative D, and impacts to surface water quality and groundwater quality and quantity would be the same as Alternative D. However, by comparison, the number of new federal wells projected under Alternative F would be less than under alternatives A, C, and D, resulting in an overall reduction of adverse impacts to water resources.

Special Designations

Special designations under Alternative F would be the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. Under this alternative, ACECs, WSAs, and the Absaroka Front Management Area would encompass 188, 19, and 43 miles of streams, respectively, which would provide greater beneficial impacts to water resources than alternatives A, C, and D, but less than alternatives B and E.

The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative F would result in greater protection for surface and groundwater than alternatives A, C, and D, but fewer than under alternatives B and E. Specifically, requirements to include a full reclamation bond to insure restoration of disturbed areas to their original condition and other habitat restoration and vegetation management requirements associated with the Greater Sage-Grouse PHMAs ACEC would reduce adverse impacts from surface-disturbing activities in greater sage-grouse PHMAs.

Resources

Measures to prevent erosion under Alternative F would result in a greater beneficial impact to surface water than under alternatives A, C, and D, but less than under alternatives B and E. Erosion and subsequent sediment loading in streams under Alternative F would be the same as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC, which includes additional management to enhance healthy native vegetation and to manage disturbed areas to predisturbance or better conditions.

Fire and fuels management under Alternative F would be the same as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC, which includes additional restrictions on the use of prescribed fire and post-fire reclamation requirements compared to Alternative D. Alternative F would result in fewer adverse impacts to surface water quality and quantity from fuels treatments and prescribed fire than under alternatives A and D. However, similar to Alternative E, Alternative F would increase adverse impacts to water quality from potential catastrophic fires, though to a lesser extent than under Alternative E.

Forests, woodlands, and forest products management practices under Alternative F would be the same as Alternative D, and impacts to water would be the same as Alternative D.

Proactive Management

Proactive management to protect and enhance water resources under Alternative F would be the same as Alternative D, and beneficial impacts to water from these actions would be the same as Alternative D.

4.1.5 Cave and Karst Resources

This section describes impacts to cave and karst resources resulting from implementation of the alternatives. Adverse impacts to cave and karst systems result from management actions that alter, degrade, or destroy cave or karst systems and their features. Conversely, actions that result in data collection and preservation or establishment of cave and karst resources and their associated geological, biological, cultural, paleontological, hydrological, and/or educational values are considered beneficial impacts. Beneficial impacts from the designations of the Spanish Point Karst, Sheep Mountain Anticline, and Little Mountain ACECs are addressed in the Special Designations section of this chapter.

Direct impacts to cave and karst resources result from management actions that physically alter, damage, or destroy cave and karst systems, including their associated geologic features (speleothems) and biologic communities. In general, recreational uses of caves have the greatest potential to directly impact cave and karst resources.

Indirect impacts to cave and karst systems can result from actions that increase the accessibility of cave and karst areas, and therefore the probability of adverse impacts due to incompatible or excessive recreational use. Indirect impacts can also result from activities that can alter water quality (e.g., agriculture, pesticide application, pollution) when degraded water infiltrates into groundwater, thereby possibly altering the chemical and biological environment of cave and karst systems.

4.1.5.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Cave and karst resources are abundant within the Bighorn Basin. Thirty-two caves are known to exist within the Planning Area, 19 of which are considered significant for their biological, cultural, geological/mineralogical/paleontological, hydrological, recreational, and/or educational or scientific values according to the Federal Cave Resources Protection Act (FCRPA).
- The cave and karst system along the west slope of the Big Horn Mountains, including the Medicine Lodge, Spanish Point, and Little Mountain areas, is important due to fragile mineral deposits or specimens (speleothems), the potential for diverse cave and karst aquatic organisms and biological communities, cultural resources, recreational opportunities, and its link to regional groundwater aquifers.
- Sediments, and mineral deposits, including speleothems, in caves are a source of paleoclimate and other scientific information, providing important opportunities for education and scientific research. Due to their sensitive and nonrenewable nature, excessive recreational use, or recreational use not consistent with cave and karst resource values, can potentially, irreparably impact these systems. Adverse impacts to cave and karst resources also would impact the biological communities that depend on them.
- The potentially hazardous, often unfamiliar nature of caves can put inexperienced recreationists at risk.

- Recreational use of caves would be managed under a cave management plan to promote the importance of cave resources, to protect and maintain cave resources and the habitat in and around them, and to enhance user experiences by managing use compatibly with resource protection.

4.1.5.2 Summary of Impacts by Alternative

Adverse impacts to cave and karst areas would result from management that increases incompatible or excessive recreational use. The principle beneficial impacts to cave and karst resources, regardless of the alternative, result from managing the recreational use of caves to protect and maintain cave resources, while enhancing user experiences through ensuring compatible use levels and promoting the importance and research of cave resources. Under Alternative A, management of cave and karst resources as the Worland Cave SRMA would preserve the recreational setting in caves and provide protection of these resources by promoting appropriate recreational uses. Alternatives B and E manage cave and karst resources as a separate Caves and Karst Extensive Recreation Management Area (ERMA), which would result in similar impacts to those under Alternative A, but to a lesser degree. Managing cave and karst resources consistent with resources objectives under alternatives C, D, and F, rather than under a specific cave and karst ERMA, would result in the fewest beneficial impacts. Protection for these areas through the designation of ACECs would be greatest under alternatives B and E, followed by alternatives A, F, D, and C, respectively. Alternatives B and E would be the most beneficial for scientific research and data collection in cave and karst areas.

4.1.5.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Numerous beneficial direct impacts to cave and karst resources may result from proactive management actions under all alternatives. Implementing BMPs to protect water quality within cave and karst areas exhibiting unique underground drainage characteristics would preserve the hydrological and biological characteristics in these areas.

Managing cave and karst resources as ROW avoidance areas and limiting motorized vehicle use to designated roads and trails in areas over important caves or cave passages would result in beneficial impacts by reducing potential destruction and minimizing surface disturbance and the potential for excessive or incompatible recreational uses in these areas. Managing the recreational use of caves under a specific management plan would result in beneficial impacts by promoting the significance and importance of cave resources through education; protecting and maintaining cave resources, including wildlife and habitat in and around caves; and enhancing user experiences by managing use levels to be compatible with resource carrying capacity and protection.

Designating the Spanish Point Karst ACEC under all of the alternatives would restrict resource uses and activities that may adversely affect cave and karst resources in this area.

Indirect beneficial impacts would result from management actions under all alternatives that maintain or improve the hydrological, biological, and chemical characteristics of water in cave and karst resources. Under all alternatives, these management actions include controlling water runoff from disturbed or developed sites; implementing local watershed management plans and/or TMDLs with interested stakeholders and the Wyoming DEQ WQD; cooperating with stakeholders to plug unneeded abandoned water wells to prevent groundwater contamination; and cooperating with the EPA, the state

of Wyoming, and local governments to develop source water wellhead protection plans (groundwater aquifers can be linked to cave and karst systems, as in the Medicine Lodge area).

Accomplishing cave resource protection and providing for user safety with controls such as timing of use to avoid crowding and closing caves to use during periods of high water runoff would result in beneficial impacts to caves. These actions would provide for the protection of- or reduce the potential degradation of cave resources.

Alternative A

Allowing commercial recreational use of Spirit Mountain cave on a case-by-case basis may result in short-term adverse impacts to this cave resource by increasing human activity and the potential for degradation of geologic or biological features in the cave.

Allowing scientific research of cave and karst areas on a case-by-case basis may result in beneficial impacts by increasing the understanding of cave and karst areas and their associated geological, biological, cultural, paleontological, hydrological, and educational values. An increased understanding of cave and karst characteristics and values may lead to improved management or may lead to the identification of specific values that require additional management to protect the resource.

Managing cave and karst resources as the Worland Cave SRMA, with goals of providing protection for cave resources and informing the public on proper recreational uses, would result in beneficial impacts to recreational opportunities and settings in this area. However, recreational use may result in adverse impacts to cave and karst resources by increasing the potential for damage and degradation.

Designating the Sheep Mountain Anticline and Little Mountain ACECs under Alternative A would result in beneficial impacts to cave and karst resources by placing additional restrictions on activities and resource uses (e.g., minerals development and motorized vehicle use) that may degrade these resources.

Alternative B

Allowing commercial recreational use of Spirit Mountain cave on a case-by-case basis would result in the same impacts as those described under Alternative A.

Scientific research of cave and karst areas would result in similar impacts as those described under Alternative A, though to a greater degree due to management to actively pursue research opportunities. Beneficial impacts to cave and karst resources from scientific research under Alternative B would be greater than Alternative A.

Managing cave and karst resources under a specific ERMA would result in long-term impacts to these resources. Management as an ERMA would provide custodial oversight of recreational activities in these areas to provide for resource protection and to resolve use and user conflicts, which would result in beneficial impacts to cave and karst resources.

Designating the Sheep Mountain Anticline and Little Mountain ACECs under Alternative B, would result in similar beneficial impacts to cave and karst resources in these ACECs as described under Alternative A, though to a greater degree with more restrictions placed on resource uses and activities that may adversely affect cave and karst resources. The Little Mountain ACEC expansion area may also include more known and yet-to-be discovered cave and karst resources in the ACEC area.

Alternative C

Management of Spirit Mountain Cave would result in similar impacts as those described under Alternative A, but to a greater degree. Encouraging commercial caving tours may increase the number of visitors and the potential degradation of geologic and biological features in caves resulting in greater adverse impacts to this area compared to alternatives A, B, and D.

Allowing scientific research in caves would result in the same beneficial impacts as those described under Alternative A.

Managing cave and karst resources consistent with resource objectives would not provide for the beneficial impacts that would result from designation of cave and karst areas as a separate recreation management area.

The BLM does not designate the Sheep Mountain Anticline and Little Mountain ACECs under Alternative C; therefore, no beneficial impacts would result in these areas by restricting activities and resource uses that may degrade cave and karst resources.

Alternative D

Alternative D allows commercial caving tours of Spirit Mountain Cave, which may increase recreational use of the cave and the potential for adverse impacts more than alternatives A and B. However, impacts would be less than under Alternative C, as Alternative D would allow, but not encourage, commercial caving tours.

Allowing scientific research in caves would result in the same beneficial impacts as those described under Alternative A. Alternative D would protect caves from White Nose Syndrome by requiring decontamination protocol under BLM IM 2010-181 or the National White Nose Syndrome protocol.

As under Alternative C, management of cave and karst resources consistent with resource objectives would provide less of a beneficial impact to cave and karst resources than alternatives A and B, which manage cave and karst resources as a separate recreation management area.

Alternative D places additional restrictions on activities and resource uses that could degrade cave and karst resource within the Sheep Mountain Anticline and Little Mountain ACECs, resulting in similar beneficial impacts as Alternative A.

Alternative E

Impacts to cave and karst resources under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis for cave and karst resources under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Impacts to cave and karst resources under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for cave and karst resources under Alternative D is representative of the impacts anticipated under Alternative F.

4.2 Mineral Resources

4.2.1 Locatable Minerals

This section describes potential impacts to exploration for and development of locatable minerals as a result of implementation of each of the alternatives. Implementation of specific management actions within a given alternative could result in some public lands being opened, segregated, or withdrawn from locatable mineral entry under the Mining Law of 1872, as amended (herein, the mining laws). Such actions could affect the ability of potential mining claimants and/or exploration and mining companies to explore and develop locatable minerals on some public lands in the Planning Area. Management actions that restrict access include short-term actions, such as 2-year land segregations, or long-term actions, such as seeking and obtaining 20-year withdrawals from the operation of the mining laws, subject to valid existing rights. In these instances, only valid, existing mining claims may be developed. Subject to such valid existing rights, exploration, staking of new mining claims, development, or mining on segregated or withdrawn federal mineral estate is prohibited. The BLM may apply Conditions of Approval (COA) in conformance with Section 6 of the Standard Oil and Gas Lease terms and conditions while recognizing valid existing rights. On withdrawn lands, mining claimants or operators must submit a plan of operations if they propose operations that would exceed casual use, regardless of the acreage proposed for surface disturbance. The BLM must first determine the validity of preexisting mining claims in withdrawals before approving these plans of operation.

Mining claimants or operators also must file a plan of operations before beginning operations that exceed casual use in areas in the NWSRS and areas designated for potential addition to the system; designated ACECs; designated wilderness areas; areas closed to motorized vehicle use; any lands or waters known to contain federally proposed or listed threatened or endangered species or their proposed or designated important habitat, unless the BLM allows for other action under a land use plan or threatened or endangered species recovery plan; and BLM-administered National Monuments and National Conservation Areas. Based on this regulatory framework, management actions that result in lands being placed or removed from any of these land-status categories either will restrict or will remove limitations on access in cases where proposed exploration for locatable minerals would otherwise be performed under a notice, without the need for prior approval from the BLM (43 CFR 3809.11 and 43 CFR 3809.21).

Adverse impacts to locatable minerals exploration or development include management actions that segregate, withdraw, or limit the development of these minerals. Beneficial impacts to locatable minerals development result from management actions that open access to federal locatable minerals, including allowing existing withdrawals or segregations to expire without seeking new withdrawals. Direct impacts to locatable mineral operations result from management actions or statutory or regulatory limitations that open or restrict the exploration for or development of these minerals. Examples of direct impacts include segregations or withdrawals from locatable mineral entry, or compliance with the Endangered Species Act (ESA) to prevent adverse impacts to threatened or endangered species or their habitat as well as compliance with the mining laws for the proper recording of mining claims and sites, recording of title transfers to mining claims and sites, payment of annual fees and filings of annual assessment work documents, and deferments of assessment work. No indirect impacts to locatable minerals are identified.

4.2.1.1 Methods and Assumptions

This analysis is based on known areas of locatable mineral development in the Planning Area, and on mineral occurrence potential (referred to as “potential” in this analysis) as identified in the *Solid Mineral Occurrence and Development Potential Report, Bighorn Basin Resource Management Plan Revision Project* (BLM 2009d). “Potential” refers to the potential for or the presence (occurrence) of a concentration of one or more locatable mineral resources. It does not refer to or imply potential for development and/or extraction of the mineral resource(s), nor does it imply that the potential concentration is or may be economic (i.e., could be extracted profitably). The BLM has identified areas where specific locatable mineral types are known to exist (“known” mineral occurrence), and areas with moderate to high potential for the presence of a specific locatable mineral type (“potential” mineral occurrence). See the *Solid Mineral Occurrence and Development Potential Report, Bighorn Basin Resource Management Plan Revision Project* (BLM 2009d) for more information regarding mineral occurrence potential.

Methods and assumptions used in this impact analysis include the following:

- Restrictions on resource uses apply throughout the life of the RMP, but can be changed by amending the RMP.
- The surface management regulations at 43 CFR 3809 (outside WSAs) and 3802 (within WSAs) apply to all surface-disturbing activities for locatable minerals.
- Lands not formally withdrawn or segregated from mineral entry will be available for locatable mineral entry, exploration, and development as per the regulations at 43 CFR 3800 and 3810.
- The BLM must approve a plan of operations that meets all applicable statutory and regulatory requirements and will not cause unnecessary or undue degradation as per 43 CFR 3809 and 3802. Unnecessary or undue degradation is defined by 43 CFR 3809.5.
- Regardless of the level of operations to be conducted (casual use, notice level, or operations under a plan of operations), a locatable mineral operator must prevent adverse impacts to threatened or endangered species and their habitat that may be affected by operations.
- Locatable mineral operators may not knowingly disturb, alter, injure, or destroy any scientifically important paleontological remains or any historical or archeological site, structure, building, or object on federal lands.
- Restrictions applicable to locatable minerals are generally limited to the prevention of unnecessary or undue degradation, as defined in 43 CFR 3809.5; additional requirements beyond the unnecessary or undue degradation standard may not apply to locatable minerals, and may be voluntary and achieved by negotiation with the claim holder.
- Notice level operations do not require approval from the BLM (i.e., there is no “federal action”) but are bound by statutory requirements, including the ESA, the National Historic Preservation Act (NHPA), and the requirement under the Federal Land Policy and Management Act (FLPMA) to prevent unnecessary or undue degradation of public lands.
- The potential for mineral resources is a prediction of the likelihood of the occurrence of these resources. The occurrence of a mineral resource does not necessarily imply that the mineral can be economically exploited or is likely to be developed; mineral occurrence potential includes both exploitable and potentially exploitable occurrences. The potential for the occurrence of a mineral resource also does not imply that the quality and quantity of the resource are known.
- On lands which are open to operations under the mining law, as amended, operators may conduct casual use operations, explore, locate new mining claims, submit notices under 43 CFR

3809, or seek approval of plans of operations under 43 CFR 3802 or 43 CFR 3809. This is the case even in areas which are currently believed to have low or no potential for the occurrence or development of locatable minerals.

- About 346,206 acres of federal mineral estate have known occurrence of bentonite (BLM 2009d). Known bentonite-bearing strata within the Planning Area (Map 4) are primarily located in the eastern half of the Planning Area, but are also found in the southern and western portions of the Planning Area near Thermopolis and Cody. Refer to the *Solid Mineral Occurrence and Development Potential Report*, (BLM 2009d) for detailed maps of other known or potential locatable mineral occurrence within the Planning Area.
- The potential for continued bentonite development activity, particularly in the eastern half and southern portions of the Planning Area, is high (BLM 2009d). Bentonite will continue to be mined using surface mining methods.
- About 114,095 acres of federal mineral estate have known or potential gypsum occurrence (BLM 2009d). Gypsum-bearing strata within the Planning Area (Map 5) occur generally in the eastern portion of the Planning Area. The potential for continued gypsum mining activity, particularly in several locations in the CYFO, is high. Gypsum will continue to be mined using open pit/surface mining methods.
- About 18,286 acres of federal mineral estate have a known occurrence and 129,926 have potential occurrence of uranium (BLM 2009d). Most known uranium-bearing strata within the Planning Area are located in the extreme northeast part of the Planning Area (Little Mountain Uranium District). Interest in uranium exploration could increase during the planning period with a rise in uranium prices. No active mining of uranium is taking place anywhere in the Planning Area.
- There are about 1,535 acres of federal minerals with a known occurrence and 211,953 acres with potential occurrence of thorium (BLM 2009d). Potential thorium-bearing strata within the Planning Area are located in small deposits in various locations throughout the Planning Area. Potential for the occurrence of thorium mineralization coincident with titaniferous black sandstone deposits in the Planning Area is generally high. Currently, there is no active exploration for or mining of thorium taking place in the Planning Area. This is not expected to change over the life of the plan.
- About 51,291 acres of federal mineral estate have a known occurrence of placer gold (BLM 2009d). The southwest-central and northwest portions of the Planning Area contain very limited quantities of placer gold. The potential for placer gold development activity is low for the planning period.
- About 1,535 acres of federal mineral estate have a known occurrence and 211,953 have potential occurrence of titaniferous black sands (BLM 2009d). Titaniferous black sandstone paleoplacer deposits occur in specific locations in the southern, eastern, and northern portions of the Bighorn Basin, but are not currently being developed in the Planning Area. Known titaniferous black sandstone deposits are likely to contain titanium and zirconium. The potential for the development of titaniferous black sands over the planning cycle is estimated to be low, although some small-scale mining of black sand is possible.
- The potential for the occurrence of all metallic minerals other than placer gold and titanium-bearing black sands in the Planning Area is low. The proper geologic conditions, namely, igneous plutons and/or metamorphosed ore bodies, do not exist in the Planning Area. Therefore, the potential for the development of these metallic minerals is considered low during

the planning period. No active mining of placer gold is taking place anywhere in the Planning Area.

- Although discoveries of other valuable deposits of locatable minerals may occur during the planning period, bentonite and gypsum will remain the dominant locatable minerals being mined in the Planning Area. See the *Solid Mineral Occurrence and Development Potential Report* (BLM 2009d) for more information on the occurrence and development potential for locatable minerals within the Planning Area.

4.2.1.2 Summary of Impacts by Alternative

Alternative E, primarily due to mineral withdrawals for ACECs and Wild and Scenic Rivers (WSR) suitable waterway segments, would result in the largest amount of acreage with restrictions to locatable mineral development (1,759,312 acres), followed by Alternative B (314,223 acres), Alternative A (72,861 acres), alternatives D and F (83,321 acres), and Alternative C (48,095 acres). Alternative E includes the largest acreage proposed for mineral withdrawal in areas of known or moderate locatable mineral potential, followed by alternatives B, A, D, F and C.

4.2.1.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Subject to valid existing rights, restrictions on exploration and development of locatable minerals would result in adverse impacts when areas are withdrawn, segregated, or classified from locatable mineral entry, or with the application of other resource restrictions that limit or prohibit mineral activity. The intensity of impacts varies by alternative and whether there are existing locatable minerals activities in an area proposed for withdrawal or segregation. The more acreage withdrawn, segregated, or classified, the more adverse impacts to exploration and development of locatable mineral resources occur. Withdrawals would result in more impacts where withdrawals apply to locatable mineral areas with known or moderate potential. Discussions of individual alternatives describe adverse impacts to exploration and development of locatable minerals from these actions. See Table 3-44 in Chapter 3, Existing and Proposed Withdrawals, Classifications, and Other Segregations in the Planning Area, for additional information about existing withdrawals and segregations and the associated resources that those actions are intended to protect. Under all alternatives, the BLM anticipates that mining for locatable minerals would likely occur using surface mining methods.

Management actions in the lands and realty program that revoke or require the review of existing withdrawals that segregate areas from locatable mineral entry would result in beneficial impacts to locatable mineral exploration and development by opening new areas to operation under the mining laws. These revocations and reviews include opening restored BOR lands, revoking 3,287 acres of Classification and Multiple Use (C&MU) lands, and reviewing 14,341 acres of power withdrawals/classifications and 14,381 acres of other agencies' withdrawals. Continuing existing classifications and segregations would withdraw these areas from operation under the mining laws, which would result in adverse impacts.

For all alternatives, the BLM would respect all valid existing rights within those areas subject to review, including unpatented mining claims within sage grouse Key Habitat Areas or PHMAs. All mining claims located within an area that are subsequently withdrawn are subject to validity examinations prior to the approval of any operations. Mining claims which have not demonstrated discovery of a valuable mineral

Locatable Minerals

deposit or use and occupancy as defined in the mining laws prior to the withdrawal date, have no valid and existing rights and could be contesting by the BLM, whether or not they are located in greater sage-grouse Key Habitat Areas or PHMAs.

Pursuing newly proposed BLM protective withdrawals and other agency withdrawal requests on a case-by-case basis would result in adverse impacts to locatable mineral exploration and development if areas are withdrawn from mineral entry.

It is important to note that because of overlapping management restrictions, withdrawals associated with resource and resource uses described in this section are not additive. A list of all withdrawals from locatable mineral entry and associated acreages by alternative are supplied in Table 4-27 in Section 4.6.1 *Lands and Realty*.

Alternative A

Under Alternative A, the BLM maintains withdrawals for locatable minerals on 72,861 acres, or approximately 2 percent, of the federal mineral estate in the Planning Area (Map 9).

Under Alternative A, the following locatable minerals and associated acreages (and percent of total known and/or potential occurrence on federal mineral estate in the Planning Area) are known to occur or have moderate to high potential for occurrence (not actual commercial development) in areas pursued for withdrawal from operation of the mining laws, as amended:

- Bentonite – 2,858 acres of known occurrence (3 percent of total occurrence)
- Gypsum – 5,958 acres of known and potential occurrence (5 percent of total occurrence)
- Uranium – 6,041 acres of known and potential occurrence (4 percent of total occurrence)
- Thorium – 290 acres of potential occurrence (less than 1 percent of total occurrence)
- Titaniferous black sands – 81 acres of potential occurrence (less than 1 percent of total occurrence)

The remainder of the discussion for this alternative identifies the major withdrawals that result from other resources and uses, regardless of known mineral occurrence or mineral potential.

Resource Uses

Specific lands and realty actions, establishing some recreation sites, and management of special designations, may result in adverse impacts to exploration for or development of locatable mineral resources. Adverse impacts may result when management actions related to these uses and designations result in either a withdrawal or a segregation of the federal mineral estate from locatable mineral entry, which closes the lands to entry under the mining laws, as amended. Conversely, lifting withdrawals, segregations, or some existing mineral classifications could open the lands to locatable mineral entry.

Under Alternative A, termination of all existing coal and phosphate withdrawals or classifications would open lands previously withdrawn from locatable mineral entry, which would result in beneficial impacts to new locatable mineral activities. Lands and realty actions under Alternative A include approximately 644 acres of land classifications under the Recreation and Public Purposes (R&PP) Act, which have the effect of segregating the classified lands from locatable mineral entry (location of new mining claims) under the mining laws, as amended.

In addition, C&MU classifications (Little Mountain Area) and Desert Land Entries (DLEs) segregate an additional 4,696 acres from locatable mineral entry. Other segregations under Alternative A include

public water reserves (2,763 acres) and power-site reservations (3,468 acres). Withdrawals from locatable mineral entry for other federal agencies, including the Federal Energy Regulatory Commission (FERC), the U.S. Department of Defense, the National Park Service, the BOR, and the USFS, total approximately 121,052 acres. See Section 4.6.1 *Lands and Realty* for more detailed discussion of classifications, segregations, and withdrawals.

Under Alternative A, the Beck Lake Scenic Area (708 acres) and the Castle Gardens Recreation Site (110 acres) are withdrawn from appropriation under the mining laws for the protection of recreation resources in these areas.

Special Designations

Under Alternative A, the BLM withdraws several WSR eligible waterway segments and ACECs from locatable mineral entry, including the Big Cedar Ridge, Red Gulch Dinosaur, Sheep Mountain Anticline, Spanish Point Karst, Five Springs Falls, and Upper Owl Creek ACECs. In addition, all designated ACECs (71,646 acres, including the withdrawn ACECs) and all areas closed to motorized vehicle use (68,115 acres) require a plan of operation before mining can begin for all activity exceeding casual use; such a requirement may either restrict or remove limitations on access to these areas for exploration for locatable minerals and may result in adverse impacts in the form of delay for claimants, who would otherwise be able to undertake these activities without prior approval from the BLM. Under all alternatives, the Heart Mountain Relocation Center National Historic Landmark (72 acres) would be withdrawn from appropriation under the mining laws.

Resources

Under Alternative A, cave and karst areas continue to be withdrawn from locatable mineral entry to prevent degradation of these resources. The BLM also continues to withdraw certain areas in the Big Cedar Ridge and Red Gulch Dinosaur Tracksite ACECs (2,062 acres) to protect paleontological resources. The BLM continues to withdraw important cultural sites from appropriation under the mining laws on a case-by-case basis. Refer to Appendix T for detailed information and acreages associated with mineral entry, mining, and withdrawals.

Alternative B

Alternative B would pursue withdrawal from appropriation under the mining laws for locatable minerals on 314,223 acres, or 8 percent, of the federal mineral estate in the Planning Area (Map 10). These withdrawals encompass more acres than under Alternative A.

Under Alternative B, the following locatable minerals and associated acreages (and percent of total known and/or potential occurrence on federal mineral estate in the Planning Area) are known to occur or have moderate to high potential for occurrence (not actual commercial development) in areas pursued for withdrawal from operation of the mining laws, as amended:

- Bentonite – 9,289 acres of known and potential occurrence (3 percent of total occurrence)
- Gypsum – 10,891 acres of known and potential occurrence (10 percent of total occurrence)
- Uranium – 26,160 acres of known and potential occurrence (18 percent of total occurrence)
- Thorium – 378 acres of potential occurrence (less than 1 percent of total occurrence)
- Titaniferous black sands – 81 acres of potential occurrence (less than 1 percent of total occurrence)

Locatable Minerals

The remainder of the discussion for this alternative identifies the major withdrawals that would result from other resources and uses, regardless of known mineral occurrence or mineral potential.

Resource Uses

Under Alternative B, all existing coal and phosphate withdrawals and classifications would continue. These withdrawals and classifications would not result in adverse impacts to exploration and development of locatable minerals, because there is generally no known interest in exploration for or development of locatable minerals in the areas where there are coal or phosphate classifications.

Lands and realty management actions under this alternative are expected to result in similar impacts to locatable minerals access as under Alternative A, but to a slightly greater extent. Lands and realty actions under Alternative B include a withdrawal for a 208-acre industrial park in Cody, Wyoming. Other segregations and withdrawals under Alternative B would result in impacts similar to those actions described for Alternative A, except for a decrease in other federal agency withdrawals. A complete list of the withdrawals, classifications, and other segregations in the Planning Area by alternative is provided in Table 4-27 in Section 4.6.1 *Lands and Realty*.

Management actions that withdraw recreational areas under Alternative B are expected to result in impacts to locatable minerals access similar to those actions under Alternative A.

Special Designations

Special designations under Alternative B that would result in withdrawal of some lands from locatable mineral entry include all WSR suitable waterway segments and all ACECs except the Little Mountain and Upper Owl Creek/Absaroka Front proposed expansion areas; the total acreage of these withdrawals due to special designations would be greater than Alternative A.

In addition, Alternative B designates more areas as ACECs (302,490 acres, including the withdrawn ACECs) and closes more areas to motorized vehicle use (170,253 acres) than Alternative A. Therefore, this alternative would result in more adverse impacts to claimants from requirements for plans of operation.

Resources

Withdrawals from locatable mineral entry for resource protection under Alternative B are anticipated to be similar to Alternative A, except that Alternative B withdraws more area for the protection of paleontological resources in ACECs. Other management actions under Alternative B to protect resources are expected to be similar to those under Alternative A.

Alternative C

Under Alternative C, withdrawals would be pursued on 48,095 acres, or 1 percent, of the federal mineral estate in the Planning Area (Map 11), a smaller amount than the other alternatives.

Under Alternative C, the following locatable minerals and associated acreages (and percent of total known and/or potential occurrence on federal mineral estate in the Planning Area) are known to occur or have moderate to high potential for occurrence (not actual commercial development) in areas pursued for withdrawal from operation of the mining laws, as amended:

- Bentonite – 2,880 acres of known and potential occurrence (1 percent of total occurrence)
- Gypsum – 3,016 acres of known and potential occurrence (3 percent)

- Uranium – 5,915 acres of known and potential occurrence (less than 4 percent of total occurrence)
- Thorium – 290 acres of potential occurrence (less than 1 percent of total occurrence)
- Titaniferous black sands – 81 acres of potential occurrence (less than 1 percent of total occurrence)

The remainder of the discussion for this alternative identifies the major withdrawals that would result from other resources and uses, regardless of known mineral occurrence or mineral potential.

Resource Uses

Under Alternative C, the BLM would terminate all coal and phosphate withdrawals and classifications, resulting in the same impacts to locatable mineral entry as under Alternative A. Other segregations and withdrawals under Alternative D would result in impacts similar to those actions under Alternative A, except there would be less area withdrawn for other agencies and public water reserves, which would benefit locatable mineral development. A complete list of the withdrawals, classifications, and other segregations in the Planning Area by alternative is provided in Table 4-27 in Section 4.6.1 *Lands and Realty*.

Under Alternative C, the Castle Gardens Recreation Site (110 acres) is withdrawn for protection of recreational use, but in contrast to the other alternatives, does not withdraw the Beck Lake Scenic Area from locatable mineral entry.

Special Designations

Under Alternative C, federal mineral estate under the Spanish Point Karst ACEC is the only special designation with a withdrawal from locatable mineral entry, resulting in the smallest adverse impact to locatable mineral entry.

Alternative C includes the smallest area designated as ACECs (11,799 acres) and closed to motorized vehicle use (9,274 acres), and would therefore result in the fewest adverse impacts to claimants from requirements for plans of operation.

Resources

The BLM expects withdrawals from locatable mineral entry for resource protection under Alternative C to be similar to Alternative A, except that the BLM would not withdraw any areas for the protection of paleontological resources.

Alternative D

Under Alternative D, withdrawals would be pursued on 83,321 acres, or 2 percent, of the federal mineral estate in the Planning Area (Map 12), a larger area than under Alternative C, but smaller than under alternatives A and B.

Under Alternative D, the following locatable minerals and associated acreages (and percent of total known and/or potential occurrence on federal mineral estate in the Planning Area) are known to occur or have moderate to high potential for occurrence (not actual commercial development) in areas pursued for withdrawal from operation of the mining laws, as amended:

- Bentonite – 3,892 acres of known and potential occurrence (less than 1 percent of total occurrence)
- Gypsum – 7,134 acres of known and potential occurrence (6 percent of total occurrence)

Locatable Minerals

- Uranium – 10,764 acres of known and potential occurrence (7 percent of total occurrence)
- Thorium – 290 acres of potential occurrence (less than 1 percent of total occurrence)
- Titaniferous black sands – 0 acres of potential occurrence

The remainder of the discussion under this alternative identifies the major withdrawals that result from other resources and uses, regardless of known mineral occurrence or mineral potential.

Resource Uses

Under Alternative D, all existing coal and phosphate withdrawals and classifications would continue unless they are no longer needed. Similar to Alternative B, this would not result in adverse impacts to exploration and development of locatable minerals, because there is generally no known interest in exploration for or development of locatable minerals in the areas where coal or phosphate classifications exist.

Similar to Alternative B, lands and realty actions under Alternative D do not open a 209-acre industrial park in Cody, Wyoming, to locatable mineral entry. Other segregations and withdrawals under Alternative D would result in impacts similar to those actions under Alternative A, except for a small decrease in land withdrawn for power-site reservations and a larger decrease in other federal agency withdrawals. A complete list of the withdrawals, classifications, and other segregations in the Planning Area by alternative is provided in Table 4-27 in Section 4.6.1 *Lands and Realty*.

Management actions that withdraw certain areas for the protection of recreational resources under Alternative D are expected to result in impacts to locatable minerals access similar to those actions under Alternative A.

Special Designations

Under Alternative D, withdrawals are pursued on the fewer acres of ACECs than Alternative B, but on more acres than alternatives A and C. In contrast to alternatives A and B, Alternative D does not include special management that would withdraw WSR eligible waterway segments. However, Alternative D would withdraw a portion of the Chapman Bench Management Area (3,425 acres) for resource protection. Alternative D designates 105,498 acres as ACECs (including the withdrawn ACECs). Alternative D closes 61,010 acres to motorized vehicle use, which would result in adverse impacts to claimants from requirements for plans of operation.

Resources

Under Alternative D, withdrawals from locatable mineral entry for resource protection of cave and karst and paleontological resources would be similar to those under Alternative B, except that the BLM would withdraw less area for the protection of paleontological resources.

Alternative E

Alternative E would pursue withdrawal from appropriation under the mining laws for locatable minerals on 1,759,312 acres, or 42 percent, of the federal mineral estate in the Planning Area (Map 13). The area of withdrawal from mineral entry under Alternative E would be substantially larger than under any other alternative due to the withdrawal of the proposed Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). This alternative would withdraw 1,686,451 more acres from mineral entry than Alternative A. As per 43 Code of Federal Regulations (CFR) 3809.100, when surface management operations are proposed on claims that pre-date a withdrawal, operations would not proceed until the

BLM has prepared a mineral examination report to determine whether or not the claim was valid before the withdrawal and if it continues to be valid.

Under Alternative E, the following locatable minerals and associated acreages (and percent of total known and/or potential occurrence on federal mineral estate in the Planning Area) are known to occur or have moderate to high potential for occurrence (not actual commercial development) in areas pursued for withdrawal from operation of the mining laws, as amended:

- Bentonite – 141,537 acres of known and potential occurrence (41 percent of total occurrence)
- Gypsum – 35,856 acres of known and potential occurrence (31 percent of total occurrence)
- Uranium – 57,983 acres of known and potential occurrence (39 percent of total occurrence)
- Thorium – 92,369 acres of potential occurrence (43 percent of total occurrence)
- Titaniferous black sands – 19,518 acres of potential occurrence (9 percent of total occurrence)

The remainder of the discussion for this alternative identifies the major withdrawals that would result from other resources and uses, regardless of known mineral occurrence or mineral potential.

Resource Uses

Impacts to locatable mineral development from resources uses would be greater under Alternative E than under any other alternative. Management within the proposed Greater Sage-Grouse Key Habitat Areas ACEC, including restrictions on ROW development, withdrawals, limitations and closures on motorized vehicle use, and land tenure adjustments would adversely impact locatable mineral development. However, authorized or permitted uses that specify allowable access would not be affected by travel management designations. Impacts to lands outside the ACEC would be the same as those identified under Alternative B.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), would be the same as Alternative B, and impacts would be similar to Alternative B. Withdrawal of the Greater Sage-Grouse Key Habitat Areas ACEC from mineral entry under Alternative E would result in more acres withdrawn due to special designations than any other alternative. Alternative E includes the largest area of designated ACECs (1,535,851 acres). In addition, surface disturbances would be limited to one disturbance per 640 acres and less than 3 percent of greater sage-grouse Key Habitat Areas, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. As per 43 CFR 3809.11, a Plan of Operations must be submitted for any operation greater than casual use within an ACEC.

Resources

Adverse impacts to locatable mineral development would be substantially greater under Alternative E than under any other alternative due to the withdrawal of the proposed Greater Sage-Grouse Key Habitat Areas ACEC for the protection of greater sage-grouse (1,232,583 acres). Management actions to protect resources outside of this ACEC would be the same as Alternative B, and impacts would be the same as described under Alternative B.

Alternative F

Withdrawals from locatable mineral entry under Alternative F would be the same as under Alternative D (Map 12), and the impacts to locatable minerals would be the same as described under Alternative D.

Resource Uses

Lands and realty actions that withdraw, classify, or segregate lands from mineral entry under Alternative F would be the same as under Alternative D, and the impacts to locatable minerals would be the same as Alternative D. A complete list of the withdrawals, classifications, and other segregations in the Planning Area by alternative is provided in Table 4-27 in Section 4.6.1 *Lands and Realty*.

Withdrawals pursued for the protection of recreational resources are the same as Alternative D, and impacts to locatable minerals would be the same as that alternative.

Special Designations

Withdrawals pursued in ACECs under Alternative F are the same as those pursued under Alternative D, and the impacts from those withdrawals are the same as described under Alternative D. However, Alternative F implements additional restrictions in the Greater Sage-Grouse PHMAs ACEC that would result in adverse impacts to claimants from requirements for plans of operation by limiting surface-disturbing activities and motorized vehicle use, as well as considering seasonal restrictions on locatable mineral development if deemed necessary to protect greater sage-grouse PHMAs. However, ACEC designation under Alternative F would also necessitate a Plan of Operation for exploration activities in PHMAs where a notice would have otherwise sufficed.

Resources

Impacts from resource protective management would be greater under Alternative F than under alternatives A and D due to restrictions on surface disturbance and motorized vehicle use, and potential seasonal restrictions within the proposed Greater Sage-Grouse PHMAs ACEC. However, authorized or permitted uses that specify allowable access would not be affected by travel management designations.

4.2.2 Leasable Minerals – Coal

The BLM does not anticipate reasonable foreseeable coal exploration, leasing, or development during the planning cycle. If the BLM receives an application for a federal coal lease, an appropriate land use and environmental analysis, including the coal screening process, would be necessary to determine whether the area(s) proposed for leasing are acceptable for coal development and leasing (in accordance with 43 CFR 3425). If the BLM determined that public lands were acceptable for further consideration for coal leasing, the land use plan would need to be amended, as necessary. The BLM would accept federal coal lease applications only for federal coal lands with development potential (Map 6) identified as suitable for further leasing consideration, after application of the coal screens and unsuitability criteria. For example, an application for a federal coal lease in greater sage-grouse PHMAs would be considered unsuitable.

4.2.2.1 Analysis of Alternatives

If interest arises, the BLM may allow coal exploration subject to the regulations at 43 CFR 3410 and subject to Appendix H guidance to mitigate surface-disturbing activities. Closing large areas to mineral leasing or applying NSO restrictions on large areas may adversely affect potential coal leasing in the

Planning Area if demand were to arise. Major and moderate constraints on mineral leasing, geophysical exploration, and minerals development also would adversely impact potential future coal leasing.

4.2.3 Leasable Minerals – Oil Shale

The BLM anticipates the potential for oil shale exploration and development activity would be low for the next planning cycle because of the relative thinness of oil shale beds, thickness of overburden, and poor quality of oil shale in the Planning Area. In 2008, the BLM released a *Programmatic Environmental Impact Statement (EIS) for Oil Shale and Tar Sands* (BLM 2009c) that amended existing RMPs in Wyoming and other states. The only areas of Wyoming addressed in this Programmatic EIS were the Washakie and Green River Basins in the southwestern part of the state. The Programmatic EIS did not include the Bighorn Basin because oil shale resources in the Bighorn Basin are not considered economically feasible to produce. Oil shale exploration, development, and leasing in the Planning Area would require additional evaluation and an RMP amendment.

4.2.3.1 Analysis of Alternatives

The BLM did not consider oil shale leasing and development under any alternative due to the absence of known, commercially exploitable resources and lack of anticipated leasing and development. The BLM does not anticipate impacts to oil shale leasing and development. However, closing large areas to mineral leasing or applying NSO restrictions on large areas may adversely affect potential oil shale leasing in the Planning Area if demand were to arise. Major and moderate constraints on mineral leasing, geophysical exploration, and minerals development also may adversely impact potential oil shale leasing.

4.2.4 Leasable Minerals – Geothermal

Lands in the Planning Area have been classified as having low to negligible potential for geothermal development, with the exception of lands surrounding the known hydrothermal spring areas near Thermopolis and Cody (BLM 2009h). Due to current policy direction guiding the development of renewable energy resources on public lands, there could be increased interest in geothermal exploration and development in the Planning Area over the next 10 to 20 years. The *Reasonable Foreseeable Development Scenario for Geothermal, Bighorn Basin Planning Area* (BLM 2009h) provides more information and related studies on geothermal resources and development potential in the Planning Area.

The definition of direct/indirect, beneficial/adverse, and short-term/long-term impacts described in Section 4.2.5 *Leasable Minerals – Oil and Gas* would be the same for geothermal exploration and development. In addition, adverse impacts to geothermal resources result from management that may limit or prohibit public use of geothermal resources (hot springs). Beneficial impacts would result from management that maintains or increases public use and access to geothermal resources.

Managing geothermal leasing on split-estate lands (federal mineral ownership and private surface ownership) would not limit or prohibit the use of warm water or normal-temperature geothermal systems for nonutility-grade home heating or other applications.

4.2.4.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Except as noted for alternatives B and D, where differences occur in leasing availability, BLM-administered land in the Planning Area that is open to oil and gas leasing will be open to geothermal leasing, subject to appropriate mitigation developed through use of the mitigation guidelines described in Appendix H.
- Unless otherwise noted, those lands identified as closed to oil and gas leasing will be closed to geothermal leasing.
- There will be low to moderate potential interest in development of geothermal resources during the planning period.
- Any potential geothermal development on federal mineral estate in the Planning Area would be carefully assessed to avoid adverse impacts to geothermal resources developed near Thermopolis and Cody, Wyoming.

4.2.4.2 Summary of Impacts by Alternative

The principal source of adverse impacts to geothermal exploration and development results from applying restrictions (i.e., managing these areas as closed or applying NSO or CSU stipulations) on areas with development potential; managing these areas as open to geothermal leasing with standard restrictions would generally result in beneficial impacts. Geothermal resources in the Planning Area are classified as moderately low to negligible and, since none of these resources are capable of generating electricity, restrictions on geothermal exploration and development are anticipated to result in minimal impacts under all alternatives. Alternatives B and E would result in the greatest potential for adverse impacts to geothermal exploration and development as they contain the largest areas closed to geothermal leasing (2,453,193 acres each), followed by alternatives D and F (361,777 acres), Alternative A (151,931 acres) and Alternative C (145,836 acres). Alternatives B, D, E, and F place additional restrictions on the geothermal development around Hot Springs State Park in Thermopolis, the only area of moderate geothermal resources potential in the Planning Area; though these restrictions would prevent commercial development, these alternatives would provide the greatest protection to the current public uses of these thermal springs.

4.2.4.3 Detailed Analysis of Alternatives

Management and restrictions for geothermal resources are the same as those for oil and gas resources. Except as noted for alternatives B and D, where there are differences in leasing availability, areas open to oil and gas leasing are open to geothermal leasing and areas closed to oil and gas leasing are closed to geothermal leasing. In addition, exploration and development of geothermal resources are subject to the same restrictions on surface-disturbing activities applied to oil and gas exploration and development. As a result, impacts to geothermal exploration and development by alternative would be the same as those described in Section 4.2.5 *Leasable Minerals – Oil and Gas*. Because commercial geothermal development requires drilling and facilities comparable to those associated with oil and gas development, management that affects oil and gas is expected to similarly affect geothermal development.

Because of the lower level of anticipated geothermal development compared to oil and gas development, impacts to geothermal resources from management actions may be less than those

associated with oil and gas development. However, the extent of impacts between alternatives, based on management actions in the alternatives, would be the same.

This section identifies areas that have specific management actions for geothermal resources separate from oil and gas management in the area. Except as noted for alternatives B and D, see Section 4.2.5 *Leasable Minerals – Oil and Gas* for a discussion of the acreages open, open with constraints, and closed, and the associated impacts comparison between alternatives.

Impacts Common to All Alternatives

Impacts to geothermal resources common to all alternatives would be similar to impacts described in Section 4.2.5 *Leasable Minerals – Oil and Gas*.

Under all alternatives, any potential geothermal development on federal mineral estate in the Planning Area would be carefully assessed to avoid adverse impacts to geothermal resources near Cody and Thermopolis, Wyoming.

Alternative A

Areas open subject to standard lease stipulations, open with constraints, and closed to geothermal exploration and development (Map 14), and resulting impacts, are the same as those described in Section 4.2.5 *Leasable Minerals – Oil and Gas* for Alternative A. Approximately 151,931 acres are closed to geothermal leasing under Alternative A, resulting in direct adverse impacts to potential development of geothermal resources on these lands. Compared to the other alternatives, Alternative A designates the least amount of land as closed to geothermal leasing.

Lands within 15 miles of the Hot Springs State Park at Thermopolis are open to geothermal leasing under Alternative A. There has been no recent expressed interest in such leasing for commercial purposes on the federal mineral estate. Development of geothermal resources in the area of Hot Springs State Park is not within BLM jurisdiction because the state of Wyoming owns and controls the park and all surface water and groundwater resources.

Alternative B

Under Alternative B, 2,453,193 acres are closed to geothermal leasing (Map 15), which would result in impacts similar to those described in Section 4.2.5 *Leasable Minerals – Oil and Gas* for Alternative B. However, under Alternative B, more acreage is closed to geothermal leasing than oil and gas leasing because federal mineral estate is closed to geothermal leasing within 15 miles of Hot Springs State Park.

Managing federal mineral estate within 15 miles of Hot Springs State Park as closed to geothermal leasing would not result in long-term adverse impacts to leasing, because the BLM does not anticipate interest in commercial geothermal leasing in this area over the next planning cycle. However, if interest in geothermal grows, there would be long-term adverse impacts to leasing.

Prohibiting geothermal development on federal mineral estate within 15 miles of Hot Springs State Park would ensure development would not alter pressures and volumes within the hydrothermal system. This would be a beneficial impact.

Alternative C

Under Alternative C, lands open to leasing subject to standard lease stipulations, open with constraints, and closed to geothermal exploration and development (Map 16), and the resulting impacts, would be roughly the same as those described for Alternative A, and described in Section 4.2.5 *Leasable Minerals – Oil and Gas* for Alternative C. Compared to the other alternatives, Alternative C designates the least amount of land as closed to geothermal leasing (145,836 acres).

Managing lands within 15 miles of the Hot Springs State Park as open to geothermal leasing would result in the same impacts as those described for Alternative A.

Alternative D

Under Alternative D, 361,777 acres are closed to geothermal leasing, which would result in impacts similar to those described in Section 4.2.5 *Leasable Minerals – Oil and Gas* for Alternative D (Map 17). However, more acreage is closed to geothermal leasing than oil and gas leasing under Alternative D because of the closure of federal mineral estate to geothermal leasing within 5 miles of Hot Springs State Park.

Managing lands within 5 miles of Hot Springs State Park as closed to geothermal leasing would result in impacts similar to those described for Alternative B, though to a lesser extent because less area would be affected if interest in geothermal development grows. Alternative D would also provide a beneficial impact by requiring geothermal resource monitoring and protection within 5 miles of Hot Springs State Park and within the Thermopolis Anticline.

Alternative E

Under Alternative E, lands open to leasing subject to standard lease stipulations, open with constraints, and closed to geothermal exploration and development are the same as Alternative B (Map 15), and impacts to geothermal resources would be the same as Alternative B.

Alternative F

Under Alternative F, lands open to leasing subject to standard lease stipulations, open with constraints, and closed to geothermal exploration and development are the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC (Map 17). In this ACEC, the BLM applies an NSO stipulation within 0.6 mile of greater sage-grouse leks, which would result in more adverse impacts to geothermal exploration and development than alternatives A, C, and D, but fewer than alternatives B and E.

4.2.5 Leasable Minerals – Oil and Gas

The potential for oil and gas occurrence in the Planning Area ranges from high to low, depending on location, as documented in the RFD. Based on oil and gas occurrence and other considerations, such as the characteristics of mineral-bearing formations and historic drilling activity, the RFD also analyzed the potential for anticipated drilling activity over the next 20 years (i.e., mineral development potential). Lands in the Planning Area are classified as having moderate to no potential for development of oil and gas resources, depending on location and based on projected drilling densities (BLM 2009a). Drilling in existing fields accounts for a large proportion of the growth, with a lesser share attributed to additional new discoveries in both conventional and unconventional reservoirs.

Unconventional oil reservoirs, specifically fractured shale oil reservoirs formed in fine-grained shale rock with low permeability, could be present in the Mowry Shale. Exploration and development of unconventional oil and gas from the Mowry Shale is discussed in the RFD. The RFD indicates that the Mowry Shale has the lowest potential for development during the planning period while also having the lowest undiscovered resource quantity. Development of the Mowry Shale would likely require horizontal drilling technology, though the BLM notes that the Mowry Shale is considered difficult to drill horizontally due to numerous interbeds of commercial bentonite and swelling shale.

The RFD considers the potential for development of CBNG in the Planning Area, depending on location, to be low, very low, or nonexistent.

There could be adverse impacts to oil and gas exploration and development activities from management actions that restrict or constrain the potential for oil and gas leasing, development, and exploration. Constraints to oil and gas development include NSO, CSU restrictions, timing limitations (TLS), or the allocation of public land for management of other resource objectives that limit or prohibit oil and gas exploration and development (e.g., visual resource management [VRM] allocations). These restrictions could include provisions imposed prior to leasing under a MLP. The MLP concept, criteria for MLP nomination, and potential resources of concern in MLP analysis areas considered in this RMP are discussed in Chapter 3, Section 3.2.5 *Leasable Minerals – Oil and Gas*.

Additional adverse impacts to exploration and development of oil and gas resources can result from specific management actions that require mitigation, certain BMPs, or other lease stipulations to protect resources that may increase project costs and timeframes. Beneficial impacts related to oil and gas exploration and development can result from management actions that ease restrictions or open areas for oil and gas exploration and development, thereby increasing the potential for leasing, exploration, and development.

Management actions to protect other resource values may directly and indirectly impact new oil and gas leases, exploration, and development. A direct impact is one that either specifically prohibits or permits oil and gas leasing, exploration, or development. Direct impacts include managing areas as closed to new oil and gas leasing. Indirect impacts result from management actions that may place or remove surface use restrictions or additional requirements on oil and gas exploration and development (e.g., BMPs or mitigation). These actions do not explicitly permit or prohibit oil and gas exploration and development activity, but may influence an operator's decision about whether to proceed. An example of an indirect impact would be a seasonal restriction on entering a greater sage-grouse Key Habitat Area for part of the year.

4.2.5.1 Methods and Assumptions

The unconstrained baseline RFD for oil and gas in the Planning Area is based on a set of reasonable geologic, engineering, and economic assumptions about resource occurrence only, and past and present activity, without management constraints on future activities. An unconstrained RFD provides a basis for comparing alternatives. Constrained oil and gas projections typically are lower than those in the unconstrained baseline RFD because of management constraints on oil and gas activities in the alternatives.

It is important to note that the RFD is not a decision, and it neither establishes nor implies a “cap” on development. Surface disturbance associated with well counts likely will be reduced in the future as the result of improvements in drilling- and well-completion technologies and techniques. Thus, the BLM uses any discussion of well counts in the RFD only to form the basis for an analysis of levels of impact. In addition, because the RFD is a snapshot in time, it cannot capture how future advances in technology

may make it possible to exploit certain oil and gas plays in the future that are currently not economical or commercially exploit.

Chapter 3 includes a summary of unconstrained baseline projections for oil and gas drilling activity in the Planning Area. Appendix T includes detailed projections of well counts by alternative, which vary by the degree of management constraints. See the RFD for oil and gas for more specific information on baseline oil and gas development and drilling potential in the Planning Area (BLM 2014a).

Table 4-17 summarizes projected new-well counts for the alternatives and the baseline unconstrained projection (only standard lease stipulations would be required) (BLM 2009q). The projected new-well counts and estimated surface disturbance associated with wells described in this section are for the period 2008 through 2027. Appendix T includes well projections by type of oil and gas well by alternative.

Table 4-17. Bighorn Basin Planning Area Projected New-Well Counts by Alternative

Alternative	Total Coalbed Natural Gas Wells	Total Conventional Oil and Gas Wells	Total Oil and Gas Wells	Percent of Total Wells on Federal Mineral Estate
Baseline Unconstrained Projection ¹	150	1,715	1,865	72.6
Alternative A	128	1,567	1,695	69.9
Alternative B	61	907	968	51.8
Alternative C	144	1,671	1,815	71.8
Alternative D	124	1,528	1,652	69.2
Alternative E	59	906	965	51.7
Alternative F	124	1,528	1,652	69.1

Source: BLM 2013a

¹Only terms and conditions of the standard lease form would be applied; operations would also be subject to existing laws, regulations, Onshore Oil and Gas Orders, and Notices to Lessees.

Methods and assumptions used in this impact analysis include the following:

- Unless otherwise noted, areas that are open to oil and gas leasing will be open to geophysical exploration subject to appropriate mitigation developed through use of the mitigation guidelines described in Appendix H.
- Unless otherwise noted, areas closed to oil and gas leasing will be closed to geophysical exploration.
- The BLM can authorize, subject to appropriate mitigation developed through use of the mitigation guidelines described in Appendix H, geophysical exploration activities in VRM Class I and II areas because the operations are short-term activities.
- The BLM does not guarantee access to mineral leases that it issues.
- Analysis considers the baseline total unconstrained oil and gas development potential taken from the RFD for oil and gas as summarized in Chapter 3 and applies the alternative constraints from the other resource programs as described in Chapter 2. The RMP will not modify existing leases; as old leases expire and new ones are issued, new leases would be subject to relevant stipulations. However, site-specific COA can be applied to applications for permit to drill (APDs)

on existing leases to avoid adverse impacts to resource values by development per 43 CFR 3101.1-2.

- Reasonable mitigation measures could include modification to siting or design of facilities, timing of operations, and specification of interim and final reclamation requirements. These modifications might occur only through site-specific post-lease actions (e.g., APDs and ROWs) that are supported by onsite conditions and/or project-specific NEPA analysis. Any exceptions, modifications, or waivers to lease stipulations will only be authorized in accordance with applicable regulatory guidelines. Surface-disturbing and other disruptive activities could occur at existing authorized facilities.
- Areas open for oil and gas leasing subject to major constraints have greater adverse impacts on oil and gas leasing, exploration, and development compared to acres subject to either moderate constraints or standard stipulations. All areas identified as open in this analysis are subject to at least standard stipulations. In addition, some of these areas are subject to moderate and/or major constraints. Table 4-18 shows acres open for oil and gas leasing subject to moderate and major constraints, as well as acres closed to oil and gas leasing for each alternative.

Table 4-18. Acres of Oil and Gas Constraints – All Alternatives

Alternative	Constraint Type (acres)		
	Moderate	Major	Closed
Alternative A	1,633,204	889,435	260,792
Alternative B	335,109	932,551	2,464,745
Alternative C	1,334,491	91,956	145,836
Alternative D	1,714,685	1,221,142	292,353
Alternative E	319,671	969,432	2,464,745
Alternative F	1,709,652	1,191,215	324,829

Source: BLM 2013a

- Moderate constraints are any stipulations or COA which may restrict the timing or placement of oil and gas development, but would not otherwise restrict the overall development. Moderate constraints include all TLS, CSUs, areas where surface-disturbing activity is avoided, and VRM Class II areas.
- Major constraints are any stipulations or COA which may restrict the timing or placement of oil and gas developments and may result in an operator dropping the development proposal. Major constraints include NSOs, areas of overlapping TLS that last more than 6 months, areas closed to surface-disturbing activity, areas where surface-disturbing activity is prohibited, and VRM Class I areas. Leaseholders have the right to explore, develop, and produce mineral resources from any valid, existing lease, even if the area containing the lease was proposed to be closed to future leasing.
- Because of overlaps between management restrictions on oil and gas leasing (i.e., CSU, TLS, and NSO), individual restrictions associated with resources and special designations described in this section are not additive. As described in the *Glossary*, the BLM has factored these overlapping restrictions into the overall oil and gas constraints (major, moderate, open, closed) for each alternative, where appropriate. For example, while a TLS restriction is generally considered a moderate constraint, overlapping TLS that restrict the use of an area for 6 months or more are considered a major constraint. In areas where overlapping management is the same and applies

year-round (e.g., two overlapping NSOs), there is no additional or additive effect. Finally, where different types of restrictions overlap (e.g., an area managed as an NSO for cultural resources and closed for wildlife values), the more restrictive management would apply. Maps 18-23 provide a visual representation of constraints by alternative.

- Oil and gas resources are considered unrecoverable in areas designated closed to leasing. They would also be considered unrecoverable in areas open to leasing but where surface use constraints prohibit development operations on areas larger than can be technically and economically developed from offsite locations. Oil and gas resources within leased in-holdings would be considered recoverable.
- Oil and gas development potential is based on the following categories:
 - High potential for hydrocarbon development indicates areas where the average well density is anticipated to be more than 100 wells per township.
 - Moderate potential for hydrocarbon development indicates areas where the average well density is anticipated to be between 20 and 100 wells per township.
 - Low potential for hydrocarbon development indicates areas where the average well density is anticipated to be 2 to fewer than 20 wells per township.
 - Very low potential for hydrocarbon development indicates areas where the average well density is anticipated to be fewer than 2 wells per township.
 - No potential for hydrocarbon development indicates areas where no wells are anticipated.
- Directional drilling viability and offset distance varies with the target formation, the top depth of the target formation, and formation productivity. Directional drilling distances of ¼ mile are assumed to be standard practice in most formations with current technology.
- For the purposes of this analysis, hydrocarbon resources more than ½ mile inside the boundary of an NSO area would generally be unrecoverable.
- Directional drilling potentially increases well development costs by approximately 10 percent to 15 percent for offset distances of up to 2,000 feet (Eustes 2003).
- Directional drilling can increase the risk of unrecoverable hydrocarbon resources in cases when the drill stem gets irretrievably stuck and the production casing cannot be set to the bottom of the production formation.

4.2.5.2 Summary of Impacts by Alternative

Management actions that restrict or constrain the potential for oil and gas leasing, development, and exploration (via NSO, CSU, and timing limitations [TLS] restrictions or managing areas as closed) would result in adverse impacts to the development and production of oil and gas; management actions that ease restrictions or maintain areas as open for oil and gas exploration and development would result in beneficial impacts to the development and production of oil and gas. All of the alternatives include management that restricts oil and gas leasing and development to varying levels; alternatives B and E would generally result in the most adverse impacts to oil and gas development and Alternative C the least. Figure 4-3 displays the acreage open to oil and gas development subject to the standard lease form, open with constraints, and closed under each alternative. Projected new well counts under each alternative are listed in Table 4-17. Areas closed to oil and gas development are smallest under Alternative C (145,836 acres) and largest under alternatives B and E (2,464,745 acres). The number of acres within the Planning Area by level of constraint is depicted in Figure 4-3. Impacts to oil and gas exploration and development from the restriction of geophysical exploration would be the greatest

under Alternative E due to closure of the proposed Greater Sage-Grouse Key Habitat Areas ACEC to geophysical exploration. The number of acres within the Planning Area closed to leasing because the management of special designations (e.g., ACECs and National Historic Trails [NHTs]) is depicted in Table 4-19. Additionally, the BLM manages lands with wilderness characteristics as closed to oil and gas leasing under alternatives B and E (471,727 acres of federal mineral estate), under Alternative F (44,538 acres of federal mineral estate), except for the Painted Hills under Alternative F, which are available for leasing with an NSO restriction. Alternatives C, D, and F establish Oil and Gas Management Areas (430,647 acres of federal mineral estate for Alternative C; 441,662 acres of federal mineral estate for alternatives D and F) allowing full development of known oil and gas resources in existing fields and exempting these areas from certain discretionary seasonal wildlife limitations and other restrictions, resulting in beneficial impacts to oil and gas exploration and development. However, alternatives D and F place additional stipulations on oil and gas-related surface disturbances in the Absaroka Front, Fifteenmile, and Big Horn Front MLP analysis areas for the protection of big game, geologic features, and LRP soils. As a result, alternatives D and F could have additional adverse impacts on oil and gas development in these MLP analysis areas compared to alternatives A and C. However, because of the generally low to very low potential for oil and gas development and redundancies with other restrictions on mineral leasing from the management of other program areas, management specific to the MLP is less likely to adversely affect oil and gas development in these areas.

The development potential for leasable oil and gas in the Planning Area ranges from moderate to no potential, depending on location. As shown in Table 4-20, alternatives A, B, E, D, and F all contain areas managed as closed to oil and gas leasing that include some areas with moderate development potential (6,759 acres for Alternative A; 220,758 acres for alternatives B and E; 2,840 acres for Alternative D; 2,834 acres for Alternative F).

¹There are no oil and gas development potential data for Wilderness Study Areas (141,068 acres), and the data in this table do not reflect those areas. All Wilderness Study Areas are closed to new leasable mineral exploration and development (BLM 2012a).

4.2.5.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Under all alternatives, management that results in areas being open, open with constraints, or closed would respectively allow, limit, or prohibit exploration and development in certain areas. This management would result in direct impacts to oil and gas development. Impacts would be similar across alternatives because the definition of areas open subject to the standard lease form, open with moderate constraints, open with major constraints, and closed are the same for all alternatives (see *Glossary*). The severity of these impacts would vary by alternative based on amount of acreage and associated oil and gas development potential. Protective measures for other resources, including limiting or prohibiting access and development or controlling the timing or nature of development, would result in adverse impacts. Restrictions on oil and gas development under each of the alternatives also would result in adverse impacts to the rate of oil and gas exploration, development, and extraction. These impacts would increase costs, both to the operator and the product end user, of exploring for, developing, and extracting oil and gas. Under all alternatives, operators must employ BMPs in the exploration, development, production, and abandonment of oil and gas resources.

Under all alternatives, areas closed to oil and gas leasing would be closed to geophysical exploration and areas open to oil and gas leasing would be open to geophysical exploration, subject to mitigation measures described in Appendix I as appropriate. Managing areas as closed would prohibit oil and gas exploration and subsequent development and extraction. This would result in adverse impacts to exploration and development of fluid mineral resources. In instances where geophysical exploration is allowed subject to mitigation, operators may incur increased costs from the use of more expensive, but less surface-disturbing techniques (e.g., small, portable foot- or helicopter-transported surveying equipment in areas with surface use restrictions). If surface use restrictions or mitigation requirements prevent or discourage an operator from effectively surveying/exploring oil and gas resources, development could be sited based on incomplete information, affecting the potential success of a future well. This could also result in increased costs to the operator and in nonproductive disturbances to land and surface resources. Alternatively, allowing geophysical exploration in areas open to oil and gas development, if performed within the constraints necessary to protect other resources, could result in beneficial impacts to oil and gas exploration and development.

In areas where federal oil and gas leases are or have been issued without stipulations, subsequently placing additional mitigation measures on exploration and development may result in adverse impacts to ongoing or future oil and gas development. Requiring additional stipulations on new leases may constrain exploration, development, production, or other actions that increase the timeframe and cost of operations. Mitigating measures attached to an APD as COA influence how an activity is accomplished, but rarely preclude the activity. Such management actions in complex areas involving impact avoidance to several resources may limit oil and gas operations.

Special designations (e.g., ACECs, NHTs, WSAs) and other management areas (e.g., recreation management areas) may result in adverse impacts to oil and gas exploration and development, depending on their location in relation to oil and gas development potential. These lands may be subject to a variety of restrictions related to oil and gas exploration or development (e.g., closures, NSO restrictions, CSU and TLS stipulations), or require certain BMPs or mitigation to preserve resource and management objectives in these areas. Special stipulations, such as required resource surveys, also may be applied. Discussions of overall constraints for oil and gas for each alternative capture impacts from

these special designations. Respective sections in this chapter discuss specific impacts of the management for each area.

Management actions that prescribe certain BMPs and mitigation would affect all alternatives on a project-specific basis, depending on the overall constraints under each alternative. While specific mitigation measures generally would be consistent, the nature and level of impacts to oil and gas development would vary among alternatives and may also vary based on site-specific conditions that would be evaluated in implementation-level environmental documents. In general, constraints on exploration, development, production, and abandonment of oil and gas resources (e.g., NSO, CSU, or TLS) would increase project timeframes and costs, and may limit the number of well pads and amount of surface disturbance on a lease. This would be an adverse impact. However, such constraints may result in beneficial impacts to other resources in a given area.

Under all alternatives, implementing mitigation measures to reduce air quality emissions from current levels and applying BMPs for oil and gas activities that could affect groundwater resources would require certain technologies and mitigation that may increase project costs. This would result in adverse impacts to oil and gas development.

On split-estate lands (areas with private surface ownership and federal mineral estate), the BLM applies the same stipulations, COAs, and/or conservation measures and as those applied on surrounding BLM-administered lands to the maximum extent permissible under existing authorities and in coordination with the landowner. The BLM would consider the views of the surface owner in these leasing determinations, such as the routing of access roads and location of well pads, which would encourage proactive issue identification and dispute resolution. However, adverse impacts may result from an increase in the timeframe for processing and developing leases, increasing project costs, or the potential relocation of well pads and infrastructure.

When necessary to protect important resources, the BLM would attach COA for operations proposed on existing oil and gas leases within areas designated as closed to leasing, which would exclude surface occupancy and surface disturbance. The BLM would do this to the maximum extent possible without violating lease rights. Such restrictions on occupancy and surface disturbance may limit the operator's ability to extract the federal oil and gas resources under lease. For example, directional drilling from an area outside such a lease to an operator-targeted bottom-hole location in a leased area may not be technically or economically feasible.

Under all alternatives, the BLM would require special status species inventories for surface-disturbing projects in known or suspected special status species habitat. Postponing or modifying projects that may affect special status species would lead to a delay in the development and/or the relocation of well pads, access roads, pipelines, or ancillary facilities.

Subject to valid existing rights, the BLM would prioritize leasing and authorizing development of fluid mineral resources in greater sage-grouse habitat areas in the following order: 1) outside of PHMAs and GHMAs, 2) non-habitat areas inside of PHMAs and GHMAs, and 3) least suitable habitat areas inside of PHMAs and GHMAs. Where adverse effects to greater sage-grouse populations or habitat are anticipated, the BLM would work with the project proponent in developing an APD to avoid, reduce and mitigate adverse impacts to the extent compatible with lessees' rights to drill and produce fluid mineral resources.

Typical impacts from cultural resource management actions on oil and gas exploration and development would include increased well development costs associated with cultural resource inventories, relocation of projects (well pads, roads, pipelines) to avoid a cultural site, implementation of offsite drilling (directional drilling) techniques, and/or site excavation if avoidance is not possible. Discovery of

previously undocumented cultural features during project construction would delay project implementation while the site is evaluated.

Under all alternatives, management actions for ROWs would allow, limit, or prohibit facilities and infrastructure necessary for the development and extraction of oil and gas resources including access roads, powerlines, and pipelines. This would impact oil and gas development. Federal regulations require ROW grants for access roads, powerlines, or pipelines that cross one lease to access another. Avoiding or excluding these authorizations could limit or prohibit legal access and infrastructure to well pads. Management that limits or prohibits ROW authorizations (ROW avoidance and exclusion areas) would result in adverse impacts to oil and gas development. Designating ROW corridors up front could eliminate or reduce land use conflicts and beneficially affect oil and gas development and pipelines.

Oil and gas exploration and development often occur in grazing allotments. Oil and gas operators would have to abide by mitigation specified in lease stipulations or in the COA for those operations. Mitigation measures required to minimize adverse impacts to livestock grazing would increase the cost of oil and gas exploration and development. These measures would include providing for the upkeep and repair of fences and gates and taking measures to prevent loss of or injury to livestock. The BLM would not expect livestock mitigation to substantially affect the technical or economic viability of oil and gas development.

Reclaiming areas of surface disturbance with native grass and forb species to prevent erosion; monitoring and treating weeds and other nonnative, invasive plant species that occupy areas disturbed by oil and gas development and production; and returning vegetation and habitat to pre-disturbance conditions is required in all cases, increasing project costs.

Under all alternatives, the extent of impacts to oil and gas development from constraints and limitations on exploration and development relates directly to oil and gas development potential in an area. Management actions that constrain development of oil and gas in high-potential areas generally would result in more impacts to development than similar management actions that constrain development in low-potential areas. The RFD for oil and gas describes the potential for oil and gas occurrence and development in the Planning Area (BLM 2014a).

Alternative A

Resource Uses

Under Alternative A, 260,792 acres of BLM-administered mineral estate would be closed to mineral leasing (Map 18). Managing areas as closed to oil and gas leasing would reduce the amount of land available for oil and gas leasing and prohibit development in these areas. This would result in direct adverse impacts to oil and gas development.

Under Alternative A, 889,435 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and major constraints (Map 18). Major constraints to oil and gas exploration and development, such as NSO restrictions or overlapping TLS restrictions, limit or prohibit development in these areas or require certain drilling techniques, BMPs, or other mitigation. This results in adverse impacts to oil and gas exploration and development. In some cases, operations can be modified to accommodate such restrictions, but these modifications can be costly, increase project timeframes, or be otherwise undesirable to oil and gas operators. Companies typically drill oil and gas wells vertically because the costs are lower and drilling problems are less likely, but they could employ directional drilling in an area with an NSO restriction to protect other resources. For example, an operator might be able to place a well pad, access road, or production facility in a less

sensitive area and drill the well directionally to recover reserves underlying the area with the NSO if under certain conditions, such as favorable geologic and drilling conditions. However, even if technically feasible, the increased costs associated with directional drilling may make some drilling activities uneconomical. Because directional drilling has certain limitations, operators may not be able to develop all the oil and gas resources from all the acreage associated with large NSO areas. Companies typically cannot use directional drilling to develop CBNG because the reservoirs are too shallow (BLM 2014a). Because of the costs associated with restrictions, an operator may decide to not develop oil and gas resources in an area with major constraints.

Under Alternative A, 1,633,204 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and moderate constraints (Map 18). Moderate constraints limit the time of construction and operation activities or require specific mitigation or lease stipulations. This would result in adverse impacts to oil and gas leasing. Moderate constraints do not necessarily remove the area from development or exploration of oil and gas or require directional drilling. Under TLS restrictions, development may become more intensive over a shorter period to complete operations before timing restrictions apply. In areas with overlapping TLS restrictions, companies may be limited to narrow timeframes to complete work, which may result in major constraints. In some cases, an operator may have to start development and then postpone operations during specific periods. If the window during which work can be done is too short, a development project may have to proceed in phases, requiring more time to complete, adding to the project's cost, and increasing the time before the investment is recovered. CSU restrictions could require specific lease stipulations to meet other resource management objectives and make the development of oil and gas uneconomical or unattractive to potential operators.

Under Alternative A, 1,354,593 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form only (Map 18). Managing areas open to oil and gas exploration and development allows oil and gas leasing and development in these areas with only standard lease stipulations. This would result in beneficial impacts.

As a result of the oil and gas constraints under Alternative A, projected drilling is reduced from the baseline unconstrained projections. The baseline scenario projects 1,354 federal wells could be drilled in the Planning Area. These include 1,249 conventional wells and 105 CBNG wells. Under Alternative A, 1,184 wells are projected (1,101 conventional wells and 83 CBNG wells). This represents an approximately 13 percent decrease from the baseline, or 148 fewer federal conventional wells and 22 fewer federal CBNG wells. Under Alternative A, 139 fewer federal oil and gas wells are expected to remain in production at the end of the planning period compared to the projected baseline scenario. This represents an approximately 5 percent decrease from the baseline scenario. Abandonment of federal wells is expected to decrease slightly (approximately 3 percent), from 957 wells under the baseline scenario, to 926 wells under Alternative A (BLM 2014a).

Designating ROW exclusion and avoidance areas would prohibit or limit ROW authorizations for roads, pipelines, or other infrastructure that may be necessary for the development of oil and gas resources. This would result in adverse impacts to oil and gas development. Under Alternative A, the BLM manages 940,943 acres as ROW avoidance areas and 61,147 acres as ROW exclusion areas.

Special Designations

Special designations (ACECs, NHTs, WSAs, and WSRs) under Alternative A may result in adverse impacts to oil and gas exploration and development. However, because these areas are generally small, the impacts to overall use of oil and gas resources would generally be limited. In addition to WSAs, Alternative A manages portions of some ACECs and some WSR eligible waterway segments as closed to

oil and gas leasing (Table 4-19). Alternative A also manages areas within ¼ mile of the Nez Perce (Neeme-poo) NHT and Other Historic Trails, seven WSR eligible waterway segments, and the Red Gulch Dinosaur Tracksite ACEC, Big Cedar Ridge, Five Springs Falls, and Upper Owl Creek ACECs as available for oil and gas leasing with an NSO restriction.

Resources

Under Alternative A, restrictions and constraints on oil and gas development would result from management actions to protect resources. The most extensive impacts to oil and gas leasing from management of resources under Alternative A would result from restrictions for greater sage-grouse, raptor nesting, and big game crucial winter range.

Alternative A allows new surface discharges of produced water at the discretion of the Wyoming DEQ and the BLM, and subject to the Wyoming water quality standards, which would generally result in beneficial impacts by giving operators flexibility to determine their preferred method of disposal.

Under Alternative A, adverse impacts to oil and gas development would result from management of greater sage-grouse leks, nesting and early brood-rearing habitat, and winter concentration areas on new and existing leases, including:

- CSU restrictions within ¼ mile of occupied leks
- TLS restrictions in early brood-rearing habitats within 2 miles of occupied leks (834,543 acres)
- TLS restrictions in identified nesting and brood-rearing habitat outside the 2-mile buffer from March 15 to July 15 (CYFO seasonal restrictions are from February 1 to July 31)
- TLS restrictions within winter concentration areas from November 15 to March 14

These restrictions would impose moderate constraints to oil and gas development, which would result in adverse impacts. The impacts of these restrictions would vary across the Planning Area, depending on the projected development potential for oil and gas resources. For BLM-administered lands, management that constrains oil and gas development around greater sage-grouse leks, in nesting and early brood-rearing habitat, and in winter concentration areas would affect approximately 337,712 acres of moderate-potential areas, 400,655 acres of low-potential areas, and 368,485 acres of very-low-potential areas. Restrictions applied in low- and very-low-potential areas may result in only limited impacts to oil and gas development. Impacts to oil and gas development from restrictions that constrain development in moderate-potential areas would be greater than restrictions that constrain development in low- and very-low-potential areas.

Under Alternative A, restrictions on surface disturbances (i.e., TLS stipulations) in raptor nesting areas would prohibit development or require lease stipulations that may make oil and gas development more difficult. This would result in adverse impacts to oil and gas resources. Under Alternative A, designated raptor nest buffer areas would include approximately 337,662 acres of BLM-administered surface. Timing restrictions on surface-disturbing activities in these areas would narrow the available time for construction activities and potentially increase project costs. This may adversely affect oil and gas development. Under Alternative A, TLS restrictions for raptor nesting areas would occur on approximately 47,429 acres with moderate oil and gas development potential, 148,729 acres with low potential, and 125,746 acres with very low potential. As with oil and gas restrictions for greater sage-grouse habitat, impacts from TLS restrictions for raptor nest areas in moderate-potential areas would be greater than restrictions in low- and very-low-potential areas.

Under Alternative A, TLS restrictions in big game crucial winter range (1,324,371 acres) would reduce the time available for oil and gas activities and potentially increase project timeframes and costs. This

would result in adverse impacts to oil and gas resources. In addition, applying CSU restrictions for big game migration corridors, narrow ridges, overlapping big game crucial winter range (72,850 acres), including within the Absaroka Front and Big Horn Front areas, would require lease stipulations that may increase project timeframes and costs. This would result in adverse impacts to oil and gas resources.

Under Alternative A, wildlife seasonal protections may be extended to surface-disturbing and disruptive activities related to project maintenance and operation (including production) on a case-by-case basis. Extending the seasonal protections described above would result in ongoing adverse impacts to oil and gas development by requiring additional coordination to schedule project activities in accordance with seasonal stipulations and potentially increasing project costs.

Alternative A prohibits surface-disturbing activities within 500 feet of surface water and riparian/wetland areas (70,715 acres). Prohibiting surface disturbance in these areas would exclude ROWs in these areas and prohibit the development of oil and gas resources, which would result in adverse impacts to oil and gas development.

Of the areas available for oil and gas leasing, 82,295 acres are in VRM Class II areas, 340,817 acres are in VRM Class III areas, and 642,361 acres are in VRM Class IV areas. In VRM Class I areas, the level of change to the characteristic landscape should be very low; therefore, VRM Class I areas are closed to oil and gas leasing. In VRM Class II areas, the level of change to the characteristic landscape should be low. Oil and gas exploration and development activities may be restricted or limited in VRM Class II areas. VRM objectives in Class II areas may limit the development of facilities. If the BLM approves oil and gas development in these areas, siting, design, and other mitigation may be required to ensure that management objectives for visual resources are met. Objectives for VRM Class III, Class IV, or unclassified area generally allow activities, subject to some level of mitigation.

The nature and extent of impacts to the oil and gas resources from VRM would vary according to the projected oil and gas development potential of the subject lands. Of the areas available for oil and gas leasing, VRM Class II areas include approximately 14,668 acres with a moderate potential for oil and gas resources, approximately 69,597 acres with a low potential for oil and gas resources, and approximately 409,616 acres with a very low potential for oil and gas resources. Impacts to oil and gas development from management as VRM Class II would be greater in moderate-potential lands than in low- and very-low-potential lands, because moderate-potential lands are more likely to be developed than low- and very-low-potential lands.

Alternative B

Resource Uses

Under Alternative B, geophysical exploration is subject to limitations on motorized vehicle use and restrictions on surface-disturbing activities. This would result in adverse impacts to oil and gas development by limiting the access and methods used for oil and gas resource surveys.

Under Alternative B, 2,464,745 acres of BLM-administered mineral estate would be closed to mineral leasing (Map 19). Managing areas as closed to mineral leasing would result in a substantial increase in area closed to oil and gas leasing compared to Alternative A (260,792 acres).

Under Alternative B, 932,551 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and major constraints (Map 19). Managing areas with major constraints would result in a 5 percent increase in area managed with major constraints compared to Alternative A.

Under Alternative B, 335,109 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and moderate constraints (Map 19). Managing areas with moderate constraints would result in an 80 percent decrease in area managed with moderate constraints compared to Alternative A. Managing more area as closed to mineral leasing and with major and moderate oil and gas constraints would likely result in increased oil and gas development on private lands under Alternative B, compared to Alternative A.

Under Alternative B, 405,620 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form only (Map 19). Managing areas as open to oil and gas leasing subject to the standard lease form would result in a 70 percent decrease in area open subject to the standard lease form compared to Alternative A.

As a result of the restrictions implemented under Alternative B, projected drilling is reduced from baseline projections. The baseline scenario projects that 1,354 federal wells could be drilled (1,249 conventional wells and 105 CBNG wells). Under Alternative B, 502 federal wells are projected (479 conventional wells and 23 CBNG wells). This represents an approximately 63 percent decrease from the baseline, or 747 fewer federal conventional wells and 82 fewer federal CBNG wells. Six-hundred ninety (690) fewer federal wells (both conventional and CBNG) are expected to remain in production at the end of the planning period. This represents an approximately 274 percent decrease from the baseline. Abandonment of federal wells is similarly expected to decrease (approximately 17 percent) from 957 wells under the baseline scenario to 795 wells under Alternative B (BLM 2014a). At the end of the planning period, projected total producing wells would be fewer under Alternative B (2,680) than Alternative A (3,182).

Under Alternative B, the BLM does not suspend existing non-producing oil and gas leases in areas closed to mineral leasing and, after such leases expire, would not offer the land for future leasing. This management may result in adverse impacts to the production of federal oil and gas where such resources are present. The respective terms (expiration dates) of such leases cannot be halted at the direction or consent (after application for suspension by the lessee or operator) of the BLM authorized officer, as would be the case if the leases were suspended. This would be the case even if lease suspension was in the interest of conservation of natural resources, encouraged the greatest ultimate recovery of oil and gas, or met other criteria warranting lease suspension (see 43 CFR 3135.2).

Managing areas as ROW avoidance and exclusion areas would result in adverse impacts similar to those described for Alternative A, although to a greater extent. Under Alternative B, the BLM manages 2,710,695 acres as ROW avoidance areas and 225,447 acres as ROW exclusion areas. The total acreage managed as ROW avoidance and exclusion is greater than Alternative A.

Under Alternative B, geophysical exploration is subject to limitations on motorized vehicle use. Areas closed to motorized vehicle use (170,253 acres) and areas where motorized vehicle use is limited to designated roads and trails (2,416,378 acres) would restrict access routes in the Planning Area and may limit the use of seismic technology to obtain subsurface stratigraphic and structural information useful for exploration of oil and gas reserves. This would result in adverse impacts to oil and gas development.

Special Designations

Compared to Alternative A, Alternative B includes more special designations and management areas (including recreation management areas) and places more restrictions on surface-disturbing activities in these areas. This results in more adverse impacts to the development of oil and gas resources. Management in these areas includes closing land to mineral leasing, and NSO and CSU restrictions. Because these areas are larger and have more restrictions, impacts to oil and gas exploration and development are expected to be more extensive than under Alternative A. Table 4-19 shows the

acreages and areas closed to oil and gas leasing due to special designations and other management areas under this alternative. Other impacts from these special designations (NSOs, TLS, and CSUs) are captured in the overall constraints for oil and gas under this alternative described above, and specific management for each area (e.g., ACECs or SRMAs) is discussed in its respective section.

Resources

Management actions to protect resources under Alternative B place greater restrictions and constraints on oil and gas development than Alternative A. The most extensive impacts to oil and gas leasing from management of resources under Alternative B would result from restrictions for greater sage-grouse, raptor nesting, and big game crucial winter range.

Under Alternative B, quantitative air quality modeling of oil and gas field development would be required to determine potential impacts from proposed emissions sources. Air quality modeling of potential oil and gas development may require mitigation strategies for projects that would exceed emission standards.

Alternative B prohibits the authorization of new surface discharges of produced water, which could result in greater adverse impacts compared to Alternative A if operators incur additional transportation or disposal costs, or are required to drill disposal wells.

The most extensive impacts to oil and gas leasing would result from protective restrictions for greater sage-grouse. Under Alternative B, adverse impacts to oil and gas development would result from management of occupied greater sage-grouse leks on future and existing leases including:

- TLS restrictions in nesting and early brood-rearing habitat and within 3 miles of occupied leks (1,526,277 acres) from February 1 to July 31
- TLS restrictions in identified nesting and brood-rearing habitat outside the 3-mile lek buffer (310,749 acres) from February 1 to July 31
- CSU restrictions for all seasonal habitats identified above to allow 1 to 15 acres of well location or 15 acres of habitat removal per 640-acre section

Also under Alternative B, adverse impacts to oil and gas development on new leases would result from:

- NSO restrictions in 0.6 mile of occupied greater sage-grouse leks (146,324 acres)
- NSO restrictions in winter concentration areas from November 15 to March 14
- The designation of greater sage-grouse Key Habitat Areas as closed to mineral leasing (1,490,758 acres)

These restrictions would result in adverse impacts by prohibiting oil and gas development or managing areas with moderate or major constraints to development. The impacts of these restrictions would vary across the Planning Area, depending on the projected development potential for oil and gas. For BLM-administered lands, management that constrains oil and gas development around greater sage-grouse leks, in nesting and early brood-rearing habitat, and in winter concentration areas would affect approximately 337,751 acres of moderate-potential areas, 656,249 acres of low-potential areas, and 548,261 acres of very-low-potential areas. Restrictions applied in low- and very-low-potential areas may result in only limited impacts to oil and gas development. Impacts to oil and gas development from restrictions that constrain development in moderate-potential areas would be greater than restrictions that constrain development in low- and very-low-potential areas. Though these constraints would affect a similar area of moderate development potential to Alternative A, adverse impacts to oil and gas from

management of greater sage-grouse would be greater under Alternative B because of the application of the more restrictive major constraints (NSOs) under Alternative B.

Limiting noise sources at the perimeter of occupied greater sage-grouse leks may require mitigation or technologies that reduce noise levels, which may increase project costs. This may result in adverse impacts to oil and gas development. Oil and gas development activities may be restricted where sound levels cannot be limited below ambient noise levels.

Under Alternative B, restrictions on surface disturbance (including TLS and CSU restrictions) in raptor nesting areas would result in adverse impacts to oil and gas development similar to those described for Alternative A, although to a greater extent due to restrictions in the increased buffer areas. Under Alternative B, raptor nest buffer areas would include approximately 616,869 acres of BLM-administered surface with both CSU and TLS restrictions, which represents an approximately 69 percent increase in area with restrictions compared to Alternative A. Restrictions in raptor nesting areas would occur on approximately 72,717 acres of moderate oil and gas development potential lands, 265,496 acres of low-potential lands, and 207,507 acres of very-low-potential lands. As a result of specific stipulations for ferruginous hawks, lands where greater sage-grouse and raptor habitats overlap could be subject to development restrictions for most of the year (9 months). These specific stipulations are in place to comply with laws such as the Migratory Bird Treaty Act and Bald and Golden Eagle Protection Act, which provide protection to individuals of a species and not entire species populations.

Managing big game crucial winter range (1,324,371 acres) with an NSO restriction and prohibiting surface-disturbing activities within ½-mile of big game migration corridors would prevent surface occupancy for oil and gas activities and increase project costs. In some cases, it may result in the inability to access oil and gas resources. These adverse impacts to oil and gas development would be greater under Alternative B than under Alternative A, which manages these areas with TLS restrictions (or CSU within certain migration routes). Managing the Absaroka Front Management Area (130,872 acres) as closed to oil and gas leasing would prohibit oil and gas development in this area, which would result in adverse impacts.

The application of the seasonal wildlife protections discussed above to project maintenance and operation (including production) activities would result in ongoing adverse impacts due to the additional burden placed on the operators to comply with seasonal stipulations. These impacts may be more adverse than under Alternative A because Alternative B requires the extension of seasonal wildlife protections for all projects determined to be detrimental to wildlife, whereas Alternative A would apply these protections on a case-by-case basis.

Alternative B prohibits OHV use for notice of staking level casual use actions in limited OHV use areas of the Fifteen Mile and Big Horn Front areas to enhance protection for recreational settings, geologic features, LRP soils, and big game, which could result in adverse impacts to operators due to added time and expense required to perform these casual use activities compared to Alternative A.

Impacts to oil and gas from prohibiting surface disturbance within ¼ mile of riparian/wetland areas (162,887 acres) would result in impacts similar to those described for Alternative A, but to a greater extent due to larger acreages.

Under Alternative B, impacts to oil and gas development from VRM would be similar to those described for Alternative A, although to a greater extent due to more acreage managed as VRM Class I and Class II. Of the areas available for oil and gas leasing, 58,107 acres are in VRM Class II areas, 67,672 acres are in VRM Class III areas, and 158,783 acres are in VRM Class IV areas. The nature and extent of impacts to oil and gas exploration and development from VRM would vary according to the projected development potential of the subject lands. Under Alternative B, of the areas available for oil and gas leasing, VRM

Class II areas include approximately 201,497 acres of moderate oil and gas development potential lands, approximately 962,308 acres of low-potential lands, and approximately 1,237,598 acres of very-low-potential lands. Under Alternative B, VRM Class II areas in moderate development potential areas increase by approximately 186,829 acres compared to Alternative A.

Alternative C

Resource Uses

Under Alternative C, 145,836 acres of BLM-administered mineral estate would be closed to mineral leasing (Map 20). Managing areas as closed to mineral leasing would result in adverse impacts similar to those described for Alternative A, although to a lesser extent. Implementing Alternative C would result in the fewest areas closed to mineral leasing compared to of the other alternatives.

Under Alternative C, 91,956 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and major constraints (Map 20). Managing areas with major constraints would result in adverse impacts similar to those described for Alternative A, although to a lesser extent. Implementing Alternative C would result in a 90 percent decrease in area managed with major constraints compared to alternatives A and B, a 91 percent decrease compared to Alternative E, a 100 percent decrease compared to alternatives D and F.

Under Alternative C, 1,334,491 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and moderate constraints (Map 20). Managing areas with moderate constraints would result in adverse impacts similar to those described for Alternative A, although to a greater extent. Implementing Alternative C would result in an 18 percent decrease in area managed with moderate constraints compared to Alternative A, a 298 percent increase compared to Alternative B, a 22 percent decrease compared to Alternative D, a 317 percent increase compared to Alternative E, and a 22 percent decrease compared to Alternative F.

Under Alternative C, 2,565,742 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form only (Map 20). Managing areas as open to oil and gas leasing subject to the standard lease form would result in beneficial impacts to oil and gas resources similar to those described under Alternative A though to a greater extent. Implementing Alternative C would result in an 89 percent increase in area open subject to the standard lease form compared to Alternative A, a 533 percent increase compared to Alternative B, a 181 percent increase compared to Alternative D, a 568 percent decrease compared to Alternative E, and a 181 percent decrease compared to Alternative F.

As a result of the restrictions implemented under Alternative C, projected drilling is reduced from the baseline projections. The baseline scenario projects that 1,354 federal wells could be drilled (1,249 conventional wells and 105 CBNG wells). Under Alternative C, 1,304 federal wells are projected (1,205 conventional wells and 99 CBNG wells). This represents an approximately 4 percent decrease from the baseline, or 44 fewer federal conventional wells and 6 fewer federal CBNG wells. Under Alternative C, 41 fewer federal wells (both conventional and CBNG) are expected to remain in production at the end of the planning period than projected in the baseline scenario. This represents an approximately 10 percent decrease. Abandonment of federal wells is expected to decrease slightly (approximately 1 percent), from 957 wells under the baseline scenario, to 948 wells under Alternative C (BLM 2009d). Projected total producing wells at the end of the planning period would be the greatest under Alternative C (3,283) compared to Alternative A (3,182), Alternative B (2,680), and Alternative D (3,100).

Under Alternative C, the BLM allows suspension of existing oil and gas leases (producing and non-producing) in areas closed to mineral leasing for reasons such as conservation of natural resources, greatest ultimate recovery of oil and gas, or other reasons outlined by regulation (see 43 CFR 3135.2). If the BLM authorized officer grants a suspension, the respective terms (expiration dates) of such leases are extended for the period of suspension. If the BLM authorized officer does not suspend existing non-producing oil and gas leases and allows them to expire, the BLM would not offer lands in these areas for future leasing. This management may result in adverse impacts to production of federal oil and gas where such resources are present. The BLM automatically extends the terms on producing leases (and leases capable of production) in paying quantities if they comply with applicable regulations (see 43 CFR 3107.2).

Under Alternative C, managing areas as ROW avoidance or exclusion areas would result in adverse impacts similar to those described for Alternative A. Under Alternative C, the BLM manages more acreage (1,173,162 acres) as ROW avoidance areas and less acreage (7,586 acres) as ROW exclusion areas. While Alternative C manages a larger area for ROW avoidance than does Alternative A (a potential adverse effect), the smaller area of ROW exclusion (the most restrictive ROW designation) under Alternative C could reduce overall adverse impacts compared to that alternative.

Special Designations

Alternative C prescribes fewer restrictions on surface-disturbing and disruptive activities for a smaller number of special designation and management areas (including recreation management areas) compared to the other alternatives. Fewer special designations and fewer restrictions in these areas would result in fewer adverse impacts to oil and gas exploration and development compared to the other alternatives. Table 4-19 shows the acreages and areas closed to oil and gas leasing due to special designations and other management areas under this alternative. Other impacts from these special designations (NSOs, TLS, and CSUs) are captured in the overall constraints for oil and gas under this alternative described above, and the specific management for each area (e.g., ACECs or SRMAs) is discussed in its respective section.

Resources

Restrictions and constraints on oil and gas development resulting from management actions to protect resources would be the least under Alternative C. The most extensive impacts to oil and gas leasing from resource management under Alternative C would result from restrictions for greater sage-grouse and raptor nesting areas.

Alternative C allows new surface discharges of produced water and for that water to be put to beneficial use, so long as it is done in a manner that minimizes environmental harm. Although the approval of these discharges would be at the discretion of the Wyoming DEQ and the BLM, and subject to the Wyoming water quality standards, Alternative C, like Alternative A, would generally result in beneficial impacts by giving operators flexibility to determine their preferred method of disposal.

Under Alternative C, there would be adverse impacts to oil and gas development resulting from management of greater sage-grouse leks, nesting and early brood-rearing habitat, and winter concentration areas on new and existing leases (excluding Oil and Gas Management Areas for TLS), including:

- CSU restrictions within ¼ mile of occupied greater sage-grouse leks
- TLS restrictions in greater sage-grouse nesting and early brood-rearing habitat within 2 miles of occupied leks (834,543 acres) from March 15 to July 15

- TLS restrictions in nesting and brood-rearing habitat outside the 2-mile buffer from March 15 to July 15
- TLS restrictions within greater sage-grouse winter concentration areas from November 15 to March 14

These restrictions would impose moderate constraints to oil and gas development, therefore resulting in adverse impacts. The impacts of these restrictions would vary across the Planning Area, depending on the projected development potential for oil and gas. For BLM-administered lands, management that constrains oil and gas development around greater sage-grouse leks and in nesting and early brood-rearing habitat and winter concentration areas would affect approximately 337,712 acres of moderate oil and gas development potential areas, 400,655 acres of low-potential areas, and 368,485 acres of very-low-potential areas. Because these restrictions are similar and would affect the same area as Alternative A, similar impacts to mineral leasing would occur.

Limiting noise sources at the perimeter of occupied greater sage-grouse leks would result in adverse impacts to oil and gas development similar to those described for Alternative B, although to a lesser extent due to the reduced time that this stipulation would apply and the exemption of Oil and Gas Management Areas from this stipulation.

Raptor nest buffer areas are smaller under Alternative C, occupying approximately 82,294 acres of the Planning Area as a whole. Approximately 47,651 acres of BLM-administered surface are within raptor nest buffer areas. These lands are subject to TLS stipulations prohibiting surface-disturbing or disruptive activities within ¼ mile of active nests from February 1 through July 31. Raptor nesting areas affect approximately 7,908 acres with moderate oil and gas development potential lands, 19,985 acres with low-potential lands, and 17,137 acres with very-low-potential lands.

Alternative C would result in the least impact from wildlife restrictions. Alternative C exempts Oil and Gas Management Areas (430,647 acres) and ROW corridors from discretionary wildlife seasonal stipulations, and opens the Absaroka Front Management Area (130,872 acres) to oil and gas leasing and development, unlike alternatives B and D, which restrict oil and gas development in the area to protect wildlife habitat. In addition, Alternative C does not apply seasonal protections to maintenance and operation (including production) actions. Therefore, potential adverse impacts to project costs and schedule described under Alternative A would not occur under this alternative.

In contrast to the other alternatives, Alternative C would not prohibit or require avoidance of surface-disturbing activities in flood plains or riparian/wetland areas. Instead, the BLM authorizes surface-disturbing activities in these areas on a case-by-case basis, resulting in the fewest adverse impacts to oil and gas development in these areas of any alternative.

The types of impacts to oil and gas development from VRM would be similar to those described for Alternative A, although the extent of these impacts would be smaller because the BLM manages more area as the least restrictive VRM Class IV under this alternative. Of the areas available for oil and gas leasing, 237,205 acres are in VRM Class II areas, 322,284 acres are in VRM Class III areas, and 1,370,292 acres are in VRM Class IV areas. The nature and extent of impacts from VRM on oil and gas exploration and development would vary according to the development potential of the subject lands. Of the areas available for oil and gas leasing, VRM Class II areas include approximately 2,978 acres with moderate oil and gas development potential. Approximately 24,516 acres are classified as low-potential lands and approximately 809,339 acres are classified as very-low-potential lands. Under Alternative C, VRM Class II areas in moderate development potential areas decrease by approximately 87 percent compared to Alternative A.

Proactive Management

Establishing Oil and Gas Management Areas (Map 24; 430,647 acres) around intensively developed existing fields (Map 26) would allow for full development of known oil and gas resources in existing field areas. This would result in beneficial impacts to oil and gas exploration and development. The BLM would manage these areas primarily for oil and gas exploration and development and consider all other surface uses secondary. Exempting Oil and Gas Management Areas and ROW corridors from discretionary wildlife seasonal stipulations would result in beneficial impacts to oil and gas development and associated infrastructure in these areas. Oil and gas operators would be able to work in these areas throughout the year, which may provide some stability to what would otherwise be cyclic development due to wildlife-based seasonal restrictions.

Alternative D

Resource Uses

Under Alternative D, geophysical exploration is subject to limitations on motorized vehicle use and restrictions on surface-disturbing activities, resulting in similar adverse impacts as Alternative B.

Under Alternative D, 292,353 acres of BLM-administered mineral estate would be closed to mineral leasing (Map 21). Managing areas as closed to mineral leasing would result in adverse impacts similar to those described for Alternative A, although to a slightly greater extent. Implementing Alternative D would result in an increase in area closed compared to Alternative A (260,792 acres) and Alternative C (145,836 acres).

Under Alternative D, 1,221,142 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and major constraints (Map 21). Managing areas with major constraints would result in adverse impacts similar to those described for Alternative A, although to a greater extent. Implementing Alternative D would result in the greatest area managed with major constraints compared to the other alternatives.

Under Alternative D, 1,714,685 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form and moderate constraints (Map 21). Managing areas with moderate constraints would result in adverse impacts similar to those described for Alternative A, although to a greater extent. Implementing Alternative D would result in a 5 percent increase in area managed with moderate constraints compared to Alternative A, a 412 percent increase compared to Alternative B, and a 29 percent increase compared to Alternative C.

Under Alternative D, 911,814 acres of federal mineral estate are open to oil and gas leasing subject to the terms and conditions of the standard lease form only (Map 21). Managing areas as open to oil and gas leasing subject to the standard lease form would result in beneficial impacts to oil and gas resources similar to those described for Alternative A, although to a lesser extent. Implementing Alternative D would result in a 33 percent decrease in area open subject to the standard lease form compared to Alternative A, a 125 percent increase compared to Alternative B, and a 65 percent decrease compared to Alternative C.

As a result of the restrictions implemented under Alternative D, projected drilling is reduced from the baseline projections. The baseline scenario projects that 1,354 federal wells could be drilled (1,249 conventional wells and 105 CBNG wells). Under Alternative D, 1,143 federal wells are projected (1,064 conventional wells and 79 CBNG wells). This represents an approximately 16 percent decrease from the baseline, or 106 fewer federal conventional wells and 26 fewer federal CBNG wells. Under Alternative D, 172 fewer federal wells (both conventional and CBNG) are expected to remain in production at the

end of the planning period than projected in the baseline scenario. This represents an approximately 43 percent decrease. Abandonment of federal wells is expected to decrease (approximately 4 percent) from 957 wells under the baseline scenario, to 918 wells under Alternative D (BLM 2009d). The projected number of total producing wells at the end of the planning period under Alternative D (3,100) would be less than under Alternative C (3,283) and Alternative A (3,182), but more than under Alternative B (2,680).

Managing areas as ROW avoidance and exclusion areas would result in adverse impacts similar to those described for Alternative A, although to a greater extent. Under Alternative D, the BLM manages more acreage (2,408,662 acres) as ROW avoidance areas but less acreage (40,802 acres) as ROW exclusion areas. The total acreage managed as ROW avoidance or exclusion areas is more than under alternatives A and C, but less than under Alternative B.

Geophysical exploration is subject to limitations on motorized vehicle use under Alternative D, which would result in impacts similar to Alternative B, although to a lesser extent because less area is closed or limited to designated roads and trails.

Special Designations

Alternative D closes more areas to mineral leasing and prescribes more restrictions on surface-disturbing and disruptive activities for special designations and management areas than alternatives A and C, but less than Alternative B. Management in these areas includes closing land to mineral leasing, and NSO and CSU restrictions. Impacts from restrictions in special designations would be similar to those under Alternative A, although to a greater extent because of the size of the affected area. Table 4-19 shows the acreages and areas closed for oil and gas leasing due to special designations and other management areas under this alternative. Other impacts from these special designations (NSOs, TLS, and CSUs) are captured in the overall constraints for oil and gas under this alternative described above, and the specific management for each area (e.g., ACECs or SRMAs) is discussed in its respective section.

Resources

Restrictions and constraints on oil and gas development resulting from management actions to protect resources would adversely impact oil and gas leasing under Alternative D. The most extensive impacts from management of resources under Alternative D would result from restrictions for greater sage-grouse and raptor nesting.

Like Alternative A, Alternative D allows new surface discharges of produced water at the discretion of the Wyoming DEQ and the BLM, and subject to the Wyoming water quality standards. However, Alternative D also requires monitoring of receiving channels for new discharges, which could trigger additional requirements for reclamation and mitigation that would increase costs to operators to maintain compliance.

Alternative D applies a MLP in the Fifteenmile MLP Analysis Area (Map 35), which includes various restrictions on oil and gas exploration and development to reduce disturbance of unique geological features and LRP soils. Restrictions that could affect leasable mineral development include subjecting oil and gas leases within the Fifteenmile MLP Analysis Area to CSU restrictions, requiring minimum lease sizes of 640 acres and having no more than one oil and gas-related facility, and not exceeding 32 acres of surface disturbance at any given time, per lease. Alternative D generally limits OHV use for notice of staking level casual use activities to within 300-feet of established roads in areas with limited travel designations. As a result of these restrictions, oil and gas exploration and development in the Fifteenmile MLP Analysis Area could experience adverse impacts due to increased costs incurred to design and locate facilities away from sensitive soils and geologic resources and implement other

mitigation requirements. However, because the large majority of the MLP Analysis Area (91 percent) has low potential for oil and gas development, the potential for adverse impacts to development in the area would be limited. Adverse impacts to oil and gas development in the Fifteenmile MLP Analysis Area would be less than under Alternative B, which applies a NSO restriction and prohibits OHV use for notice of staking level casual use actions in the area, and more than alternatives A and C, which only apply case-by-case restriction to surface-disturbing activities.

Under Alternative D, constraints on resource uses in greater sage-grouse PHMAs would be more restrictive to oil and gas development than constraints outside PHMAs, and therefore would result in greater adverse impacts. Managing greater sage-grouse leks, nesting and early brood-rearing habitat, and winter concentration areas inside PHMAs (Map 42 and Map 42a) includes:

- NSO stipulation to prohibit or restrict surface-disturbing activities or surface occupancy within a 0.6-mile radius of occupied sage-grouse leks (116,522 acres)
- TLS stipulation to restrict disruptive activity within a 0.6-mile radius of occupied sage-grouse leks from March 15 to June 30 (116,522 acres)
- TLS to prohibit or restrict surface-disturbing and/or disruptive activities in suitable sage-grouse nesting and early brood-rearing habitat within PHMAs, regardless of distance from the lek from March 15 to June 30.
- TLS to prohibit or restrict surface-disturbing and disruptive activities in greater sage-grouse winter concentration areas that support PHMA populations from December 1 to March 14

Managing greater sage-grouse leks, nesting and early brood-rearing habitat, and winter concentration areas outside PHMAs (Map 42 and Map 42a) includes:

- NSO stipulation to prohibit or restrict surface-disturbing activities or surface occupancy within a ¼-mile radius of occupied sage-grouse leks (4,273 acres)
- TLS stipulation to restrict disruptive activity within ¼ mile of occupied sage-grouse leks from March 15 to June 30 (4,273 acres)
- TLS to prohibit or restrict surface-disturbing and/or disruptive activities in sage-grouse nesting and early brood-rearing habitat within 2 miles of the lek or perimeter of any occupied lek from March 15 to June 30
- TLS to prohibit or restrict surface-disturbing and/or disruptive activities in greater sage-grouse winter concentration areas from December 1 to March 14

These restrictions would impose moderate to major constraints to oil and gas development, resulting in adverse impacts. The impacts of these restrictions would vary across the Planning Area, depending on the projected development potential for oil and gas. For BLM-administered lands, constraints on oil and gas development around greater sage-grouse leks, in nesting and early brood-rearing habitat, and in winter concentration areas under Alternative D are more prohibitive and would affect more acreage of moderate- and low-potential areas than alternatives A and C.

Similar to Alternative B, Alternative D would limit noise sources at the perimeter of occupied greater sage-grouse leks to not exceed 10 dBA above ambient noise; however, as new research is completed, Alternative D would establish more specific limitations through coordination with the WGFD and partners, which could result in less adverse impacts than under Alternative B.

Restrictions on surface disturbance in raptor nesting areas under Alternative D would result in similar adverse impacts as those under Alternative A, although to a lesser extent due to smaller buffer areas. TLS and CSU restrictions around raptor nests, which vary by raptor species, would affect a total of

173,892 acres of BLM-administered surface. There would be restrictions in raptor nesting areas on approximately 12,035 acres of moderate oil and gas development potential lands, 58,607 acres of low-potential lands, and 49,507 acres of very-low-potential lands. As a result of specific stipulations for ferruginous hawks, lands where greater sage-grouse and raptor habitats overlap could be subject to development restrictions for most of the year (9 months). These specific stipulations are in place to comply with laws such as the Migratory Bird Treaty Act and Bald and Golden Eagle Protection Act, which provide protection to individuals of a species and not entire species populations.

Alternative D applies TLS restrictions in big game crucial winter range (1,324,371 acres), which would result in similar impacts as Alternative A. However, Alternative D would exempt Oil and Gas Management areas from discretionary big game seasonal stipulations. This would allow development of oil and gas resources in these areas without these restrictions and would result in beneficial impacts to oil and gas development.

Managing the Absaroka Front Management Area (130,872 BLM-administered surface acres) with a mix of CSU, TLS, NSO, and closed to leasing would prohibit oil and gas development or require lease stipulations that may increase project timeframes and costs. This would be an adverse impact to oil and gas development.

Alternative D also includes an MLP on 253,112 acres in the Absaroka Front MLP Analysis Area and 379,308 acres in the Big Horn Front MLP Analysis Area (Map 35), and applies additional stipulations on oil and gas development and off-road vehicular use to protect big game crucial winter range and migration corridors and recreational settings for hunting in these areas. In Zone 1 of the Absaroka Front MLP Analysis Area, Alternative D requires minimum lease sizes and places limitations on the density and total acreage of oil and gas-related surface disturbance per lease. Areas outside elk crucial winter range require a minimum lease size of 640 acres and a maximum of one oil and gas-related facility that does not exceed 32 acres of surface disturbance per lease, whereas areas inside elk crucial winter range require a minimum lease size of 1,280 acres and a maximum of one oil and gas-related facility that does not exceed 64 acres of surface disturbance per lease. Similar restrictions are applied in Zone 3, with the application of specific CSU and TLS stipulations to protect forest vegetation types and recreation settings for hunting. Although Zone 2 is generally available for oil and gas leasing, parcels must be leased in pairs and require a Master Development Plan to minimize impacts to big game. In order to achieve economically viable production within the Absaroka Front MLP Analysis Area while complying with the restrictions described above, it may be necessary for operators to utilize directional and/or horizontal drilling techniques from multi-well pads, which could increase project costs.

Alternative D applies a NSO restriction within ½-mile of big game migration corridors within the Big Horn Front MLP Analysis Area, which would result in similar adverse impacts as Alternative B. The application of CSU and TLS stipulations, minimum lease size requirements (1,280 acres), and limitations on the density (one location per lease) and total acreage of oil and gas-related surface disturbance (64 acres per lease), would result in similar adverse impacts to oil and gas development as described for elk crucial winter range within Zone 1 of the Absaroka Front MLP Analysis Area.

MLP stipulations on oil and gas development, particularly in areas outside of elk crucial winter range, could result in adverse impacts by limiting exploration and development opportunities and requiring additional mitigation measures that could increase project costs. However, because of the generally low to very low potential for oil and gas development across the majority of the Absaroka Front and Big Horn Front MLP Analysis Areas (99 percent and 100 percent, respectively) and redundancies with restrictions from the management of other programs, the potential for adverse impacts specifically from MLP management would be limited. Overall, the application of MLPs to the Absaroka Front and Big Horn Front MLP analysis areas could result in additional adverse impacts compared to management

under alternatives A and C, which apply less extensive TLS and/or CSU restrictions in big game crucial winter range and migration routes. Management of the Absaroka Front and Big Horn Front MLP analysis areas would result in fewer adverse impacts than management under Alternative B, which closes the entirety of the Absaroka Front MLP Analysis Area to mineral leasing and applies NSO restrictions to big game crucial winter range in the Big Horn Front MLP Analysis Area. Additionally, Alternative D generally allows OHV use within 300 feet of established roads for notice of staking level casual use actions in areas limited to designated road and trails in the Big Horn Front MLP Analysis Area, whereas Alternative B prohibits these actions.

Similar to Alternative B, seasonal wildlife limitations would also apply to project maintenance and operation (including production) activities. Potential adverse impacts from this management would be the same as described under that alternative.

Under Alternative D, surface-disturbing activities are prohibited within 500 feet and avoided up to ¼ mile if needed to protect sensitive resources of perennial surface waters and riparian/wetland areas. Impacts to oil and gas development would be similar to those described for Alternative A. Additionally, avoiding surface-disturbing activities would further prohibit the activity unless the impacts could be mitigated, thus increasing project timeframes and costs associated with mitigation or making oil and gas resources in these areas uneconomical to develop. This would be an adverse impact on oil and gas development.

The types of impacts to oil and gas development from VRM under Alternative D would be similar to those described for Alternative A, although the extent of these impacts would be greater because more area is managed as VRM Class I and Class II under this alternative. Of the areas available for oil and gas leasing, 35,701 acres are in VRM Class II areas, 133,742 acres are in VRM Class III areas, and 542,980 acres are in VRM Class IV areas. The nature and extent of impacts from VRM to oil and gas exploration and development would vary according to the development potential of the subject lands. Of the areas available for oil and gas leasing, VRM Class II areas include approximately 75,428 acres defined as having moderate oil and gas development potential. Approximately 182,737 acres are classified as low-potential lands and approximately 809,339 acres are classified as very-low-potential lands. Under Alternative D, VRM Class II areas in moderate development potential areas increase by approximately 60,760 acres compared to Alternative A.

Proactive Management

Alternative D designates Oil and Gas Management Areas on 441,662 acres (124,683 acres less than under Alternative C) to be managed primarily for oil and gas exploration and development. Designating Oil and Gas Management Areas would result in similar, but less beneficial impacts, than Alternative C due to the reduced acreage under this alternative. Alternative D also may require additional reclamation or compensatory offsite mitigation in Oil and Gas Management Areas where the level and density of development exceeds existing field development and requires that oil and gas development in the Oregon Basin Oil Field results in no net gain of surface disturbance. These stipulations could have an adverse impact by limiting the pace and increasing the costs of development in Oil and Gas Management Areas under Alternative D, whereas Alternative C includes no such restrictions.

Alternative E

Resource Uses

Under Alternative E, lands open to leasing subject to standard lease stipulations, open with constraints, and closed to oil and gas leasing, as well as associated projections of new well development, are similar to Alternative B (Map 22).

Impacts to oil and gas exploration and development from resource uses under Alternative E would be the similar to Alternative B, except within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), where impacts would be greater due to additional constraints on ROW development and surface disturbance. Alternative E would manage a total of 1,610,729 acres as ROW avoidance areas and 1,322,879 acres as ROW exclusion areas, which is greater than any other alternative and would result in the most adverse impacts to oil and gas development.

The management of the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres) is the single largest contributing factor to the increase in ROW exclusion areas under Alternative E, compared to Alternative B. The size of ROW exclusion areas under this alternative (42 percent of the BLM-administered surface in the Planning Area) may affect the ability of project proponents to site future ROWs across BLM-administered lands for projects such as CO₂ for enhanced oil recovery operations or new transmission lines outside of existing corridors. The extensive exclusion areas under Alternative E may also increase the concentration of linear ROWs on and through private lands compared to the other alternatives. Where such exclusion areas occur in large, contiguous blocks (such as the Greater Sage-Grouse Key Habitat Areas ACEC), finding practicable alternative routes that avoid BLM-administered lands may be difficult.

Surface disturbances would be limited to one disturbance per 640 acres and less than 3 percent of the total sage-grouse habitat (subject to valid existing rights), compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. However, the BLM anticipates that even with these additional restrictions, oil and gas wells would be developed and ROWs across BLM-administered land would be approved at the same rate as Alternative B, and impacts would be similar to Alternative B.

As with Alternative B, the BLM does not suspend existing non-producing oil and gas leases in areas closed to mineral leasing and, after such leases expire, would not offer the land for future leasing under Alternative E. However, Alternative E would result in additional adverse impacts to the development of existing oil and gas leases in the Greater Sage-Grouse Key Habitat Areas ACEC (Map 27). Specifically, upon the expiration or termination of existing leases, nominations or expressions of interest for parcels would not be accepted in this ACEC, resulting in greater losses of future oil and gas development opportunities when compared to the other alternatives. Additional conservation measures and appropriate Fluid Mineral best management practices (BMPs) would also apply in the Greater Sage-Grouse Key Habitat Areas ACEC on split estate.

Alternative E would also close the proposed Greater Sage-Grouse Key Habitat Areas ACEC to geophysical exploration, which would limit the use of seismic technology to obtain subsurface stratigraphic and structural information useful for exploration of oil and gas reserves to a greater extent than any other alternative.

CTTM designations for motorized vehicle use are the same as Alternative B, and impacts to oil and gas development would be the same as Alternative B.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), would be the same as Alternative B, and impacts would be similar to Alternative B. Due to the relative size and additional restrictions on surface-disturbing activities, ROW development, and geophysical exploration applied for the Greater Sage-Grouse Key Habitat Areas ACEC, special designation management under Alternative E would result in the most adverse impacts to oil and gas exploration and development of any alternative. Table 4-19 shows the acreages of closures due to special designations and other management under this alternative.

Resources

Restrictions for resource protection are the same as Alternative B, except within the Greater Sage-Grouse Key Habitat Areas ACEC, which applies management actions for the conservation of greater sage-grouse habitat. Restrictions implemented in this ACEC with adverse impacts to oil and gas development would include closure of the area to geophysical exploration and new ROW development, and a lower threshold on allowable surface disturbance. Alternative E also places additional restrictions on the development of infrastructure, such as impoundment ponds/pits, reserve pits, evaporations ponds, and other activities associated with oil and gas development, that could result in the contamination of sensitive water resources. Restrictions and constraints on oil and gas development resulting from management actions to protect resources would therefore be the greatest under Alternative E.

Alternative F

Resource Uses

Under Alternative F, lands closed to oil and gas leasing and open to oil and gas leasing subject to the terms and conditions of the standard lease form are similar to Alternative D. However, Alternative F applies an NSO stipulation within 0.6 mile of occupied sage-grouse leks in the proposed Greater Sage-Grouse PHMAs ACEC and limits anthropogenic disturbances to, on average, no more than one per 640 acres and no greater than 3 percent loss of sagebrush habitat within this ACEC, compared to 5 percent in Alternative D. These management actions would result in greater adverse impacts to oil and gas exploration and development relative to alternatives A and D. Under Alternative F, 1,191,215 acres of federal mineral estate are open to oil and gas leasing subject to major constraints (Map 23), which constitutes an increase over alternatives A, B, C, and E (25 percent, 22 percent, 92 percent, and 18 percent, respectively), and a 2.5 percent decrease compared to Alternative D.

Federal mineral estate open to oil and gas leasing subject to moderate constraints are decreased under Alternative F (1,709,652 acres) in comparison to Alternative D (1,714,685 acres), (Map 23).

Implementing Alternative F would result in a 4.5 percent increase in area managed with moderate constraints compared to Alternative A, a 410 percent increase compared to Alternative B, a 28 percent increase compared to Alternative C, a 0.3 percent increase compared to Alternative D, and a 435 percent increase compared to Alternative E.

As a result of the restrictions implemented under Alternative F, projected drilling is reduced from the baseline projections. The baseline scenario projects that 1,354 federal wells could be drilled (1,249 conventional wells and 105 CBNG wells). Under Alternative F, 1,141 federal wells are projected (1,062 conventional wells and 79 CBNG wells). This represents an approximately 16 percent decrease from the baseline, or 187 fewer federal conventional wells and 26 fewer federal CBNG wells. Under Alternative F, 173 fewer federal wells (both conventional and CBNG) are expected to remain in production at the end

of the planning period than projected in the baseline scenario. This represents an approximately 44 percent decrease. Abandonment of federal wells is expected to decrease (approximately 4 percent) from 957 wells under the baseline scenario to 917 wells under Alternative F (BLM 2009c; BLM 2013p). The projected number of total producing wells at the end of the planning period under Alternative F (3,054) would be less than under Alternative D (3,100), Alternative C (3,283), and Alternative A (3,182), but more than under alternatives B and E (2,680).

Management of the Greater Sage-Grouse PHMAs ACEC under Alternative F requires additional consideration and mitigation of impacts for leased mineral estate similar to management of Key Habitat Areas under Alternative E, but to a lesser degree (Map 23). Like Alternative E, the BLM requires a full reclamation bond to insure restoration of disturbed areas to their original condition in the Greater Sage-Grouse PHMAs ACEC and places greater limitations on surface-disturbing activities. Additional conservation measures and appropriate Fluid Mineral BMPs also apply in the Greater Sage-Grouse PHMAs ACEC on split estate. However, unlike Alternative E, Alternative F considers waivers to these stipulations where resource uses do not preclude the achievement of sage-grouse habitat objectives.

Under Alternative F, the BLM manages 2,315,730 acres as ROW avoidance areas and 133,734 acres as ROW exclusion areas. The management of ROW avoidance and exclusion areas would result in the same impacts to those described for Alternative D. However, the BLM anticipates that even with these additional restrictions, ROWs across BLM-administered land would be approved at the same rate as Alternative D, and impacts would be similar to Alternative D.

Similar to Alternative D, geophysical exploration is subject to limitations on motorized vehicle use and restrictions on surface-disturbing activities under Alternative F; however, Alternative F applies additional limitations within the proposed Greater Sage-Grouse PHMAs ACEC, where geophysical exploration is allowed only by helicopter-portable drilling methods in accordance with seasonal timing restrictions. Alternative F CTTM is the same as Alternative D, except that travel within greater sage-grouse PHMAs is limited to designated roads and trails. Impacts from Alternative F would be the same as Alternative D, except in PHMAs where impacts would be more adverse due to additional access constraints. As under all the management alternatives, authorized or permitted uses that specify allowable access are not precluded by travel management designations.

Special Designations

Impacts to oil and gas exploration and development from special designations under Alternative F would be the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres), where more adverse impacts would result due to additional restrictions on surface disturbance, geophysical exploration, and motorized vehicle use. Similar to Alternative D, the impacts from this alternative would be more adverse than alternatives A and C, and less adverse than alternatives B and E. Table 4-19 shows the acreages of closures due to special designations and other management under this alternative.

Resources

Except for lands within the Greater Sage-Grouse PHMAs ACEC, impacts to oil and gas exploration and development from management actions to protect resources would be similar to Alternative D. However, Alternative F limits surface disturbances to one per 640 acres and 3 percent or less of the Wyoming DDCT analysis area, compared to 5 percent under Alternative D. Overall, additional protections for greater sage-grouse under Alternative F would result in more adverse impacts to oil and gas development than alternatives A, C, and D, but less than alternatives B and E.

Proactive Management

The designation and management of Oil and Gas Management Areas under Alternative F is the same as for Alternative D (Map 25); however, in areas where the Oil and Gas Management Area is overlapped by the Greater Sage-Grouse PHMA ACEC, management for the latter would be applied, resulting in more adverse impacts to oil and gas exploration and development.

4.2.6 Leasable Minerals – Other Solid Leasable Minerals

No other solid leasable minerals are currently leased or produced in the Planning Area. Other solid leasable minerals in the Bighorn Basin are not currently considered economically viable to produce (BLM 2009d). Future demand for other solid leasable minerals will likely increase over time in parts of Wyoming and the U.S. West, but this is not anticipated to result in any new leasing or production in the Planning Area (BLM 2009d). See Section 4.2.2 *Leasable Minerals – Coal* and Section 4.2.3 *Leasable Minerals – Oil Shale* for information on these solid leasable minerals.

4.2.6.1 Analysis of Alternatives

Under alternatives B, D, E, and F, known tar sand deposits/areas, including Sherard Dome and Trapper Canyon, would be closed to leasing. However, the BLM does not anticipate new leasing or development of tar sands, or anticipates only minimal interest in these deposits, during the planning period. Therefore, the BLM anticipates only minimal adverse or beneficial impacts to the exploration or development of these resources under any alternative.

4.2.7 Salable Minerals

Implementing management actions under the alternatives may result in direct impacts that open, limit or deny access to and disposal of mineral materials from public lands in the Planning Area. Adverse impacts to mineral materials disposal can result from management actions that restrict or limit disposals of mineral materials, or that place specific stipulations or mitigation requirements on development activity. Beneficial impacts to mineral materials disposal can result from management that encourages such disposal or opens areas to disposal.

Indirect impacts result from actions that place or remove restrictions or place additional requirements on exploration and development activities for mineral materials. For example, a VRM restriction to protect the integrity of a historic trail that could either prevent or constrain exploration or development of mineral materials, or one that requires the development activity be performed so that it is not readily apparent.

Short-term impacts may include such seasonal restrictions to accessing mineral material resources to protect greater sage-grouse, or delays caused by requiring completion of resource surveys (such as cultural resources) before commencing mining operations. Long-term impacts may include transferring federal mineral estate, including the mineral materials therein, to private ownership, thereby potentially removing the resource from public access.

4.2.7.1 Methods and Assumptions

This analysis focuses on the impacts to mineral materials as a whole in the Planning Area. However, because sand and gravel are the principal salable minerals found in commercial quantities in the

Planning Area, wherever possible, this analysis describes specific impacts to the disposal of sand and gravel. Acreages of occurrence and potential for other mineral materials, such as limestone, were not available at the time of analysis.

The BLM based this analysis on occurrence potential (referred to as “potential” in this analysis) for minerals identified in the *Solid Mineral Occurrence and Development Potential Report, Bighorn Basin Resource Management Plan Revision Project* (BLM 2009d). “Potential” refers to the potential for or the presence (occurrence) of a concentration of one or more mineral resources. It does not refer to or imply potential for development and/or extraction of the mineral resource(s). It does not imply that the potential concentration is or may be economic (i.e., could be extracted profitably). The mineral potential classification system is based on the level of potential and the level of certainty of data supporting the possible existence of minerals. The system classifies level of potential as No (O), Low (L), Moderate (M), High (H), and Not Determined (ND). The system classifies level of certainty as A (lowest certainty), B, C, and D (highest certainty). See *Glossary* or the *Solid Mineral Occurrence and Development Potential Report, Bighorn Basin Resource Management Plan Revision Project* (BLM 2009d) for more information on the mineral potential classification system.

Methods and assumptions used in this impact analysis include the following:

- Existing BLM-approved mineral material sites will remain open to mineral materials disposal.
- The potential for occurrence of mineral materials exists across the Planning Area.
- New mineral materials disposal sites in areas open to mineral materials disposal will be subject to site-specific analysis prior to approval.
- In most cases, demand for mineral materials during the planning period will be directly proportional to the rate of other resource development in a given area. New disposals could be requested to establish closer proximity to development areas, since generally, mineral materials are of low unit value compared to their cost to transport them from source to market.
- The BLM has discretionary authority to permit mineral materials disposal. It may choose to approve or disapprove such sales or permits, on a case-by-case basis, within the Planning Area.
- Common varieties of mineral materials are considered salable under the Materials Act of 1947. Uncommon varieties of such minerals may be locatable and subject to administration under the mining laws, as amended.
- Disposal of topsoil from public lands is prohibited.
- Area closures and surface and timing restrictions could result in adverse impacts by reducing access to mineral materials.
- Known sand and gravel deposits (Map 29), with a rating of high (H) and a certainty level of D, occur particularly along major drainages throughout the Planning Area and are depicted on Map 15 of the *Solid Mineral Occurrence and Development Potential Report, Bighorn Basin Resource Management Plan Revision Project* (BLM 2009d). There are about 352,472 acres of sand and gravel with a known or potential for occurrence in the Planning Area. Refer to the *Solid Mineral Occurrence and Development Potential Report, Bighorn Basin Resource Management Plan Revision Project* (BLM 2009d) for additional, detailed maps of mineral materials potential within the Planning Area.

- Sand and gravel deposits with an occurrence potential rating of moderate and certainty level of C (M/C) exist in small quantities on the western portion of the Planning Area. There are approximately 347,450 acres of known occurrence and 5,022 acres of potential occurrence of sand and gravel in the Planning Area. The remainder of the Planning Area has a rating of low (L) with a certainty level of C (L/C).
- Sand and gravel deposits, which are likely to be developed, appear to be available in sufficient quantity and quality to sustain moderate to large increases in local and regional needs.
- Scoria (clinker) may be found associated with coalbeds which occur in the Mesaverde, Meeteetse, and Fort Union formations. Potential for the occurrence of scoria in the vicinity of these formations was rated as high (H) in the Gebo, Grass Creek, and Meeteetse coal fields with a certainty level of C (H/C).
- The potential for future commercial mining of scoria (clinker) from BLM-administered lands or mineral estate in the Planning Area is estimated to be moderate wherever these resources may be found and available.
- Known common-variety limestone within the Madison Formation has an occurrence potential of high (H) with certainty of D (H/D). Such occurrences are located along parts of the perimeter of the Planning Area. In the remainder of the Planning Area, the potential for limestone occurrence (not including limestone fragments found in colluvium, terrace, or alluvial deposits), is rated as low (L) with a certainty level of C (L/C).
- The development potential for continued and future commercial mining of common-variety limestone from federal mineral estate in the Planning Area is estimated to be moderate to high.
- The potential for the occurrence of common clay is rated as moderate (M) with a certainty level of C (M/C).
- The potential for future commercial mining of common clay from federal mineral estate in the Planning Area is estimated to be low to moderate.
- Throughout the Planning Area, weathered sandstone, siltstone, limestone, and granite covered in part with lichens are present. Sandstones and siltstone outcrops in the Morrison, Cloverly, Mesaverde, Lance, and Fort Union formations are commonly considered to be moss rock if they are partially adorned with colorful lichens. In these formations, there is a high (H) potential for moss rock with a certainty level of D or C (H/D or H/C). Potential for moss rock occurrence in other parts of the Planning Area is rated as low (L) to moderate (M) with a certainty level of B (L/B to M/B).
- The potential for future commercial development of moss rock from federal mineral estate in the Planning Area is estimated to be high in areas where resources exist, and are available for disposal.
- In the Planning Area, flagstone is a mineral material that is typically found in the Chugwater, Cloverly, Sundance, Mesaverde, and Fort Union formations. In outcrops of the lowermost Sundance Formation, occurrence potential for flagstone is high (H) with a certainty level of C (H/C). Elsewhere in the Planning Area, the potential for flagstone is rated as low (L) to moderate (M) with a certainty level of C (L/C to M/C).
- The potential for future commercial development of flagstone from federal mineral estate in the Planning Area is estimated to be high in areas where flagstone resources exist, and are available for disposal.

- Potential for petrified wood to be found mixed in with Quaternary terrace or alluvial deposits, after having been transported from the Absaroka Mountains, is moderate (M) to high (H) with a certainty level of C (M/C to H/C).
- The potential for future commercial development of petrified wood from federal mineral estate in the Planning Area is estimated to be low.

4.2.7.2 Summary of Impacts by Alternative

Principal impacts to the development of mineral materials (e.g., sand and gravel) result from management that prohibits or limits (adverse impacts) or opens (beneficial impact) areas to mineral materials disposal. Such management commonly includes restrictions on surface-disturbing activities or closures to mineral materials disposal. Alternative E would result in the greatest adverse impacts to mineral materials, as this alternative closes 3,144,151 acres to mineral materials disposal, including areas within 0.25 mile of riparian/wetland areas, lands with wilderness characteristics managed to maintain their wilderness characteristics (471,727 acres), and some ACECs. Closures under alternatives B (2,590,220), D and F (374,894 acres), C (343,962 acres), and A (228,649 acres) would result in decreasing adverse impacts to mineral materials disposal.

4.2.7.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Restrictions on development of mineral materials may result in adverse impacts to exploration and development activities when either closures or prohibitions to surface-disturbing activities apply, because the mineral materials could not be accessed. The intensity of impacts is anticipated to vary by alternative. The more acreage closed or prohibited from surface disturbance, the more the adverse impacts to this development of mineral material resources. In addition, closing areas to mineral materials with known or moderate potential would result in more adverse impacts than closing areas with no or low potential.

Management actions common to all alternatives that would adversely affect mineral materials disposal include closing cave and karst areas and WSAs to mineral materials disposal and prohibiting surface disturbance in the Bighorn River Habitat Management Plan (HMP)/Recreation Area Management Plan (RAMP) tracts and parts of the Yellowtail Wildlife Habitat Management Area. Discussions of individual alternatives describe adverse impacts from closures or prohibitions to surface disturbance.

Under all alternatives, new mineral materials disposal in areas open to mineral materials disposal are subject to site-specific analysis before approval. Approval of mineral materials disposal would require appropriate mitigation and site-specific reclamation fees based on a current mining and reclamation plan. The application of mitigation and a site-specific reclamation fee may prescribe certain activities or mitigation that could reduce the economic viability of mineral materials disposal and result in adverse indirect impacts to mineral materials disposal.

Prohibiting the disposal of topsoil in the Planning Area would result in impacts to mineral materials resources. Adverse impacts would result from the continued unavailability to disposal of this mineral materials resource via sale, permit, or free use to qualified entities.

Alternative A

Alternative A would close a total of 228,649 acres, 5 percent of federal mineral estate in the Planning Area, to mineral materials disposal (Map 30). Closing these areas to mineral materials disposal would prohibit the development of mineral materials in these areas, if such deposits were present in a closed area. This may result in long-term adverse impacts to such disposals. Management that prohibits surface-disturbing activities and closes areas to the disposal of mineral materials would result in more adverse impacts in areas with known or moderate potential for the occurrence of mineral materials.

Disposal of sand and gravel would be closed on 19,051 acres with known and potential occurrence in the Planning Area (Map 29).

Resource Uses

Under Alternative A, surface-disturbing activities including mineral materials disposal would be prohibited to protect certain recreational uses, including fishing and hunting access areas (8,025 acres), Five Springs Falls Campground (40 acres), the Cody archery range (102 acres), and certain R&PP lease areas.

Surface-disturbing activities in The Rivers SRMA would be prohibited. Development of mineral materials may be allowed, on a case-by-case basis, in the following areas: Absaroka Foothills, Bighorn River, and West Slope SRMAs, and the Tour de Badlands, Tatman Mountain, Trapper Creek, Paint Rock, Brokenback/Logging Road, South Bighorns, Canyon Creek, Red Canyon Creek, McCullough Peaks, Horse Pasture, Beck Lake, and Newton Lake Ridge areas.

Special Designations

Closures/prohibitions of surface-disturbing activities resulting from special designations under Alternative A that would adversely affect mineral materials disposal include the fossil-concentration area in the Big Cedar Ridge ACEC (264 acres), Red Gulch Dinosaur Tracksite (1,798 acres) and WSAs (141,068 acres). Closures for segments of certain WSR eligible waterway segments comprise approximately 20,000 acres. This alternative also requires the avoidance of surface-disturbing activities in areas in view within ¼ mile of the Nez Perce (Neeme-poo) NHT and significant segments of Other Trails, potentially placing additional stipulations or mitigation on development activity occurring in those areas.

Resources

Management actions for resources that restrict, prohibit, or limit mineral materials disposal would prevent development in these areas. This would result in adverse impacts to mineral materials disposal. Mineral materials disposal are prohibited within 500 feet of surface water and riparian/wetland areas, except where the activity can be mitigated. Mineral materials disposal may be restricted to protect important cultural sites on a case-by-case basis. In addition, on-the-ground surveys and monitoring of surface-disturbing activities for all Potential Fossil Yield Classification (PFYC) 4 and 5 formations and, on a case-by-case basis, PFYC 3 formations, and prohibitions against resuming activities within 50 feet of a paleontological discovery until the BLM authorized officer so allows, may delay development of the resource or require the relocation of facilities.

Mineral materials disposal would be required to conform to the visual objectives that correspond to each area's VRM classification. Under Alternative A, approximately 481,911 acres, or 15 percent, of BLM-administered surface is designated as VRM Class I and II areas where changes to the characteristic landscape should be low. Adverse impacts may result where placement and design of facilities and pits associated with salable mineral mining activity would have to be redesigned, resulting in increased

project costs. Where impacts could not be mitigated, these areas would be effectively closed to mineral materials disposal. The remainder of the Planning Area is classified as VRM Class III or IV, where activities would generally be allowed subject relatively reduced visual mitigation measures.

Alternative B

Closing public lands to mineral materials disposal would result in similar impacts as those described for Alternative A, although to a greater extent because more land would be closed. Alternative B would close or prohibit surface disturbance, therefore prohibiting mineral materials disposal on a total of 2,590,220 acres, or 62 percent, of federal mineral estate in the Planning Area (Map 31); Alternative B closes 2,361,571 more acres to mineral materials disposals than Alternative A.

Disposal of sand and gravel would be closed on 223,378 acres of land with a known or potential for occurrence under Alternative B (Map 29). The amount of area closed to sand and gravel disposal in known and potential areas is greater than under Alternative A, which would result in more adverse impacts to mineral materials.

Resource Uses

Under Alternative B, the BLM would prohibit surface-disturbing activities including mineral materials disposal to protect recreational uses, as described under Alternative A for fishing and hunting access areas, the Five Springs Falls campground, the Cody archery range, and certain R&PP lease areas. In addition, surface-disturbing activities are prohibited in the following recreation management areas: the Red Canyon Creek, the West Slope, Canyon Creek, McCullough Peaks, Horse Pasture, Beck Lake, Newton lake Ridge, and The Rivers SRMAs, as well as the Tour de Badlands, Tatman Mountain, Trapper Creek, Paint Rock, and Brokenback/Logging Road RMZs.

The Absaroka Foothills and Bighorn River SRMAs, and the Basin Gardens Play Area RMZ and Basin Gardens RMZ, are closed to the development of mineral materials under this alternative.

Special Designations

The management of special designations under Alternative B would result in greater adverse impacts on the disposal of mineral materials than Alternative A due to the severity of restrictions and the larger number of these areas. Specific closures/prohibitions of surface-disturbing activities resulting from special designations include the fossil-concentration area in the Big Cedar Ridge ACEC and the Brown/Howe Dinosaur Area, Carter Mountain, Five Springs Falls, Chapman Bench, Clarks Fork Basin/Polecat Bench, Clarks Fork Canyon, Foster Gulch Paleontological Area, McCullough Peaks South Paleontological Area, Rainbow Canyon, Rattlesnake Mountain, and Sheep Mountain ACECs, approximately 200,000 acres. Other closures/prohibitions include within 3 miles and in view within 5 miles of the Heart Mountain Relocation Center National Historic Landmark, the Nez Perce NHT, and Other Trails, as well as all land in WSAs (141,068 acres). Additionally, closures along segments of certain WSR suitable waterway segments comprise approximately 20,000 acres.

Under Alternative B, all lands with wilderness characteristics would be managed to preserve their wilderness characteristics and would be closed to the disposal of mineral materials. Closures on these lands comprise 476,349 acres. In comparison, Alternative A does not include specific management for mineral materials disposal in lands with wilderness characteristics.

Resources

Management actions for resources that restrict, prohibit, or limit mineral materials disposal would prevent development in these areas. This would result in adverse impacts to mineral materials disposal.

Under Alternative B, adverse impacts to mineral materials would generally be greater than under Alternative A.

Disposal of mineral materials would be prohibited within ¼ mile of riparian/wetland areas, Blue or Red Ribbon waters (trout streams), certain rivers, big game crucial winter range (1,324,371 acres), and within ¼ mile of waters containing special status fish species.

Mineral materials disposal would be prohibited within 3 miles and in view within 5 miles of important cultural resources. Management to protect paleontological resources may have a greater effect under Alternative B than the other alternatives, because surveys and monitoring would be required for surface disturbance in PFYC 3, 4, and 5 formations, and permission from the authorized officer would be required to resume activities within 100 feet of a paleontological discovery.

VRM Class I and II areas under Alternative B would constitute 1,939,213 acres, or 61 percent, of BLM-administered surface. Impacts to mineral materials disposal would be similar to Alternative A, although to a greater extent because more acreage would be subject to increased VRM restrictions. Alternative B would result in more impacts from constraints associated with VRM classifications than Alternative A.

Alternative C

Closing areas to mineral materials disposal would result in similar impacts as those described for Alternative A, although to a greater extent because more area is closed. Alternative C would close or prohibit surface disturbance on a total of 343,962 acres, or 8 percent, of federal mineral estate in the Planning Area to the disposal of mineral materials (Map 32), more acreage than under alternatives A and less acreage than under Alternative B.

Disposal of sand and gravel is closed on 36,940 acres with known or potential occurrence areas in the Planning Area under Alternative C (Map 29). The acreage closed to sand and gravel disposal in known and potential areas is more than under Alternative A, but less than under Alternative B.

Resource Uses

Managing resource uses under Alternative C would result in the least adverse impacts to mineral materials disposal compared to the other alternatives. Mineral materials operations in the following recreational use areas could be allowed on a case-by-case basis: fishing and hunting access areas, the Five Springs Falls campground, the Cody Archery Range, and certain R&PP lease areas.

Special Designations

Management of special designations under Alternative C would have the least adverse impact on the disposal of mineral materials in relation to the other alternatives. Specific mineral materials disposal closures under this alternative include within ¼ mile and in view within 1 mile of the Heart Mountain Relocation Center National Historic Landmark, the Nez Perce NHT, and Other Trails (with exceptions), as well as on lands in WSAs (141,068 acres). ACECs and other special designations would not adversely affect mineral materials under Alternative C, except in the Brown/Howe Dinosaur Area ACEC, where mitigation, paleontological sensitivity surveys, and monitoring are required for surface-disturbing activities.

Resources

Management actions for resources that restrict, prohibit, or limit mineral materials disposal would prevent development in these areas. This would result in adverse impacts to mineral materials disposal.

Under Alternative C, adverse impacts to mineral materials disposal would generally be less than under the other alternatives.

Under Alternative C, mineral materials disposal would be allowed in flood plains or riparian/wetland areas on a case-by-case basis.

Areas within ¼ mile and in view within 1 mile of important cultural sites would be closed to disposal of mineral materials. Impacts from management to protect paleontological resources would be similar to Alternative A, except that potential delays due to surveying and monitoring of surface-disturbing activity would affect a smaller area because this management applies only in PFYC 5 areas.

VRM Class I and II areas under Alternative C would constitute 474,003 acres, or 15 percent, of BLM-administered surface. Impacts to mineral materials disposal would be similar to Alternative A, although to a lesser extent because less acreage would be subject to VRM Class I and II restrictions. Alternative C would result in the fewest impacts from constraints associated with VRM classifications.

Alternative D

Alternative D closes the least amount of land to mineral materials disposal, and therefore results in the least impacts to salable minerals compared to the other alternatives. Alternative D would close or prohibit surface disturbance, thereby excluding mineral materials disposal, on a total of 374,894 acres, or 4 percent, of federal mineral estate in the Planning Area (Map 33), the least of all alternatives.

Alternative D would close 41,227 acres to disposal of sand and gravel, including less than 1 percent of the areas where there is known or occurrence of sand and gravel (Map 29). The amount of area closed to sand and gravel disposal in known and moderate potential areas is the least of all alternatives, thereby resulting in the fewest adverse impacts.

Resource Uses

Under Alternative D, surface-disturbing activities are allowed, including salable minerals exploration and development, in recreational sites and trails on a case-by-case basis if the effects can be avoided or mitigated. While this would result in less of an impact than alternatives A and B, which prohibit surface-disturbing activities near recreation sites, an adverse impact would result from project delays and costs associated with mitigation. Similar impacts would result by requiring avoidance, minimization and/or compensation for all surface-disturbing activities in the following areas: Bighorn River SRMA and ERMA; West Slope of the Bighorns SRMA (including Canyons RMZ and Brokenback/Logging Road RMZ); Middle Fork of the Powder River SRMA; Canyon Creek SRMA; campgrounds, trailheads, day use areas, river access sites, and similar recreation sites in The Rivers SRMA; Basin Gardens Play Area SRMA; and the Horse Pasture SRMA.

Development of mineral materials may be allowed, on a case-by-case basis, in the following areas: Absaroka Mountain Foothills SRMA, Absaroka ERMA, Beck Lake SRMA, Newton Lake Ridge SRMA, Basin Gardens area, and Tour de Badlands and Tatman Mountain RMZs.

Special Designations

Based on the types of restrictions and acreage affected, Alternative D would result in the second-greatest extent of adverse impacts on the disposal of mineral materials from special designations. Specific closures/prohibitions of surface-disturbing activities resulting from special designations include the fossil-concentration area in the Big Cedar Ridge ACEC and the Five Springs Falls, Clarks Fork Canyon, Paleocene-Eocene Thermal Maximum (PETM), and Sheep Mountain ACECs, for a total of 34,279 acres.

Alternative D also would prohibit mineral materials disposal within the 72 acres of the Heart Mountain Relocation Center National Historic Landmark Urban Center, while surface-disturbing activities would be avoided within 3 miles of the Nez Perce (Neeme-poo) NHT and up to 2 miles of other Historic Trails. Under Alternative D, WSAs would be closed to mineral materials disposal (141,068 acres).

Resources

With the exception of activities within important greater sage-grouse habitats, such as within 0.6 mile of occupied leks in PHMAs and a 500-foot buffer for surface waters and riparian/wetland areas, few management actions explicitly prohibit surface-disturbing activities or mineral materials disposal to protect other resources under Alternative D. However, several management actions require avoidance and would prohibit surface-disturbing activity unless the impacts can be mitigated, resulting in adverse impacts to mineral materials disposal through increased costs and delays associated with mitigation. Under Alternative D, some of the areas where surface-disturbing activity must be avoided include areas up to ¼ mile if needed to protect surface waters and riparian/wetland areas; within ¼ mile of any WGFD-rated Blue or Red Ribbon fisheries; and within big game crucial winter range from November 15 through April 30.

Alternative D prohibits mineral materials disposal for resource protection in the Chapman Bench Management Area (3,425 acres).

Surface-disturbing activities would be avoided under Alternative D to protect the foreground of important cultural resources up to 3 miles. This would increase costs associated with mitigation or prohibit disposal if the impacts cannot be mitigated, which would adversely affect the disposal of mineral materials. Impacts from management to protect paleontological resources would be the same as Alternative A. Unlike A, permission from the authorized officer would be required to resume activities within 100 feet of a paleontological discovery.

VRM Class I and II areas under Alternative D would constitute 872,939 acres, or 27 percent, of BLM-administered surface. Impacts to mineral materials disposal would be similar to Alternative A, although to a greater extent because more acreage would be subject to more stringent VRM restrictions.

Alternative E

Under Alternative E, closing public lands to mineral materials disposal would result in similar impacts as Alternative B, although to a greater extent because more land would be closed. Alternative E would close areas or prohibit surface disturbance, therefore prohibiting mineral materials disposal, on a total of 3,144,151 acres, or 75 percent, of federal mineral estate in the Planning Area (Map 34). Alternative E represents the largest acreage of mineral materials closures compared to the other alternatives, and approximately 100 percent more acreage than Alternative A.

Disposal of sand and gravel would be closed on 261,552 acres of land with a known or potential for occurrence of sand and gravel under Alternative E (Map 29). The amount of area closed to sand and gravel disposal in known and moderate potential areas is greater under Alternative E than under any other alternative, which would result in more adverse impacts to mineral materials than the other alternatives. Specifically, these additional closures to sand and gravel disposal may eliminate existing sources of sand and gravel in the area, requiring the sourcing of these minerals from more distant sites.

Resource Uses

Closing public lands to mineral materials disposal would result in similar impacts as those described for Alternative B, although to a greater extent due to the closure of the Greater Sage-Grouse Key Habitat

Areas ACEC. Mineral materials closures outside this ACEC are the same as Alternative B, and impacts would be the same as Alternative B.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), would be the same as Alternative B, and impacts would be similar to Alternative B. Due to the relative size and additional restrictions on surface-disturbing activities applied for the Greater Sage-Grouse Key Habitat Areas ACEC, special designation management under Alternative E would result in the most adverse impacts to mineral materials disposal of any alternative.

Resources

Impacts to salable minerals from resource management actions would be similar to Alternative B, but slightly greater in the Greater Sage-Grouse Key Habitat Areas ACEC due to additional limitations on surface disturbance and closure of the area to mineral materials disposal for the protection of greater sage-grouse. Greater long-term adverse impacts would result from the requirement that salable mineral pits no longer in use be restored to meet sage-grouse habitat conservation objectives under Alternative E.

Alternative F

Management of salable minerals under Alternative F is the same as Alternative D (Map 33), and impacts would be consistent with those described under Alternative D.

Resource Uses

Impacts from the management of mineral materials disposal and surface-disturbing activities under this alternative would be the same as Alternative D in areas outside the Greater Sage-Grouse PHMAs ACEC. More adverse impacts would occur inside the ACEC, where anthropogenic disturbances are limited to one per 640 acres and no greater than 3 percent loss of sagebrush habitat within this ACEC, compared to 5 percent under Alternative D. This alternative would therefore result in greater adverse impacts to salable minerals than Alternative D, but less than alternatives A, B, and E, which close more areas to mineral materials disposal.

Special Designations

Impacts to mineral materials disposal from special designations under Alternative F would be the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres), where more adverse impacts would result due to additional restrictions on surface disturbance.

Resources

Impacts to salable minerals from resource management actions would be similar to Alternative D, but slightly more adverse within the Greater Sage-Grouse PHMAs ACEC due to additional limitations on surface disturbance. Similar to greater sage-grouse Key Habitat Areas under Alternative E, greater long-term adverse impacts would result from the requirement that salable mineral pits no longer in use be restored to meet sage-grouse habitat conservation objectives.

4.3 Fire and Fuels Management

This section describes potential impacts on fire and fuels management from management of other resource programs. Implementation of the alternatives would affect the planning, management, implementation, and cost of fire management. Direct impacts involve restrictions on fire and fuels management. Indirect impacts include actions resulting in a change in risk or incidence of wildland fires; size, intensity, or destructive nature of wildland fires; fire suppression costs; and fuel loading. For example, mechanical treatments used to manage or reduce fuel loads result in indirect impacts by reducing the risk or incidence of wildland fire.

Fire is an integral part of natural ecosystem function; however, the natural fire regime has been altered in the Planning Area. While the alteration of the natural fire regime (also referred to as Fire Regime Condition Class or Vegetation Condition Class) is considered an adverse impact to fire ecology, actions contributing to an increase in the incidence of wildfires or that limit the ability to effectively fight wildfires in areas where use of fire would not meet resource objectives are considered adverse impacts to fire management. For example, actions limiting fire suppression tactics, thereby resulting in large burn areas or more intense fires, would be considered adverse impacts. Management that increases the ability to effectively and efficiently respond to and control wildfires and management that helps meet resource objectives are considered beneficial impacts.

Management restricting the intensity and effectiveness of fuels treatments would result in increased fuel loading and increased fire hazard. Wildland fuels management objectives are to “manage fuels to restore and maintain landscapes, and promote fire-adapted communities and infrastructure. Fire and fuels management actions will focus on restoring natural fire regimes and frequencies, and accomplishing Desired Plant Community objectives” and to “restore natural fire regimes and frequencies to the landscape, and utilize fire and vegetation treatments to accomplish Desired Plant Community objectives.” Management that increases the effectiveness of and ability to meet these objectives would result in beneficial impacts.

For the purpose of this analysis, short-term impacts to fire and fuels management include impacts occurring within 5 years. Long-term impacts are those remaining or occurring after 5 years. The BLM anticipates short- and long-term impacts to fire and fuels management. Long-term impacts generally include impacts to the overall management of fire and fuels in the Planning Area. Short-term impacts to fire and fuels result from surface disturbance that increases the potential for the establishment of invasive species and other fuels.

The following description of impacts is organized into three sections: wildfires (unplanned ignitions), prescribed fires (planned ignitions), and stabilization and rehabilitation following fire. Methods and assumptions are described under the first section only, wildfires (unplanned ignitions), but apply to all three sections.

4.3.1 Wildfires (Unplanned Ignitions)

4.3.1.1 Methods and Assumptions

Wildland fire is a general term describing any non-structure fire that occurs in vegetation and/or natural fuels. In addition to discussions of impacts specific to wildfire management, this section also discusses general impacts that could apply to both wildfire and prescribed fire management. These general impact discussions use the term “wildland fire management” to indicate that they apply to both wildfire and prescribed fire management; impact discussions specific to wildfire management use that term.

The analysis of impacts on fire and fuels management is based on the following assumptions, which apply to wildfires, prescribed fires, and stabilization/rehabilitation:

- Wildfires in wildland urban interface areas typically will be suppressed with unlimited tactics.
- Suppression costs are expected to be similar between all the alternatives.
- Fire regime condition class (FRCC) inventories performed for the *Northern Zone Fire Management Plan* (BLM 2004b) are still accurate.
- Air quality currently is not affecting the ability to conduct prescribed burns; however, the more stringent air quality standards are, the more likely they will be to affect the ability to perform prescribed burns.
- Compared to limited tactics, unlimited tactics would reduce the amount of acres burned annually, but increase the amount of surface disturbance from suppression activities and result in the need for more rehabilitation of damage caused by suppression activities. Unlimited fire suppression tactics also alter the condition class of the vegetation by preventing wildfire to play its appropriate role in maintaining fire-adapted ecosystems.
- Nonnative species alter the risk of wildland fire. Current BLM policy is to ensure seeds used for rehabilitation are free of noxious weeds when reseeding is necessary.
- Annual bromes (e.g., cheatgrass) and invasive species can elevate the risk of fire and actually alter the natural fire regime; therefore, alternatives contributing to the invasion and spread of invasive species are anticipated to adversely affect fire and fuels management.
- In areas of cultural resource sensitivity, use of heavy equipment typically is limited to existing roads and trails, except where human safety is at risk.
- Cultural resource surveys are conducted, where applicable, for all prescribed burns, other fuel treatments, and rehabilitation.
- Current policy (BLM Manual 1745) requires use of native plant species for rehabilitation, except in certain situations (e.g., when native seeds are not available or resource management objectives cannot be met with native species).

4.3.1.2 Summary of Impacts by Alternative

All alternatives use wildland fires (wildfires managed for resource benefit and prescribed fires) to restore fire-adapted ecosystems and reduce hazardous fuels. Alternative C would result in the greatest potential for adverse impacts from human caused, unplanned ignitions due to increased access and additional travel routes. Conversely, Alternative C would also result in the greatest beneficial impacts from active fuels management (i.e., this alternative allows the widest use of fuels treatments) and the greatest ability to employ fire suppression tactics, followed by alternatives A, D, F, B, and E. Alternative C includes the greatest amount of mechanical fuels treatments by acreage (60,000 acres), followed by alternatives A, D, and F (30,000 acres each), and alternatives B and E (5,000 acres each), resulting in beneficial impacts to fire and fuels management by reducing fuels and thereby the potential for fire spread and severity. Fire suppression restrictions (e.g., prohibiting the use of heavy equipment on fragile soils) increase the potential for wildfire spread in the short term and may increase the need for stabilization and rehabilitation as more wildfires occur. However, intensive fire suppression that reduces the natural role of fire in the ecosystem may result in large catastrophic wildfires in the long term that require more intensive stabilization and rehabilitation activities. Under all of the alternatives, implementing the BLM Emergency Stabilization and Rehabilitation standards in the *BLM Burned Area Emergency Stabilization and Rehabilitation Handbook* (BLM 2007a) would prescribe activities that would

allow rehabilitation of areas following a wildfire and reduce the potential for future fires in burned areas.

4.3.1.3 Detailed Analysis of Alternatives

This section divides the analysis of impacts to fire and fuels management from the alternatives into three areas – impacts from restrictions from resources and special designations, impacts from resource uses, and impacts from proactive management actions. This analysis groups special designations with resources because the resource values within the special designations are the reason for management that would limit or restrict fire and fuels management techniques in these areas.

Impacts Common to All Alternatives

Restrictions from Resources and Special Designations

Although certain management of other resource programs and special designations may limit fire suppression tactics, in cases where human life or safety may be at risk, emergency fire suppression tactics would be used and would become a higher priority than any resource protection or management stipulations.

Avoiding the use of waters that contain high-risk aquatic invasive species for suppression activities (except in cases where public and firefighter safety are threatened) may limit fire suppression activities when other sources of water are unavailable or inadequate to meet fire suppression. This would adversely impact wildfire management.

Avoiding the aerial application of fire suppressant chemicals within 300 feet of perennial waters and restricting the use of fire retardant chemicals as appropriate to protect rock art and water quality would limit the potential to effectively control fires in these areas. This would adversely affect the management of wildland fires.

Suppressing fires that threaten greater sage-grouse habitats and crucial winter wildlife habitat within Wyoming big sagebrush communities and conducting fire management activities to minimize overall wildfire size and frequency in sagebrush plant communities where greater sage-grouse habitat objectives are at risk may create adverse impacts to fire ecology by affecting the natural fire regime in the ecosystem. Actions that suppress the natural role of fire in the ecosystem may result in fuels accumulation and eventually lead to larger and more intense fires. However, suppressing fires in these areas may also decrease the incidence of damaging wildfires to sagebrush habitat and greater sage-grouse and enhance the ability to manage fires in these areas. In some scenarios, a proactive fire management approach may be advisable (e.g., establishing fuels treatments at strategic locations to minimize the size of wildfire and limit further loss of greater sage-grouse habitat) and could result in long-term benefits to fire and fuels management by reducing the incidence and spread of wildfire in greater sage-grouse habitat.

Standard operating procedures would influence the way wildfire suppression tactics may take place within habitat deemed important for special status species. If additional species become listed under the ESA, it is likely that the conservation measures developed to protect and restore such species would have long-term impacts on the types and timing of vegetation treatments allowable within their important habitats.

Prohibiting the use of bulldozers in areas of important cultural resources or historic trails for fire suppression, unless an archeologist and/or resource advisor is present, may have adverse impacts on

fire and fuels management by limiting the ability to effectively fight wildfires in these areas depending on availabilities and response times of archeologists and/or resource advisors. Assigning an archeologist and/or resource advisor to all fires with heavy equipment employed beyond minimum impact suppression techniques may delay fire suppression activities and adversely impact fire management.

Under all alternatives, management of vegetation and invasive species would result in long-term impacts to fire and fuels management. Under all alternatives, vegetation that does not meet DPC has the highest risk of losing important ecosystem components. Mechanical treatment in these areas may not be sufficient to diversify fuel conditions and reduce the potential for wildland fire occurrence or spread. Management actions that limit the potential for the spread or establishment of invasive species would generally have a beneficial impact to fire and fuels management. As invasive species dominate plant communities, fuels tend to build up in these areas. In general, invasive species and grasses, such as cheatgrass, are highly flammable and their presence can result in increased incidence and spread of fire. Long-term adverse impacts to fire and fuels management may result from annual increases in invasive species establishment and spread. Establishment and spread of invasive species would result in alterations of the fire behavior and fire ecology in the Planning Area, and may change the management response to fire.

Under all alternatives, management for wildland fire in special designations would create long-term impacts to fire and fuels management. Typically, areas that include special designations (e.g., ACECs or eligible WSRs) include management that prohibits the use of fire suppression techniques, such as the use of heavy equipment or fire retardant and chemicals, that would affect the resources and characteristics for which the area is designated.

Resource Uses

Allowing the sale of permits to meet public demand for personal use of posts, poles, firewood, sawlogs, Christmas trees, and other vegetative products may reduce fuel loading in those areas. The reduction in fuel loading would decrease the complexity of suppression operations and increase firefighter and public safety.

Under all alternatives, land tenure adjustments may affect fire and fuels management due to ownership changes and the response to fire and fuels in lands managed by private or state owners. Isolated public land parcels within or near private lands may increase the complexity of BLM involvement in the suppression of wildfires and management of fuels, particularly in wildland urban interface areas. Land tenure adjustments that create larger blocks of public land by reducing inholdings would benefit BLM's fire and fuels management by decreasing such complexities.

The management of livestock grazing using the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N) would maintain enough fine fuels to allow for the use of wildland fire for resource benefit, where appropriate. In addition, adherence to these standards and guidelines would reduce the potential for conversion of healthy rangelands into invasive species (e.g., cheatgrass) dominated systems, which may reduce the frequency and spread of fires. Vegetation management actions to meet the *Wyoming Standards for Healthy Rangelands* would also result in a diversity of age-class, cover, and fuel loads in all plant communities that may reduce the size and intensity of wildfires in the long term.

Proactive Management

Under all alternatives, the response to wildland fire would be based on the ecological, social, and legal consequences of the potential action; the circumstances under which a fire occurs; the likely

Wildfires (Unplanned Ignitions)

consequences to firefighter and public safety and welfare; natural and cultural resources; and values to be protected.

Maintaining and implementing an FMP to address fire management on a landscape scale and to meet DPC objectives and resource management objectives would result in long-term beneficial impacts to fire and fuels management. The FMP would define a program to manage wildland fires based on the RMP and provides for firefighter and public safety; fire management strategies, tactics, and alternatives; and addresses values to be protected consistent with management objectives, activities in the area, and federal, state, and local laws and regulations.

Cooperating with other agencies and landowners to conduct landscape level fuel treatments would have beneficial impacts on fire and fuels management by enhancing coordinated fuels management and restoring fire-adapted ecosystems.

Reducing hazardous fuels in the wildland urban interface would result in long-term beneficial impacts to fire and fuels management by limiting the incidence and spread of fires in these areas. Reducing the incidence and spread of fire in wildland urban interface areas would reduce the complexity of managing wildfires that cross ownership boundaries. Protecting homes and other structures from wildfires would result in long-term impacts to fire and fuels management by requiring fire suppression or fuels treatments in these areas.

Achieving a balance between treating areas that have departed from the historic fire regime (FRCC 3) and areas that are functioning within an appropriate fire regime (FRCC 1) would result in beneficial impacts on fire and fuels management. Treatment in FRCC 3 areas to return the fire ecology to the appropriate historic fire regime, along with stabilization and rehabilitation, would help decrease fuel loading in these areas and reduce the potential for future catastrophic fires in areas that have departed from their historic fire regime. Treating areas that are functioning within an appropriate fire regime (FRCC 1) would ensure that fire and fuels management maintains resource objectives within these areas. Balancing treatments in these areas would allow for an effective approach to managing fires based on FRCC and the appropriate fire regime and ecology in these areas. To varying degrees, vegetation treatments under all the alternatives would result in improvement in FRCC in the Planning Area and movement towards DPC for the treated areas.

Alternative A

Surface Disturbance

Surface disturbance results in adverse impacts to fire and fuels management by increasing the potential for invasive species establishment and spread in disturbed areas and, subsequently, the occurrence and severity of unplanned ignitions. Under Alternative A, the BLM projects a total of 136,253 acres of short-term surface disturbance on BLM-administered land during the life of the plan. After reclamation, a total of 15,646 acres of long-term surface disturbance is projected under Alternative A.

Restrictions from Resources and Special Designations

The management actions restricting fire suppression and fuels management discussed below would result in adverse impacts to wildfire management under Alternative A.

Reviewing the impacts of fire suppression to special status plant species on a case-by-case basis may limit fire suppression tactics in these areas, and thus may result in adverse impacts to fire and fuels management.

Prohibiting the use of heavy equipment for fire suppression in the Red Gulch Dinosaur Tracksite ACEC, the Carter Mountain ACEC, the Five Springs Falls ACEC, and the Little Mountain ACEC would result in adverse impacts to fire and fuels management by limiting the available techniques for fire suppression and mechanical treatment in these areas. Management objectives in special designations and SRMAs would help guide the response to wildland fire under Alternative A.

Prohibiting the use of chemical and dye retardants in the Red Gulch Dinosaur Tracksite ACEC would limit the available techniques for fire suppression in these areas, which may result in adverse impacts to fire and fuels management by limiting the ability to suppress wildfires in these areas.

Prohibiting the use of motorized and mechanized vehicles to suppress fires in certain WSR eligible waterway segments in the WFO, and prohibiting fire retardant along BLM-administered land within certain WSR eligible waterway segments would result in adverse impacts to fire and fuels management. Prohibiting the use of motorized vehicles to suppress fires may limit response times and efficiency of fighting wildfires in these areas and lead to increased wildfire severity and spread. Prohibiting fire retardant within certain WSR eligible waterway segments would result in adverse impacts by limiting fire suppression techniques in these areas.

Managing areas as VRM Classes I (141,127 acres) and II (340,784 acres) may limit the type or location of hazardous fuels reduction techniques when they alter the visual character of the landscape. Such restrictions may lead to an increase in fire size and spread in VRM Class I and II areas and adjacent areas. Fire and fuels management may benefit in VRM Class III and IV areas, where a wider range of hazardous fuel reduction techniques with the potential to alter the visual character of the landscape would be allowed.

Resource Uses

Mineral resources development may affect fire and fuels management by developing new facilities and associated infrastructure. Such development may change BLM's response to wildland fire due to increased human presence (i.e., workers) and the location of facilities in the Planning Area. Mineral exploration and development may also result in adverse impacts by increasing the potential for human caused fires in these areas.

Using wildland fire to revitalize decadent forest stands, improve forest stand density, and increase cover would result in beneficial impacts to fire and fuels management by helping reach DPC objectives and restoring areas to FRCC 1 and 2. Allowing a variety of silvicultural practices and cutting methods under Alternative A would have beneficial impacts on fire and fuels management by increasing the options available for fuels treatments. Managing forests and woodlands to meet forest and rangeland health standards would reduce hazardous fuel accumulations and reduce the potential for catastrophic wildfires.

The designation of utility corridors and authorization of ROWs may have beneficial impacts on fire and fuels management by removing or reducing built up fuels and by serving as fuel breaks and fire lines. Utility corridors and access road ROWs may also result in beneficial impacts by providing access for firefighters and other fire and fuels management activities. Alternately, the designation of ROWs and increased human presence associated with the construction and use of ROWs may increase the potential for unplanned ignitions in the Planning Area.

Travel and transportation management would result in both adverse and beneficial impacts to the management of wildland fires. Travel designations that allow access may result in adverse impacts due to increased incidence of human caused fires. Allowing access to more remote locations may also increase the potential for fire in areas that are more difficult to respond to and where fires are

Wildfires (Unplanned Ignitions)

subsequently more difficult to control. Alternatively, travel routes may result in beneficial impacts by increasing access, response time, and flexibility in management when responding to fires.

Under Alternative A, management for recreation in the Planning Area would have long-term impacts to wildfires. Recreation use would result in the increased risk of human caused unplanned ignitions from campfires, vehicles, cook stoves, other recreation related activities. The risk of recreation-related wildfire would be highest around campgrounds, trailheads, and recreation management areas where recreational use is greatest.

Livestock grazing management would result in short-term and long-term impacts to fire and fuels management. Livestock grazing primarily affects the distribution, amount, height, and vigor of herbaceous species such as perennial grasses, which can determine fire characteristics. Livestock grazing can contribute to a reduction of fine fuels, which may reduce the spread of wildland fire. A decrease in fire spread may result in an increased accumulation of larger fuel sources such as shrub vegetation between fires, which may contribute to larger fires in the long term. Properly managed livestock grazing may also reduce flame length, fire line intensity, and rate of spread, which would have a beneficial impact on suppression activities. Fire line intensity and flame length are important measures of potential suppression success.

Proactive Management

Alternative A bases the response to wildland fire on ecological, social, and legal consequences; the circumstances under which a fire occurs; the likely consequences on firefighter and public safety and welfare; natural and cultural resources; and values to be protected.

Alternative A uses wildland fires (**wildfires managed for resource benefit and prescribed fires**) to restore fire-adapted ecosystems and reduce hazardous fuels. This use of wildland fire would reduce the need for mechanical fuels treatment and the potential for large-scale fires in the long term, while also helping to meet resource objectives. This would result in beneficial impacts to fire and fuels management. Under Alternative A, the BLM projects approximately 30,000 acres of mechanical fuels treatment would occur during the life of the plan (Appendix T). Mechanical fuels treatments would result in beneficial impacts to fire and fuels management by reducing fuel buildup, the potential for fire spread, and fire severity.

Alternative B

Surface Disturbance

Adverse impacts to fire and fuels management from surface disturbance would be similar to those described under Alternative A, though to a lesser degree. Under Alternative B, the BLM projects a total of **73,940** acres of short-term surface disturbance on BLM-administered land during the life of the plan. Implementing Alternative B would result in a 46 percent decrease in short-term surface disturbance on BLM-administered land compared to Alternative A. After reclamation, the BLM projects a total of **10,893** acres of long-term surface disturbance under Alternative B. Implementation of Alternative B would result in a 31 percent decrease in long-term surface disturbance on BLM-administered land compared to Alternative A.

Restrictions from Resources and Special Designations

Management actions restricting fire suppression, fuels management, or wildland fire planning would result in adverse impacts to wildland fire management. In general, restrictions on fire management for the protection of resource objectives are greater under Alternative B than under Alternative A.

Alternative B includes similar fire suppression and heavy equipment restrictions as Alternative A, with several exceptions. Alternative B prohibits fire suppression and the use of chemicals within ¼ mile of any known special status plant species population. In addition, restrictions on motorized vehicles to suppress fires and restrictions on the use of fire retardants apply to all WSR suitable waterway segments. Alternative B includes more special designations and recreation management areas, which would restrict the response to wildfire in these areas to protect the resource characteristics for which the areas were designated.

Adverse impacts to fire and fuels management from VRM allocations would be similar to those described under Alternative A, though to a greater extent due to more area allocated as VRM Class I and II under Alternative B.

Resource Uses

Under Alternative B, management actions for minerals would have similar impacts as those described under Alternative A, though to a lesser degree due to decreased minerals development under Alternative B.

Using natural processes to revitalize decadent forest stands, improve forest stand density, and increase canopy cover would result in short-term adverse impacts on fire and fuels management by limiting the use of some wildland fire as a fuels management technique. However, using natural processes for fuels management may result in long-term beneficial impacts by returning fire to its natural role in the ecosystem.

Impacts to fire and fuels management from the utility corridors designated under Alternative B would be similar to those under Alternative A, though to a lesser degree as less acreage is designated as ROW corridors. Managing more acreage as ROW avoidance and exclusion areas would reduce the prevalence of fuel breaks and fire lines but would also decrease human presence and the potential for unplanned ignitions.

The beneficial and adverse impacts to fire and fuels management from travel and transportation management under Alternative B would be similar to those described under Alternative A, though to a lesser degree due to increased restrictions and less area available for motorized travel.

Management for recreation would have similar impacts to fire and fuels management described under Alternative A, though to a greater degree. Alternative B includes fewer upgrades to sites already developed for recreational use, but the increased area managed as SRMAs—and associated new development—may increase the potential for unplanned ignitions in these areas due to increased recreation activity.

The types of impacts on fire and fuels management from livestock grazing would be similar to those described for Alternative A. However, all these impacts would occur to a much lesser degree because a larger area is closed to livestock grazing under this alternative (1,984,211 acres versus 5,009 acres under Alternative A).

Proactive Management

Under Alternative B, response to wildland fires may vary from full suppression in areas where fire is undesirable, to monitoring fire behavior in areas where fire can be used as a management tool, based on resource goals and objectives. Alternative B utilizes wildland fires and other treatments to restore fire-adapted ecosystems and to reduce hazardous fuels. Mechanical fuels treatments would be similar to those described under Alternative A, though to a lesser degree since only 5,000 acres are projected for mechanical fuels treatments under Alternative B (an approximately 83 percent decrease from

Wildfires (Unplanned Ignitions)

Alternative A) (Appendix T). Mechanical fuels treatment under Alternative B would result in fewer beneficial impacts than under Alternative A.

Although the use of fire suppression under Alternative B is more restricted than under Alternative A, the BLM anticipates that proactive management to employ wildland fire (wildfires managed for resource benefit and prescribed fires) to achieve management objectives and to restore fire-adapted ecosystems would result in long-term beneficial impacts to fire and fuels management throughout the Planning Area. Under Alternative B, the emphasis on restoring the natural role of fire in the ecosystem may result in adverse impacts in the short term as reduced mechanical fuel treatments may result in an increased incidence of fire. In the long term, it is unlikely that beneficial impacts to fire and fuels would result due to historic fire suppression activities, changes to fuel loading, and human occupancy and use of the Planning Area. Long-term restoration of natural conditions is less likely than under Alternative A. The greater restrictions on mechanical fuels treatments and suppression under Alternative B would result in greater potential adverse impacts to private lands as unplanned ignitions, and subsequent wildfires that may spread to private lands, are more likely under this alternative.

Alternative C

Surface Disturbance

Impacts to fire and fuels management from surface disturbance would result in similar impacts as those described under Alternative A, though to a greater degree. Under Alternative C, the BLM projects a total of 245,642 acres of short-term surface disturbance on BLM-administered land during the life of the plan. Implementing Alternative C would result in an 80 percent increase in short-term surface disturbance on BLM-administered land compared to Alternative A, a 233 percent increase compared to Alternative B. After reclamation, a total of 41,485 acres of long-term surface disturbance is projected under Alternative C. Implementing Alternative C would result in a 164 percent increase in long-term surface disturbance on BLM-administered land compared to Alternative A, a 282 percent increase compared to Alternative B.

Restrictions from Resources and Special Designations

Management actions restricting fire suppression, fuels management, or wildland fire planning would result in adverse impacts to wildland fire management. In general, Alternative C contains the fewest restrictions on fire management for the protection of other resource objectives.

Fire suppression impacts due to special status plant species are the same as under Alternative A.

Besides the restrictions and impacts described under *Impacts Common to All Alternatives*, Alternative C includes no other specific restrictions on fire and fuels management related to resource objectives or special designations. Alternative C would allow for the highest level of fire suppression compared to the other alternatives.

Impacts to fire and fuels from VRM allocations would be similar to those described under Alternative A, though to a slightly lesser extent because a smaller area is managed as VRM Class I and II.

Resource Uses

Management for minerals would result in impacts similar to those described under Alternative A, though to a greater extent due to more minerals development under Alternative C.

Using logging and timbering instead of wildland fire and other natural processes to revitalize decadent forest stands, improve forest stand density, and increase canopy cover would result in long-term

adverse impacts on fire and fuels management by limiting the natural role of wildland fire in ecosystems. However, logging and timbering would result in short-term beneficial impacts by reducing fuel loads and the possibility of catastrophic fires.

Impacts to fire and fuels management from the utility corridors designated under Alternative C would be similar to those under Alternative A, but to a lesser degree because the BLM designates fewer corridors under this alternative, though more than alternatives B and D. ROW avoidance or exclusion acreage under Alternative C would result in similar impacts to those under Alternative A, but to a greater degree.

Impacts to fire and fuels management from travel and transportation management under Alternative C would be similar to those described under Alternative A, though to a greater degree. Alternative C has fewer areas closed to travel and more area open to cross-country motorized travel compared to other alternatives.

Under Alternative C, impacts to fire and fuels management from recreation would be similar to those described under Alternative A, though to a greater degree due to an increase in the development of recreation sites and facilities. Alternative C manages fewer areas as SRMAs compared to the other alternatives. However, based on projected surface disturbance (Appendix T) Alternative C would lead to the development of the most recreation sites and the largest increase in the potential for unplanned ignitions in these areas.

Management for livestock grazing would result in impacts similar to those described for Alternative A.

Proactive Management

Under Alternative C, the response to wildfire would be the same as that described for Alternative B.

Under Alternative C, the BLM would use wildland fire (wildfires managed for resource benefit and prescribed fires) to restore fire-adapted ecosystems for commodity production and to reduce hazardous fuels. Alternative C places more emphasis on fire and fuels management for the use of resources compared to Alternative B, which utilizes wildland fire to restore the natural processes of ecosystems.

Impacts from mechanical fuels treatments would be similar to those described for Alternative A, although to a greater degree because 60,000 acres are projected for mechanical fuels treatments under Alternative C (a 100 percent increase compared to Alternative A) (Appendix T). The use of mechanical fuels treatment under Alternative C would be greater than under alternatives A, B, and D.

Alternative D

Surface Disturbance

Impacts to fire and fuels management from surface disturbance would result in similar impacts as those described under Alternative A, though to a greater degree. Under Alternative D, a total of 140,175 acres of short-term surface disturbance is projected on BLM-administered land during the life of the plan. Implementing Alternative D would result in a 3 percent increase in short-term surface disturbance on BLM-administered land compared to Alternative A, a 90 percent increase compared to Alternative B, and a 43 percent decrease compared to Alternative C. After reclamation, a total of 18,306 acres of long-term surface disturbance is projected under Alternative D. Implementing Alternative D would result in a 17 percent increase in long-term surface disturbance on BLM-administered land compared to Alternative A, a 69 percent increase compared to Alternative B, and a 56 percent decrease compared to Alternative C.

Wildfires (Unplanned Ignitions)

Restrictions from Resources and Special Designations

Management actions restricting fire suppression, fuels management, or wildland fire planning would result in adverse impacts to fire and fuels management. In general, restrictions on fire management for the protection of other resource objectives under Alternative D are greater than under alternatives A and C, but less than under Alternative B.

Allowing the application of fire suppression chemicals within ¼ mile of known or documented populations of BLM special status plant species with the consent of the authorized officer would result in the least adverse impact to the use of suppression tactics of any alternative.

Special designations under Alternative D would result in similar adverse impacts to fire and fuels management as those under Alternative A, but to a greater degree. In addition to the ACECs restricting fire suppression tactics that are similarly designated under Alternative A, the BLM restricts the use of heavy equipment during fire suppression operations over important caves and cave passages in the Craig Thomas Little Mountain Special Management Area (SMA). Unlike alternatives A and B, Alternative D does include WSR eligible or suitable waterway segments that would restrict the use of fire suppression techniques along these waterways.

Impacts from allocation of VRM Class I and II areas would be similar to those described under Alternative A. Due to the area allocated as VRM Class I and II, adverse impacts to fire and fuels management from VRM allocations would be greater than those under alternatives A and C, but less than those under Alternative B.

Resource Uses

Under Alternative D, mineral resource exploration and development would have similar impacts to those under Alternative A, though to a lesser degree due to decreased minerals development projected under Alternative D. Adverse impacts from management of mineral resources under Alternative D would be greater than Alternative B, but less than Alternative C.

Forests, woodlands, and forest products management under Alternative D would result in similar impacts to those under Alternative A.

Impacts to fire and fuels management from the designation of utility corridors under Alternative D would be similar to those described under Alternative A, though to an extent similar to Alternative C as a similar acreage is designated for ROW corridors. Alternative D manages more acreage as ROW avoidance or exclusion areas than alternatives A and C, but less than Alternative B, with proportional impacts.

Impacts to fire and fuels management from travel and transportation management under Alternative D would be similar to those described under Alternative A, fewer than under Alternative C, and greater than under Alternative B.

The impacts to fire and fuels management from recreation would be similar to those under Alternative A, but to a greater degree. Management of SRMAs under Alternative D would result in similar impacts to those under Alternative B, but to a lesser degree.

Livestock grazing management under Alternative D would result in similar impacts to fire and fuels management as those under Alternative A. Emphasizing livestock grazing as a tool to improve resource conditions may result in beneficial impacts if grazing reduces fine fuels in certain areas (Diamond et al. 2009).

Proactive Management

Under Alternative D, the response to wildland fire would be the same as described under Alternative B. Fire and fuels management would result in similar impacts, in degree and extent, as those described under Alternative A. Under Alternative D, emphasizing the use of wildland fires (wildfires managed for resource benefit and prescribed fires) and other vegetation treatments to accomplish resource management objectives may result in additional beneficial impacts to fire and fuels management.

Alternative E

Surface Disturbance

Adverse impacts to fire and fuels management from surface disturbance would be the same as alternatives A and B, but to a lesser degree. Under Alternative E, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, and pipelines) in greater sage-grouse Key Habitat Areas to not exceed one disturbance per 640 acres and cover less than 3 percent of the total sage-grouse habitat, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. This restrictive management could reduce potential disturbance-related invasive species spread and subsequent increases in fire severity when compared to the other alternatives. Among the alternatives, Alternative E would result in the least amount of short- and long-term surface disturbance on BLM-administered land (71,829 acres and 10,676 acres, respectively). Implementing Alternative E would result in a 48 percent decrease in short-term surface disturbance on BLM-administered land compared to Alternative A, a 3 percent decrease compared to Alternative B, a 71 percent decrease compared to Alternative C, and a 49 percent decrease compared to Alternative D. Implementing Alternative E would result in a 32 percent decrease in long-term surface disturbance on BLM-administered land compared to Alternative A, a 2 percent decrease compared to Alternative B, a 74 percent decrease compared to Alternative C, and a 42 percent decrease compared to Alternative D.

Restrictions from Resources and Special Designations

Under Alternative E, management actions restricting fire suppression, fuels management, or wildland fire planning would result in the greatest adverse impacts to wildland fire management. In general, restrictions on fire management for the protection of resource objectives are greater under Alternative E than under the other alternatives. Under Alternative E, the BLM designs and implements fuels treatments in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres) with an emphasis on protecting existing sagebrush ecosystems and the benefits of fuel breaks would be evaluated against the additional loss of sagebrush cover. In greater sage-grouse Key Habitat Areas, sagebrush canopy cover may not be reduced to less than 15 percent unless a fuels management objective requires an additional reduction in sagebrush cover to meet strategic protection of priority sage-grouse habitat and conserve habitat quality for the species. Additional limits on fuels management (based on habitat type and invasive species composition) also apply in the Greater Sage-Grouse Key Habitat Areas ACEC under Alternative E, but with exceptions to allow fuels treatments that would limit wildfire risk. In areas outside of the Greater Sage-Grouse Key Habitat Areas ACEC, fire suppression and fuels management are the same as Alternative B, and impacts to fire and fuels management would be the same as described under that alternative.

Visual Resource Management (VRM) under Alternative E is the same as Alternative B, and impacts to fire and fuels management would be the same as Alternative B.

Wildfires (Unplanned Ignitions)

Resource Uses

Under Alternative E, management actions for minerals would have similar impacts as alternatives A and B, though to a lesser degree due to additional restrictions on minerals development under Alternative E.

Management of utility corridors under Alternative E is the same as Alternative B, and impacts to fire and fuels management would be the same as Alternative B. Alternative E manages more acreage as ROW exclusion areas than any other alternative, which would reduce the prevalence of fuel breaks and fire lines but would also decrease human presence and the potential for unplanned ignitions to a greater degree than under the other alternatives. Impacts to fire and fuels management from the management of forests, woodlands, and forest products; travel and transportation; recreation; and livestock grazing under Alternative E would be the same as Alternative B. As under Alternative B, closure of the greater sage-grouse Key Habitat Areas to livestock grazing may contribute to a buildup of fine fuels, which would facilitate the spread of larger wildland fire in the short term; however, the return to a more natural fire regime would reduce the potential for larger catastrophic wildfires in the long term.

Proactive Management

Under Alternative E, response to wildland fires, mechanical fuels treatment, and use of wildland fires to achieve management objectives are the same as Alternative B for areas outside of the Greater Sage-Grouse Key Habitat Areas ACEC, and impacts to fire and fuels management would be the same as Alternative B. Inside the Greater Sage-Grouse Key Habitat Areas ACEC, Alternative E focuses fuels treatments on interfaces with human habitation or significant existing disturbances, designs fuels management projects to reduce wildland fires, and applies seasonal restrictions for implementing fuels management treatments according to the type of seasonal habitats present. Compared to the other alternatives, management methods applied under Alternative E for the protection of greater sage-grouse may result in the greatest short-term adverse impact to fire and fuels management by limiting the types of treatments used, but would decrease the risk of large, catastrophic fires in the long term through a return to natural fire regimes.

Alternative F

Surface Disturbance

Adverse impacts to fire and fuels management from surface disturbance under Alternative F would be greater than those described under Alternative A, but less than under Alternative D. Management practices relating to surface disturbance are the same as Alternative D, except within areas of the proposed Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). In this ACEC, the BLM manages the density of disturbance to not exceed an average of one disruptive activity location per 640 acres and cover less than 3 percent of the total sage-grouse habitat, compared to a larger allowable disturbance of 5 percent in under Alternative D. This management would reduce potential disturbance-related invasive species spread and subsequent increases in fire severity when compared to Alternative D. Total short- and long-term surface disturbances on BLM-administered land under Alternative F would be 137,064 acres and 17,663 acres, respectively. Implementing Alternative F would result in a 1 percent increase in short-term surface disturbance on BLM-administered land compared to Alternative A, an 86 percent increase compared to Alternative B, a 44 percent decrease compared to Alternative C, a 2 percent decrease compared to Alternative D, and a 92 percent increase compared to Alternative E. Implementing Alternative F would result in a 14 percent increase in long-term surface disturbance on BLM-administered land compared to Alternative A, a 64 percent increase compared to Alternative B, a

57 percent decrease compared to Alternative C, a 2 percent decrease compared to Alternative D, and a 66 percent increase compared to Alternative E.

Restrictions from Resources and Special Designations

Special designations under Alternative F would result in similar adverse impacts to fire and fuels management as those under alternatives A and D, but to a greater degree due to additional protections for other resource objectives within the Greater Sage-Grouse PHMAs ACEC. Similar to Alternative E, Alternative F designs and implements fuels treatments in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres) with an emphasis on protecting existing sagebrush ecosystems and the benefits of fuel breaks would be evaluated against the additional loss of sagebrush cover. In greater sage-grouse PHMAs, sagebrush canopy cover may not be reduced to less than 15 percent unless a fuels management objective requires additional reduction in sagebrush cover to meet strategic protection of priority sage-grouse habitat and conserve habitat quality for the species. Additional limits on fuels management would also apply in the Greater Sage-Grouse PHMAs ACEC under Alternative F, including seasonal restrictions for implementing fuels management treatments.

In areas outside of the Greater Sage-Grouse PHMAs ACEC, management for fire suppression and fuels management are the same as Alternative D, and impacts to fire and fuels management would be the same as Alternative D.

VRM under Alternative F is the same as under Alternative D, and impacts to fire and fuels management would be the same as Alternative D.

Resource Uses

Under Alternative F, mineral resource exploration and development would have similar impacts as Alternative D, though to a lesser degree due to decreased minerals development projected under Alternative F.

Impacts to fire and fuels management from travel and transportation management under Alternative F would be similar to Alternative D, but to a lesser degree because travel is limited to designated roads and trails on a larger acreage under Alternative F.

Overall, impacts from livestock grazing management on wildfires would be similar to under Alternative D, and reduced compared to impacts under alternatives B and E that close greater-sage grouse Key Habitat Areas to livestock grazing and may increase the potential for wildfires from fine fuel buildups. Alternative F focuses on implementing grazing management to strategically reduce fine fuels in greater sage-grouse PHMAs (35 percent of BLM-administered surface lands), and could reduce the potential for wildfires in the long term in these areas.

Impacts to fire and fuels management from the management of forests, woodlands, and forest products; lands and realty; ROWs; recreation; and livestock grazing under Alternative F are the same as those described under Alternative D.

Proactive Management

Under Alternative F, the response to wildland fire mechanical fuels treatment and use of wildland fires to achieve management objectives are the same as Alternative D for areas outside of the Greater Sage-Grouse PHMAs ACEC, and impacts to fire and fuels management would be the same as Alternative D. Inside the Greater Sage-Grouse PHMAs ACEC, Alternative F designs fuels management projects to reduce wildland fires and apply seasonal restrictions for implementing fuels management treatments according to the type of seasonal habitats present. Compared to the other alternatives, management methods applied under Alternative F for the protection of greater sage-grouse may result in more

adverse impacts to fire and fuels management when compared to alternatives A, C, and D by limiting the types of treatments used.

4.3.2 Prescribed Fires (Planned Ignitions)

Prescribed fires can be implemented as a tool to meet resource objectives, such as for wildlife habitat enhancement, forage production, and fuel reduction.

Impacts described above in Section 4.3.1 *Wildfires (Unplanned Ignitions)* for wildland fires would apply to prescribed fires. Prescribed fires, a type of wildland fire, include any fire intentionally ignited by management under an approved plan to meet specific objectives. Restrictions on fire management techniques and equipment would apply to the management and control of prescribed fires. This section describes only impacts specific to managing prescribed fires. Prescribed fire that has exceeded, or is expected to exceed, prescription parameters or otherwise meets the criteria for conversion to wildfire is considered an escaped prescribed fire. This may occur when a prescribed fire burns out of control or moves outside established fire lines due to wind or other factors; under these circumstances, the escaped prescribed fire is classified as a wildfire.

Direct impacts to prescribed fire include restrictions or stipulations from other resources prohibiting or limiting prescribed fires in certain areas or at certain times of the year. Prescribed fire can result in short-term adverse impacts associated with the actual fire event. However, prescribed fire reduces fuel loads and the potential for larger-scale catastrophic fires and aids in the achievement of vegetation and resource objectives. This typically results in long-term beneficial impacts to resources and ecosystems.

4.3.2.1 Methods and Assumptions

Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes methods and assumptions used in the analysis of impacts to fire and fuels management (including prescribed fire). This analysis focuses on impacts to the management of prescribed fires.

4.3.2.2 Summary of Impacts by Alternative

The use of prescribed fire to achieve measurable objectives and to reduce fuel loading would result in beneficial impacts to fire and fuels management. Conversely, restricting the use of prescribed fire would result in adverse impacts to fire and fuels management, such as the ability to reduce fuel loads. Limiting the use of prescribed fire may also affect the ability of the fire and fuels program to meet fire management goals. Alternative E would restrict the use of prescribed fire the most, followed by alternatives B, D, F, A, and C, respectively. Alternative C would result in the greatest beneficial impacts to fire and fuels management from the use of prescribed fire compared to the other alternatives. Alternative C would impose the fewest restrictions on the use of prescribed fire, resulting in the application of prescribed fire on a projected 80,000 acres over the life of the plan, followed by alternatives A, D, and F (40,000 acres each), Alternative B (20,000 acres), and Alternative E (18,000 acres). Alternatives D and F also emphasize the use of prescribed fire to meet resource management objectives, but apply greater restrictions on its use compared to Alternative C.

4.3.2.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Managing prescribed fires to comply with Wyoming DEQ air quality standards and smoke management rules may result in adverse impacts to the management of prescribed fires by limiting the scale and extent of prescribed fires necessary to achieve fuel reduction targets and other resource objectives.

Maintaining and implementing an FMP, consistent with this RMP to address fire management on a landscape scale and to meet DPC objectives and resource management objectives would result in long-term impacts to the management of prescribed fire.

In order to implement and document a prescribed fire, NEPA compliance requires an interdisciplinary team to conduct site-specific analysis, including ESA and NHPA consultation. In accordance with current BLM prescribed fire policy, a Prescribed Fire Plan is required for prescribed fires. The Prescribed Fire Plan is a site-specific implementation document containing specific resource objectives, prescription criteria, and provisions for suppression if the fire escapes. The presence of resources identified during surveys (e.g., cultural sites, sensitive species habitat) would determine the parameters of prescribed fires in these areas and may prohibit prescribed fire or require specific mitigation or BMPs to ensure prescribed fire is implemented consistent with resource objectives. Additional restrictions on surface-disturbing activities (which include mechanical fuels treatments and prescribed fires) for the protection of resource values identified in the alternatives would further limit the use of prescribed fire in certain areas.

The use of prescribed fire would result in long-term beneficial impacts to fire and fuels management by moving areas towards DPC, reducing fuel loading, and reducing the potential for future catastrophic fires. However, through the removal of existing vegetation and exposure of soil, prescribed fire may increase the potential for the establishment and spread of invasive species (such as cheatgrass) which may increase the incidence and spread of fire.

Taking into account invasive herbaceous species, Fire Regime Groups, and FRCCs when considering treatments, including prescribed fire, would result in beneficial impacts to fire and fuels management. Planning prescribed fires in consideration of invasive species may limit the potential for invasive species establishment and spread, which may decrease the potential for fire incidence and spread and reduce the potential for future prescribed fire or other treatments. Implementing prescribed fires based on FRCC would concentrate prescribed fire activity in areas that would benefit from treatments, and may help return areas to their historic fire regimes.

In determining whether the use of prescribed fire is appropriate in a given scenario, the BLM must consider the requirement under all alternatives that a Burn Plan proposing the use of prescribed fire in greater sage-grouse or crucial winter wildlife habitats must be supported by NEPA analysis detailing how the proposed treatment would support species conservation objectives and minimize potential risks. This requirement would place greater limitations on BLM's ability to proactively manage wildland fires.

Under current BLM policy, areas where prescribed burns occur are generally deferred from livestock grazing for at least two consecutive growing seasons, based on management objectives consistent with the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N). The BLM may adjust the two-growing-seasons deferral requirement based on environmental conditions and management objectives. Prescribed burns generally are not possible where domestic livestock producers are unable to absorb the cost of the deferral period. This policy may restrict the ability to use prescribed fire as a

Prescribed Fires (Planned Ignitions)

management tool in certain areas. This may adversely affect the management of prescribed fire. Wild horses in HMAs also could adversely affect burned areas.

Alternative A

Surface Disturbance

Surface disturbance can result in the establishment of invasive species, which increases the potential for fire occurrence and spread. In areas where invasive species become established or spread after surface disturbance, the BLM may use prescribed fire as a management tool to reduce these fuels. Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes total surface-disturbance acreages and compares alternatives.

Implementation of Alternative A is projected to result in 40,000 acres of short-term surface disturbance on BLM-administered land from prescribed fire. No long-term surface disturbance is projected (Appendix T).

Restrictions from Resources and Special Designations

Closing all BLM-administered land in WSR eligible waterway segments to vegetative treatments (including prescribed fire) would result in adverse impacts to fire and fuels management. Prohibiting prescribed fire in these areas would limit the tools available to manage hazardous fuels in these areas, which may increase the potential for larger-scale fires.

Restrictions on heavy equipment and fire suppression activities identified for wildland fire under Section 4.3.1 *Wildfires (Unplanned Ignitions)* would apply to prescribed fires in WSR eligible waterway segments. These restrictions would require other techniques for the control of prescribed fires, if the BLM implemented prescribed fires in these areas.

Management that prohibits or limits surface-disturbing activities for the protection of resources values would result in adverse impacts to fire and fuels management by prohibiting or limiting prescribed fires in these areas. Restrictions on prescribed fires (and other mechanical fuels treatments) may result in the accumulations of fuels and the potential for large-scale catastrophic fires in these areas, which may result in greater adverse impacts in the long term to the resource values for which restrictions are applied. Restrictions for the protection of resources that would limit or prohibit prescribed fire under Alternative A such as prohibiting surface-disturbing activities within 500 feet of surface water, TLS in big game crucial winter ranges, and CSU restrictions within ¼ mile of occupied greater sage-grouse leks would result in adverse impacts.

Resource Uses

Management of ROWs and minerals that increases the amount of roads and the linear clearing of vegetation may result in beneficial impacts to prescribed fire. These linear clearings can serve as fire breaks or fire lines for the control of prescribed fire and reduce the need to clear additional vegetation for the control of prescribed fire.

Proactive Management

Under Alternative A, and in accordance with the Northern Zone FMP, the BLM would use prescribed fire to meet other resource management objectives (e.g., wildlife habitat or range condition) and to reduce hazardous fuels. The BLM would implement prescribed burns on 150 to 500 acres of BLM-administered land per year (totaling approximately 40,000 acres), based on the potential for initial burns, and then as needed to maintain historic vegetation and disturbance regimes.

As described in the FMP, the BLM would perform baseline and post-treatment monitoring following prescribed fire. Post-treatment monitoring is required to determine the accomplishment of direct treatment objectives and resource management objectives. Direct treatment objectives usually are attributes such as plant mortality, fuel consumption, burn pattern (mosaic), and total acreage. Resource management objectives usually concern post-treatment vegetation attributes such as cover, frequency, production, density, and stocking level of a desired species.

Implementation of the Northern Zone FMP would result in long-term impacts to fire and fuels management by requiring the following activities following a prescribed fire:

- Pre and post Fire Regime and Condition Class evaluation
- At least one photo point location, which can be returned to, preferably taken in four opposing directions both pre- and post-treatment
- A Northern Zone Fuels Treatment Monitoring Form completed and filed in the Range Improvement Projects project file
- A geographic information system (GIS) database that includes a completed attribute table and pre- and post-treatment shape files of the treatment perimeter

In addition, the BLM will evaluate a representative number and type of treatments to document the effectiveness of modifying fire behavior. For example, the zone fuels specialist may calculate pre- and post-treatment fire behavior for at least each fuel model treated in the zone.

These activities would provide appropriate evaluation and documentation of prescribed fire activities, which may increase the efficiency and effectiveness of future prescribed fire activities to meet resource objectives and reduce fuel loading.

Alternative B

Surface Disturbance

Surface disturbance may result in the establishment of invasive species, which increases the potential for fire occurrence and spread. In areas where invasive species become established or spread after surface disturbance, the BLM may use prescribed fire as a management tool to reduce these fuels. Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes total surface-disturbance acreages and compares alternatives.

Implementing Alternative B is projected to result in 20,000 acres of short-term surface disturbance on BLM-administered land from prescribed fires (Appendix T). Short-term surface disturbance from prescribed fire would be less than under Alternative A. No long-term disturbance is projected.

Restrictions from Resources and Special Designations

Restrictions that limit or prohibit prescribed fire for the protection of resource values would result in similar impacts to those described under Alternative A, though to a greater degree. In general, management under Alternative B focuses on the protection and conservation of resources and resource values. Under Alternative B, restrictions on surface-disturbing activities for the protection of resources that would limit or prohibit prescribed fire would be greater than under Alternative A.

Under Alternative B, the BLM seasonally stipulates fuels treatments (including prescribed fire) in the Chapman Bench, Clarks Fork Canyon, Rattlesnake Mountain, and Sheep Mountain ACECs, as well as the Absaroka Front Management Area. Seasonal stipulations may adversely affect fire and fuels management by limiting prescribed fire as a tool for fuels reduction in these areas.

Prescribed Fires (Planned Ignitions)

Closing all WSR suitable waterway segments to prescribed fire would result in the same impacts as those described under Alternative A.

Restrictions on heavy equipment and fire suppression activities identified for wildland fire under Section 4.3.1 *Wildfires (Unplanned Ignitions)* would apply to prescribed fires in WSR suitable waterway segments. These restrictions would require other techniques for the control of prescribed fires, if the BLM implements prescribed fires in these areas.

Alternative B also prohibits surface-disturbing activities within ¼ mile of, or within riparian/wetland areas, which would limit the use of mechanical vegetation treatments and prescribed fire necessary to restore ecosystem health in some kinds of riparian systems. This would result in a greater impact than Alternative A which limits surface-disturbing activity within 500 feet of riparian/wetland areas.

Alternative B includes more special designations where management is prescribed for the protection of resource values than Alternative A. As a result, prescribed fire and other fuels treatments are decreased in these areas more than under Alternative A.

The restrictions on prescribed fire use under Alternative B would likely result in greater adverse impacts to private lands, as the potential for wildfires starting in heavily fuel-laden areas spreading onto private lands would be greater under Alternative B, compared to Alternative A.

Resource Uses

Impacts to prescribed fire from management for ROWs and minerals would result in similar impacts as those described under Alternative A, though to a lesser degree due to decreased mineral activity and more acreage managed as ROW avoidance or exclusion areas. Designating less area for utility corridors than Alternative A would result in similar beneficial impacts, but to a lesser degree.

Proactive Management

Under Alternative B, the BLM would use **wildland fires (wildfires managed for resource benefit and prescribed fires)** and other vegetative treatments to restore fire-adapted ecosystems for natural resource systems and to reduce hazardous fuels. Prescribed fire would reduce fuels and the potential for future large-scale catastrophic fires. This would result in beneficial impacts to fire and fuels management. Under Alternative B, the BLM would use habitat enhancement treatments (including prescribed fire) in sagebrush communities on at least 200 acres of BLM-administered land per year; prescribed fire would occur on a total of approximately 20,000 acres over the life of the plan.

Management identified in the Northern Zone FMP for prescribed fire monitoring may be carried forward under Alternative B, consistent with management under this alternative. Impacts would be the same as those described for Alternative A.

Alternative C

Surface Disturbance

Surface disturbance may result in the establishment of invasive species, which increases the potential for fire occurrence and spread. In areas where invasive species become established or spread after surface disturbance, the BLM may use prescribed fire as a management tool to reduce these fuels. Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes total surface-disturbance acreages and compares alternatives.

Implementing Alternative C is projected to result in 80,000 acres of short-term surface disturbance on BLM-administered land from prescribed fires (Appendix T). Short-term surface disturbance from

prescribed fires would be greater than under alternatives A, B, and D. No long-term surface disturbance is projected.

Restrictions from Resources and Special Designations

Seasonally stipulating fuels treatments in the Absaroka Front Management Area would result in the same impacts as those described under Alternative B.

Restrictions that limit or prohibit prescribed fire for the protection of resource values would result in similar impacts to those described under Alternative A, though to a lesser degree. In general, Alternative C reduces restrictions for the protection of resources, allowing greater use of prescribed fire compared to the other alternatives.

Resource Uses

Impacts to prescribed fire from minerals development under Alternative C would result in similar impacts as those described under Alternative A, though to a greater degree. Alternative C is projected to result in the greatest amount of oil and gas development, and the amount of roads would increase proportionally. Alternative C designates the second-largest area for utility corridors, which would result in proportional beneficial impacts to prescribed fire. Impacts from ROW management would result in similar impacts to those under Alternative A, although to a lesser degree because the BLM would manage more acreage as ROW avoidance or exclusion areas.

Proactive Management

Utilizing wildland fires (wildfires managed for resource benefit and prescribed fires) to restore fire-adapted ecosystems would result in the same impacts as those described under Alternative B. Under Alternative C, the BLM would implement prescribed fire and other treatments in sagebrush communities as opportunities and funding allow; prescribed fire would occur on approximately 80,000 acres.

Management identified in the Northern Zone FMP for prescribed fire monitoring may be carried forward under Alternative C, consistent with management under this alternative. Impacts would be the same as those described for Alternative A.

Alternative D

Surface Disturbance

Surface disturbance may result in the establishment of invasive species, which increases the potential for fire occurrence and spread. In areas where invasive species become established or spread after surface disturbance, the BLM may use prescribed fire as a management tool to reduce these fuels. Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes total surface-disturbance acreages and compares alternatives.

Implementing Alternative D is projected to result in the same acreage as Alternative A of short- and long-term surface disturbance on BLM-administered land from prescribed fire.

Restrictions from Resources and Special Designations

Restrictions that limit or prohibit prescribed fire for the protection of resource values would result in similar impacts as those described under Alternative A, though to a greater degree. Under Alternative D, restrictions on surface-disturbing activities for the protection of resources that would limit

Prescribed Fires (Planned Ignitions)

or prohibit prescribed fire would be greater than under alternatives A and C, but less than under Alternative B.

Seasonal stipulations on fuels treatments under Alternative D would result in similar adverse impacts to fire and fuels management as those under Alternative B in the Absaroka Front Management Area, but to a lesser degree overall as it designates fewer ACECs with seasonal stipulations.

Restrictions on heavy equipment and fire suppression activities identified for wildland fire in Section 4.3.1 *Wildfires (Unplanned Ignitions)* would also apply to prescribed fires. These restrictions would require other techniques for the control of prescribed fires, if the BLM implemented prescribed fires in these areas.

Alternative D also prohibits surface-disturbing activities within 500 feet of perennial surface water and riparian/wetland areas and avoids surface-disturbing activities within ¼ mile of sensitive habitat, of perennial surface water, and riparian/wetland areas, which would result in impacts similar to those described for Alternative B, but to a lesser degree. This would result in a greater impact than Alternative A, which limits surface-disturbing activity within 500 feet of riparian/wetland areas.

Management of special designations under Alternative D would result in similar impacts to those under Alternative B, but to a lesser degree because there is less acreage within special designations. Overall, the restrictions on prescribed fire under Alternative D would result in similar adverse impacts to private lands as under Alternative B, but to a lesser degree because Alternative D stipulates fuels treatments in less area and performs mechanical fuels treatments and prescribed burns on more acreage (Appendix T).

Resource Uses

Minerals development under Alternative D would result in similar beneficial impacts to prescribed fire as those under Alternative A, but to a lesser degree because less acreage is available for oil and gas development. Utility corridors designated under Alternative D would result in beneficial impacts similar to those described under Alternative A, but to a greater degree than Alternative B. Alternative D manages the second-largest area as ROW avoidance or exclusion areas, which would result in proportional adverse impacts to prescribed fire.

Proactive Management

The BLM would use prescribed fire under Alternative D to a similar extent as under Alternative A, but with a greater emphasis placed on using prescribed fire to accomplish resource management objectives.

Management identified in the Northern Zone FMP for prescribed fire monitoring may be carried forward under Alternative D, consistent with management under this alternative. Impacts would be the same as those described for Alternative A.

Alternative E

Surface Disturbance

Surface disturbance may result in the establishment of invasive species, which increases the potential for fire occurrence and spread. In areas where invasive species become established or spread after surface disturbance, the BLM may use prescribed fire as a management tool to reduce these fuels. Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes total surface-disturbance acreages and compares alternatives.

Implementing Alternative E is projected to result in 18,000 acres of short-term surface disturbance on BLM-administered land from prescribed fires (Appendix T). Short-term surface disturbance from prescribed fire under Alternative E is projected to be the least of all the alternatives; no long-term disturbance is projected.

Restrictions from Resources and Special Designations

Restrictions that limit or prohibit prescribed fire for the protection of resource values would result in similar impacts to those described under Alternative A, though to a greater degree. In general, management under Alternative E focuses on the protection and conservation of resources and resource values. Under Alternative E, restrictions on surface-disturbing activities for the protection of resources that limit or prohibit prescribed fire would be the greatest among the alternatives.

Alternative E includes the largest acreage of special designations where management is prescribed for the protection of resource values; as a result, prescribed fire and other fuels treatments are decreased in these areas more than under the other alternatives. Seasonal fuels treatment stipulations in ACECs under Alternative E are similar to Alternative B except in the Greater Sage-Grouse Key Habitat Areas ACEC, which includes seasonal restrictions on fuels treatments. Alternative E also prohibits the use of fire to treat sagebrush in portions of greater sage-grouse Key Habitat Areas located in less than 12-inch precipitation zones. For ACECs and other special designations outside the Greater Sage-Grouse Key Habitat Areas ACEC, management of and impacts to prescribed fire use would be the same as Alternative B.

Overall, management of special designations under Alternative E would result in similar impacts to private lands to those described under Alternative B, but to a greater extent due to a larger area of special designations with restrictions on fuels treatments and a correspondingly increased likelihood of fire spreading from public lands with high fuel loads to adjacent private lands.

Resource Uses

Under Alternative E, impacts to prescribed fire from management for ROWs and minerals development would result in similar impacts as those described under Alternative A, though to a lesser degree due to additional restrictions on these activities in the Greater Sage-Grouse Key Habitat Areas ACEC. Outside the Greater Sage-Grouse Key Habitat Areas ACEC, ROW and minerals management under Alternative E are the same as Alternative B, and impacts to prescribed fire management would be the same as Alternative B.

Proactive Management

Alternative E uses wildland fires (wildfires managed for resource benefit and prescribed fires) and other vegetative treatments to restore fire-adapted ecosystems for natural resource systems and to reduce hazardous fuels in a similar manner to Alternative B. Therefore, impacts to prescribed fire management would be the same as Alternative B except within the Greater Sage-Grouse Key Habitat Areas ACEC.

In the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), Alternative E places additional restrictions on the use of prescribed fire including prohibiting fuels treatments in known winter range unless the treatments are designed to strategically reduce wildfire risk around or in the winter range and restrict the use of fire to treat sagebrush in less than 12-inch precipitation zones (e.g., Wyoming big sagebrush or other sagebrush species). However, if as a last resort and after all other treatment opportunities have been explored and site specific variables allow, the use of prescribed fire for fuel breaks that would disrupt the fuel continuity across the landscape could be considered in stands where cheatgrass is a very minor component in the understory (Brown 1982). Based on prescribed measures,

Prescribed Fires (Planned Ignitions)

Alternative E would monitor and control invasive vegetation post-treatment and require use of native seeds for fuels management treatment based on availability, adaptation (site potential), and probability of success.

Alternative F

Surface Disturbance

Surface disturbance may result in the establishment of invasive species, which increases the potential for fire occurrence and spread. In areas where invasive species become established or spread after surface disturbance, the BLM may use prescribed fire as a management tool to reduce these fuels. Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes total surface-disturbance acreages and compares alternatives.

Alternative F is projected to result in the same acreage of short- and long-term surface disturbance on BLM-administered land from prescribed fire as alternatives A and D (Appendix T).

Restrictions from Resources and Special Designations

Under Alternative F, restrictions on surface-disturbing activities for the protection of resources that limit or prohibit prescribed fire are greater than under alternatives A, C, and D, but less than under alternatives B and E. Impacts resulting from restrictions that limit or prohibit prescribed fire would be similar to Alternative D, but to a greater degree due to the additional acreage with special designations under Alternative F.

Seasonal stipulations on fuel treatments under Alternative F would result in similar impacts to fire and fuels management as those under Alternative D, but to a greater degree overall because seasonal stipulations are placed on an additional 1,116,698 acres in the Greater Sage-Grouse PHMAs ACEC.

In areas outside of the Greater Sage-Grouse PHMAs ACEC, management for the use of prescribed fire is the same as Alternative D, and impacts to fire and fuels management would be the same as Alternative D.

Resource Uses

Minerals development under Alternative F would result in similar beneficial impacts to prescribed fire as alternatives A and D, though to a lesser degree due to additional restrictions on these activities in the Greater Sage-Grouse PHMAs ACEC. Utility corridors designated under Alternative F would result in beneficial impacts similar to those described under alternatives A and D, and to a greater degree than alternatives B and E. Under Alternative F, lands managed as ROW avoidance and exclusion areas are similar to Alternative D (ROW avoidance areas are based on greater sage-grouse Key Habitat Areas under Alternative D and PHMAs under Alternative F), and impacts would be similar to those listed under Alternative D.

Proactive Management

Under Alternative F, the BLM uses prescribed fire to a similar extent as under Alternative D, but with greater emphasis on using prescribed fire to accomplish resource management objectives. Impacts to prescribed fire management would be similar to those described under alternatives A and D except within the Greater Sage-Grouse PHMAs ACEC.

In the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres), Alternative F would place additional restrictions on the use of prescribed fire including prohibiting fuels treatments in known greater sage-grouse winter range unless the treatments are designed to strategically reduce wildfire risk around or in

the winter range. Within greater sage-grouse PHMAs, Alternative F also limits the use of fire to treat sagebrush in areas receiving less than 12 inches of annual precipitation, and designs post-fuels management projects to ensure long-term persistence of seeded or pre-treatment native plants.

In areas outside the Greater Sage-Grouse PHMAs ACEC, prescribed fire management would be the same as Alternative D, and impacts to fire and fuels management would be the same as Alternative D.

4.3.3 Stabilization and Rehabilitation

The BLM undertakes stabilization and long-term rehabilitation actions to repair lands damaged by wildfire that are unlikely to recover naturally. Emergency stabilization and burned area rehabilitation are part of a holistic approach to address post-wildfire issues, including soil impacts, vegetation restoration, invasive species establishment and spread, and damage that can occur resulting from suppression activity and long-term (more than 3 years) restoration. Rehabilitation includes, but is not limited to, contour felling, mulching, seeding, and control of invasive plants.

Emergency stabilization refers to planned actions performed by a Burned Area Emergency Response team within 1 year of containment of a wildfire to stabilize and prevent unacceptable degradation to natural and cultural resources. Burned area rehabilitation refers to efforts undertaken within 3 years of containment of a wildfire to repair or improve fire-damaged land unlikely to recover naturally to desired management conditions, or to repair or replace minor facilities damaged by fire. The spread of cheatgrass, in particular, is possible in areas burned or disturbed due to fire suppression activities. Widespread presence of cheatgrass can alter the local fire regime and fire-recurrence interval.

This analysis describes the impacts to stabilization and rehabilitation in relation to fire and fuels management. Impacts to stabilization and rehabilitation directly affect the management of fire and fuels and the potential for future fire occurrence and spread. Beneficial impacts to fire and fuels management results from management actions that encourage appropriate stabilization and rehabilitation following a wildfire. Adverse impacts to fire and fuels management result from management that limits stabilization and rehabilitation activities.

Direct impacts to stabilization and rehabilitation include restrictions that prohibit or limit stabilization and rehabilitation actions or techniques.

4.3.3.1 Methods and Assumptions

Section 4.3.1 *Wildfires (Unplanned Ignitions)* describes methods and assumptions used in the analysis of impacts to fire and fuels management (including stabilization and rehabilitation).

4.3.3.2 Summary of Impacts by Alternative

The principal impacts to stabilization and rehabilitation in relation to fire and fuels management result from management that affects the occurrence and spread of wildfire, and management that limits or restricts rehabilitation and stabilization tactics or activity. Under all alternatives, the BLM would conduct stabilization and rehabilitation consistent with BLM policy and guidance and in accordance with the FMP. An increase in fire suppression restrictions associated with wildfire management (as described in Section 4.3.1 *Wildfires (Unplanned Ignitions)*) that increases the potential for wildfire occurrence and spread in the short term may increase the need for stabilization and rehabilitation as more wildfires occur. However, intensive fire suppression that reduces the natural role of fire in the ecosystem may result in large catastrophic wildfires in the long term that require more intensive stabilization and

rehabilitation activities. Restrictions on wildfire suppression are greatest under alternatives B and E. There are no restrictions or limitations on stabilization and rehabilitation in specific areas under any of the alternatives.

4.3.3.3 Detailed Analysis of Alternatives

Stabilization and rehabilitation efforts relate directly to the occurrence of wildfires. Funding for stabilization and rehabilitation activities comes from fire funds for the suppression of wildfire. As a result, impacts to stabilization and rehabilitation reflect impacts to management of fire and fuels described in Section 4.3.1 *Wildfires (Unplanned Ignitions)*. Management that increases the occurrence and spread of wildfire (or decreases fire suppression) would impact stabilization and rehabilitation.

Impacts Common to All Alternatives

Implementing the BLM Emergency Stabilization and Rehabilitation standards in *BLM Burned Area Emergency Stabilization and Rehabilitation Handbook* (BLM 2007a) would result in beneficial impacts to fire and fuels management in the Planning Area by prescribing activities that would successfully rehabilitate areas following a wildfire and reduce the potential for future fires in burned areas.

Achieving a balance between treating areas that have departed from the historic fire regime (FRCC 3) and areas that are functioning within an appropriate fire regime (FRCC 1) would result in beneficial impacts on fire and fuels management. Treatment in FRCC 3 areas to return the fire ecology to the appropriate historic fire regime would help decrease fuel loading in these areas and require additional rehabilitation and stabilization to ensure that these areas recover. Without appropriate stabilization and rehabilitation in FRCC 2 and 3 areas, the potential for the occurrence and spread of wildfire in these areas would increase.

Using certified noxious weed seed-free vegetation products on all BLM-administered land (including during rehabilitation and stabilization activities) would result in beneficial impacts on fire and fuels management by decreasing the potential for the establishment of noxious weeds following seeding of rehabilitated areas.

Alternative A

Under Alternative A, the Northern Zone FMP would continue to guide stabilization and rehabilitation. Impacts to the fire and fuels program would result from increased workload associated with writing and implementing an Emergency Stabilization and Response plan for rehabilitation activities, in coordination with other appropriate agencies, landowners, and affected livestock operators. Consistent with the Northern Zone FMP, treatment in and around a disturbed area affected by wildfire would continue until resource specialists determine there is no longer a threat of noxious weeds. If necessary, this treatment would continue beyond the timeframe for Emergency Stabilization and Response funding.

As described in the Northern Zone FMP, the BLM would perform baseline and post-rehabilitation monitoring under Alternative A. Post treatment monitoring is required to determine the accomplishment of direct treatment objectives and resource management objectives. Monitoring rehabilitation efforts would follow the same general protocol as described for prescribed fire, to the extent practical. Monitoring stabilization and rehabilitation would provide appropriate evaluation and documentation of rehabilitation activities, which may increase the efficiency and effectiveness of future rehabilitation activities to meet resource objectives, reduce fuel loading, and reduce the potential for additional fires in the area. This would result in beneficial impacts to fire and fuels management.

Alternative B

There is no separate management under Alternative B for stabilization and rehabilitation activities following a fire. Similar to Alternative A, the BLM would perform stabilization and rehabilitation consistent with the *BLM Emergency Stabilization and Rehabilitation* standards in the *BLM Burned Area Emergency Stabilization and Rehabilitation Handbook* (BLM 2007a).

In addition, the BLM may carry forward under Alternative B stabilization and rehabilitation activities and monitoring identified in the Northern Zone FMP, with impacts similar to those described for Alternative A.

Alternative C

There is no separate management under Alternative C for stabilization and rehabilitation activities following a fire. Similar to alternatives A and B, the BLM would perform stabilization and rehabilitation consistent with the *BLM Emergency Stabilization and Rehabilitation* standards in the *BLM Burned Area Emergency Stabilization and Rehabilitation Handbook* (BLM 2007a).

In addition, the BLM may carry forward under Alternative C stabilization and rehabilitation activities and monitoring identified in the Northern Zone FMP, with impacts similar to those described for Alternative A.

Alternative D

There is no separate management under Alternative D for stabilization and rehabilitation activities following a fire. Similar to alternatives A, B, and C, the BLM would perform stabilization and rehabilitation consistent with the *BLM Emergency Stabilization and Rehabilitation* standards in the *BLM Burned Area Emergency Stabilization and Rehabilitation Handbook* (BLM 2007a).

In addition, the BLM may carry forward under Alternative D stabilization and rehabilitation activities and monitoring identified in the Northern Zone FMP, with impacts similar to those described for Alternative A.

Alternative E

Under Alternative E, the BLM would perform stabilization and rehabilitation consistent with the *BLM Emergency Stabilization and Rehabilitation* standards in the *BLM Burned Area Emergency Stabilization and Rehabilitation Handbook* (BLM 2007a).

Alternative E also provides separate management for stabilization and rehabilitation activities in the Greater Sage-Grouse Key Habitat Areas ACEC. In greater sage-grouse Key Habitat Areas, Alternative E would design post-fuels management projects (including emergency stabilization and rehabilitation management) to ensure long-term persistence of seeded or pre-treatment native plants. This may require temporary or long-term changes in livestock grazing management, wild horse and burro management, travel management, or other activities to achieve and maintain the desired condition of the fuels management project. Alternative E would also provide management to consider potential changes in climate when proposing post-fire seedings and consider seed collections from the warmer component within a species' current range for selection of native seed.

In addition, under Alternative E, the BLM may carry forward stabilization and rehabilitation activities and monitoring identified in the Northern Zone FMP, with impacts similar to Alternative A.

Alternative F

Under Alternative F, the BLM would perform stabilization and rehabilitation consistent with the *BLM Emergency Stabilization and Rehabilitation* standards in the *BLM Burned Area Emergency Stabilization and Rehabilitation Handbook* (BLM 2007a).

Alternative F also provides separate management for stabilization and rehabilitation activities in the Greater Sage-Grouse PHMAS ACEC. In the ACEC, Alternative F would design post-fuels management projects to ensure long-term persistence of seeded or pre-treatment native plants to reestablish disturbed areas with healthy native or desired plant communities based on pre-disturbance conditions or desired species composition. This may require temporary or long-term changes in livestock grazing management, wild horse and burro management, travel management, or other activities to achieve and maintain the desired condition of the fuels management project. Similar to Alternative E, Alternative F would provide management to consider potential changes in climate when proposing post-fire seedings using native plants. Seed collections from the warmer component within a species' current range would be considered under Alternative F.

Under Alternative F, post-fire stabilization and rehabilitation activities in the Greater Sage-Grouse PHMAS ACEC would also include the establishment of exclosures (free of livestock grazing) that would be used to assess recovery. Livestock grazing would be excluded from burned areas until woody and herbaceous plants achieve sage-grouse habitat objectives. Lastly, where burned sage-grouse habitat cannot be fenced from other unburned habitat, the entire area (e.g., allotment/pasture) should be close to grazing until recovered.

Under Alternative F, the BLM may carry forward stabilization and rehabilitation activities and monitoring identified in the Northern Zone FMP, with impacts similar to Alternative A.

4.4 Biological Resources

Vegetation Resources

Impacts Common to All Alternatives

This section describes potential impacts to all vegetation types (Map 36) under all alternatives. The sections that follow describe potential impacts to individual vegetation resources (i.e., forests and woodlands, grasslands and shrublands, or riparian/wetland resources).

There would be surface disturbance under all alternatives, and all alternatives apply BMPs for surface-disturbing activities. For each individual vegetation resources section, projected short- and long-term surface disturbance are assumed to be evenly distributed throughout the Planning Area. Impacts to specific vegetation types would therefore be proportional to the acreage of these vegetation types in the Planning Area, subject to any restrictions on surface disturbance that apply specifically to that vegetation type (e.g., prohibiting surface disturbance in riparian/wetland areas). Impact acreage for vegetation types are not absolute, but serve as a relative comparison among alternatives.

Surface disturbance directly affects plant communities through vegetation removal and mechanical damage to plants. Indirect impacts to vegetation from surface disturbance on vegetation include soil compaction, alteration of soil horizons, erosion, changes in hydrology, and invasive species encroachment. These indirect impacts would limit recovery or rehabilitation of vegetation communities following disturbance. Conversely, vegetation treatments (e.g., mechanical treatments, fire), while involving short-term disturbance, would result in long-term beneficial impacts to vegetation communities. Vegetation treatments would pursue objectives to increase species and structural diversity, control invasive species, improve the quality and quantity of vegetation for wildlife and livestock, restore habitat connectivity, and create or maintain the desired vegetation structure.

Depending on the air quality conditions in the area at the time of proposed treatments, the BLM may implement restrictions on prescribed burns and vegetation treatments in forests and woodlands to maintain air quality. Planning and timing restrictions on vegetation treatments to minimize emissions associated with fugitive dust or smoke would result in short-term adverse impacts to forests, woodlands, and forest products.

Development of facilities and infrastructure associated with transportation networks, minerals, and recreation would increase habitat fragmentation in the Planning Area, could remove vegetation, and contribute to the introduction and the spread of invasive species. ROWs concentrated in a corridor tend to localize or confine disturbance to a smaller area and reduce disturbance in areas identified as sensitive.

Renewable energy development, especially in the form of wind turbines, could result in adverse impacts by fragmenting vegetation communities and requiring mechanized maintenance that has the potential to make these communities more vulnerable to invasive species establishment and wildfire. However, there are no current or pending ROW authorizations for wind facilities in the Planning Area. The limited projected surface disturbance from these activities would have a minimal impact on vegetation.

Recreation use in vegetation communities could result in indirect short-term adverse impacts from unplanned ignitions and unauthorized woodcutting in forestlands in and adjacent to campgrounds, and degradation of vegetation along trails and roads. Unless properly designed and managed, the development of recreation trails, both motorized and nonmotorized, could erode soils, which would

cause adverse impacts to vegetation communities. Increased development of nonmotorized and motorized trails and trailheads can increase recreational use and associated impacts to vegetation communities (e.g., the potential spread and establishment of invasive species and risk of unplanned ignitions) over time. Adverse impacts would generally be more intense from roads and trails that allow motorized vehicle use.

Using the *Wyoming Standards for Healthy Rangelands* (Appendix N) to determine the minimum acceptable conditions for public rangelands would improve the health and diversity of vegetation communities. Impacts to vegetation from livestock grazing management on BLM-administered lands include the removal of forage by livestock, which may alter the amount, condition, composition, and vigor of vegetation. Grazing during the growing season or summer months may reduce the vigor of desired species and change in species composition. Livestock concentration around supplemental minerals or water would disturb soil, remove vegetation, and alter plant community composition.

Livestock, wild horses, and wildlife could contribute to the introduction and spread of invasive species, including noxious weeds. Livestock, wild horses, and wildlife may transport seeds of invasive species into the Planning Area (Bartuszevige and Endress 2008). Areas where animals concentrate and disturb the soil would be particularly vulnerable to infestations of invasive species. Range improvements that disturb the soil surface would provide locations for invasive species to become established. Heavy grazing of native vegetation may increase the susceptibility of an area to invasive species infestation. However, livestock grazing management that promotes healthy ecosystem function would create conditions more resistant to the spread of invasive species.

Managing for greater sage-grouse seasonal habitat objectives (see Chapter 2, Table 2-5) would have mixed impacts depending on cover types and desired condition goals. Sagebrush and grass communities would directly benefit from greater sage-grouse habitat objectives, especially in localized situations such as nesting habitat to maintain residual cover. Cover types containing tree species may be adversely impacted in these same areas to manage for a desired condition on shrub/grassland sites.

The BLM anticipates that potential impacts from VRM classifications, soil and water resources, air quality, invasive species, NHTs and other historic trails, transportation, wildlife, and special status species would influence the location, size, and shape of vegetation treatments and restrict the location and construction of access roads for activities such as forest and woodland treatments.

Summary of Impacts by Alternative

Certain types of management that restrict surface-disturbing activities and other resource uses would generally protect vegetation communities. Table 4-21 provides an overview of select protective management actions by alternative for each plant community in the Planning Area. The purpose of this table is to provide a broad overview comparison of the alternatives. The proceeding sections further discuss the effects of these and other management actions for each plant community.

4.4.1 Vegetation – Forests, Woodlands, and Forest Products

Actions that restrict forest management practices or contribute to the decline in abundance, distribution, or health of forests or woodlands, and availability, quality, and quantity of forest products would result in adverse impacts. Conversely, actions that enhance management, improve health, and protect and restore forests and woodlands in the Planning Area provide beneficial impacts.

Direct impacts to forests, woodlands, and forest products result from management actions that affect forest structure, species composition/diversity, vigor, health, vegetative community type, or other forest/woodland characteristics. Management actions that limit timber availability and restrict timber extraction methods directly affect forest products. Indirect impacts to forests, woodlands, and forest products include any change in forest and woodland characteristics due to natural forces (e.g., insect and disease, fire and drought conditions), management actions from other resources, or failure to implement management actions.

In addition to human activities, natural processes could produce beneficial or adverse impacts to forest and woodland communities. In an old growth forest, natural regeneration restores genetic diversity, sustained yield, and uneven-aged stands that provide economic benefits such as continuous production, insect and disease control, soil and water conservation, and the elimination of planting costs.

Alternatively, natural regeneration can introduce conifers into aspen stands, thereby reducing the size of, or out-competing the aspen stands. Aspen stands create natural fuel breaks and provide other benefits such as scenic qualities and habitat for wildlife. Refer to Map 36 for forest and woodland resources.

4.4.1.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- No current forest or woodland inventory or age and species classifications are available for the Planning Area.
- The condition, species content, and vitality of the forest and woodland ecosystem rest on the foundation of the soils, topography, slope/aspect, and microclimate and climatic forces specific to the region.
- Distributing and managing vegetative treatments will vary in forest and woodland areas depending on the desirable goals (e.g., fuel reduction in a Wildland Urban Interface [WUI] area).
- Livestock grazing in forests and woodlands generally remains compatible with forest management under all alternatives. Many forests and woodland areas are inaccessible to livestock due to steep slopes, physical barriers, or proximity to other portions of grazing allotments.
- Old growth stands, or those the BLM would manage for old growth, will follow the Healthy Forests Restoration Act (2003) Section 102 for maintaining and managing these stands.
- Public demand sales for firewood, Christmas trees, posts and poles, and other forest products would continue.
- Forest health, forest restoration, and hazardous fuels reduction objectives will be the major determining factors in forest management.
- Forests and woodlands are important for the watershed, visual resources, and wildlife habitats. Some of these values are natural and some are sociological. For example, wildlife needs habitat,

not visual quality. Human, sociological, economic, and cultural influences relate to managing forestlands and must be considered.

- Management of the forest could increase the water yield from the forest.
- Water quality could be adversely impacted in the short term due to mechanical forest treatments (soil erosion, etc.), but overall, the consequences of these treatments, as related to water quality, are anticipated to be negligible.
- Aspens generally are declining due to succession and other factors that lead to encroachment of evergreen species into aspen stands; for example, shade-tolerant conifers invade and eventually shade out aspen stands, contributing to their decline.

4.4.1.2 Summary of Impacts by Alternative

Impacts to forests, woodlands, and forest products would result from surface-disturbing activities or actions that increase the chance of catastrophic wildfire or degrade forest health through increased erosion and disease. Surface disturbance would adversely affect forests and woodlands under all alternatives, but would have the greatest impact under Alternative C, followed by alternatives D, F, A, B, and E. Alternative C would also place the fewest restrictions on motorized vehicle use and new road construction, which, in addition to increasing erosion, would increase the risk of unplanned ignitions and unauthorized woodcutting that would degrade forest health. Beneficial impacts to forests and woodlands would result from more intense forest management practices and silvicultural treatments that would improve forest health and reduce the risk of catastrophic wildfires, which pose the greatest threat to forests and woodlands. Forest products would also benefit from similar treatments that increase the availability of commercially viable stands. Alternative C, followed by alternatives D and F, A, and B and E, implements the largest number of silvicultural practices and other treatments to actively manage forests and woodlands. Beneficial impacts would also result from management actions that restrict surface-disturbing activities within certain specially managed areas, such as ACECs, where forests and woodlands are present. However, such actions may also limit silvicultural treatments in certain areas. Alternative E manages the most acres of forests and woodlands within ACECs, followed by alternatives F, B, D, A, and C. Therefore, while Alternative E would result in the least surface-disturbing activities that may affect forests and woodlands, it would also place the most restrictions on proactive management that would improve forest health and reduce the risk of catastrophic fire.

4.4.1.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

In addition to the impacts described above, the following paragraphs provide a general description of potential impacts to forests, woodlands, and forest products that would not differ among alternatives.

Forest management, including timber harvest, would contribute to improving overall forest health throughout the Planning Area. These types of actions would reduce the potential for catastrophic fires, reduce the number of diseased trees, enhance age and species diversity, and reduce the spread of invasive species. Specific proactive management actions common to all alternatives would restore the historic processes, composition, and structures of forests and woodlands, thereby maintaining the desired harvest level. Under all alternatives, the BLM manages to maintain sustainable populations of forest and woodland tree species within the context of other intermingled resources and resources

uses. This management approach would generally have beneficial impacts on forest and woodland communities, but in some cases may require compromise with competing uses.

There would be direct long-term adverse impacts to forest management in localized areas of new important cultural resources discoveries, because these sites would require protection. Such cultural sites could restrict the location of vegetative treatments and access roads, thereby decreasing the accessibility and the forest acreage available for treatments.

Consolidation of land ownership would have a long-term beneficial impact on forest resources through facilitation of management actions in blocks of forestland. If implemented, forest management activities would not be constrained by ownership boundaries. Easement acquisition and land tenure adjustments would help enhance access and aid in implementing forest management actions.

Objectives for acquiring or maintaining access to forested areas would keep these areas open to active forest management. Conversely, land transactions could fragment ownership and impact management of forests, woodlands, and forest products if management objectives are inconsistent; however, the low level of land designated for possible disposal would have negligible impacts on forests, woodlands, and forest products in the Planning Area as a whole.

Short-term impacts regarding the timing or location of vegetative treatments and the availability of forest products could result from temporary CSU restrictions, seasonal NSO restrictions, or no surface development restrictions within buffers for special status species and raptor nest sites in forests and woodlands. Seasonal restrictions for forest management may apply to existing or newly designated ACECs, WSAs, or lands with wilderness characteristics managed to preserve their wilderness characteristics.

Alternative A

Surface Disturbance

Alternative A would result in approximately 15,646 acres of long-term surface disturbance that may contribute to the decline in abundance, distribution, or health of forests and woodlands (Table 4-1); approximately 1,465 acres of long-term disturbance is projected to occur in forest and woodland communities, based on the percent cover of these vegetation types in the Planning Area. The BLM projects 30,000 acres of short-term surface disturbance from silvicultural treatments (Appendix T). Short-term surface disturbance would increase the potential for short-term adverse impacts to forests and woodlands through soil erosion and potential spread of invasive species. The use of BMPs would minimize these impacts. The long-term benefits from silvicultural treatments would reduce the likelihood of catastrophic fire through fuel removal, increase opportunities for natural regeneration, and control insects and disease. The use of silvicultural treatments may also create beneficial impacts by altering forests and woodlands toward DPC. The degree to which these treatments would alter forests and woodlands toward DPC would depend on the location, timing, and other factors of the treatments.

Resource Uses

Under Alternative A, oil, gas, and other minerals development would involve 25,552 acres of short-term surface disturbance, a portion of which could adversely impact forests and woodlands by contributing to a decline in abundance, distribution, or health (Appendix T). Under Alternative A, most of the Planning Area remains open to mineral extraction, and the extent of RFD of minerals facilities is second greatest under this alternative compared to the other alternatives. Most of the impacts would be temporary during the life of the operation, with most areas of disturbance reclaimed following closure of

operations; however, short-term adverse impacts from minerals development would include forest health degradation and habitat fragmentation.

Alternative A permits motorized vehicle use on existing roads and trails in most of the Planning Area. The level of public access granted from motorized travel may increase the potential for unplanned ignitions, unauthorized woodcutting, and the spread of invasive species. This would result in adverse impacts to forests, woodlands, and forest products. Permitting off-road motorized vehicle use in areas with limited travel designations to access dispersed campsites would result in road and trail proliferation that would increase erosion, degrade vegetation, and increase the potential for unplanned ignitions, adversely affecting forests, woodlands, and forest products.

Special Designations

Special designations could beneficially impact forests and woodlands if they place additional restrictions on activities that contribute to forest decline or degrade forest health (e.g., long-term surface disturbance). Special designations also could adversely impact forests and woodlands and forest products when they restrict vegetation treatments to achieve DPC or limit timber extraction availability or methods. Under Alternative A, the forests and woodlands in ACECs (see Table 4-21) would experience limited beneficial impacts due to restrictions on surface-disturbing activities and motorized travel. However, when restrictions limit certain silvicultural treatments they would adversely affect forests, woodlands, and forest products. Alternative A restricts motorized vehicle use in WSAs, which would reduce the likelihood of unplanned ignitions and could result in beneficial impacts.

Resources

Under Alternative A, wildland fire is used to restore fire-adapted ecosystems and to reduce hazardous fuels. Wildland fire at the appropriate intensity would provide beneficial impacts to forests and woodlands in the short term by reducing hazardous fuels to decrease the chance of stand-replacing fires, and in the long term, by diversifying stand age and improving forest health.

Management actions specific to wildlife and special status species could beneficially impact forests and woodlands if they restrict activities that degrade forest health. Conversely, they could adversely impact forests, woodlands, and forest products if they restrict forest management practices (e.g., vegetation treatments) or extraction activities. Under Alternative A, a seasonal TLS to prohibit all activity within a ¼-mile radius of active special status raptor species nests would restrict forest management practices, which may adversely impact forests, woodlands, and forest products. The BLM restores and maintains 25 to 200 acres of aspen stands per year for wildlife values until the number of managed acres reaches 2,000 to 4,000. This increases woodland abundance. Wildlife grazing and browsing could adversely impact the regeneration of aspen and other trees and shrubs.

Proactive Management

Alternative A allows harvesting in commercial forestland in a manner that protects and benefits watershed, wildlife, and riparian/wetland habitat values and emphasizes areas where forest health is a primary concern. This management would create long-term beneficial impacts, both to forests and forest products, by maintaining or improving forest health and improving the quality of forest products over the life of the plan. Under Alternative A, the BLM generally closes timber access and haul roads after completion of timber management, which limits vehicle access and the associated risk of unplanned ignitions and the spread of invasive species. This could beneficially impact forests.

Alternative A allows precommercial thinning in overstocked areas and regenerated timber sale areas when trees reach the 20- to 30-year age class, which would reduce stand density and allow the

healthiest trees to grow faster to harvest. This would create long-term beneficial impacts to forest products. In addition, reducing stand density makes forests more resistant to bark beetle infestation (Leatherman et al. 2007), and salvaging infested stands can slow the spread of bark beetles while preventing other safety hazards associated with dead stands (USFS 2007). Forest management actions under Alternative A slow the spread of bark beetles and result in beneficial impacts to forests.

Precommercial thinning also can benefit forests and woodlands in the long term, if performed at the appropriate intensity, by reducing the fuel load and the chance of catastrophic wildfire. Under this alternative, the BLM manages wildland fire and logging or timbering whenever possible to revitalize decadent stands, improve stand density, and increase canopy cover. This management action would benefit forest health but would not benefit forest products. Alternative A permits clear-cuts of no more than 900 feet in any direction, unless a long-term benefit to habitat results, which would create beneficial impacts to forest products by maintaining timber availability. However, clear-cuts could adversely affect forest health if they are large enough to substantially alter the microclimate or regeneration time of the forest or substantially increase soil erosion.

Planting conifer areas exposed by wildfire or harvesting if they do not regenerate naturally within 15 years of the disturbance would beneficially impact forest products by accelerating regeneration and therefore reducing the rotation time between harvests. Proactive management actions, such as performing woodland treatments in all woodland types and managing conifer encroachment to improve forest health conditions, would create beneficial impacts to forests and woodlands by improving forest health or increasing the abundance, distribution, and stand diversity of forests and woodlands. Alternative A employs a variety of silvicultural practices (e.g., clear cutting, shelterwood, tree and group selection) to accomplish forest health goals, which, if effects remain consistent with forest health objectives, would beneficially impact forests, woodlands, and forest products.

Alternative B

Surface Disturbance

Alternative B would result in 31 percent less acreage of long-term surface disturbance that may contribute to the decline in abundance, distribution, or health of forests and woodlands than Alternative A (Table 4-1). Alternative B would involve approximately 20,000 acres of short-term surface disturbance from silvicultural treatments, which would have fewer short-term adverse impacts on forests and woodlands than Alternative A. However, because fewer acres would be subject to treatment, Alternative B would have fewer long-term beneficial impacts on forests and woodlands (Appendix T). Under Alternative B, the potential for catastrophic fire would be greater and the ability to reduce insects and disease would be less than under Alternative A. The use of silvicultural treatments would create beneficial impacts of altering forests and woodlands toward DPC as identified similar to Alternative A, although to a lesser degree because of the smaller treatment area.

Resource Uses

Under Alternative B, oil, gas, and other minerals development would involve 17,306 acres of short-term surface disturbance (Appendix T), a portion of which may adversely impact forests and woodlands by contributing to a decline in abundance, distribution, or health of these areas. Although most of the Planning Area remains open to mineral extraction, compared to Alternative A, Alternative B has less RFD of minerals facilities. Most of the impacts would be temporary during the life of the operation with most areas of disturbance reclaimed following closure of operations. However, there may be short-term adverse impacts from minerals development, including forest health degradation and habitat

fragmentation. Alternative B would result in less adverse impact to forests and woodlands from minerals development than Alternative A.

Alternative B limits motorized vehicle use to designated roads and trails in most of the Planning Area, which would result in impacts similar to those under Alternative A, but to a lesser degree. Restricting motorized vehicle use to fewer travel routes also may adversely impact forest products by limiting access for commercial timber harvest. Prohibiting off-road motorized vehicle use for dispersed campsite establishment in areas with limited travel designations would eliminate the potential for new road and trail proliferation and reduce the impacts from this management action described under Alternative A.

Special Designations

Under Alternative B, the BLM manages a greater portion of forests and woodlands in the Planning Area within special designation areas (see Table 4-21). The BLM designates the Sheep Mountain and Rattlesnake Mountain ACECs, which contain aspen and conifer stands, under Alternative B. These ACECs implement restrictions on surface-disturbing activities and motorized vehicle use, and the BLM manages them as renewable energy and ROW avoidance areas. The BLM allows, where feasible, and stipulates vegetation and silvicultural treatments and fuels management in these ACECs. Alternative B closes WSAs to motorized vehicle use. Under Alternative B, the BLM restricts minerals development, road construction, and motorized vehicle use, while allowing vegetation treatments and prescribed fire, in lands with wilderness characteristics (all of which are managed to preserve their wilderness characteristics under this alternative). These management actions would beneficially impact forests and woodlands in these areas by maintaining their abundance and reducing the chance for wildfire. However, Alternative B also closes lands with wilderness characteristics to commercial or personal-use woodcutting, adversely affecting forest products by reducing their availability and eliminating the ability to performing commercial aspen and bark beetle treatments that would improve forest health. Special designations under Alternative B would involve more stipulations and restrictions applied to vegetative and silvicultural treatments and motorized vehicle use than Alternative A, which may result in limited adverse impacts to forest health and the availability of forest products. Overall, special designations under Alternative B would create more beneficial impacts to forests, woodlands, and forest products than under Alternative A by increasing restrictions on activities and resource uses that can degrade forest health or increase the chance of wildfire.

Resources

Under Alternative B, the BLM utilizes wildland fires to restore fire-adapted ecosystems for natural resource systems and to reduce hazardous fuels, resulting in similar beneficial impacts to those described under Alternative A. Most of the Planning Area is in FRCC Classes 2 and 3, which have the highest risk of catastrophic fire and of having lost or losing key ecosystem components (see Section 4.3 *Fire and Fuels Management*). Alternative B emphasizes natural processes that would take longer to achieve forest health objectives compared to Alternative A. This type of vegetation management would increase the risk, versus Alternative A, that Alternative B would be inadequate to diversify fuel conditions enough to substantially reduce the risk of catastrophic fire.

Under Alternative B, a TLS to prohibit activity within a 1-mile radius of active special status raptor species nests would have a greater adverse impact on forests, woodlands, and forest products than under Alternative A. Under Alternative B, the Absaroka Front Management Area, which is not managed under Alternative A, restricts some resource uses (e.g., mineral leasing and motorized vehicle use) that would reduce the abundance, distribution, or health of the 48,794 acres of forests and woodlands in its boundaries. Management of this area would allow silvicultural/vegetation and fuels treatments that

would benefit forest and woodland health and forest products. Alternative B restores 100 acres of aspen stands per year with similar beneficial impacts as identified under Alternative A.

Proactive Management

Under Alternative B, the BLM manages forests and woodlands for watershed stability, wildlife habitat, and forest health with an emphasis on natural processes to manage towards achieving forest health objectives. Alternative B permits timber harvesting and other silvicultural practices only where natural processes are unable to accomplish forest health goals, which would result in adverse impacts to forest products by reducing their availability. The BLM closes timber access and haul roads no longer required, which would create beneficial impacts similar to those under Alternative A by limiting motorized vehicle access. Alternative B only allows precommercial thinning for fuels treatment, which would create beneficial impacts to forests and woodlands by reducing fuel loads and the chance of catastrophic fire, and to forest products by improving future harvest quality. However, forest management actions under Alternative B may result in denser, more mature stands with less diverse age structure. Compared to Alternative A, Alternative B could result in greater adverse impacts by increasing the risk of spreading bark beetles. Overall, management of precommercial thinning under Alternative B is more restrictive than Alternative A and would result in less benefit to forest products and forest health.

Alternative B prohibits clear-cuts, which would beneficially affect forest health by preventing potential soil erosion. Conversely, prohibiting clear-cuts would adversely affect forest products by decreasing timber availability and restricting extraction methods, and would eliminate a management tool useful in the regeneration of early successional species (e.g., aspen and lodgepole pine) and treatment of insects and diseases. Additionally, restrictions on timber harvesting on BLM-administered lands may increase harvesting on private or other federal and state lands to make up for decreased availability on BLM-administered lands.

The BLM plants conifer areas exposed by wildfire and harvesting if they do not regenerate naturally within 20 years, resulting in less benefits to forest products than Alternative A, due to the longer rotation time. The BLM limits vegetative treatments and forest management only to areas where natural processes do not achieve forest health goals. The use of primarily natural processes to improve forest health would reduce the potential for erosion and the spread of invasive species, which would be short-term beneficial impacts. However, this practice could slow the rate of fuels production, thereby increasing the risk of catastrophic fire. This would result in long-term adverse impacts to forest health.

Under Alternative B, long-term beneficial impacts to old growth forests would result from managing for no net loss of this forest stand type over a 30-year period and in an appropriate proportion to other timber classes in a hydrologic unit code (HUC) Level 4 sub-basin. Such management would be more beneficial for old growth forest stands than Alternative A, where no specific management exists, but would lead to greater adverse impacts to forest products availability and slower production of new timber in areas managed for old growth than under Alternative A.

Alternative C

Surface Disturbance

Alternative C would result in approximately 165 percent more acreage of long-term surface disturbance that may contribute to the decline in abundance, distribution, or health of forests and woodlands than Alternative A (Table 4-1). Alternative C would result in 40,000 acres of short-term surface disturbance from silvicultural treatments (Appendix T). Potential short-term adverse impacts to forests and woodlands from surface disturbance would be greatest under Alternative C. However, compared to the

other alternatives, under Alternative C potential long-term beneficial impacts from these treatments are greatest. Long-term beneficial impacts include reducing the risk of catastrophic fire, increasing opportunities for natural regeneration, and reducing the spread of insects and disease. The use of silvicultural treatments would create the benefits of altering forests and woodlands toward DPC similar to Alternative A, although to a greater degree because the treatment area would be larger.

Resource Uses

Under Alternative C, oil, gas, and other minerals development would involve 25,912 acres of short-term surface disturbance, a small portion of which could adversely impact forests and woodlands by contributing to a decline in abundance, distribution, or health (Appendix T). Most of the Planning Area remains open to mineral extraction, and the RFD of minerals facilities is the greatest under Alternative C. Most of the impacts would be temporary during the life of the operation, with most areas of disturbance reclaimed following closure of operations. However, short-term adverse impacts from minerals development include forest health degradation and habitat fragmentation. Alternative C would result in the greatest adverse impacts to forests and woodlands from minerals development.

Alternative C would result in impacts from motorized vehicle use similar to those under Alternative A, but to a greater degree. The BLM limits motorized vehicle use to designated roads and trails in a larger area, but also opens a larger area to unrestricted off-road use, with impacts comparable those under Alternative A. Permitting off-road motorized vehicle use to access dispersed campsites would cause impacts similar to those under Alternative A.

Special Designations

Under Alternative C, the BLM manages the smallest acreage of forests and woodlands in the Planning Area within special designations (see Table 4-21). Only two ACECs are designated under this alternative. Although these designations would provide the least beneficial impact to forests and woodlands by limiting long-term surface disturbance, this alternative would result in the least adverse impact from restricting silvicultural treatments that improve forest and woodland health and generate forest products. Motorized vehicle use is less restricted in WSAs, which could create less beneficial impact in these areas by reducing the risk of unplanned ignitions.

Resources

Under Alternative C, the BLM utilizes wildland fires to restore fire-adapted ecosystems for natural resource systems, to reduce hazardous fuels, and to enhance forage for commodity production. This utilization of wildland fire under Alternative C would create beneficial impacts to forests and woodlands similar to Alternative A, and could benefit forest products more if the BLM used prescribed burns to affect forests similarly to precommercial thinning. Under Alternative C, the BLM would use mechanical, chemical, and biological treatments across the landscape as needed to restore vegetative diversity and reduce the risk of larger, more intense fires. This would benefit forests, woodlands, and forest products. Alternative C would present the least risk that vegetation management acreage is inadequate to diversify fuel conditions enough to substantially reduce the risk of catastrophic fire.

Under Alternative C, restrictions around special status raptor nests that potentially limit extraction and management practices are the least stringent, which would result in the least adverse impact to forests, woodlands, and forest products. Limiting motorized vehicle use to designated roads and trails subject to seasonal limitations in the Absaroka Front Management Area would create greater beneficial impacts than Alternative A by reducing the risk of unplanned ignitions in the 48,794 acres of forests and woodlands in the area. However, Alternative C allows more oil and gas development in this area that may adversely impact forests and woodlands. The BLM promotes aspen regeneration under all

alternatives and focuses woodland treatments on aspen stands under Alternative C. The BLM does not restore aspen woodlands for wildlife habitat or set a targeted annual acreage of aspen stand regeneration (such as under alternatives A and B) under this alternative; therefore, beneficial impacts from aspen regeneration may be less than under alternatives A and B.

Proactive Management

Under Alternative C, the BLM manages forests and woodlands to achieve a sustained supply of forest products. Alternative C allows timber harvesting in areas classified as commercial timberland, which would create the greatest beneficial impact to forest products by maximizing their availability. The BLM allows timber access and haul roads to remain open to meet other resource goals or for new recreational purposes, which may result in adverse impacts to forests and woodlands by increasing the potential for unplanned ignitions and the spread of invasive species. Alternative C allows precommercial thinning when trees reach the 10- to 20-year age class or are at least 5- to 15-feet tall. This would benefit forest products more than under the other alternatives by releasing the healthiest trees from competition at the earliest age so that they grow faster to harvest. Forest management actions under Alternative C may also result in less dense stands with a more diverse age structure than other alternatives. This would create the most beneficial impacts to forests and woodlands by potentially slowing the spread of bark beetles. Precommercial thinning also could benefit forests and woodlands, if performed at the appropriate intensity to reduce fuels and the chance of catastrophic fire. Alternative C allows clear cuts up to 100 acres, which would provide greater forest product availability than alternatives A and B and similar availability to Alternative D. Allowing larger clear cuts than under Alternative A may result in more adverse impacts to forests and woodlands, depending on the stand composition and slope of the site, from increasing regeneration time and soil erosion.

Under Alternative C, efforts to retain old growth forest areas at appropriate locations and distribution levels in an HUC Level 4 sub-basin as evaluations occur would result in similar beneficial impacts to those under Alternative B, but to a lesser extent. The less restrictive management under Alternative C may be less beneficial to the retention of this forest type than under Alternative B, but also would result in less adverse impacts to forest products production.

Planting conifer areas exposed by wildfire and harvesting if they do not regenerate naturally within 10 years would create the greatest benefit to forest products compared to the other alternatives. Logging or timbering before wildland fire and other natural processes to improve stand density would benefit forest products by increasing the availability and health of timber. Alternative C employs a variety of silvicultural practices (e.g., clear cutting, shelterwood, tree and group selection) to accomplish forest health goals, which, if effects remain consistent with forest health objectives, would benefit forests and forest products. In general, Alternative C would create the greatest benefit to forest products and more beneficial impacts to forests and woodlands than Alternative A, as long as managing forests for commodity production can reduce fuel levels without degrading forest health.

Alternative D

Surface Disturbance

Alternative D would result in approximately 17 percent more acreage of long-term surface disturbance that may contribute to the decline in abundance, distribution, or health of forests and woodlands than Alternative A (Table 4-1). Silvicultural treatments would result in impacts to forests and woodlands similar to those under Alternative A. Under Alternative D, the potential for catastrophic fire would be similar to Alternative A and the ability to reduce insects and disease would be similar to that under

Alternative C. The use of silvicultural treatments to manage forests and woodlands toward DPC would result in impacts similar to those under Alternative A.

Resource Uses

Minerals development under Alternative D would result in impacts to forests and woodlands similar to those under Alternative A. Motorized vehicle use would result in adverse impacts to forests and woodlands similar to Alternative A, although to a lesser degree because the BLM limits motorized vehicle use to designated roads and trails in more areas and limits off-road travel for big game retrieval to within 300 feet of established roads. More limitations on motorized vehicle use would benefit forest products less than Alternative A.

Special Designations

Under Alternative D, the BLM manages more forests and woodlands in special designations than alternatives A and C, but less than Alternative B. The BLM designates the Sheep Mountain ACEC, which would result in impacts similar to those under Alternative B, although to a lesser extent because Alternative D applies fewer restrictions on surface-disturbing activities. Restricting motorized vehicle use in WSAs would limit the potential for unplanned ignitions. This would create more beneficial impacts than Alternative C, but fewer than alternatives A and B.

Resources

Fire and fuels management under Alternative D would result in impacts to forests and woodlands similar to those under Alternative A. Management actions specific to protecting wildlife and special status species and their habitat would result in more adverse impacts to forests, woodlands, and forest products than alternatives A and C, but fewer than Alternative B. Actions to restore aspen woodlands would be similar to those under Alternative C and would result in similar impacts.

Proactive Management

Under Alternative D, proactive management actions for forests, woodlands, and forest products would be similar to those under Alternative A, with more beneficial impacts to forest products from allowing clear cuts up to 100 acres, more precommercial thinning, and managing endemic insects and disease with the full range of silvicultural techniques and treatment methods. Management actions to preserve old-growth stands would benefit forests and woodlands more than under Alternative A, which includes no such actions.

Alternative E

Surface Disturbance

Alternative E would result in 48 percent less acreage of long-term surface disturbance that may contribute to the decline in abundance, distribution, or health of forests and woodlands than Alternative A (Table 4-1), and a similar but slightly smaller acreage of surface disturbance than Alternative B. Under Alternative E, surface-disturbing activities that may contribute to the decline in abundance, distribution, or health of forests and woodlands would be the same as Alternative B, except for areas within the Greater Sage-Grouse Key Habitat Areas ACEC. In this ACEC, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) to not exceed one disturbance per 640 acres and cover less than 3 percent of the total priority sage-grouse habitat, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B; this additional surface disturbance restriction would result in greater beneficial effects than under Alternative B, as the Greater Sage-

Grouse Key Habitat Areas ACEC encompasses areas of forests and woodlands in addition to sagebrush steppe (shrubland) vegetation. Alternative E would involve the same acreage (20,000 acres) of short-term surface disturbance from silvicultural treatments as Alternative B.

Resource Uses

Under Alternative E, oil, gas, and other minerals development would result in 17,297 acres of short-term surface disturbance (Appendix T), a portion of which may adversely impact forests and woodlands by contributing to a decline in abundance, distribution, or health of these areas. Impacts from mineral development under Alternative E would be similar to Alternative B, but the location of development may vary due to greater limitations on surface disturbance within the Greater Sage-Grouse Key Habitat Areas ACEC under Alternative E. As with Alternative B, the majority of the impacts would be temporary during the life of the operation with most areas of disturbance reclaimed following closure of operations.

Management of motorized vehicle use and livestock grazing are similar to Alternative B, and impacts to forests and woodlands under Alternative E would therefore be similar to those described under Alternative B. Compared to Alternative A, limitations and closures to motorized vehicle use for resource protection, including seasonal motorized vehicle closures in greater sage-grouse Key Habitat Areas and for the protection of big game species, would result in beneficial impacts to forests and woodlands under Alternative E.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land in the Greater Sage-Grouse Key Habitat Areas ACEC. As a result, the BLM would manage a greater portion of forests and woodlands in the Planning Area with special designation areas under Alternative E (see Table 4-21). Overall, the relative size and additional restrictions on surface-disturbing activities in special designation areas under Alternative E would create more short-term beneficial impacts to forests, woodlands, and forest products than the other alternatives.

Resources

Under Alternative E, fire and fuels management practices and impacts are the same as Alternative B, with the exception of lands within the Greater Sage-Grouse Key Habitat Areas ACEC, which would be managed with an emphasis on protecting existing sagebrush ecosystems. In general, fuels treatments would be minimized in greater sage-grouse Key Habitat Areas and focused instead on interfaces with human habitation or significant existing disturbances. The build-up of fuels from limitations on fire management activities under Alternative E, which restricts the use of fire to treat sagebrush in less than 12-inch precipitation zones, may increase the potential for catastrophic fires in forest and woodland vegetation in the short term, but may decrease the risk of catastrophic fire in the long term through a return to more natural fire regimes. However, effects from the additional restrictions in this ACEC may be limited since its management also requires strategically and effectively designed fuels treatments to reduce wildfire to the greatest extent possible, potentially resulting in attempts to address areas of inadequate fuels treatments before catastrophic wildfires begin.

Vegetation management would be the same as Alternative B, with exception of lands within the Greater Sage-Grouse Key Habitat Areas ACEC, where management would emphasize the restoration and preservation of native sagebrush ecosystems to create a landscape pattern that most benefits sage-grouse. Activities in this ACEC that control juniper encroachment or stimulate herbaceous growth at interfaces with sagebrush habitats may also adversely impact forests and woodlands under

Alternative E. As a whole, vegetation and fire management practices under Alternative E may result in short-term adverse impacts to forests and woodlands by restricting activities that could improve forest health (e.g., fuels reduction) and allow the collection of forest products.

Proactive Management

Forest and woodland management under Alternative E is the same as Alternative B, and impacts to forests and woodlands would be the same as Alternative B.

Alternative F

Surface Disturbance

Impacts to forests and woodlands from surface disturbances under Alternative F are projected to be greater than alternatives A, B, and E, but less than alternatives C and D. Alternative F would result in approximately 12 percent more acreage of long-term surface disturbance that may contribute to the decline in abundance, distribution, or health of forests and woodlands than Alternative A. Management practices relating to surface disturbance would be the same as Alternative D, except within areas of the proposed Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). In this ACEC, the density of disturbance would not exceed an average of one disruptive activity location per 640 acres and cover less than 3 percent of the greater sage-grouse PHMAs, compared to a larger allowable disturbance of 5 percent under Alternative D. This additional restrictive management over that large ACEC (35 percent of BLM-administered surface land) would generally provide a short-term benefit to forest and woodland resources by limiting the size and extent of disturbances, but may reduce the ability to control insects and disease and may increase the potential for catastrophic fire in the area compared to alternatives A and D. However, in general the BLM anticipates Alternative F would result in the same acreage (30,000 acres) of short-term surface disturbance from silvicultural treatments as Alternative D, though the location of those treatments under Alternative F may vary due to the additional restrictions on anthropogenic disturbances.

Resource Uses

Alternative F manages mineral resource exploration, development, and extraction similar to Alternative D, and impacts to forests and woodlands would be similar to Alternative D. However, Alternative F places additional restrictions on mineral development, including limiting disturbances to one per 640 acres and 3 percent or less of the greater sage-grouse PHMAs. This additional restrictive management would reduce impacts from surface disturbance compared to alternatives A, C, and D, but not compared to alternatives B or E.

Management of motorized vehicle use under Alternative F would provide greater protections for forests and woodlands than under alternatives A, C, and D, but fewer protections than under alternatives B and E. Alternative F manages motorized vehicle use the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC, where such travel is limited to designated roads and trails, reducing potential adverse impacts compared to Alternative D. Under Alternative F, disturbances associated with the creation of new roads and trails is projected to be less than alternatives A, C, and D, but higher than under alternatives B and E. Additional limitations on motorized vehicle use would have greater adverse impacts on forest products than alternatives A, C, and D, but less than alternatives B and E. As stated under Alternative A, authorized or permitted uses that specify allowable access are not affected by travel management designations.

Special Designations

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. Overall, the relative size and additional restrictions on surface-disturbing activities in special designation areas under Alternative F would result in greater short-term beneficial impacts to forests and woodlands than Alternative D.

Resources

Fire and fuels management would result in impacts to forests and woodlands similar to those under alternatives A and D, except in the Greater Sage-Grouse PHMAs ACEC. Additional restrictions on fuels treatment and prescribed fire in this ACEC would prioritize the conservation and restoration of native sagebrush habitats over other priorities, and would design and implement fuels treatments with an emphasis on protecting existing sagebrush ecosystems. Additional restrictions on where and how fuels treatments are implemented may increase the build-up of fuels under Alternative F and increase the potential for catastrophic fire in the short term; however, the extent of this build-up may be limited due to management under this alternative that designs treatments to reduce wildfire to the greatest extent possible. Overall, specific management actions to protect wildlife, special status species, and their habitats under Alternative F would result in more adverse impacts to forests, woodlands, and forest products than alternatives A, C, and D, but fewer than alternatives B and E.

Proactive Management

Under Alternative F, management of forests and woodlands is the same as Alternative D, and the impacts would be the same as Alternative D.

4.4.2 Vegetation – Grassland and Shrubland Communities

Adverse impacts to grassland and shrubland communities include actions that contribute to the decline in abundance or distribution of these communities. Conversely, beneficial impacts to grassland and shrubland communities include actions that protect or restore the communities in the Planning Area.

Direct impacts to grassland and shrubland communities result from surface disturbance and other activities that remove vegetation and cause mechanical damage to plants. Surface-disturbing activities generally result in an adverse direct impact. Activities such as livestock grazing, wildlife use, wildland fire, and vegetative treatments (e.g., planned ignitions, chemical, or biological) also result in direct adverse or beneficial impacts to these communities.

Indirect impacts to grassland and shrubland communities result from activities that alter the quality and health of these communities. For example, activities that compact soil, cause erosion, cause changes in hydrology, and cause invasive species encroachment would cause indirect impacts. Beneficial impacts to grassland and shrubland communities include vegetative treatments to improve these communities and activities that minimize, reduce, or prevent the spread of invasive species into these communities.

4.4.2.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Current trends in plant succession and vegetation health would continue.
- Some existing plant communities likely would not be reestablished to pre-disturbance structure and density for more than 20 years. Actual reclamation success and timeframes are subject to high variability based on the characteristics of the affected plant community, climatic factors, and other site-specific conditions. For example, the reestablishment of Wyoming big sagebrush communities following disturbance from prescribed fire or wildfire has been known to take over 100 years (Cooper et al. 2007).
- Short-term vegetation impacts depend on the length of time it takes for a disturbed area to become revegetated, generally a 1- to 5-year timeframe.
- For the purposes of this analysis, grassland and shrubland communities include the 'Sagebrush Shrubland' and 'Salt Desert Shrub' cover types listed in Table 4-21, with intermixed grassland components as described in Chapter 3, Section 3.4.2 *Vegetation – Grassland and Shrubland Communities*.
- Grassland and shrubland communities would be maintained with a mix of species composition, cover, and age classes.
- Based on the definition of surface-disturbing activity (mechanized actions), an increased source of surface disturbance in the Planning Area will be from bentonite and gypsum development.
- Surface disturbances increase the likelihood of the spread of invasive species in an area.
- The placement of supplements can affect the distribution of livestock grazing in grassland and shrubland communities.
- The primary conduit for the initial establishment of the spread of invasive species is through the road network.
- Herbivory use in the form of grazing and browsing is important for maintaining the health of grassland and shrubland communities. Improper or unmanaged herbivory can decrease plant vigor and ground cover, lead to increased erosion, degrade soil nutrients and water retention, and impact rangeland health.
- Grazing practices can maintain, improve, or degrade rangeland health. *The Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N) are designed to maintain or improve rangeland health and are applied under all alternatives.
- Fire plays an intricate role in these communities, particularly shrubland communities.
- Prescribed fire is a tool used to manage vegetative communities and can result in short-term adverse impacts with long-term beneficial impacts to wildlife, certain desirable wildlife habitats, and in some cases forage availability and productivity.

4.4.2.2 Summary of Impacts by Alternative

Adverse impacts to grassland and shrubland communities would result from surface-disturbing activities and other actions that alter the distribution and abundance of grassland and shrubland communities and change the community structure and diversity. Therefore, management actions that result in more surface disturbance would result in more adverse impacts to these communities. Alternative C would involve the most surface disturbance to grassland and shrubland communities, followed by

alternatives D, F, A, B, and E. Other adverse impacts may result from concentrated livestock grazing that compacts soil and degrades the health of vegetation communities. However, proper grazing practices would reduce the potential for these impacts and may improve resource conditions in certain areas. Under alternatives B and E, allotment monitoring practices, Allotment Management Plan (AMP) development, livestock flushing practices, and rangeland improvements would cause the fewest adverse impacts to grassland and shrubland communities, but would also restrict grazing from certain areas where it could be used as a management tool to improve resource conditions.

Reclamation practices under Alternative E would facilitate the restoration of disturbed areas the most, followed by alternatives B, F, D, A, and C. Special designations and other resource programs under alternatives B and E protect the most grasslands and shrublands from surface disturbance and degradation due to off-road motorized vehicle use, followed by alternatives F, D, A, and C. However, Alternative E would involve the least amount of treatment to prevent wildfires and eradicate invasive species. Alternatives A, D, F, and C allow for more treatment of grassland and shrubland communities, but overall, adverse impacts due to surface disturbance under these alternatives are likely to be greater than under Alternative E. Alternative C would result in the greatest adverse impact to grassland and shrubland communities, followed by alternatives A, D, F, B, and E.

4.4.2.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Impacts to grassland and shrubland communities under the various alternatives would be similar; however, the extent and intensity of impacts would vary by alternative. Therefore, discussions for individual alternatives describe impacts to grassland and shrubland communities from surface-disturbing activities, motorized vehicle use, livestock grazing management, special designations, fire management, wildlife management/use, and proactive management actions under the individual alternatives. The following paragraphs generally describe impacts to grassland and shrubland communities regardless of the alternative selected.

Minerals development impacts to grassland and shrubland communities would include long- and short-term impacts, small and localized removal of vegetative surface cover, and larger disturbances covering many acres. There would be surface disturbance from bentonite and gypsum mining under all alternatives, increasing with the area available for locatable mineral entry. Mineral development would alter the distribution and abundance of grassland and shrubland communities and change community structure and diversity. Long-term impacts would mostly be associated with permanent structures and road construction, but some grassland and shrubland communities would not reestablish to pre-disturbance structure and density for more than 20 years. The severity of impacts would depend on the precipitation zone, amount of activity, and the success of reclamation efforts for disturbed areas. The *Impacts Common to All Alternatives* section under *Vegetation Resources* describes impacts from other surface-disturbing activities, including ROW development that would affect grasslands and shrublands.

Motorized vehicle use on public lands may result in adverse short-term and long-term impacts to vegetation in grassland and shrubland communities. A one-time disturbance from off-road motorized vehicle use causes physical damage to vegetation by breaking stems and branches and may disturb the soil surface, depending on soil conditions, slope, and ground cover. With a one-time disturbance, plants and disturbed areas usually recover. However, with repeated use, new trails become established. This results in the long-term reduction of vegetation cover and density, and changes species composition. In

areas with significant biological soil crusts, a one-time off-road disturbance can remain visible for many months and is prone to repeated use.

Livestock grazing can cause both adverse and beneficial impacts to vegetation communities. Historically, overgrazing of native perennial grasses has contributed to the spread of nonnative annual grasses (DiTomaso 2000). However, proper grazing in grassland and shrubland communities does not adversely impact rangeland health, and may improve it in certain instances. Manier and Hobbs (2007) found that livestock grazing in sagebrush communities can increase plant species richness and diversity, and Muscha and Hild (2006) found no substantial difference in biological crust cover between areas grazed and areas with light to moderate grazing throughout Wyoming. Improving plant vigor, increasing vegetative cover, and reducing invasive species infestations can occur through removing old growth and decadent vegetation that inhibits new growth. Healthier plant communities are more resistant to the spread of invasive species and other undesirable plant species. Livestock grazing of noxious weeds at crucial points in their life-cycles can decrease the spread of invasive species. Proper livestock grazing management also increases a plant community's resistance to cheatgrass invasion after a disturbance such as wildland fire (Davies et al. 2009).

Under all of the alternatives, wild horse grazing—if concentrated or localized year-round—within HMAs may result in adverse impacts to grassland and shrubland communities by compacting soils and removing vegetation. Expanding the McCullough Peaks HMA under alternatives B and D may increase the extent of adverse impacts to grasslands and shrublands from concentrated wild horse grazing.

Wildland fire and prescribed fire have both adverse and beneficial impacts to grassland and shrubland communities. In the short term, wildland fires remove vegetation and create an opportunity for the establishment or spread of invasive and noxious weeds. Many invasive species respond rapidly after fire, and can out-compete native species. In areas where invasive species are present, wildland fire increases the likelihood of invasive species expansion. Firefighters and their equipment may also introduce or spread invasive species. Some mechanical control activities disturb the soil surface and remove vegetation, creating an opportunity for invasive species to become established or spread.

In the long term, because of the role fire historically played in these communities, fire would increase vegetative diversity across the landscape, rejuvenate decadent plants, and improve the overall health of these communities. In shrubland communities, impacts from fire usually are long-term and depend on the scale and severity of the disturbance. The potential for sagebrush shrublands to return after fire depends on the acreage burned, the distance to seed sources, and the spread of invasive species, such as cheatgrass, which can increase fire frequency. Limiting or protecting acreage from fire may, in some cases, lessen direct loss of grassland and shrubland communities and reduce the potential spread of invasive species in the short term. However, considering the historic role of fire in maintaining vegetative composition and structure, the lack of fire may decrease the overall health of these communities. Wildlife impacts to vegetation depend on population levels, the distribution of animals, and the ability of animals to move. Crucial winter ranges for mule deer and pronghorn, where shrubs are heavily used, may exhibit vegetation shifts from sagebrush, bitterbrush, and mountain mahogany to conifers, grasses, forbs, and annuals, and in some cases, bare ground. Management actions that prohibit surface-disturbing activities to protect special status species, such as the greater sage-grouse, in grassland and shrubland communities also would benefit vegetation in these areas.

Specific proactive management actions common to all alternatives would benefit grasslands and shrublands to ensure that the selected alternative will meet the goals and objectives for these resource programs. Proactive management actions common to all alternatives include managing vegetative communities in accordance with the *Wyoming Standards for Healthy Rangelands* (Appendix N) and continuing to use ecological site descriptions (ESDs), resource objectives, specific management

practices, or other reasonable or practical options to maintain or achieve the standards; continuing to regularly monitor and evaluate climatic and vegetative data to analyze shifts in rangeland production to implement actions, if necessary, to ensure the long-term productivity of rangeland; using certified noxious-weed-free vegetation products on all BLM-administered lands; and maintaining 10 to 30 percent sagebrush canopy cover on suitable lands in greater sage-grouse PHMAs. Refer to Chapter 2 for goals, objectives and a complete list of management actions common to all alternatives for grassland and shrubland communities.

Alternative A

Surface Disturbance

Under Alternative A, approximately 116,578 acres of short-term and 13,387 acres of long-term surface disturbance is projected to occur in grassland and shrubland communities, based on the percent cover of these vegetation types in the Planning Area. Under Alternative A, impacts to grassland and shrubland communities associated with surface-disturbing activities would be primarily adverse. Short-term adverse impacts include soil erosion, loss of species diversity, and invasive species spread; however, the relatively small size of individual disturbed areas and the implementing BMPs would minimize these short-term impacts. Long-term impacts from development last longer than 5 years and primarily include a decrease in abundance and distribution of grasslands and shrublands. Table 4-21 lists the acreages of grasslands and shrublands protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under Alternative A.

Routinely seeding, or requiring permittees and operators to seed, disturbed areas with native plant species would encourage native vegetation cover, maintain biological integrity, help shift vegetative communities toward DPC, and reduce the potential for the spread of invasive species. These would be beneficial impacts to grassland and shrubland communities. Conversely, seeding with only native species may reduce reclamation success compared to using the species most likely to restore vegetative cover, whether native or nonnative. Alternative A does not require a reclamation plan, the purpose of which is to incorporate measures to support the return of as much of the disturbed acreage to its predisturbed state as quickly as feasible upon conclusion of operations from a given surface pad. Not requiring comprehensive measures and monitoring to ensure the reclamation of areas following surface disturbance would result in a greater short-term adverse impact. However, reestablishing vegetation cover over disturbed soils within 5 years of initial seeding would encourage native vegetative structure and reduce long-term impacts associated with exposed soils (e.g., establishment and spread of invasive species). These would be beneficial impacts to grassland and shrubland communities.

Resource Uses

Under Alternative A, oil, gas, and other minerals development is project to result in 25,552 acres of short-term surface disturbance and 1,184 new oil and gas wells, a portion of which would adversely impact grassland and shrubland communities by contributing to a decline in their abundance, distribution, or health (Appendix T). Most of the Planning Area would remain open to mineral extraction. Alternative A makes available 4,130,352 acres for locatable mineral entry, which would involve long-term surface disturbance in the portion of that acreage where development occurs. Alternative A would result in impacts to grassland and shrubland communities from bentonite and gypsum development. Some of the impacts would be temporary during the life of the operation, with areas of disturbance reclaimed following closure of operations, but some areas may not reestablish pre-disturbance structure and density for more than 20 years.

Invasive species would adversely affect grassland and shrubland communities under Alternative A. The spread of invasive species reduces diversity in grasslands and shrublands and, in the case of cheatgrass spread, alters the fire regime so that fires burn frequently and rapidly. Under Alternative A, the BLM would perform vegetation treatments to control or eradicate invasive species on 2,000 acres. The projected surface disturbance from vegetative treatments under Alternative A would result in short-term adverse impacts, but would benefit grassland and shrubland communities over the long term.

Alternative A would involve the second-most acreage of surface disturbance from pipeline and road development. Pipeline disturbance would be short-term, because reclamation would return herbaceous cover to the disturbance areas following construction. However, grassland and shrublands in low precipitation zones may not return to pre-disturbance cover for more than 20 years. The amount of new road construction in grassland and shrubland communities would impact these areas proportionately through the loss of vegetation and potential spread of invasive species. New roads also would fragment grassland and shrubland communities, which may reduce species diversity.

Motorized vehicle use is limited to existing roads and trails in most of the Planning Area under Alternative A. Even when confined to roads, motorized vehicles increase the potential for invasive species spread and poorly designed or maintained roads may increase erosion and affect adjacent vegetation. Areas with grasslands and shrublands that allow OHV activities, but are further restricted by limiting use to designated roads and trails, include the Absaroka Mountain Foothills SRMA and Bighorn River SRMA. Alternative A allows OHV use in areas with limited travel designations for big game retrieval and dispersed campsite access, which could result in road and trail proliferation that would damage vegetation and impact grasslands and shrublands. Areas where damage from off-road use is most likely include stream crossings, areas with highly erosive soils, steep slopes, areas with important biological soil crusts, and vegetative communities with plants, such as Wyoming big sagebrush, susceptible to physical damage. Motorized vehicle use under Alternative A would result in adverse impacts to grassland and shrubland communities.

Livestock grazing management under Alternative A would have both adverse and beneficial impacts to grassland and shrubland communities (see Table 4-21). Under Alternative A, the BLM emphasizes monitoring on category “I” allotments, treats monitoring on category “M” and “C” allotments as a low priority, and develops and implements AMPs as needed to meet multiple use objectives. By emphasizing monitoring only on higher priority allotments, undesirable conditions in lower priority allotments may not be identified and deterioration or improvement in grassland and shrubland communities may not be realized in a timely manner. However, concentrating monitoring on category “I” allotments would beneficially affect these allotments because undesirable conditions would be identified more quickly. When appropriately managed according to the *Wyoming Guidelines for Livestock Grazing Management* and other appropriate BMPs, livestock grazing would benefit grasslands and shrublands as described under *Impacts Common to All Alternatives*.

The BLM requires livestock flushing on a case-by-case basis, allowing for the potential spread of invasive species via livestock to grazed grassland and shrubland communities. However, identifying and flushing potential vector livestock would reduce the threat of invasive species spread in some instances. Rangeland improvements such as reservoirs, pits, pipelines, and wells would involve removing vegetation and may concentrate livestock and increase the potential spread of invasive species. Due to allotment monitoring practices, AMP development, livestock flushing practices, and projected rangeland improvements, livestock grazing under Alternative A would, overall, benefit grasslands and shrublands by continuing to improve these vegetation types in the Planning Area.

Special Designations

Special designations would benefit grasslands and shrublands where the designations protect areas from resource uses or activities that may damage or destroy vegetation or increase the potential for wildfire or invasive species spread. The primary purpose of the Carter Mountain ACEC designated under Alternative A is to protect grassland and shrubland communities. The setting consideration zone (SCZ) around the Nez Perce (Neeme-poo) NHT and other trails may protect areas of grasslands and shrublands from disturbance. Table 4-21 lists the acreages of grassland and shrubland communities in special designation areas; the designations would limit adverse impacts to these vegetation communities.

Resources

The vegetation treatments applied according to the fire and fuels management actions under Alternative A may be inadequate to reduce fuel conditions enough to substantially diminish the risk of catastrophic fire. Most of the Planning Area is in FRCC Classes 2 and 3, which have the highest risk of catastrophic fire or of having lost or losing key ecosystem components (see Section 4.3 *Fire and Fuels Management*). Intense fires in areas where fuels exceed historical levels may destroy the seeds of perennial grasses and shrubs and alter soils to increase the risk of invasive species establishment. The BLM would apply most of the total projected prescribed fire and fuels treatment acreage under Alternative A (70,000 acres) to grassland and shrubland communities not meeting DPC objectives (Appendix T).

Under Alternative A, the BLM utilizes wildland fires to restore fire-adapted ecosystems and to reduce hazardous fuels. Alternative A would involve the second highest level of surface disturbance from prescribed fire and fuels treatments. Prescribed fire would cause a short-term adverse impact to grasslands and shrublands by destroying vegetation, increasing soil erosion, and increasing the potential spread of invasive species. However, the relatively small size of individual treatment areas and the use of BMPs would minimize these short-term impacts. Prescribed fire and fuels treatments would benefit grassland and shrubland communities in the long term by reducing fuels and preventing catastrophic fires. Overall, fire and fuels management under Alternative A would result in long-term beneficial impacts to shrubland and grassland communities.

Wildlife management actions under Alternative A would indirectly benefit grassland and shrubland communities. Alternative A prohibits domestic sheep grazing on pronghorn crucial winter range, unless adverse impacts can be avoided or mitigated, reducing the potential for increased herbivory that may shift shrubland communities to conifers, grasses, forbs, and annuals. Limiting surface-disturbing activities around greater sage-grouse leks and in winter, nesting, and early brood-rearing habitats would create short-term beneficial impacts to grassland and shrubland communities in these areas. However, if these restrictions prevent vegetation treatments that would improve grassland and shrubland health in the long term, they may adversely impact communities in these areas. The short-term beneficial impacts of preventing vegetation loss from surface disturbance may outweigh potential loss of long-term benefits from vegetation treatments.

Proactive Management

Alternative A would result in beneficial long-term impacts to grassland and shrubland health by managing grassland and shrubland communities on 600,000 acres of BLM-administered land toward DPC objectives for watershed protection and livestock grazing. Managing toward DPC objectives improves overall community health, improves plant vigor, reduces the potential for erosion, and improves forage for livestock and wildlife. Because the BLM implements these management actions on

a portion of grassland and shrubland communities, Alternative A would create limited long-term beneficial impacts to grasslands and shrublands.

Alternative B

Surface Disturbance

Under Alternative B, approximately 63,263 acres of short-term and 9,320 acres of long-term surface disturbance is projected in grassland and shrubland communities, based on the percent cover of these vegetation types in the Planning Area. Impacts to grassland and shrubland communities associated with surface-disturbing activities would be less than Alternative A under this alternative. Table 4-21 lists the acreages of grasslands and shrublands protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

Under Alternative B, the BLM analyzes surface-disturbing activities by mapping soils, collecting soil samples for physical and chemical analysis, and evaluating current erosion conditions. Alternative B requires that disturbed areas be reestablished with 50 percent of native vegetative cover within three growing seasons, and 80 percent cover within five growing seasons of initial seeding, based on preexisting conditions. Alternative B also manages disturbed areas to reestablish healthy native plant communities based on preexisting composition or other species, as identified in an approved management plan. Approving reclamation plans before all surface-disturbing activities under this alternative would minimize short-term adverse impacts by requiring project proponents to propose comprehensive measures and monitoring to ensure reclamation of areas following surface disturbance. Reclamation practices under Alternative B increase the chance of successful reestablishment of grasslands and shrublands in disturbed areas. Based on management of reclamation and the amount of long-term disturbance acreage projected under Alternative B, this alternative would result in less short- and long-term adverse (and more beneficial) impacts to grassland and shrubland communities than Alternative A.

Resource Uses

Under Alternative B, oil, gas, and other minerals development would result in 17,306 acres of short-term surface disturbance and 502 new oil and gas wells, resulting in impacts similar to those under Alternative A, but to a lesser degree (Appendix T). Alternative B leaves less area available for locatable mineral entry (3,888,990 acres) than Alternative A, which would result in less long-term surface disturbance. Some of the impacts would be temporary during the life of the operation, with areas of disturbance reclaimed following closure of operations.

Adverse impacts from invasive species would be similar to those under Alternative A, but to a lesser degree. Alternative B would involve fewer acres of surface disturbance to control or eradicate invasive species. However, due to the projected overall surface disturbance, reclamation practices, and motorized vehicle use restrictions, Alternative B also would leave less area vulnerable to invasive species establishment. Therefore, Alternative B would result in less adverse impacts to grassland and shrubland communities from invasive species than Alternative A.

Alternative B would involve fewer acres of disturbance from pipeline and road development, and increase the chance of successful reestablishment of grasses and shrubs following construction, compared to Alternative A. Alternative B also would result in less new road construction. Compared to Alternative A, projected new roads under Alternative B and management designed to manage for large contiguous blocks of important plant communities along with managing more acreage as ROW

avoidance and exclusion areas would present less potential for fragmentation of grasslands and shrublands and associated loss of diversity.

Motorized vehicle use under Alternative B would cause impacts to grasslands and shrublands similar to those under Alternative A, but to a lesser degree. Most of the Planning Area is limited to designated roads and trails, including areas in the West Slope and Badlands areas, limiting impacts to grasslands and shrublands from motorized vehicle use. Alternative B prohibits off-road motorized vehicle use for big game retrieval and dispersed campsites, which would reduce adverse impacts to grasslands and shrublands by preventing road and trail proliferation and vegetation damage. Alternative B would involve more long-term surface disturbance associated with the creation of new roads and trails for recreational purposes than Alternative A, with proportional impacts to grasslands and shrublands from vegetation removal. Compared to Alternative A, Alternative B would result in less adverse impacts to grassland and shrubland communities from motorized vehicle use.

Alternative B would result in extensive monitoring and grazing management to identify and improve grassland and shrubland conditions in a timely manner. Under Alternative B, the BLM monitors all allotments and develops or revises AMPs for all “I” allotments or allotments not meeting the *Wyoming Standards for Healthy Rangelands* (Appendix N). The authorized officer can require livestock flushing for up to 72 hours to reduce the threat of invasive species spread via livestock to grassland and shrubland communities. Alternative B would result in fewer disturbed acres from rangeland improvements such as reservoirs, pits, pipelines, and wells (Appendix T) than Alternative A, posing less threat to grasslands and shrublands from invasive species spread and livestock concentration. Conversely, decreasing surface-disturbing rangeland improvement activities may adversely affect some grassland and shrubland communities where problems with livestock distribution cannot be addressed without these projects. Due to allotment monitoring practices, AMP development, livestock flushing practices, and projected rangeland improvements, livestock grazing management under Alternative B would result in less adverse and more beneficial impacts to grasslands and shrublands than Alternative A.

Under Alternative B, the BLM closes greater sage-grouse Key Habitat Areas and elk and bighorn sheep crucial winter range to livestock grazing (Table 4-21). This management would have a beneficial impact on some grasslands and shrublands by increasing vegetation cover and reducing the chance of soil compaction and invasive species spread. However, a recent land management modeling effort over large areas in eastern Nevada concluded that the proposed removal of livestock grazing alone had little impact on vegetation resiliency, rather, active restoration (e.g., prescribed fire, mechanical and chemical treatments) was required to improve degraded habitats (Provencher et al. 2007). Other research indicates removing grazing will increase woody plant cover and may reduce species richness and diversity (Manier and Hobbs 2007). Any beneficial impacts to grasslands and shrublands in greater sage-grouse Key Habitat Areas and bighorn sheep crucial winter range from the removal of livestock grazing may, therefore, be limited. The removal of livestock grazing would also mean that any beneficial impacts to these areas that would result from properly managed livestock grazing under Alternative A, such as increased resilience to disturbance and removal of decadent vegetation, would not be realized under Alternative B.

Special Designations

Proposed special designations to protect grassland and shrubland communities under Alternative B include the Carter Mountain (existing and expansion areas), Little Mountain (expansion area), Clarks Fork Canyon, Chapman Bench, Rattlesnake Mountain, and Sheep Mountain ACECs. Under Alternative B, the BLM manages all lands with wilderness characteristics specifically to preserve their wilderness characteristics, and restrict resource uses and activities in these areas that may damage grassland and

Vegetation – Grassland and Shrubland Communities

shrubland vegetation. Alternative B applies a buffer around the Heart Mountain Relocation Center National Historic Landmark and the Nez Perce (Neeme-poo) NHT to restrict surface-disturbing activities and motorized vehicle use, which would benefit grassland and shrubland communities in these areas to a greater extent than Alternative A. Table 4-21 lists the acreages of grassland and shrubland communities in special designation areas under Alternative B.

Resources

Under Alternative B, the BLM utilizes wildland fires and other vegetation treatments to restore fire-adapted ecosystems and to reduce hazardous fuels. However, Alternative B would result in fewer acres of prescribed fire and fuels treatments (25,000 acres) than Alternative A, which would increase the risk of catastrophic fire due to inadequate fuel reductions (Appendix T). This alternative would result in less long-term beneficial impacts from preventing fire that may destroy and permanently alter grassland and shrubland communities, compared to Alternative A.

Wildlife management actions under Alternative B would indirectly benefit grassland and shrubland communities to a greater extent than Alternative A. Alternative B prohibits all new domestic sheep grazing on pronghorn crucial winter range, reducing the potential for overgrazing due to dietary overlap of the two species more than Alternative A. Under Alternative B, the Absaroka Front Management Area, to which the BLM does not apply specific management actions under Alternative A, restricts some resource uses (e.g., mineral leasing and motorized vehicle use) that would remove vegetation or damage grassland and shrubland health. Compared to Alternative A, Alternative B places greater limitations on surface disturbance around greater sage-grouse leks and in winter, nesting, and early brood-rearing habitats, which would result in a greater beneficial impact. However, Alternative B may also reduce long-term beneficial impact in these areas in comparison to Alternative A by restricting vegetation treatments in areas where the plant community is extremely degraded, especially by the occurrence of noxious weeds, or by the increase in certain conifer species (e.g., juniper). The short-term beneficial impacts of preventing vegetation loss from surface disturbance may outweigh potential loss of long-term benefits from vegetation treatments where they are necessary to restore degraded vegetation communities.

Proactive Management

Under Alternative B, the BLM must achieve or make progress towards the reference state plant community based on the ESD for the site in all grasslands and shrublands, benefitting these communities by making progress toward improving vegetation conditions. The BLM would also manage to maintain large contiguous blocks of native plant communities, which would result in beneficial impacts to grassland and shrubland communities; however, Alternative B includes fewer acres of vegetation treatments to improve vegetation conditions than Alternative A (Appendix T).

Alternative C

Surface Disturbance

Under Alternative C, approximately 210,171 acres of short-term and 35,495 acres of long-term surface disturbance is projected in grassland and shrubland communities, based on the percent cover of these vegetation types in the Planning Area. Under Alternative C, the impacts to grassland and shrubland communities associated with surface-disturbing activity is more than any other alternative. Table 4-21 lists the acreages of grasslands and shrublands protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

Under Alternative C, the BLM analyzes surface-disturbing activities by mapping soils, collecting soil samples for physical and chemical analysis, and evaluating current erosion conditions on a case-by-case basis. Alternative C requires that disturbed areas are reestablished with 30 percent of desired vegetative cover within three growing seasons (with no long-term cover requirement) and requires reclamation plans on a case-by-case basis, which would result in a greater beneficial impact from stabilizing soil than Alternative A, but less than alternatives B and D. Allowing the use of approved nonnative seed and reestablishing plant communities to increase commodity production in disturbed areas may result in more immediate soil stabilization in the short term (depending on the species used) than Alternative A, but would also adversely impact disturbed areas by reducing the potential for reestablishing native plant communities in the long term. Based on the reclamation actions under Alternative C and the amount of long-term disturbance acreage projected, this alternative would result in the greatest adverse (and least beneficial) short- and long-term impacts to grassland and shrubland communities.

Resource Uses

Under Alternative C, oil and gas and other minerals development would result in 25,912 acres of short-term surface disturbance and 1,304 new oil and gas wells, resulting in impacts similar to those under Alternative A, but to a greater degree (Appendix T). Locatable minerals development under Alternative C would result in similar long-term surface disturbance and associated impacts as those under Alternative A. Overall, minerals development under Alternative C would result in the greatest adverse impacts to grassland and shrubland communities.

Adverse impacts from invasive species would be similar to those under Alternative A, but to a greater degree. Alternative C would result in the most acres of invasive species control or eradication activities. However, Alternative C would also leave the largest area vulnerable to new invasive species establishment due to new surface disturbance (245,642 acres), less rigorous reclamation requirements, and the least restrictive management of motorized vehicle use. Based on these factors, Alternative C would result in the greatest adverse impacts to grassland and shrubland communities from invasive species, relative to the other alternatives.

Alternative C would result in the greatest acreage of disturbance from pipeline and road development and the smallest chance of successful reestablishment of grasses and shrubs following construction. Alternative C also would result in the most new road construction. The projected new roads under Alternative C would result in the greatest potential for fragmentation of grasslands and shrublands and the associated loss of species diversity relative to the other alternatives, particularly since this alternative does not, like Alternative B, manage for large contiguous blocks of important plant communities and manages less acreage as ROW avoidance and exclusion areas.

Motorized vehicle use under Alternative C would result in impacts to grasslands and shrublands similar to those under Alternative A, but to a greater degree. Alternative C limits motorized vehicle use to designated roads and trails in more area than Alternative A, but closes less area. Under Alternative C, the BLM also limits motorized vehicle use to designated roads and trails with seasonal closures in the Absaroka Front Management Area, which encompasses grassland and shrubland communities. Under Alternative C, BLM actions would result in the most long-term surface disturbance from motorized vehicle use, of which a portion would directly impact grasslands and shrublands by removing vegetation. Allowing off-road motorized vehicle use for big game retrieval and dispersed campsites as long as there is no resource damage would put grassland and shrubland communities at greater risk of adverse impacts than Alternative B in this regard. Overall, Alternative C would result in the greatest adverse

impacts to grassland and shrubland communities from motorized vehicle use, compared to the other alternatives.

Under Alternative C, the BLM varies the intensity of allotment monitoring, giving priority to category “1” allotments and those not meeting the *Wyoming Standards for Healthy Rangelands* (Appendix N). By emphasizing monitoring only on higher priority allotments, undesirable conditions in lower priority allotments may not be identified and deterioration or improvement in grassland and shrubland communities may not be realized in a timely manner. Not requiring livestock flushing would result in the greatest risk of invasive species spread to grasslands and shrublands via livestock. Alternative C would result in the most disturbance acreage from rangeland improvements such as reservoirs, pits, pipelines, and wells (Appendix T), posing the greatest threat from invasive species spread—exacerbated due to the lack of livestock flushing—and livestock concentration. Conversely, this alternative has the greatest potential to address some improper livestock distribution-related concentrated herbivory issues that require rangeland improvement projects and, therefore, the beneficial impacts from properly managed livestock grazing, described under *Impacts Common to All Alternatives*, would also be greatest under this alternative. Under this alternative, the BLM does not manage livestock grazing to enhance other resource values; the BLM would manage grasslands and shrublands at a lower seral stage to increase herbaceous forage production. Potential adverse impacts to grasslands and shrublands from allotment monitoring and grazing management practices, livestock flushing practices, and surface disturbance from projected rangeland improvements would outweigh the potential beneficial impacts from livestock grazing management. Overall, livestock grazing management would result in the greatest adverse impacts to grassland and shrubland communities under Alternative C.

Special Designations

No ACECs, specific to Alternative C, would protect substantial amounts of grasslands and shrublands. Protective SCZ around the Nez Perce (Neeme-poo) NHT and Other Historic Trails, of similar size to Alternative A, may protect areas of grasslands and shrublands from disturbance. The BLM also applies a protective buffer around the Heart Mountain Relocation Center National Historic Landmark under this alternative. Table 4-21 lists the acreages of grassland and shrubland communities in special designation areas under Alternative C.

Resources

Under Alternative C, the BLM utilizes wildland fires and other vegetation treatments to restore fire-adapted ecosystems, reduce hazardous fuels, and enhance forage for commodity production. Alternative C would administer prescribed fire and fuels treatments on 40,000 more acres than Alternative A and would therefore reduce the risk of catastrophic fire through fuel reduction to a greater extent (Appendix T). This alternative would result in the most long-term beneficial impact from preventing fire that may destroy and permanently alter grassland and shrubland communities, compared to the other alternatives.

Wildlife management actions under Alternative C would indirectly benefit grassland and shrubland communities the least. Alternative C allows domestic sheep grazing on pronghorn crucial winter range, increasing the potential for overgrazing. Alternative C would allow more resource uses (e.g., oil, gas, and other mineral leasing) in the Absaroka Front Management Area that may result in more adverse impacts to grassland and shrubland communities in its boundaries than under Alternative B. Compared to the other alternatives, Alternative C applies the least surface-disturbance restrictions around greater sage-grouse leks and in nesting and early brood-rearing habitats, does not apply restrictions in winter concentration areas, and exempts Oil and Gas Management Areas from discretionary wildlife seasonal stipulations. These management actions would result in the least short-term beneficial impacts by

preventing vegetation removal or degradation in these areas, compared to the other alternatives. However, Alternative C allows vegetation treatments over a greater area than the other alternatives, providing a long-term benefit by reducing fuel loads. The short-term adverse impacts of vegetation loss from surface disturbance may outweigh potential long-term benefits from vegetation treatments.

Proactive Management

Under Alternative C, the BLM manages to achieve or make progress toward the appropriate community phase for all grasslands and shrubland sites. Alternative C would result in the most acreage of vegetation treatments to improve vegetation conditions (Appendix T); however, no grasslands and shrublands are managed toward DPC. Alternative C would result in the fewest beneficial impacts from proactive management toward achieving historical community structure and composition. However, the projected area of prescribed burns and vegetation treatments under Alternative C would result in beneficial impacts across the greatest area to achieve rangeland health standards, relative to the other alternatives, in areas needing active restoration due to substantial habitat degradation.

Alternative D

Surface Disturbance

Under Alternative D, approximately 119,933 acres of short-term and 15,663 acres of long-term surface disturbance is projected in grassland and shrubland communities, based on the percent cover of these vegetation types in the Planning Area. Although the BLM projects that Alternative D would result in slightly more surface disturbance than Alternative A, more stringent reclamation and restoration practices may result in fewer long-term adverse impacts from surface disturbance. Table 4-21 lists the acreages of grasslands and shrublands protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

The reclamation and restoration practices under Alternative D would result in similar beneficial impacts to those under Alternative A, but to a greater degree. Incorporating erosion rates and soil stability into soil survey efforts, developing specific objectives and timeframes for reclamation plans in coordination with stakeholders, and beginning interim and final reclamation at the earliest feasible time would result in greater beneficial impacts than alternatives A and C, but less than Alternative B.

Resource Uses

Under Alternative D, oil, gas, and other minerals development would result in 25,229 acres of short-term surface disturbance and 1,143 new oil and gas wells, affecting grassland and shrubland communities similar to Alternative A. Locatable minerals development under Alternative D would result in long-term impacts to grasslands and shrublands similar to those under Alternative A. Alternative D closes the second least area in grasslands and shrublands to locatable minerals development and may result in more adverse impacts from long-term surface disturbance than Alternative A. However, the demand for locatable minerals entry, and therefore the level of development and impact, would be similar under all alternatives.

Adverse impacts from invasive species would be similar to those under Alternative A, but to a lesser degree. Alternative D controls or eradicates invasive species on the same amount of land as Alternative A and surface disturbance under Alternative D would leave a similar amount of land vulnerable to invasive species spread. However, the more rigorous reclamation requirements and restrictive management of motorized vehicle use would limit the establishment and spread of invasive species more than Alternative A.

Vegetation – Grassland and Shrubland Communities

ROW development under Alternative D, including roads and pipelines, would result in impacts similar to those under Alternative A, but to a lesser degree because managing more acreage as ROW avoidance or exclusion areas would limit habitat fragmentation more than ROW management under alternatives A and C.

Motorized vehicle use under Alternative D would result in adverse impacts similar to those under Alternative A, but to a lesser degree. Alternative D closes slightly more area to motorized vehicle use than Alternative A, limits motorized vehicle use to designated roads and trails in more area and restricts off-road motorized vehicle use for big game retrieval to within 300 feet of established roads, resulting in less adverse impacts to grasslands and shrublands than alternatives A and C, but more than Alternative B.

Livestock grazing management under Alternative D would result in adverse impacts to grasslands and shrublands similar to Alternative A. However, allowing livestock grazing in areas closed to grazing as a tool to maintain or improve resource conditions may result in more beneficial impacts.

Special Designations

Proposed special designations that would protect grassland and shrubland communities under Alternative D include the Carter Mountain, Little Mountain, Clarks Fork Canyon, and Sheep Mountain ACECs. In addition, the designation of the Craig Thomas Little Mountain SMA and the Chapman Bench Management Area would limit resource uses and activities that can adversely affect grassland and shrubland communities. Special designations under Alternative D would result in more beneficial impacts to grasslands and shrublands than alternatives A and C, but less than Alternative B.

Resources

Fire and fuels management practices and the area treated to reduce fuels under Alternative D would result in impacts similar to those under Alternative A.

Wildlife management actions under Alternative D would result in similar beneficial impacts as those under Alternative A, but to a greater degree. Alternative D prohibits sheep grazing on pronghorn crucial winter range, restricts resource uses in the Absaroka Front Management area, and restricts surface-disturbing activities around greater sage-grouse leks and in winter, nesting, and early brood-rearing habitats more than Alternative A. Restricting surface-disturbing activities may limit vegetation treatments in areas needing restoration where the plant community is extremely degraded; however, the short-term beneficial impacts of preventing vegetation loss from surface disturbance may outweigh potential loss of long-term benefits from vegetation treatments. Overall, wildlife management would result in more indirect beneficial impacts than alternatives A and C, but less than Alternative B.

Proactive Management

Proactive management under Alternative D would result in similar beneficial impacts as those under Alternative B, but to a lesser degree. Under Alternative D, the BLM would manage to maintain large contiguous blocks of native plant communities, similar to Alternative B. However, Alternative D would manage to achieve or make progress toward the appropriate community phase for grassland and shrubland sites. Some areas under Alternative D would be managed for a higher plant community state or phase (based on state and transition models in ESDs) where site-specific management objectives determine that a higher plant community state or phase is desirable.

Alternative E

Surface Disturbance

Under Alternative E, surface-disturbing activities that would affect grassland and shrubland communities are the same as Alternative B, except within areas of the Greater Sage-Grouse Key Habitat Areas ACEC. In this ACEC, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) to not exceed one disturbance per 640 acres and cover less than 3 percent of the total sage-grouse habitat, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. Alternative E also requires beneficial reclamation and rehabilitation activities in the Greater Sage-Grouse Key Habitat Areas ACEC that would prioritize the reestablishment of native vegetation communities in sagebrush steppe communities to a greater extent than under the other alternatives. Under Alternative E, approximately 61,457 acres of short-term and 9,242 acres of long-term surface disturbance is projected in grassland and shrubland communities, based on the percent cover of these vegetation types in the Planning Area, which is the least amount of any alternative (see Table 4-21).

Resource Uses

Under Alternative E, oil, gas, and other minerals development would involve 17,297 acres of short-term surface disturbance (Appendix T), a portion of which may adversely impact grassland and shrubland communities. Impacts from mineral development under Alternative E would be similar to Alternative B, but the location of development may vary due to greater limitations on locatable and mineral materials development in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). As with Alternative B, the majority of the impacts would be temporary during the life of the operation with most areas of disturbance reclaimed following closure of operations.

Adverse impacts from invasive species would be similar to Alternative B, but to a lesser degree due to additional management practices within the Greater Sage-Grouse Key Habitat Areas ACEC. Although Alternative E places additional limitation on the use of herbicides to control the spread of invasive species in that ACEC, it would result in the smallest area vulnerable to invasive species establishment due to reduced surface disturbance and more stringent reclamation practices. Overall, Alternative E would result in the fewest adverse impacts to grassland and shrubland communities from invasive species of any alternative.

Disturbance from pipeline and road construction would be the same as Alternative B. However, additional restrictions on ROW applications and more stringent vegetation management and habitat restoration requirements under Alternative E in the Greater Sage-Grouse Key Habitat Areas ACEC would decrease potential adverse impacts to grasslands and shrublands from ROWs compared to the other alternatives. Management of the Greater Sage-Grouse Key Habitat Areas ACEC designed to preserve large contiguous blocks of important plant communities by managing the area as ROW exclusion areas and limiting new ROWs to access valid existing rights would provide the greatest protection from fragmentation of grassland and shrubland communities and associated loss of diversity of any alternative.

Management of motorized vehicle use and livestock grazing are similar to Alternative B, and impacts to grassland and shrubland communities under Alternative E would therefore be similar to that alternative. Travel management and livestock grazing under Alternative E, includes the most limitations and closures for resource protection of any alternative.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land in the Greater Sage-Grouse Key Habitat Areas ACEC. As a result, the BLM would manage a greater portion of grasslands and scrublands in the Planning Area as special designation areas under Alternative E (see Table 4-21). Requirements to include a full reclamation bond to insure restoration of disturbed areas to their original condition and other habitat restoration and vegetation management requirements associated with the Greater Sage-Grouse Key Habitat Areas ACEC would reduce adverse impacts from surface-disturbing activities in greater sage-grouse Key Habitat Areas. Overall, the relative size and additional restrictions on surface-disturbing activities in special designation areas under Alternative E would create more beneficial impacts to grassland and shrubland communities than the other alternatives.

Resources

Alternative E would result in fewest acres of prescribed fire and fuels treatments (18,000 acres) among the alternatives, which would result in the greatest risk of catastrophic fire due to inadequate fuel reductions (Appendix T). This alternative would also result in the fewest long-term beneficial impacts from preventing fire that may destroy and permanently alter grassland and shrubland communities among the alternatives. Management emphasizing the protection of existing sagebrush ecosystems in the Greater Sage-Grouse Key Habitat Areas ACEC may restrict potential fuels treatments, increasing the short-term risk of catastrophic fire in these areas when compared to the other alternatives. However, Alternative E also includes management that requires strategically and effectively designed fuels treatments and sets canopy cover and invasive species thresholds for areas to be treated; this focus on the overall health of the primarily sagebrush steppe communities in the Greater Sage-Grouse Key Habitat Areas ACEC may result in long-term beneficial impacts and healthier grassland and shrubland communities in these areas.

With exception of lands within the Greater Sage-Grouse Key Habitat Areas ACEC, vegetation management under Alternative E is the same as Alternative B. Vegetation management in the Greater Sage-Grouse Key Habitat Areas ACEC emphasizes the restoration and preservation of native sagebrush ecosystems to create a landscape pattern that most benefits sage-grouse habitat. However, Alternative E may result in fewer long-term beneficial impacts in these areas by restricting vegetation treatments in plant community that are degraded, especially by the occurrence of noxious weeds, or by the increase in certain conifer species (e.g., juniper). The short-term beneficial impacts of preventing vegetation loss from surface disturbance may outweigh the potential loss of long-term benefits from vegetation treatments where they are necessary to restore degraded vegetation communities. Overall, the management of resources under Alternative E would result in the most short- and long-term beneficial impacts to grassland and shrubland communities when compared to the other alternatives.

Proactive Management

Grassland and shrubland management under Alternative E is generally the same as Alternative B, and the beneficial and adverse impacts would be the same as Alternative B. However, under Alternative E, the Greater Sage-Grouse Key Habitat Areas ACEC includes additional limitations on surface-disturbing activities and manages vegetation communities consistent with the reference state of the appropriate ESD, resulting in additional beneficial impacts to grasslands and shrublands in the ACEC compared to Alternative B.

Alternative F

Surface Disturbance

Alternative F would result in approximately 117,273 acres of short-term and 15,113 acres of long-term surface disturbance in grassland and shrubland communities based on the percent cover of these vegetation types in the Planning Area, which is less than alternatives A, D, and C but greater than alternatives B and E. The management of surface-disturbing activities and reclamation is the same as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). In this ACEC, the BLM applies the density of disturbance management requirements proposed under Alternative F for the Greater Sage-Grouse PHMAs ACEC, which would result in similar beneficial impacts from reduced disturbance across a large portion of the Planning Area and from increased reclamation of disturbances. However, unlike Alternative E, Alternative F still allows ROW, renewable energy, and mineral development in the Greater Sage-Grouse PHMAs ACEC, resulting in greater adverse impacts from disturbance and fragmentation from resource uses under Alternative F compared to Alternative E.

Resource Uses

Alternative F manages resource exploration, development, and extraction the same as Alternative D, and impacts to grasslands and shrublands would be similar to Alternative D. However, Alternative F places additional restrictions on mineral development, including limiting disturbances to one per 640 acres and 3 percent or less of the greater sage-grouse PHMAs. Oil, gas, and other minerals development would result in 25,223 acres of short-term surface disturbance, affecting a smaller area of grassland and shrubland communities than alternatives A, C, or D.

Adverse impacts from invasive species would be the same as alternatives A and D, but to a lesser degree due to additional restrictions on resource uses and management to prevent and treat invasive species in the Greater Sage-Grouse PHMAs ACEC. Alternative F controls or eradicates invasive species on the same amount of land as alternatives A and D; however, a decrease in surface disturbance under Alternative F would leave a smaller amount of land vulnerable to spread of invasive species.

ROW development under Alternative F would result in impacts similar to Alternative A, but to a lesser degree because more acreage is managed as ROW avoidance or exclusion areas under Alternative F. Compared to alternatives A, C, and D, this additional restrictive ROW management would decrease adverse effects from road and pipeline disturbance and habitat fragmentation in grassland and shrubland communities.

Motorized vehicle use under Alternative D would result in adverse impacts similar to those under alternatives A and D, but to a lesser degree. Travel management under Alternative F would be the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC, where motorized vehicle use would be limited to designated roads and trails. This additional management would result in fewer adverse impacts to grasslands and shrublands from motorized vehicle use than under alternatives A, C, and D.

Impacts resulting from livestock grazing under Alternative F would be the same as Alternative D, with the exception of areas in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). Livestock grazing management in this ACEC includes multiple management actions that would benefit grasslands and shrublands, including requirements for land health assessments to determine whether rangeland health standards are being met, reviews against greater sage-grouse habitat objectives during grazing permit renewal, location and timing restrictions on grazing (e.g., following drought or fires), restrictions on vegetation treatments that reduce sagebrush cover, and greater restrictions on range improvement

Vegetation – Riparian/Wetland Resources

projects. The ACEC-related restrictions would provide additional tools to ensure livestock grazing management would not adversely affect vegetation communities.

Special Designations

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. Overall, the size and additional restrictions on surface-disturbing activities in special designation areas under Alternative F would result in greater beneficial impacts to grassland and shrubland communities than alternatives A and C, but less than alternatives B and E.

Resources

Disturbance from fuels treatments and prescribed fire under Alternative F would be the same as Alternative D and would result in impacts similar to those under Alternative A. However, in the Greater Sage-Grouse PHMAs ACEC, additional restrictions on fuels treatment and a management priority of protecting sagebrush communities would result in impacts similar to those under Alternative E in the Greater Sage-Grouse Key Habitat Areas ACEC.

Wildlife management actions under Alternative F would be the same as Alternative D and would provide the same benefits to grassland and shrubland communities as under that alternative. However, with the exception of areas within the Greater Sage-Grouse PHMAs ACEC, additional protections for greater-sage-grouse and sagebrush habitats would provide benefits to grassland and shrubland communities similar to those under Alternative E. These benefits would come from restricting resource uses across the ACEC that would remove vegetation or degrade grassland and shrubland health, as well as a management focus on maintaining or restoring sagebrush habitat. However, similar to under Alternative E, these additional restrictions may also result in adverse impacts to grasslands and shrublands where they restrict the use of certain vegetation treatments that may improve the health of degraded areas. Overall, wildlife management under Alternative F would result in more beneficial impacts to grassland and shrubland communities than alternatives A, C, and D, but fewer than alternatives B and E.

Proactive Management

Under Alternative F, management of grassland and shrubland communities would be the same as Alternative D, and the beneficial and adverse impacts would be the same as Alternative D. However, in the Greater Sage-Grouse PHMAs ACEC, Alternative F would manage some areas for a higher plant community state or phase (based on state and transition models in ESDs) on a case-by-case basis where site-specific management objectives determine that a higher plant community state or phase is desirable.

4.4.3 Vegetation – Riparian/Wetland Resources

An impact to riparian/wetland resources alters the physical, chemical or biological components of the ecosystem. Actions that contribute to the decline in abundance, distribution, or functionality of riparian/wetland resources would be adverse impacts. Conversely, beneficial impacts result from management actions that protect or restore riparian/wetland resources in the Planning Area.

Direct impacts to riparian/wetland resources result from disturbing vegetation or ground surface in these communities. Indirect impacts to riparian/wetland communities result from actions in a watershed that cause a change in riparian/wetland functionality (e.g., increased rates of sediment loading or changes in hydrology), a change in water chemistry, or spread of invasive species. Short-term

impacts occur in the 5 years following the disturbance and include increased sediment loading into streams and the potential spread of invasive species. Long-term impacts last longer than 5 years and primarily include loss of habitat due to development or other activities that degrade riparian/wetland resources (e.g., permanently altering stream morphology and associated vegetation).

4.4.3.1 Methods and Assumptions

Evaluating potential impacts to riparian/wetland areas caused by changes in functionality or invasive species establishment focuses on resource management actions that (1) cause surface disturbances or limit the impacts for surface disturbances, and (2) are substantially different among the proposed alternatives. Estimates of projected surface disturbances are used as the primary metric for determining the relative level of potential indirect impact to riparian/wetland areas. The determination as to the jurisdiction of a wetland, in addition to determining the extent and of and the delineation of the wetland area, will be routinely conducted for all undertakings with potential to impact wetlands or waters of the U.S. on a case-by-case basis and therefore, will not be discussed within this document.

Methods and assumptions used in this impact analysis include the following:

- Surface disturbances generally increase the potential for accelerated sediment loading to streams.
- Surface disturbances generally increase surface runoff to streams due to an increase in impervious surface, changes in water routing, and loss of vegetation.
- Surface disturbance, transportation networks, ungulate use, and recreation increase the likelihood of invasive species introduction and spread in an area.
- The greater the amount of surface disturbance in a watershed, the greater the probability that excess surface runoff and sediment will enter the stream and contribute to the loss of riparian/wetland functionality.
- Placing salt and mineral supplements outside of riparian/wetland communities is one tool that can reduce wildlife and livestock use of riparian/wetland areas.
- Surface runoff to streams generally increases as livestock stocking rates increase. This is not a linear relationship. For example, low stocking rates typically have no measurable impact on surface runoff, moderate stocking rates typically have a negligible impact on surface runoff, high stocking rates have a measurable impact on surface runoff, and consecutive years of high stocking rates have the highest potential for increasing surface runoff to streams.
- Herbivory use is typically disproportionately higher in riparian/wetland communities than in upland communities. Improper or unmanaged herbivory can adversely impact these areas throughout the year, but surface impacts (due to hoof action) are generally greater in the spring and early summer, when soils are wet and, therefore, more vulnerable to compaction and stream banks are more vulnerable to sloughing. Livestock, especially cattle, tend to congregate in these communities during the hot season (mid to late summer). While stocking rates for an allotment or pasture may be low to moderate, the utilization levels in riparian/wetland areas can be high.
- Riparian areas are evaluated during application of the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N).
- Grazing practices can maintain, improve, or degrade rangeland health. *The Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands*

Administered by the BLM in the State of Wyoming (Appendix N) are designed to maintain or improve rangeland health. Approximately 10 percent of the public land in the Planning Area is evaluated annually for rangeland health.

- Riparian/wetland areas, except for laterally unstable cobble substrate-based streams, possess the ability to recharge and rebound faster than other vegetative areas in the Planning Area.
- All riparian/wetland areas are evaluated per the *Wyoming Standards for Healthy Rangelands* (Appendix N) and managed toward proper functioning condition (PFC). Management toward DPC is assumed to exceed the requirements of managing toward desired future condition (DFC), which is assumed to exceed the requirements of managing toward PFC.

4.4.3.2 Summary of Impacts by Alternative

Adverse impacts to riparian/wetland resources arise from surface-disturbing and other activities that increase erosion and sediment loading into surface waterbodies and degrade vegetation health. Major sources of these impacts include mineral resources development, motorized vehicle use, road construction, and wild horse and improper livestock grazing management. Alternative C would result in the greatest projected total surface disturbance, followed by alternatives D, F, A, B, and E. Surface disturbance is anticipated to result in proportional levels of erosion and sedimentation, and as such, impacts to riparian/wetland resources are expected to be greatest under Alternative C, the least under alternatives B and E, and similar under alternatives A, D, and F. Alternative E would result in the greatest direct beneficial impact to riparian/wetland resources by imposing greater restrictions on surface-disturbing activities in proximity to riparian/wetland resources and by instituting more beneficial proactive management actions such as watershed improvement projects, followed by alternatives B, F, D, A, and C. Alternatives B and E prohibit livestock forage supplements within 0.5 mile of riparian/wetland resources to prevent vegetation degradation and soil compaction in these areas. Alternatives A, D, and F prohibit livestock forage supplements within 0.25 mile of riparian/wetland resources. Alternative C does not provide similar protections from livestock forage supplements. Overall, Alternative E would result in the fewest adverse impacts to riparian/wetland resources, followed by alternatives B, F, D, A, and C.

4.4.3.3 Detailed Analysis of Alternatives

Allowable uses and management actions that may impact riparian/wetland resources include surface-disturbing activities, motorized vehicle use, recreation, livestock grazing, and proactive management actions. Impacts to soil and water, which may impact riparian/wetland resources, are discussed in Section 4.1.3 *Soil* and Section 4.1.4 *Water*.

Impacts Common to All Alternatives

The types of potential impacts to riparian/wetland resources are similar under all alternatives. However, the intensity of impacts would vary by alternative, as described for each.

Implementing any of the alternatives may cause direct and indirect impacts to riparian/wetland resources. Because riparian/wetland areas are limited and often the most productive lands, they are disproportionately affected by humans, livestock, wild horses, and wildlife, compared with the same types or extent of actions in upland areas. The BLM generally avoids, whenever possible, direct impacts to riparian/wetland areas under all alternatives and minimizes impacts from projects or resource uses

that involve riparian areas through applying BMPs. In addition, the BLM manages lotic and lentic riparian/wetland areas to meet PFC and the *Wyoming Standards for Healthy Rangelands* (Appendix N).

Riparian vegetation is more susceptible to grazing impacts during the spring, when soils are wet and more vulnerable to compaction, and during the hot season (July and early August), as livestock is naturally attracted to areas with water and thermal cover. Many grazing management strategies, such as rotation, deferment, rest from use, and the manipulation of season of use and grazing intensity would be implemented to manage vegetation composition, cover, and vigor to maintain or achieve PFC in riparian areas. As the BLM does not practice wild horse relocation in HMAs, year-round wild horse grazing may adversely impact, unless fenced, riparian areas in HMAs and impair the ability to maintain or achieve PFC in these areas.

Changes in water chemistry can affect riparian/wetland areas primarily through changes in plant species composition, which may affect utilization of the area by wildlife and livestock. Indirect impacts caused by changes in water chemistry have not been a major factor in the Planning Area historically and are not expected to be in the future. Impacts caused by wildlife are generally less than those caused by livestock, particularly cattle and wild horses in operational HMAs. As is the case with livestock, wildlife also is attracted to and often congregates in wetland areas; however, the size and foraging habitat of wildlife limits adverse impacts. In localized areas, elk have affected riparian habitats through trampling, wallowing, and grazing. Likewise, the impacts associated with wild horse management activities would be similar to those described for livestock grazing, except localized to the 4,570 acres of riparian/wetlands in existing HMAs.

The management of special status species generally involves restricting activities in the vicinity of special status plants or wildlife either year-round or during specific times of the year. As a result, riparian/wetland areas in the vicinity of buffer zones of special status species can benefit from the lower level of public use. In addition, efforts at conserving species, such the Ute ladies'-tresses (a wetland species), can directly benefit riparian condition.

Alternative A

Surface Disturbance

Prohibiting surface-disturbing activities within 500 feet of surface water and riparian/wetland areas unless impacts can be mitigated would reduce the acreage of surface disturbance in these areas. Therefore, the principal impacts to riparian/wetland resources associated with surface-disturbing activities would be indirect impacts. Indirect adverse impacts to riparian/wetland resources would be associated with surface-disturbing activities in the watershed. Short-term impacts include increased sediment loading into streams and the potential spread of invasive species. Long-term impacts include loss of habitat due to development. As a summary, Table 4-21 lists the acreages of riparian/wetland areas protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

While most surface-disturbing activity will not be near riparian/wetland areas, these areas may be indirectly impacted due to soil erosion in the uplands, which may increase sediment released into streams. Alternative A would result in short-term and long-term soil erosion rates of approximately 567,492 and 25,065 tons per year, respectively that may adversely affect riparian/wetland resources (see Section 4.1.3 *Soil*). Higher sediment loading to a stream may dramatically alter its form and, consequently, the integrity of the riparian/wetland resources adjacent to it. The impact of increased sediment loading depends on the stream's ability to pass the sediment through the system and largely depends on the size (i.e., discharge volume) of the stream and the channel slope gradient. In segments

of a stream that have lower gradients, deposition occurs and the stream channel aggrades (builds), possibly becoming braided and shallow. In some instances, the aggradations of the streambed may cause the stream to down cut or degrade (become more incised) as the stream seeks to restore its equilibrium. The additional material eroded from the upstream channel is transported down to a depositional area and the cycle continues. In such cases, the functionality of the riparian/wetland areas in both the aggraded stream reach, and the incised stream reach, change.

Resource Uses

Most of the Planning Area remains open to mineral extraction under Alternative A; the associated surface disturbance would be the second highest of the alternatives. While the BLM prohibits surface-disturbing activity associated with mineral development within 500 feet of riparian/wetlands, this type of activity in the uplands, including well pad construction, pipeline development, and road construction, may increase sediment loading in streams. Under Alternative A, the BLM allows the surface discharge of produced water if it meets state of Wyoming water quality standards. Water production from oil and gas development represents a new water source in a watershed that augments existing water flows. In the event that produced water from CBNG or traditional gas development is disposed of on the surface, riparian/wetland vegetation may be affected. Impacts may be both beneficial (e.g., increased water quantity that may benefit riparian/wetland vegetation or create new riparian/wetland areas) and detrimental (e.g., increased dissolved compounds that may adversely impact riparian/wetland vegetation), as discussed in more detail in Section 4.1.4 *Water*. The short- and long-term nature of these impacts would vary considerably based on the duration, quality, and quantity of produced water discharges.

Invasive species are particularly undesirable in riparian/wetland areas because they do not have the same high level of soil-binding properties that many native riparian/wetland species (e.g., willows and sedges) have. The proximity of surface disturbances to riparian/wetland areas is one of the primary ways in which invasive species would spread to these areas. Prohibiting surface disturbance within 500 feet of riparian/wetland areas would help reduce the opportunity to spread invasive species to these areas. Invasive species and pest management under Alternative A includes allowing aerial application of pesticides and requiring livestock flushing on a case-by-case basis. Application of chemicals near water may reduce water quality, adversely affecting the health of riparian/wetland resources. Requiring livestock flushing would reduce the opportunity of spreading ingested invasive species seeds or material to riparian/wetland areas.

One of the most prevalent increases in surface runoff caused by human activity is due to an increase in impervious cover (e.g., roads, parking lots, and rooftops). Roads are not only impervious, they also route water. While small increases in surface runoff may have a beneficial impact on riparian/wetland areas because more water may be available for plant growth, they may also cause an increase in channel incision. Channel incision could disconnect the stream from its flood plain (i.e., gully formation) and, if the stream becomes incised enough, alter conditions in associated riparian/wetland areas. For this reason, it is undesirable to have a road close to a stream or crossings where runoff from the road is more likely to reach the stream.

Alternative A permits motorized vehicle use on existing roads and trails across the largest area but would result in the least acres of surface disturbance associated with new road and trail creation, compared to the other alternatives. However, Alternative A allows the use of off-road motorized vehicles to retrieve big game and to access dispersed campsites, which may cause undue environmental degradation and accelerated soil erosion in riparian/wetland areas. Motorized vehicle use and the associated greater access that it grants to recreationists, may adversely impact riparian/wetland

resources by introducing invasive species near streams or wetlands and increasing erosion and sediment loading in streams. Recreational activities, such as camping, often occur near riparian/wetland areas and may result in adverse impacts through soil compaction and trash accumulation in or near these areas. More developed recreation areas would increase this potential, although most impacts are expected to be mitigated by managing recreational use to maintain or improve riparian/wetland resource conditions along intensively used streams and reservoirs. Recreation management areas such as SRMAs that restrict surface disturbance in these areas would have a beneficial impact on riparian/wetland resources.

Most of the Planning Area remains open to livestock grazing under this alternative. Concentrated livestock, wild horse, or wildlife grazing would increase runoff in a watershed due to soil compaction and loss of vegetative cover, with the amount of bare ground being the primary factor. Consistent with guidance provided by the University of Wyoming Cooperative Extension Service (Horn 2005), Alternative A prohibits the placement of salt, mineral, or forage supplements within ¼ mile of water, wetlands, and riparian areas, which limits the direct impacts from livestock grazing on these areas. Livestock range improvement projects would distribute livestock over a large landscape, but would also create concentrated use in local areas. Over the long term, these improvements would potentially improve the stability and resiliency of riparian/wetland resources.

Special Designations

Special designations would result in beneficial impacts to riparian/wetland areas when they place additional restrictions on activities that degrade watershed health (e.g., surface-disturbing activities and motorized vehicle use). These restrictions have an indirect beneficial impact on riparian/wetland areas because these areas are not subject to large-scale surface-disturbing activities. Table 4-21 lists the acreage of wetlands in each type of special designation under Alternative A and Section 4.1.4 *Water* lists the miles of streams within special designations.

Resources

Implementing watershed improvement practices in Wyoming's Bighorn Basin water quality plans to reduce sediment loadings in streams and river segments and, when approved, including them in various BLM activity plans and use authorizations would benefit riparian/wetland resources.

Under Alternative A, the BLM utilizes wildland fires to restore fire-adapted ecosystems and to reduce hazardous fuels. The loss of vegetative cover from both wildland fires and prescribed fires would increase runoff and sediment to streams and other waterbodies in the short term. A rainstorm following a fire may overwhelm downstream waterbodies by contributing excessive amounts of sediment, large woody debris, and water to the system in a short period. Fires that burn more intensely would cause more adverse impacts to the watershed. Fires of the appropriate intensity generate a vegetation response that may have beneficial impacts on a watershed by helping to recharge water tables and increasing the amount of herbaceous cover, thereby improving livestock, wild horse, and wildlife distribution and lessening erosion.

Management actions under Alternative A designed to protect wildlife and special status species habitat from the impacts of surface-disturbing and disruptive activities will also protect riparian/wetland resources from these activities. For example, applying NSO and CSU restrictions in crucial wildlife habitat would reduce the chance of sediment loading into streams in these areas. Other beneficial impacts include performing restoration of streams and fisheries habitat on a case-by-case basis, which would have direct beneficial impacts on riparian/wetlands areas.

Proactive Management

Proactive management under Alternative A primarily consists of managing riparian/wetland areas to meet PFC and prohibiting surface-disturbing activities within 500 feet of surface water and riparian/wetland areas. This 500-foot buffer would prohibit surface-disturbing activities on 70,715 acres of BLM-administered land within and around riparian/wetland areas. Management actions that strive to improve streams and conserve riparian/wetland areas generally result in long-term beneficial impacts to riparian/wetland resources. Watershed improvement projects, while potentially causing short-term impacts from surface disturbance, would result in long-term benefits to these areas by reducing sediment loading, improving stream conditions, and facilitating PFC, DFC, or DPC management objectives.

Alternative B

Surface Disturbance

The impacts to riparian/wetland resources under Alternative B from surface-disturbing activities would be similar to those under Alternative A, but to a lesser degree. Alternative B prohibits surface-disturbing activities within ¼ mile of all riparian/wetland areas; therefore, the principle impacts from surface disturbance would be indirect. Alternative B also includes more restrictions on surface-disturbing activities for the protection of other resources such as for special designations, crucial winter range, and recreation management areas than Alternative A. Across the Planning Area, the BLM projects that this alternative would involve less surface disturbance than Alternative A (Table 4-1), which would reduce impacts to riparian/wetland resources. Alternative B is also projected to result in less short-term and long-term erosion (approximately 30 percent less than Alternative A), which would reduce potential adverse impacts to riparian/wetland resources (see Section 4.1.3 *Soil*). As a summary, Table 4-21 lists the acreages of riparian/wetland areas protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

Resource Uses

The projected amount of surface disturbance associated with mineral development under Alternative B is less than Alternative A. Most of the impacts would be temporary during the life of the operation, with most areas of disturbance reclaimed following closure of operations; however, in the short term, mineral extraction activities would increase the potential for riparian/wetland health degradation. Activities such as well pad and road construction would increase runoff and sediment loading in streams. Alternative B prohibits the surface discharge of produced water on BLM-administered surface, negating the impacts (both beneficial and adverse) present under Alternative A.

The smaller amount of surface disturbance under Alternative B, compared to the other alternatives, will result in the least impact associated with invasive species in riparian/wetlands due to surface-disturbing activities. Alternative B prohibits aerial application of pesticides within ½ mile of riparian/wetland resources but allows exceptions to manage riparian weed species, a beneficial impact. Alternative B allows the authorized officer to require livestock flushing before allowing livestock to move onto or within BLM-administered land. Similar to Alternative A, discretionary livestock flushing will limit the risk of spreading invasive species to riparian/wetland areas from ingested seeds or material.

Alternative B would result in fewer acres of short- and long-term surface disturbance from new road creation associated with ROW development in the Planning Area than Alternative A, and would therefore result in similar but less adverse impacts than described under Alternative A.

Alternative B permits motorized vehicle use on existing roads and trails over less area than Alternative A, but would result in more acres of surface disturbance associated with the creation of new roads and trails for recreational purposes than Alternative A. Limiting motorized vehicle use to designated roads and trails would limit public access and reduce the associated potential impacts to riparian/wetland areas, as described under Alternative A. Off-road motorized vehicle use to retrieve big game and access dispersed campsites is prohibited in areas with limited travel designations and would limit erosion and sediment loading from trail proliferation near riparian/wetland areas. Alternative B places less emphasis on developing camping or recreation sites, reducing the potential for adverse impacts associated with concentrated recreational activities compared to Alternative A.

Livestock grazing management is more restrictive under Alternative B and more area is closed to grazing compared to Alternative A. A ½-mile buffer prohibiting the placement of salt, mineral, or forage supplements near water, wetlands, and riparian areas, would provide greater protection for these resources from livestock and native ungulate grazing. Alternative B would also result in fewer livestock improvement projects than Alternative A. While this would limit disturbance associated with these activities in the short term, riparian/wetland areas would not receive the long-term benefits of these improvement projects. For example, fewer water development projects may increase herbivory in riparian/wetland areas because livestock, wild horses, and wildlife concentrate near natural water sources.

Special Designations

Compared to Alternative A, Alternative B proposes more special designations containing riparian/wetland habitat (see Table 4-21 and Section 4.1.4 *Water*) and places more restrictions on surface-disturbing activities in these special designation areas. Prohibitions on surface-disturbing activities would limit adverse impacts to riparian/wetland resources in these areas.

Resources

Developing watershed improvement practices in cooperation with local governments to reduce sediment loading in stream and river systems and, once developed, including them in all activity plans and permitted activities would beneficially impact riparian/wetland resources.

Under Alternative B, the BLM utilizes wildland fires to restore fire-adapted ecosystems for natural resource systems and to reduce hazardous fuels. This utilization of wildland fire under Alternative B would result in impacts similar to those under Alternative A, but over less area. Therefore, under Alternative B, long-term beneficial impacts from prescribed fire would be less extensive than under Alternative A.

Management actions designed to protect wildlife and special status species habitat apply greater restrictions on surface-disturbing activities than Alternative A and therefore have a greater beneficial impact on riparian/wetland resources. Riparian/wetland areas in the Absaroka Front Management Area (444 acres), not identified under Alternative A, would benefit from the restrictions on some resource uses (e.g., mineral leasing and motorized vehicle use). Management actions designed to improve fisheries would also have a greater beneficial impact under Alternative B. The BLM would restore or reclaim important fisheries habitat through upland management and hydrologic function enhancement actions on at least 3 miles of lotic stream system. These restoration activities would result in beneficial impacts to riparian/wetland resources.

Proactive Management

Proactive management under Alternative B results in greater benefits to riparian/wetland resources than Alternative A. Alternative B manages riparian/wetland areas to meet DPC and prioritizes those riparian/wetland areas not meeting PFC. Management toward DPC is assumed to exceed the requirements of managing toward PFC and would therefore result in improved functioning and healthier riparian/wetland areas. As noted above, Alternative B prohibits surface-disturbing activities within ¼ mile of all riparian/wetland areas. This buffer would prohibit surface-disturbing activities on 162,887 acres of BLM-administered land adjoining riparian/wetland areas. Applying an NSO restriction on wetland areas greater than 40 acres would limit erosion and other detrimental impacts associated with oil and gas activity. In addition, Alternative B allows sediment reduction structures on a case-by-case basis, which would further protect riparian/wetland health. Watershed improvement projects under Alternative B are anticipated to disturb more acres than Alternative A. While these treatments may result in short-term impacts from surface disturbance, they would have greater long-term benefits on riparian/wetland areas than Alternative A.

Alternative C

Surface Disturbance

Unlike alternatives A and B, Alternative C allows surface-disturbing activities in flood plains or riparian/wetland areas and this alternative may therefore result in direct adverse impacts. By allowing surface-disturbing activities on a case-by-case basis, Alternative C is more likely to risk the impairment of riparian/wetland health through the introduction of invasive species and the removal of vegetation. Based on the percent cover of this vegetation type and the total projected surface disturbance (Table 4-1), there may be 1,846 acres of the short-term and 312 acres of the long-term surface disturbance in riparian/wetland areas on BLM-administered surface under this alternative. In addition, Alternative C has the largest projected total acreage of surface disturbance (Table 4-1) and would result in the greatest indirect adverse impacts to riparian/wetland resources from increased erosion and sediment loading. By allowing direct disturbance of riparian/wetland areas, Alternative C could result in the greatest adverse impact to riparian/wetland resources compared to the other alternatives. As a summary, Table 4-21 lists the acreages of riparian/wetland areas protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

Resource Uses

The projected amount of surface disturbance associated with mineral development under Alternative C is the highest of the alternatives. Most of the Planning Area remains open to mineral extraction and the RFD of minerals facilities is the greatest under Alternative C, compared to the other alternatives. Most of the impacts would be temporary during the life of the operation, with most areas of disturbance reclaimed following closure of operations; however, in the short term, surface disturbance associated with minerals development may impair riparian/wetland areas. Under Alternative C, the BLM allows the proper disposal of water produced through mineral production activities. When surface discharge occurs in waterways on BLM-administered land, Alternative C requires the discharge of produced water be done in such a manner as to cause minimal environmental harm, while still contributing to designated uses. Impacts to riparian/wetland resources from the discharge of produced water would be similar to those under Alternative A, but to a greater degree due to more projected oil and gas activity.

Fewer restrictions on surface-disturbing activities in proximity to riparian/wetland areas under Alternative C would result in greater adverse impacts associated with invasive species than the other

alternatives. An increase in invasive species would alter the vegetative communities, introducing species that use more water and lack the same high level of soil-binding properties as native riparian/wetland species. Invasive species and pest management under Alternative C prohibits aerial application of pesticides within 100 feet of riparian/wetlands but allows exceptions to manage riparian weed species. This management practice would result in impacts similar to those described under Alternative B. Alternative C does not require livestock flushing, which increases the chance of spreading ingested invasive species in riparian/wetland areas used by livestock.

Alternative C would result in the most short- and long-term surface disturbance from road and trail creation associated with recreational use and ROW development in the Planning Area. More roads in the Planning Area would increase associated erosion and surface runoff, which, in turn, would route water and sediment into nearby streams. As a result, road development under Alternative C would result in the greatest adverse impacts to riparian/wetland resources in the Planning Area.

Motorized vehicle use under Alternative C would result in impacts similar to those under Alternative A, but to a greater degree. Alternative C limits motorized vehicle use to existing roads and trails in most of the Planning Area and closes the least area to motorized vehicle use compared to the other alternatives, resulting in more adverse impacts to wetlands and riparian resources. Alternative C also allows the use of off-road motorized vehicles to retrieve big game and access dispersed campsites, which may cause vegetation damage and erosion in some riparian/wetland areas. If demand warrants, the BLM would develop or upgrade recreation sites and associated amenities, resulting in impacts similar to Alternative A.

Most of the Planning Area would remain open to livestock grazing under Alternative C. The BLM manages livestock grazing to optimize commodity production while meeting rangeland health standards but not specifically to enhance other resource values; therefore, Alternative C would have the fewest beneficial impacts to riparian/wetland resources. In contrast to the other alternatives, Alternative C does not prohibit the placement of salt, mineral, or forage supplements near riparian/wetland areas, resulting in the greatest potential adverse impact to riparian/wetland areas. Concentrated livestock grazing or substantial increases in wild horse use may increase runoff in a watershed due to soil compaction and loss of vegetative cover. In addition, uncontrolled livestock grazing in these areas has a greater potential to introduce invasive species. Alternative C would result in the most livestock improvement projects. In the short term, these projects would result in increased surface disturbance; in the long term, however, these projects would result in the most beneficial impacts to riparian/wetland resources compared to the other alternatives.

Special Designations

Alternative C places the least restriction on surface-disturbing activities in special designations and designates the fewest number of these areas. As shown in Table 4-21 and Section 4.1.4 *Water*, Alternative C protects the fewest acres of wetlands and miles of streams within special designations. As a result of the limited additional protections provided by special designations, Alternative C would result in the fewest beneficial impacts to riparian/wetland areas.

Resources

Alternative C utilizes wildland fires and other vegetation treatment to restore fire-adapted ecosystems and enhance forage for commodity production and to reduce hazardous fuels. This management could result in an increase in wildland fires in the Planning Area, which would result in vegetative cover loss and sediment loading in streams.

Alternative C applies fewer management restrictions on surface-disturbing and disruptive activity designed to protect wildlife and special status species. Riparian/wetland areas in the Absaroka Front Management Area (444 acres) would receive fewer beneficial impacts than under Alternative B since some resource uses (e.g., oil and gas and other mineral leasing) that would be restricted under Alternative B would be allowed under this alternative. Management actions designed to improve fisheries are similar to Alternative A and would therefore result in similar beneficial impacts. Native ungulate grazing is anticipated to cause impacts to riparian/wetland areas similar to Alternative A.

Proactive Management

Alternative C manages riparian/wetland areas to meet PFC, giving priority to those areas functioning at-risk with a downward trend or in nonfunctioning condition. Prioritizing areas that do not meet the standard allows the BLM to efficiently allocate management resources to those areas most in need. Alternative C allows surface-disturbing activities in flood plains and riparian/wetland areas on a case-by-case basis. By not prohibiting surface-disturbing activities, Alternative C results in the fewest beneficial impacts compared to the other alternatives. Watershed improvement projects under Alternative C are anticipated to disturb the fewest number of acres. While fewer treatments would result in less short-term impacts in terms of surface disturbance, they would provide fewer long-term benefits to these areas.

Alternative D

Surface Disturbance

Prohibiting surface-disturbing activities within 500 feet of surface water and riparian/wetland areas unless impacts can be mitigated would reduce the direct adverse impacts from surface disturbance in these areas similar to Alternative A. Alternative D is projected to result in 3 percent more short- and 17 percent more long-term erosion than Alternative A, with proportional indirect impacts to riparian/wetland resources—though the more stringent reclamation practices under Alternative D, relative to Alternative A, may limit erosion impacts to riparian/wetland areas to a greater degree. As a summary, Table 4-21 lists the acreages of riparian/wetland areas protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative. Although Alternative D is projected to result in more surface disturbance than Alternative A, with proportional indirect impacts to riparian/wetland areas, Alternative D includes more measures, described below, to limit direct adverse impacts to riparian/wetland areas from surface-disturbing activities.

Resource Uses

The BLM projects that Alternative D would result in a similar amount of surface disturbance from mineral development as Alternative A, resulting in a similar degree of adverse impacts. Most of the impacts would be temporary during the life of the operation, with most areas of disturbance reclaimed following closure of operations; however, in the short term, surface disturbance associated with minerals development may impair riparian/wetland areas. Impacts from produced water would be similar to those under Alternative C, although to a lesser degree because the BLM projects fewer new oil and gas wells under this alternative.

Adverse impacts from invasive species spread in riparian/wetland areas would be similar to those under Alternative A, but to a lesser degree. Management practices regarding pesticide application and livestock flushing would be similar to those under Alternative A, but applying a NSO on wetlands greater than 20 acres and on designated 100-year flood plains under Alternative D would limit the potential for invasive species spread to a greater extent.

Road development under Alternative D would result in impacts similar to Alternative A.

Under Alternative D, motorized vehicle use would result in impacts similar to Alternative A, but to a lesser degree. Alternative D limits motorized vehicle use to designated roads and trails in more areas and closes more areas to motorized vehicle use compared to Alternative A. Localized impacts from opening areas to motorized vehicle use would result in surface disturbance and potential indirect adverse impacts to riparian/wetland areas. Restricting off-road motorized vehicle use to within 300 feet of established roads would limit the extent of the adverse impacts described under Alternative A. Developing recreation sites would result in similar potential adverse impacts to those under Alternative A; however, Alternative D recognizes more SRMAs that contain riparian/wetland habitat, such as the Bighorn River, The Rivers, Canyon Creek, Middle Fork of the Powder River, and Beck Lake SRMAs, which would limit surface disturbance and the associated impacts in these areas.

Livestock grazing management would result in impacts to riparian/wetland areas similar to Alternative A.

Special Designations

Special designations under Alternative D would result in similar beneficial impacts to riparian/wetland areas as under Alternative A, but to a greater degree. Alternative D proposes more special designations containing riparian habitat (see Table 4-21 and Section 4.1.4 *Water*) and places more restrictions on surface-disturbing activities in these special designations than alternatives A and C, but less than Alternative B.

Resources

Watershed improvement practices under Alternative D would result in similar beneficial impacts to riparian/wetland resources as under Alternative B.

Fire and fuels management under Alternative D would result in impacts similar to Alternative A.

Management actions to protect wildlife and special status species under Alternative D would result in similar beneficial impacts to those under Alternative A, but to a greater degree. Restrictions on mineral development in the Absaroka Front Management Area, which contains 887 acres of riparian/wetland area, would result in more beneficial impacts than under Alternative C, but less than Alternative B. Restoring streams and fisheries habitat would result in similar beneficial impacts as those under Alternative A.

Proactive Management

Proactive management under Alternative D would result in similar beneficial impacts to those under Alternative C, but to a greater degree. The BLM manages certain riparian/wetland areas containing streams with unique recreational or fishery values to obtain DFC. Management toward DFC is assumed to exceed the requirements of managing toward PFC and would therefore result in improved functioning and healthier riparian/wetland areas, although not to the degree afforded by management toward DPC (as under Alternative B). Alternative D prohibits surface disturbing activities within 500 feet and avoids surface-disturbing activities within ¼ mile of perennial surface water and riparian/wetland areas, which would provide a similar beneficial impact to riparian/wetland areas as Alternative A, but with additional protections outside of the 500-foot buffer. Watershed improvement projects would result in impacts similar to Alternative A.

Alternative E

Surface Disturbance

The management of surface-disturbing activities and their impacts to riparian/wetland resources under Alternative E would be similar to Alternative B. Alternative E includes the same 0.25 mile riparian/wetland area protective buffer as Alternative B, and therefore impacts would be primarily indirect. Alternative E is projected to result in the least amount of short- and long-term erosion (approximately 2.9 percent less than Alternative A, and approximately 2.2 percent less than Alternative B), which would result in the least potential adverse impacts to riparian/wetland resources compared to the other alternatives (see Section 4.1.3 *Soil*). Table 4-21 details the acreages of riparian/wetland areas protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

Resource Uses

Under Alternative E, oil, gas, and other minerals development would involve 17,297 acres of short-term surface disturbance (Appendix T), a portion of which may adversely impact riparian/wetland resources. Impacts from mineral development under Alternative E would be similar to Alternative B, but the location of development may vary due to greater limitations on surface disturbance in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres) under Alternative E. Alternative E would also provide additional long-term benefits through full reclamation of disturbed sites within greater sage-grouse Key Habitat Areas. Impacts from increased runoff and sediment loading to streams, as well as the surface discharge of produced water, would be similar to Alternative B, and less than all other alternatives.

Under Alternative E, adverse impacts from the spread of invasive species would be similar to Alternative B, but to a lesser extent due to the fewer projected acres of surface disturbance under Alternative E. In particular, Alternative E management of the Greater Sage-Grouse Key Habitat Areas ACEC exclude surface-disturbing mineral developments and ROWs to a greater extent than any other alternative, reducing the potential spread of invasive species in disturbed areas over a large portion of the Planning Area.

Overall, adverse impacts to riparian/wetland areas from projected new roads and management under Alternative E would be similar to Alternative B, and would result in fewer adverse impacts than the other alternatives. Disturbance from pipeline, road development, and new road construction would be the same as Alternative B; however, the location of these disturbances may vary under Alternative E as a result of the management of the Greater Sage-Grouse Key Habitat Area ACEC as a ROW exclusion area.

Management of motorized vehicle use and livestock grazing are the same as Alternative B, and impacts to riparian/wetland resources would therefore be the same as Alternative B. Compared to Alternative A, limitations and closures to motorized vehicle use for resource protection, including seasonal motorized vehicle closures in greater sage-grouse Key Habitat Areas and for the protection of big game species, would result in beneficial impacts to riparian/wetland areas under Alternative E.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land in the Greater Sage-Grouse Key Habitat Areas ACEC. As a result, the BLM would manage a greater portion of riparian/wetland areas in the Planning Area with special designations under Alternative E (see Table 4-21). Overall, the relative size and additional restrictions on surface-disturbing activities in special designation areas under Alternative E

would limit adverse impacts to riparian/wetland areas to a greater extent than under the other alternatives.

Resources

Watershed improvement practices under Alternative E are the same as Alternative B and would provide the same beneficial impacts to riparian/wetland areas as Alternative B. Under Alternative E, fire and fuels management practices and impacts are the same as Alternative B with the exception of lands within the Greater Sage-Grouse Key Habitat Areas ACEC, which would be managed with an emphasis on protecting existing sagebrush ecosystems. In general, fuels treatments are minimized in priority sage-grouse habitat and are focused instead on interfaces with human habitation or significant existing disturbances. Limiting areas subject to fuels treatments could reduce short-term impacts from prescribed fire compared to Alternative A, but could increase long-term adverse impacts compared to the other alternatives if additional fuel loading leads to an increase in high-intensity fires.

Impact from management designed to protect wildlife and special status species habitat would be the same as under Alternative B, except in the Greater Sage-Grouse Key Habitat Areas ACEC where restrictions on surface-disturbing activities would result in greater beneficial impacts than under the other alternatives.

Proactive Management

Under Alternative E, riparian/wetland management would be the same as Alternative B, and the impacts would be the same as Alternative B.

Alternative F

Surface Disturbance

Surface disturbance impacts to riparian/wetland areas under Alternative F are projected to be greater than alternatives A, B, and E, but less than alternatives C and D. Management practices relating to surface disturbance would be the same as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres) where additional restrictions on surface disturbance would apply. Prohibiting surface-disturbing activities within 500 feet of surface water and riparian/wetland areas would reduce the direct adverse impacts from surface disturbance in these areas similar to Alternative A. Alternative F is projected to result in more surface disturbance than Alternative A, with proportional indirect impacts to riparian/wetland areas. Table 4-21 details the acreages of riparian/wetland areas protected from some common surface-disturbing activities (e.g., ROWs and locatable mineral development) under this alternative.

Resource Uses

Under Alternative F, management practices for resource exploration, development, and extraction would be similar to Alternative D, and impacts to riparian/wetland areas would generally be the same as Alternative D. However, Alternative F would place additional restrictions on mineral development and include management that limits disturbances to one per 640 acres and 3 percent or less of the greater sage-grouse PHMAs, compared to 5 percent under Alternative D. When compared to alternatives A, C, and D, the restrictive management of Alternative F over the large area of the ACEC would generally provide greater benefit to riparian/wetland areas by limiting the size and extent of mineral development and other disturbances.

Impacts from motorized vehicle use under Alternative F would provide greater protections for riparian/wetland areas than under alternatives A, C, and D, but fewer protections than under alternatives B and E. CTTM management practices for Alternative F are the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC, where motorized vehicle use would be limited to designated roads. Under Alternative F, disturbances associated with the creation of new roads and trails is projected to be less than alternatives A, C, and D, but higher than alternatives B and E. Overall, the limitations placed on motorized vehicle use under Alternative F would result in fewer adverse impacts to riparian/wetland areas than alternatives A and D by reducing erosion and sedimentation while also limiting vehicle activity within riparian/wetland areas.

Impacts resulting from livestock grazing under Alternative F would be the same as Alternative D, with the exception of areas in the Greater Sage-Grouse PHMAs ACEC. The Greater Sage-Grouse PHMAs ACEC is managed to reduce hot season grazing on riparian and meadow complexes through fencing and herding techniques, as well as seasonal use restrictions or livestock distribution changes. This ACEC management would protect or enhance vegetation and water quality in riparian/wetland areas by managing livestock grazing in these areas during the period of the year when they are most susceptible to damage from herbivory. Overall, the additional livestock grazing restrictions under Alternative F would result in greater beneficial impacts to riparian/wetland areas than alternatives A or D.

Special Designations

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. As a result, the BLM would manage a greater portion of riparian/wetland areas and wetlands in the Planning Area with special designations under Alternative F (see Table 4-21). Overall, the relative size and additional restrictions on surface-disturbing activities in special designation areas under Alternative F would result in greater beneficial impacts to riparian/wetland areas in comparison to alternatives A and D.

Resources

Watershed improvement practices under Alternative F would result in the same beneficial impacts to riparian/wetland resources as alternatives B and D.

Fuels treatments and prescribed fire management under Alternative F is the same as Alternative D except in the Greater Sage-Grouse PHMAs ACEC. Restrictions on fuels treatment and prescribed fire under Alternative F in the Greater Sage-Grouse PHMAs ACEC are similar to management in the Greater Sage-Grouse Key Habitat Areas ACEC under Alternative E; impacts to riparian/wetland areas would be similar to those under Alternative E.

Impact from management designed to protect wildlife and special status species habitat would be the same as under Alternative D except in the Greater Sage-Grouse PHMAs ACEC, where restrictions on surface-disturbing activities and managing riparian/wetland areas to achieve proper functioning condition/attain ESD would result in greater beneficial impacts than under the Alternative D. Overall, management wildlife and special status species habitat under Alternative F would result in more beneficial impacts to riparian/wetland areas than alternatives A, C, and D, but less than alternatives B and E.

Proactive Management

Under Alternative F, the management of riparian/wetland areas would be the same as Alternative D, and the beneficial and adverse impacts would be same as Alternative D.

4.4.4 Invasive Species and Pest Management

The presence of invasive species in the Planning Area is considered an adverse impact. Actions that contribute to the introduction of invasive species, the spread of existing invasive species populations, or that avoid, reduce, or prohibit invasive species control activities in the Planning Area also would be adverse impacts. Beneficial impacts include management actions that reduce or contain the spread of, or eradicate, invasive species in the Planning Area.

Direct impacts to the management of invasive species typically result from actions that disturb soil or that otherwise create environments (i.e., seedbed) for the establishment of invasive plant species (Map 36). Indirect impacts result from activities that avoid, reduce, or prohibit invasive species control activities in the Planning Area. The transport of invasive species seed or other plant parts by wildlife, livestock, vehicles, wind, or water to other locations, thereby expanding the distribution or increasing the range of spread of weeds, is also considered an indirect impact.

4.4.4.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Roadways, trails, ROWs, and corridors are major routes that can spread invasive species through transport on motor vehicles and off-road motorized vehicle uses. Invasive species also can spread through watercourses, wind, and by wildlife and livestock movement.
- The amount of new surface disturbance associated with an alternative is a good index of potential impact by invasive species. The larger the acreage of surface disturbance, the greater the potential adverse impact by invasive species.
- Success of reclamation measures prescribed as a condition of development is unknown and could either overestimate or underestimate the potential impact from weeds.
- Enforcement of restrictions related to recreation and off-road motorized vehicle use and dispersed travel can be assumed only if adequate funding and personnel are available to do the job.
- Instruction Memorandum (IM) 2006-073 (BLM 2006c) establishes policy and guidance for use of certified weed-free seed and mulch to prevent the establishment of new invasive species population in restoration projects on public lands.
- *Partners Against Weeds – An Action Plan for the BLM* (BLM 1996), establishes a strategy to prevent weeds through cooperation with all partners. It outlines goals and specific actions to help prevent and control the spread of weeds. This action plan, along with any future updates and guidance, would be followed to control and prevent weed problems.
- Seeds from some weeds can remain dormant and viable in the soil for periods that exceed the 5-year division between short- and long-term impacts. Therefore, favorable site conditions may serve to reintroduce invasive species to reclaimed sites without additional surface disturbance.
- The area evaluated for potential impacts includes the Planning Area and Big Horn, Hot Springs, Park, and Washakie County weed-control districts.
- The acreage of long-term disturbance (Appendix T) includes facilities that cannot be reclaimed and that, in most cases, would not provide long-term habitats for invasive species. For example, well pads, communication sites, powerlines, roads, wind-energy facilities, and other infrastructure would replace existing native vegetation with pervious or impervious surfaces for a period exceeding 5 years.

- Integrated Pest Management includes chemical, mechanical, biological, and cultural techniques.
- The introduction of aquatic invasive invertebrates, vertebrates, microorganisms, and pathogens can threaten the stability of ecosystems, create serious human health consequences, and cause substantial economic burdens. Large majorities of native and nonnative species do not pose a threat to natural or human systems. However, if any of these species were to become a concern, the WFO and CYFO would cooperate and coordinate with appropriate government agencies, private industry, and other interested parties involved in public education efforts and control, management, and research of invasive species.

4.4.4.2 Summary of Impacts by Alternative

Invasive species are expected to spread under all alternatives. Surface disturbance can increase the spread of invasive species by either damaging native vegetation and creating a space for the establishment of invasive species, or introducing invasive species seed and plant matter from machinery and other equipment. Correspondingly, alternatives projected to involve the greatest amount of surface disturbance would have the greatest potential to increase the spread of invasive species. Reclamation requirements, especially the development of reclamation plans prior to initiating surface-disturbing activities, would decrease long-term disturbance and the likelihood of invasive species establishment. Based on projected surface disturbance, Alternative C would result in the greatest potential spread of invasive species, followed by alternatives A, D, F, B, and E. Alternatives D and F are projected to result in greater surface disturbances than Alternative A, but they contain additional reclamation requirements that would result in a reduced potential for the spread of invasive species.

Fire and fuels management, motorized vehicle use, and livestock grazing would have the greatest impact on the spread of invasive species. Though disturbance caused by fire can spread invasive species, when conditions are favorable and proactive management to reestablish native plants follows closely after, fire can be a tool to reestablish historic fire regimes that favor native plants over invasive species. Alternative C would result in the greatest short-term adverse impacts from disturbance due to fire and fuels management and the greatest potential long-term benefits from restoration of historic fire regimes, followed by alternatives A, D, F, B, and E. Closing areas to motorized vehicle use can help prevent the unintentional spread of invasive species; alternatives B and E restrict travel across the largest portion of the Planning Area, and would provide the greatest potential reduction in the spread of invasive species from motorized vehicles, followed by alternatives F, D, A, and C. The potential adverse impacts from livestock grazing related spread of invasive species would be greatest under Alternative C due to fewer management options to control their spread (e.g., the option to require livestock flushing); alternatives A, D, F, B, and E contain more management options to control livestock grazing related invasive species spread.

4.4.4.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

All alternatives could result in proliferation of noxious and invasive weeds into areas considered weed-free, and there may be an increase in noxious and invasive weeds where they already exist. In general, surface-disturbing activities (e.g., mineral development, road construction) would adversely impact invasive species and pest management under all alternatives. Reclamation of these areas reduces the chance of invasive species establishment. Vegetation treatments would beneficially impact the management of invasive species under all alternatives. Treatments may cause short-term impacts to

vegetation by decreasing vegetation production and increasing establishment of early successional species. Long-term impacts could include increased production and diversity of vegetation communities, thereby controlling the spread of invasive species.

ROW authorizations would contribute to the spread of invasive species under all alternatives. The road network is a major conduit for the initial spread of invasive species, although the availability to access areas also results in the opportunity to find and treat new infestations. ROWs concentrated in a corridor tend to localize or confine disturbance to a smaller area and reduce disturbance in areas identified as sensitive, which would minimize potential impacts from invasive species spread.

Indirect, adverse, short- and long-term impacts from transportation of materials, people, and vehicles occur throughout the Planning Area at recreation sites, trailheads, trails, and transportation routes. Invasive species are established in some of these areas and their seeds are spread to other areas by vehicles, people, livestock, and wildlife. Due to the permanent nature of most recreation sites, trails, and transportation routes, most associated adverse impacts under all alternatives are anticipated to be long-term.

Fire and fuels management is likely to impact invasive species and pest management. By destroying or damaging invasive plants and seeds, beneficial impacts can be realized based on the timing and location of fire. Conversely, adverse impacts from suppression activities that disturb soil and from fires that remove native vegetation and expose soil result in conditions that provide a seedbed for weed establishment, such as cheatgrass. Most weeds can out-compete native species and typically respond rapidly after fire. The likelihood of weed expansion after a wildland fire increases in areas where weeds occur or are nearby. Firefighters and their equipment may also introduce or spread weeds. Impacts of fire management are not just limited to terrestrial invasive species; the use of water for fire suppression and rehabilitation activities can also contribute to the spread of aquatic invasive species, which are anticipated to become a greater management challenge in the Planning Area. Under all alternatives, fire-fighting equipment must be cleaned in areas with high-risk aquatic invasive species to prevent the spread of these species. The adverse impacts from fire management may be direct or indirect because the impact(s) may or may not occur immediately.

Because all alternatives would be managed according to the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N), the types of adverse impacts from livestock grazing and wild horse use to vegetation and soil are expected to be similar among alternatives. The number and distribution of native ungulates and current allowable management levels of wild horses also are anticipated to be similar among alternatives, because the number of AUMs does not change by alternative. The impacts of livestock, wild horse, and native ungulate grazing on the management of invasive species from all alternatives are anticipated to result in a mix of beneficial and adverse impacts.

Livestock, wild horse grazing, and native ungulate grazing, depending on its timing and intensity, can cause variable impacts to invasive species. Short- and long-term adverse impacts associated with livestock, wild horse, and native ungulate grazing are anticipated primarily where these species concentrate (e.g., water sources, trails, favored forage) and include transport of weed seeds and disturbance of soil, creating environments for the spread of invasive species. As the vegetation of riparian/wetland areas is fragile and these areas are vulnerable to wildlife, wild horse, and livestock concentrations, so too are they vulnerable to the spread of invasive species. High densities of native ungulates can reduce or eliminate shrub seed production and impair recruitment of young shrubs (Kay 1995). In addition, as vegetation stubble height is reduced, there can be a shift in cattle preference and damage to vegetation (Hall and Bryant 1995). These impacts would be expected to result in adverse impacts by increasing the establishment of invasive species.

Livestock grazing management in accordance with guidelines associated with the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N) may result in beneficial impacts by improving rangeland health and decreasing the potential for the spread and establishment of invasive species. Studies have shown that proper livestock grazing management can increase a plant community's resistance to cheatgrass invasion after a disturbance such as wildland fire and effectively control other invasive species (Hall and Bryant 1995, Stohlgren et al. 1999, Davies et al. 2009). In addition, livestock grazing in sagebrush communities can increase plant species richness and diversity (Manier and Hobbs 2007), decreasing vulnerability to invasive species spread. The impacts described by these studies are expected to remain site-specific in the Planning Area under all alternatives.

Proactive management actions common to all alternatives that may control the spread of invasive species include watershed stabilization, the use of certified noxious weed-free vegetation products, developing and maintaining an invasive species and pest management plan, and subjecting surface-disturbing activities to the *Wyoming BLM Mitigation Guidelines for Surface-Disturbing and Disruptive Activities* (Appendix H) and the BLM Reclamation Policy (BLM 2012b). The BLM also continues to collaborate with cooperating agencies and interested stakeholders in educating public lands users about the control of invasive species, funding development and implementation of integrated pest management, and reducing and preventing the expansion of cheatgrass. Other management actions common to all alternatives can adversely impact the control of invasive species, such as restricting aerial pesticide application when its use conflicts with other resource management objectives.

Alternative A

Surface Disturbance

The surface disturbance projected for Alternative A would contribute to the spread of invasive species, in both the short and long term. Short-term impacts would occur during the 5 years following disturbance while the soil is bare of vegetation and reclamation activities strive to stabilize the soil and revegetate the area. Long-term impacts would last longer than 5 years due to reclamation efforts not completely effective in preventing weed establishment.

Surface-disturbing activities from all actions listed in Appendix T provide opportunities for the establishment and spread of invasive species. It is anticipated that BLM actions under Alternative A would impact 136,253 acres over the short term and 15,646 acres over the long term in the Planning Area (Table 4-1). The impacts from invasive species spread due to surface disturbance under Alternative A are anticipated to be proportional with the intensity of reasonable foreseeable actions shown in Appendix T.

Under Alternative A, the BLM determines the rate of erosion and the degree of soil stability during rangeland health evaluations. The BLM requires the reestablishment of vegetative cover in disturbed areas within 5 years of initial seeding and routine seeding on a priority basis in disturbed areas, but does not require reclamation plans. Based on reclamation measures, Alternative A would have the highest opportunity for the spread of invasive species in disturbed areas. Under Alternative A, activities to control invasive species would disturb the surface of approximately 2,000 acres (Appendix T) that would be reclaimed in the long term. Surface disturbance to control weeds is likely to occur in areas already infested, and therefore is not likely to contribute to the spread of invasive species.

Resource Uses

Under Alternative A, mineral development would result in 25,552 acres of short-term and 13,033 acres of long-term surface disturbance (Appendix T). Most of the Planning Area would remain open to mineral extraction. Most of the impacts would be temporary during the life of the operation with most areas of disturbance reclaimed following closure of operations. Typically, a large portion of a mineral material site is disturbed leaving the area prone to the spread of invasive species.

Forest and woodland treatments and forest products would result in 30,000 acres of short-term surface disturbance under Alternative A, but that same acreage would be reclaimed (Appendix T). Alternative A allows for clear-cutting, which may cause adverse impacts by generating changes to the microclimate and destabilizing soil, thus facilitating the spread of weeds where seed sources are present. Harvesting timber on commercial forestland in a manner to protect watershed and riparian/wetland habitat values would minimize potential impacts from invasive species, which are more likely to spread to degraded habitats. Alternative A allows salvage of dead stands on a case-by-case basis but does not use the full range of silviculture treatments to manage endemic insect and disease outbreaks.

Utility corridors and linear ROWs in the Planning Area, including pipelines and powerlines, would result in 5,691 acres of short-term disturbance; however, impacts associated with these activities would be reclaimed and mitigated to the extent practicable through standard operating procedures, resulting in minimal long-term disturbance (Appendix T). Motorized vehicle use to maintain these corridors has the potential to cause adverse impacts by contributing to the spread of weeds. The road network is a major conduit for the initial spread of invasive species, although the availability to access areas also results in the opportunity to find and treat new infestations. Alternative A results in 1,966 acres of short-term and 983 acres of long-term surface disturbance from road construction. The risk of adverse impacts due to the spread of invasive species is expected to increase proportionally with the long-term surface disturbance from new road construction.

Under Alternative A, the creation of new roads and trails for recreational purposes would result in 1,233 acres of short-term and 835 acres of long-term surface disturbance. Adverse impacts would result from the spread of invasive species into potentially undisturbed areas in the Planning Area, and may be correlated with the amount of surface disturbance (Appendix T). Alternative A closes 68,115 acres to motorized vehicle use, resulting in beneficial impacts by slowing the potential spread of invasive species transported by motor vehicles. Restricting motorized vehicle use (e.g., limiting motorized vehicle use to designated roads and trails in areas with fragile soils) would reduce the threat of invasive species establishment and spread.

The degree of recreational site development under Alternative A may result in adverse and beneficial impacts. The BLM projects recreational site development to result in approximately 350 acres of long-term surface disturbance, which may leave these areas more vulnerable to invasive species spread. However, when recreational developments confine dispersed recreation to areas with higher use (e.g., vehicle barriers), beneficial impacts may result by reducing surface disturbance and the potential for introduction of invasive species to undisturbed areas. In addition, detection and treatment of new noxious weed infestations are more likely at centrally developed locations than over larger areas with more dispersed recreational activity. At developed sites, educational and prevention materials can be displayed and interpreted to the public resulting in the potential for lower risk of new infestations over time. However, when developments are likely to generate more visitors (e.g., trail or access route improvements) then they are likely to cause adverse impacts, as recreationists spread the seeds and material of weeds. In general, recreation management actions under Alternative A call for more development, if demand warrants, of facilities to augment and enhance visitor use and enjoyment

Invasive Species and Pest Management

including fire rings, comfort stations, parking areas, road improvements and vehicle barriers, the impacts of which are likely to be site specific.

Alternative A prohibits the placement of salt, mineral, or forage supplements within ¼ mile of water, wetlands, riparian, or other areas with sensitive vegetation, such as reclaimed or reforested areas. This restriction would provide beneficial impacts by preventing livestock and native ungulate concentration, therefore reducing the potential to spread invasive species in these areas.

Under Alternative A, the BLM evaluates “I” category livestock grazing allotments and AMPs to determine if they are meeting the *Wyoming Standards for Healthy Rangelands*, resulting in the least amount of monitoring among the alternatives. Based on the lack of a required 72-hour holding period for livestock (see ‘Proactive Management’ below) and less monitoring of grazing allotments, livestock grazing under Alternative A is anticipated to have short- and long-term adverse impacts.

Special Designations

In general, special designations under Alternative A (ACECs and WSAs) place restrictions on surface-disturbing activities (e.g., mineral development, ROW development, and fire suppression) that may facilitate the spread of weeds. These restrictions would result in beneficial impacts to the management of invasive species. Current management designates nine ACECs under Alternative A.

Resources

Resource management actions would result in adverse and beneficial impacts to invasive species and pest management. Managing to maintain or enhance native vegetation would result in indirect beneficial impacts by controlling the spread of weeds. Other resource programs may also result in adverse impacts to managing invasive species, primarily by limiting their control (e.g., restricting the application of pesticides) to avoid conflicts with other resource management objectives.

Management actions specific to Alternative A allow the aerial application of pesticides on a case-by-case basis, the most efficient means of controlling invasive species at the landscape scale, thereby beneficially affecting invasive species and pest management.

Alternative A utilizes fire to restore fire adapted ecosystems and reduce hazardous fuels. Vegetation response following planned ignitions and mechanical and chemical treatment varies depending on a set of factors such as fire conditions, timing, and pre- and post-treatment weather conditions. Impacts to the spread of invasive species from fire and fuels management under Alternative A are likely to be site and species specific. No specific management actions that address the use of fire to control weed species exist under Alternative A. Based on projected surface disturbance (Appendix T), fire and fuels management under Alternative A may result in adverse impacts in areas where fire facilitates the spread of invasive species, such as cheatgrass, and beneficial impacts where it restores native fire-adapted vegetation.

Under Alternative A, vegetation management involves implementing DPC objectives for watershed protection, forestland management, and livestock grazing on 600,000 acres. Widespread vegetation management may result in beneficial impacts by controlling and monitoring the spread of invasive species in these managed areas. Vegetation not meeting DPC has the highest risk of having lost or losing key ecosystem components that make these areas more vulnerable to invasive species establishment. Managing riparian/wetland areas toward achieving PFC would result in beneficial impacts by controlling the spread of invasive species in these areas.

Proactive Management

Proactive management actions specific to the invasive species and pest management program would focus on aerial pesticide restrictions and livestock flushing. Allowing the aerial application of pesticides on a case-by-case basis would result in the greatest beneficial impact to the management of invasive species by placing the fewest restrictions on aerial pesticide application.

The transport of invasive species seeds and material by livestock and native ungulates occurs when they attach to the animals' coats and feet or are ingested. One method to control the spread of invasive species ingested by livestock is to hold the animals in one area before they are allowed to move to other areas. A holding period of 72 hours allows the animals to flush the ingested weed material from their systems so they would not transport the ingested material to uninfested areas. Alternative A requires livestock flushing on a case-by-case basis, but does not require a holding period before moving livestock onto or within public lands. Proactive management actions under Alternative A are expected to help control the spread of invasive species.

Alternative B

Surface Disturbance

The projected long-term disturbance acreage for Alternative B is approximately 31 percent less than Alternative A. Compared to Alternative A, Alternative B has stricter requirements (e.g., 50 percent pre-disturbance of vegetative cover within three growing seasons, 80 percent cover within 5 years of initial seeding, topsoil salvage, and development of a reclamation plan before surface disturbance) regarding the reclamation of disturbed areas. These measures would result in beneficial impacts decreasing the likelihood of invasive species establishment and spread. Although the extent of treatments for invasive species and pests would be less under this alternative—indicated by the projected surface disturbance from invasive species and pest management (Appendix T)—the less overall surface disturbance and proactive reclamation requirements under Alternative B may result in less adverse impacts due to the lower potential for the spread of invasive species in comparison to Alternative A.

Resource Uses

Under Alternative B, mineral development would result in 17,306 acres of short-term surface disturbance and 6,206 acres of long-term surface disturbance, likely having the less adverse impacts to invasive species management than Alternative A (Appendix T). The types of impacts from mineral development under Alternative B would be similar to those under Alternative A.

Forest and woodland treatments and recovery of forest products are projected to result in 20,000 acres of short-term surface disturbance under Alternative B (Appendix T); however, all of this acreage would be reclaimed. Alternative B prohibits clear-cutting, which is likely to result in beneficial impacts by maintaining microclimatic and soil conditions so there is less opportunity for the establishment of invasive species. Timber harvest is only allowed in areas where natural processes are unable to accomplish forest health goals, likely resulting in less use of motorized machinery that can disturb soils and carry invasive species seeds. Under Alternative B, these practices would have a more beneficial impact by slowing the spread of invasive plant species, compared to Alternative A. However, managing endemic insect and disease outbreaks only as necessary for human health and safety and prohibiting precommercial thinning would adversely affect pest management by limiting bark beetle control efforts.

Utility corridors and linear ROWs in the Planning Area, including pipelines and powerlines, would involve 3,975 acres of short-term and 721 acres of long-term surface disturbance (Appendix T); Alternative B

would involve 1,229 acres of short-term and 615 acres of long-term surface disturbance due to road construction. These disturbances would result in impacts similar to Alternative A, but to a lesser degree. The risk of adverse impacts from the spread of invasive species is expected to increase proportionally with long-term surface disturbance from new road construction.

Under Alternative B, the creation of new roads and trails for recreational purposes would result in 2,776 acres of short-term and 1,068 acres of long-term surface disturbance, slightly more disturbance than Alternative A (Appendix T). The resulting impact would be the potential spread of invasive species into new areas where disturbance occurs. Alternative B closes more area to motorized vehicle use and limits motorized vehicle use to designated roads and trails in more area, compared to Alternative A. Restricting motorized vehicle access would reduce the area to which vehicles may spread invasive species; however, restricting vehicle access would also make detection and subsequent treatment of new or expanding weed areas more difficult. Prohibiting off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations would result in beneficial impacts by controlling the spread of invasive species from motorized travel. For known weed infestations selected for treatment, the BLM may authorize motorized vehicle use for performing treatment activities, where appropriate. Overall, adverse impacts from motorized vehicle use would be less than under Alternative A.

In areas developed for recreational use outside of SRMAs, further development to enhance recreation and visitor services would generally be less extensive under Alternative B than Alternative A. However, recreational development in SRMAs and RMZs would be greater under Alternative B. Developments would include new trails and trailheads, access route improvements, and new motorized touring loops that may increase public access and the potential for invasive species spread but may also consolidate recreational activity to facilitate potential detection and treatment. Due to more intensive management of SRMAs and RMZs to maintain the desired recreation setting and, therefore, the more active control of invasive species, recreational use under Alternative B would result in fewer adverse impacts to invasive species and pest management than under Alternative A.

Alternative B prohibits the placement of salt, mineral, or forage supplements within ½ mile of water, wetlands, riparian, or other areas with sensitive vegetation such as reclaimed or reforested areas. This alternative provides the largest buffer and would, therefore, provide greater beneficial impacts than Alternative A by controlling the spread of invasive species by livestock and native ungulates in these vulnerable areas.

Under Alternative B, the BLM closes large areas—including crucial winter range for elk and greater sage-grouse Key Habitat Areas—to livestock grazing, allowing existing uses pending site-specific analysis. Closing areas to livestock grazing would limit the transport of invasive species and reduce the overall consumption of native vegetation, improving plant vigor, and resulting in more effective native plant competition over possible invasive species introduction. However, prohibiting livestock grazing may preclude its use as a tool to control invasive species in certain areas (Stohlgren et al. 1999, DiTomaso 2000). The opportunity for risk of introduction of noxious weed seeds by wildlife or birds would still remain under this alternative.

The BLM monitors those allotments not meeting rangeland health standards due to livestock grazing under Alternative B. This management action may require an increase in rangeland monitoring, compared to Alternative A, which would provide beneficial impacts by monitoring the spread of invasive species to better serve control and treatment efforts.

Special Designations

In general, special designations (e.g., ACECs and WSAs) under Alternative B place more restrictions on surface-disturbing activities (e.g., mineral development, ROW development, and fire suppression) that facilitate the spread of invasive species, compared to Alternative A. In addition to the nine ACECs designated under Alternative A, four existing ACECs would be expanded, and eight new ACECs designated under Alternative B. Although seasonal stipulations on invasive, nonnative pest species control in the Chapman Bench, Clarks Fork Canyon, Rattlesnake Mountain, and Sheep Mountain ACECs may adversely impact invasive species management by restricting control methods or timing, ACEC designations under this alternative would place restrictions on actions most likely to contribute to the spread of invasive species, resulting in the more beneficial impacts to invasive species control, compared to Alternative A. Two back country byways would be designated and developed under Alternative B. If these designations and facility developments increase use from motorized vehicles, then adverse impacts may result from increased potential to spread invasive species along these byways.

Resources

Alternative B would utilize fire to restore fire adapted ecosystems and reduce hazardous fuels. Vegetation response following planned ignitions and mechanical and chemical treatment typically varies depending on a set of factors such as fire conditions, timing, and pre- and post-treatment weather conditions. Alternative B uses mechanical, chemical, or biological treatments in the wildland urban interface to protect structures and private property from fire. Mechanical treatments may cause adverse impacts by increasing the potential of invasive species spread, because the surface disturbance associated with these treatments would occur in habitat that may already be degraded. In other situations, such as in areas affected by cheatgrass, burning has a greater adverse effect on weed spread than some mechanical treatments may have (Keeley 2006). Although fire and fuels management under Alternative B may result in less short-term surface disturbance than Alternative A (Appendix T) and therefore less adverse impacts by spreading invasive species, it would also result in less long-term beneficial impacts from restoring native fire-adapted vegetation.

Under Alternative B, vegetation management would be less extensive than Alternative A. Though the BLM would manage to achieve or make progress towards the reference state plant community based on the ESD for the site and maintain native plant communities on contiguous blocks of BLM-administered land. This would result in beneficial impacts by limiting new areas susceptible to invasive species spread due to improved habitat integrity. The greater reliance on natural processes for vegetation treatment under this alternative would result in a smaller beneficial impact that vegetation management under Alternative A. Alternative B also prohibits the aerial application of pesticides within 1 mile of special status plant species populations, which may result in adverse impacts by limiting widespread pesticide use to control invasive species spread. As managing riparian/wetland areas toward DPC is assumed to exceed the requirements of managing toward PFC, Alternative B may result in greater beneficial impacts than Alternative A by controlling the spread of invasive species in these areas.

Proactive Management

The BLM prohibits the aerial application of pesticides within ½ mile of riparian/wetland areas and aquatic habitats under Alternative B. Although this restriction may adversely affect the control of invasive species, exceptions can be made to manage riparian weed species when the beneficial impacts of invasive species control are greater than the risks to aquatic habitat from pesticides applied in conformance to label requirements.

Allowing the authorized officer, on a case-by-case basis, to hold livestock that may have ingested invasive species material or seeds for a period of 72 hours would reduce the potential of livestock to transport invasive species material or seeds under Alternative B. This allows the animals to flush the ingested invasive species material from their systems before moving on to or within public lands. It is anticipated that this action, more than actions under other alternatives, may reduce the adverse, indirect impacts associated with the spread of invasive species from livestock.

Alternative C

Surface Disturbance

Alternative C is projected to result in the greatest acreage of short-term surface disturbance. The projected long-term disturbance acreage for Alternative C is approximately 165 percent more than Alternative A, 283 percent more than Alternative B, and 127 percent more than Alternative D. Alternative C has less stringent reclamation requirements (e.g., 30 percent desired vegetative cover within three growing seasons, and no subsequent requirement) than alternatives B and D, but potentially more stringent requirements than Alternative A by requiring reclamation plans on a case-by-case basis. Additionally, seeding of areas not meeting resource objectives using approved seed mixes containing both native and nonnative species may allow for the selection of species most capable of competing with invasive species and, therefore, reduce the chances of invasive species establishment in these areas relative to Alternative A. Alternative C is likely to result in the most short- and long-term adverse impacts by providing the most opportunity for invasive species spread in disturbed areas. Although the extent of treatments for invasive species and pests would be twice that of alternatives A and D and 40 times more than Alternative B—indicated by the projected surface disturbance from invasive species and pest management (Appendix T)—the greater overall surface disturbance and limited requirements for revegetation under Alternative C may have the greatest adverse impacts to invasive species and pest management.

Resource Uses

Under Alternative C, mineral development would result in 25,912 acres of short-term and 13,180 acres of long-term surface disturbance (Appendix T). Thus, Alternative C would result in similar adverse impacts to those under Alternative A, but to a greater degree. Most of the Planning Area would remain open to mineral extraction, with the least acreage closed compared to the other alternatives. Most of the impacts would be temporary during the life of the operation with most areas of disturbance reclaimed following closure of operations.

Forest and woodland treatments and recovery of forest products would result in 40,000 acres of short-term surface disturbance under Alternative C, but no long-term surface disturbance due to complete reclamation of these sites (Appendix T). Alternative C would allow larger clear-cuts than Alternative A and the continued use of spur roads to complete other resource goals or for new recreational purposes would increase the potential spread of invasive species from vehicle use in these areas. Commercial forestland would be open to timber harvesting, resulting in the greatest adverse impacts for potential invasive plant species spread from motorized machinery and soil disturbance, compared to the other alternatives. However, managing endemic insect and disease with the full range of silviculture techniques and treatment methods and allowing precommercial thinning and salvage operations would beneficially impact pest management such as bark beetle control.

Utility corridors and linear ROWs in the Planning Area, including pipelines and powerlines, would involve 8,559 acres of short-term and 2,563 acres of long-term surface disturbance (Appendix T), which would

result in impacts similar to Alternative A, but to a greater degree. Alternative C would involve 4,638 acres of short-term and 2,319 acres of long-term surface disturbance from road construction alone, the most of all alternatives (Appendix T). The risk of adverse impacts due to the spread of invasive species is expected to increase proportionally with long-term surface disturbance from new road construction.

Under Alternative C, the creation of new roads and trails for recreational purposes would result in 12,907 acres of short-term and 12,735 acres of long-term surface disturbance, the most of all the alternatives (Appendix T). The resulting impact would be the potential spread of invasive species into new areas where disturbance occurs. Alternative C limits motorized vehicle use to designated roads and trails in less acreage than alternatives B and D—though more acreage than Alternative A—closes the least acreage to motorized vehicle use, and allows off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations, which would result in the greatest potential adverse impacts from the spread of invasive species, compared to the other alternatives. Conversely, less restrictive travel management under this alternative would allow the greatest access to detect new and treat existing invasive species infestations, which may result in a beneficial impact to the control of these species.

In areas developed for recreational use, impacts from recreational development under Alternative C would be similar to those under Alternative A, but to a greater degree. The potential visitor increase to recreational areas may be greater than Alternative B, but if the BLM upgrades or develops facilities in response to demand, the consolidation of recreational activity may result in beneficial impacts to invasive species and pest management as described under Alternative A. Alternative C manages the least areas as SRMAs, and therefore would pursue the least intensive management to maintain the desired recreation setting, resulting in the least beneficial impact to invasive species control.

Alternative C allows the placement of salt, mineral, or forage supplements in wetlands, riparian, or other areas with sensitive vegetation such as reclaimed or reforested areas to maximize livestock use. The potential concentrated livestock use and associated soil disturbance and invasive species spread would be the greatest under Alternative C, compared to the other alternatives.

Under Alternative C, the BLM excludes livestock grazing from the same areas as Alternative A, but manages livestock grazing to optimize commodity production while meeting rangeland health standards, not to provide for the enhancement of other resource values. The potential adverse impacts by allowing livestock grazing in areas where it is likely to contribute to, rather than help control, the spread of invasive species would be greatest under this alternative. Alternative C, by prioritizing monitoring on “I” category allotments and those allotments not meeting rangeland health standards due to current livestock grazing, would result in more monitoring to aid invasive species detection and treatment than Alternative A.

Special Designations

In general, special designations (e.g., ACECs and WSAs) under Alternative C would place the least restrictions on surface-disturbing activities (e.g., mineral development, ROW development, and fire suppression) that facilitate the spread of invasive species. Furthermore, only the Spanish Point Karst and Brown/Howe Dinosaur Area ACECs would be designated under this alternative, providing the fewest beneficial impacts from special designations from limiting surface disturbance to control the spread of invasive species, compared to the other alternatives.

Resources

Alternative C would utilize fire to restore fire adapted ecosystems and reduce hazardous fuels. Vegetation response following planned ignitions and mechanical and chemical treatment varies

depending on a set of factors such as fire conditions, timing, and pre- and post-treatment weather conditions. Mechanical, chemical, or biological treatments would be used across the landscape as needed to restore vegetative diversity and reduce the risk of unnatural fire. Although fire management actions result in the greatest amount of surface disturbance in the short term, by restoring vegetative diversity the risk of invasive species establishment would decrease, resulting in beneficial impacts in the long term. Under Alternative C, the BLM would seek to restore vegetation diversity while decreasing the risk of unnatural fire. Fire management under this alternative is likely to result in the greatest long-term beneficial impact, compared to the other alternatives.

Under Alternative C, the BLM manages grasslands and shrublands toward meeting the *Wyoming Standards for Healthy Rangelands* (Appendix N) in the greatest acreage, compared to the other alternatives. However, the BLM does not manage to maintain native species on contiguous blocks of BLM-administered land. Managing all riparian/wetland areas to meet or make progress toward PFC while prioritizing areas functioning at-risk with a downward trend or in nonfunctioning condition would focus management on those areas most vulnerable to invasive species spread and may result in a greater beneficial impact than riparian/wetland management under Alternative A. Due to the larger extent of vegetation management, Alternative C may result in more beneficial impacts to control the spread of invasive species than alternatives A, B, and D.

Prohibiting the aerial application of pesticides within ½ mile of special status plant species would result in a greater potential adverse impact than Alternative A, but less than Alternative B, by limiting widespread pesticide use to control invasive species.

Proactive Management

The BLM prohibits aerial application of pesticides within 100 feet of riparian/wetland areas and aquatic habitats under Alternative C. Although this restriction would adversely affect the control of invasive species, exceptions could be made to manage riparian weed species, when the beneficial impacts of invasive species control are greater than the risks from pesticides to aquatic habitat when applied in conformance with the label. Proactive management under Alternative C includes expansion of integrated pest management for identified infestations, a beneficial impact, but a reduction in livestock management measures (i.e., livestock flushing) that may prevent new infestations, an adverse impact.

Alternative D

Surface Disturbance

The projected long-term disturbance acreage for Alternative D is approximately 17 percent more than Alternative A, 68 percent more than Alternative B, and 56 percent less than Alternative C. Overall, Alternative D has more stringent reclamation requirements than alternatives A and C, but less than Alternative B. The BLM allows nonnative species for seeding, which would result in similar beneficial impacts to those under Alternative C. Alternative D is likely to result in more short-term adverse impacts than Alternative A, but less long-term adverse impacts by employing reclamation practices that reduce the opportunity for invasive species spread in disturbed areas. The extent of treatments for invasive species and pests under Alternative D is similar to that under Alternative A.

Resource Uses

Under Alternative D, mineral development would result in 25,229 acres of short-term and 12,733 acres of long-term surface disturbance (Appendix T). Mineral development under Alternative D would result in similar adverse impacts to those under Alternative A, but to a lesser degree.

Forest and woodland treatments and recovery of forest products would result in impacts similar to Alternative A, but to a greater degree from allowing clear cuts up to 100 acres. However, managing endemic insects and disease with the full range of silviculture techniques and treatment methods and allowing precommercial thinning and salvage operations would create beneficial impacts similar to Alternative C.

Under Alternative D, utility corridors, new road construction, and linear ROWs, including pipelines and powerlines, would result in impacts similar to Alternative A. However, managing more area as ROW avoidance or exclusion areas under this alternative may consolidate ROW development and, therefore, limit the dispersal of invasive species.

Under Alternative D, the creation of new roads and trails for recreational purposes would involve 5,820 acres of short-term and 3,941 acres of long-term surface disturbance, the second most of the alternatives (Appendix T). The resulting impact would be the potential spread of invasive species into new disturbed areas. Alternative D closes the second largest acreage to motorized vehicle use and limits motorized vehicle use to designated roads and trails in the second largest acreage compared to other alternatives. Alternative D also limits off-road vehicle travel for big game retrieval and dispersed campsite access to within 300 feet of established roads. Under Alternative D, beneficial and adverse impacts to invasive species management would be greater than under alternatives A and C, but less than under Alternative B.

Recreational development under Alternative D in areas outside SRMAs would result in impacts similar to Alternative C. Recreation management actions in SRMAs would result in impacts similar to those under Alternative B, but to a lesser extent because SRMAs encompass less acreage under Alternative D.

Livestock grazing management under Alternative D would result in impacts similar to Alternative A. Allotment monitoring would cause beneficial impacts similar to Alternative C, but to a greater degree. Prioritizing monitoring on allotments that do not meet rangeland health standards due to all livestock grazing, not just current, may increase monitoring in more areas vulnerable to invasive species spread.

Special Designations

Special designations under Alternative D would result in impacts similar to Alternative A, but to a greater degree. In addition to the nine ACECs designated under Alternative A, Alternative D designates four new ACECs and two new management areas that emphasize resource protection, placing more restrictions on resource uses and activities likely to contribute to the spread of invasive species. Although seasonal stipulations on controlling invasive, nonnative pest species in the Chapman Bench Management Area and the Clarks Fork Canyon and Sheep Mountain ACECs may adversely affect invasive species management by restricting control methods or timing, ACEC designations under Alternative D would create more beneficial impacts than under alternatives A and C by limiting the spread of invasive species.

Invasive Species and Pest Management

Resources

Fire and fuels management practices under Alternative D would result in impacts to invasive species and pest management similar to Alternative A in both extent and intensity. Similar to Alternative B, Alternative D places more emphasis on using fire as a resource management tool, which may beneficially impact invasive species management if the BLM uses fire more frequently in areas where it helps to control the spread of invasive species.

Vegetation management under Alternative D would create beneficial impacts similar to Alternative B, but to a lesser degree and extent. Based on the amount of projected surface disturbance (Appendix T), Alternative D would actively manage a similar amount of vegetation as Alternative A. However, Alternative D would maintain contiguous blocks of native plant communities and manage some areas under for a higher plant community state or phase (based on state and transition models in ESDs) where site-specific management objectives determine that a higher plant community state or phase is desirable. As a result, vegetation management under Alternative D would result in beneficial impacts similar to Alternative B but to a greater extent. Management of riparian/wetland vegetation would create beneficial impacts similar to Alternative C, but to a greater degree because Alternative D manages certain areas to obtain DFC, which requires more intensive management than PFC.

Avoiding aerial applications of herbicides within ½ mile of BLM special status plant species would result in similar adverse impacts to invasive species management as those under Alternative C, but to a lesser degree.

Proactive Management

Proactive management actions to control the spread of invasive species under Alternative D would create impacts similar to Alternative A.

Alternative E

Surface Disturbance

Under Alternative E, the projected long-term disturbance acreage is least among the alternatives and is approximately 31 percent, 2 percent, 74 percent, 42 percent, and 40 percent less than alternatives A, B, C, D, and F, respectively. Reclamation requirements of disturbed areas under Alternative E would be the same as Alternative B, except in the Greater Sage-Grouse Key Habitat Areas ACEC, which would include additional proactive reclamation requirements for disturbed sites. Although the use of herbicides would be minimized under this alternative in the Greater Sage-Grouse Key Habitat Areas ACEC, the overall amount of surface disturbance, proactive reclamation requirements, and additional management measures in the ACEC would result in the least potential for the spread of invasive species when compared to the other alternatives.

Resource Uses

Mineral development would result in 17,297 acres of short-term surface disturbance and 6,202 acres of long-term surface disturbance under Alternative E. Although these overall disturbance estimates are the same as Alternative B, the location of mineral development may vary due to greater limitations on surface disturbance in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres) under Alternative E.

Approximately 20,000 acres of short-term surface disturbance associated with forest and woodland treatments and recovery of forest products are projected to result under Alternative E (Appendix T);

however, all of this acreage would be reclaimed. Under Alternative E, timber harvest management would be the same as Alternative B, and the associated surface disturbance impacts to invasive species management would be the same as Alternative B. In general, the practices of Alternative E would be the same as Alternative B and would have the most beneficial impact by slowing the spread of invasive species over the largest area of any alternative.

Rates of invasive species establishment and spread are expected to increase proportionally with long-term anthropogenic surface disturbances. Disturbance from pipeline, road development, and new road construction would be the same as Alternative B. However, the location of these disturbances may vary under Alternative E, which manages more areas as ROW exclusion areas than any other alternative.

Recreational developments such as new trails, trailheads, access route improvements, and new motorized touring loops would be the least extensive under Alternative E. These types of developments could result in increased public access and the potential for invasive species spread. Alternative E requires that Special Recreation Permits in the proposed Greater Sage-Grouse Key Habitat Areas ACEC have neutral or beneficial effects to sage-grouse habitat, potentially limiting the recreational activities that may contribute to the spread of invasive species. Therefore, recreational use under Alternative E would result in fewer adverse impacts to invasive species and pest management when compared to the other alternatives.

Management of motorized vehicle use and livestock grazing are the same as under Alternative B, and impacts to invasive species management would therefore be the same as Alternative B.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land in the Greater Sage-Grouse Key Habitat Areas ACECs. The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative E would result in additional benefits to invasive species management in comparison to the other alternatives. Specifically, requirements to include a full reclamation bond to insure restoration of disturbed areas to their original condition and other habitat restoration and vegetation management requirements associated with the Sage-Grouse Key Habitat Areas ACEC, would reduce adverse impacts from surface-disturbing activities in the largest area when compared to the other alternatives.

Resources

Under Alternative E, fire and fuels management practices and impacts are the same as Alternative B with the exception of lands within the Greater Sage-Grouse Key Habitat Areas ACEC, which would be managed with an emphasis on protecting existing sagebrush ecosystems. The design and implementation of fire management within the Greater Sage-Grouse Key Habitat Areas ACEC would be conducted with an emphasis on protecting existing sagebrush ecosystems and would promote the persistence of native plant communities. Among all of the alternatives, fire and fuels management under Alternative E would result in the least short-term surface disturbance (Appendix T) and therefore the least adverse impact of spreading invasive species. In general, the additional fuel management restrictions of areas within the Greater Sage-Grouse Key Habitat Areas ACEC would encourage the long-term establishment of native plant communities. Therefore, Alternative E would result in more long-term beneficial impacts to invasive species management by restoring native vegetation than the other alternatives.

With the exception of lands within the Greater Sage-Grouse Key Habitat Areas ACEC, vegetation management under Alternative E would be the same as Alternative B. Vegetation management in the

Greater Sage-Grouse Key Habitat Areas ACEC will emphasize the restoration and preservation of native sagebrush ecosystems to create a landscape pattern which most benefits sage-grouse. These actions would require the use of native seeds for restoration based on availability, adaptation, and probability of success. Management actions would also be designed to ensure long-term persistence of restorations. The additional vegetation and habitat restoration management strategies of Alternative E would result in the greatest beneficial impacts by promoting growth and establishment of native plant communities, particularly native sagebrush communities, within the largest acreage of all the alternatives.

Proactive Management

Under Alternative E, the same invasive species management methods outlined for Alternative B would apply, but different control and treatment methods would be practiced in the Greater Sage-Grouse Key Habitat Areas ACEC. These include the restriction of activities that facilitate the spread of invasive plants and the development and implementation of methods for prioritizing and restoring sagebrush steppe invaded by nonnative plants. In addition, project vehicles would avoid driving through infestations and would be washed when accessing and/or leaving sites. To help protect against invasive plants within the Greater Sage-Grouse Key Habitat Areas ACEC, Alternative E would provide assurance that soil cover and native herbaceous plants are at their ESD potential. In areas without ESDs, reference sites would be used to identify appropriate vegetation communities and soil cover. Under Alternative E, the use of herbicides would be minimized within the Greater Sage-Grouse Key Habitat Areas ACEC and would only be used as a last resort to achieve clearly defined goals and objectives. Flash burners, mowing, and selected hand-cutting would be prioritized in these areas, which may restrict grazing permit holders to more labor-intensive methods to control weeds when compared to the other alternatives. Additional proactive management, as well as the resulting beneficial and adverse impacts, would be the same as Alternative B in areas outside of the Greater Sage-Grouse Key Habitat Areas ACEC. Although the limited use of herbicide may result in an adverse impact on the control of invasive plants, the long-term activity restrictions and additional management practices within the Greater Sage-Grouse Key Habitat Areas ACEC would result in the greatest beneficial impact to the control of invasive species when compared to the other alternatives.

Alternative F

Surface Disturbance

Under Alternative F, the projected long-term disturbance is approximately 40 percent more than Alternative E, 39 percent more than Alternative B, and 12 percent more than Alternative A. The projected long-term disturbance is approximately 57 percent and 2 percent less than alternatives C and D, respectively. With the exception of areas in the Greater Sage-Grouse PHMAs ACEC, the reclamation requirements of Alternative F would be the same as Alternative D. Although more short-term adverse impacts are expected to result from Alternative F than Alternative A, less long-term impacts would occur by employing reclamation practices that reduce the opportunity for invasive species spread in disturbed areas, especially within the Greater Sage-Grouse PHMAs ACEC where additional reclamation requirements would apply.

Resource Uses

Mineral development would result in 25,223 acres of short-term and 12,731 acres of long-term surface disturbance under Alternative F (Appendix T). The mineral development of Alternative F would result in

a lesser degree of adverse impacts than those under alternatives A, C, and D, but more than alternatives B and E.

Approximately 30,000 acres of short-term surface disturbance associated with forests and woodlands treatments and recovery of forest products are projected to result under Alternative F (Appendix T); less than under Alternative A and the same as Alternative D. Impacts from utility corridors, new road construction, and linear ROWs, including pipelines and powerlines, would be the same as Alternative D. However, the location of these developments under Alternative F may vary due to the additional restrictions on anthropogenic disturbances in greater sage-grouse PHMAs under this alternative. The management of ROW avoidance or exclusion areas under Alternative F would be similar to Alternative D and would result in similar impacts.

The creation of new roads and trails for recreational purposes would involve 5,750 acres of short-term and 3,917 acres of long-term surface disturbances under Alternative F, which is similar to Alternative D, more than alternatives A, B, and E, and less than Alternative C. Alternative F closes the same acreage to motorized vehicle use as Alternative D and limits motorized vehicle use to designated roads and trails in the second-largest acreage compared to the other alternatives. The adverse impacts to invasive species management resulting from travel management practices under Alternative F would be greater than alternatives E and B, but less than alternatives A, C, and D.

Under Alternative F, recreational management actions would be the same as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC. As with Alternative E, Alternative F requires that Special Recreation Permits in the proposed Greater Sage-Grouse PHMAs ACEC have neutral or beneficial effects to sage-grouse habitat. Therefore, the recreation management actions of Alternative F would result in impacts similar to alternatives D and E, and would have beneficial impacts on invasive species management by reducing the amount of recreational travel that could contribute to the spread of invasive species.

Impacts resulting from livestock grazing under Alternative F would be the same as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC. Livestock grazing and allotment management in the Greater Sage-Grouse PHMAs ACEC require the incorporation of sage-grouse habitat objectives and management considerations in all BLM grazing allotments through AMPs or permit renewals. Therefore, greater beneficial impacts to invasive species management would result under Alternative F through the management of native sage-grouse habitat within the ACEC.

Special Designations

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative F would result in additional benefits to invasive species management in comparison to the other alternatives. Similar to Alternative E, requirements to include a full reclamation bond to insure restoration of disturbed areas to their original condition and other habitat restoration and vegetation management requirements associated with the Greater Sage-Grouse PHMAs ACEC would reduce adverse impacts from surface-disturbing activities in a larger area than alternatives A, D, and C.

Resources

Under Alternative F, fire and fuel management practices would result in the same impacts to invasive species and pest management as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC. In general, fire management within the Greater Sage-Grouse PHMAs ACEC would be conducted with an emphasis on protecting existing sagebrush ecosystems and would promote the persistence of native

Invasive Species and Pest Management

plant communities. Similar to Alternative D, fire and fuels management under Alternative F would result in less short-term surface disturbance (Appendix T) than alternatives A and C, creating a beneficial impact to invasive species management by reducing the opportunity of establishment and spread in recently disturbed areas. Like Alternative E, the additional fuel management restrictions within areas of the Greater Sage-Grouse PHMAs ACEC of Alternative F would encourage the long-term establishment of native plant communities. Long-term fuel management practices under Alternative F would result in more beneficial impacts to invasive species management than would alternatives A, C, and D.

Vegetation management under Alternative F would create the same beneficial impacts as Alternative D, but to a greater degree and extent due to additional vegetation management and habitat restoration actions within the Greater Sage-Grouse PHMAs ACEC that would focus on creating landscape patterns that most benefit sage-grouse. Similar to Alternative E, these actions would require the use of native seeds for restoration activities. Methods for prioritizing and restoring sagebrush steppe invaded by nonnative plants would be developed and implemented under Alternative F while also managing towards achieving a higher or lower plant community state or phase (based on state and transition models in ESDs). However, depending on the condition plant community, achievement of higher plant community or phase may be impossible or impractical. The additional vegetation and habitat restoration management strategies of Alternative F would result in the greatest beneficial impacts by promoting the growth and establishment of native plant communities within the largest acreage of all the alternatives.

Proactive Management

Proactive management actions to control the spread of invasive species under Alternative F would be the same as Alternative D, except within areas of the Greater Sage-Grouse PHMAs ACEC. Within the Greater Sage-Grouse PHMAs ACEC, Alternative F would manage some areas for a higher plant community state or phase (based on state and transition models in ESDs) on a case-by-case basis where site-specific management objectives determine that a higher plant community state or phase is desirable. In addition, project vehicles would be washed and required to avoid driving through infestations to access sites within the Planning Area. The use of herbicides would be minimized within the Greater Sage-Grouse PHMAs ACEC and flash burners, mowing, and selected hand-cutting would be prioritized in these areas. Similar to Alternative E, this management action may restrict grazing permit holders to more labor-intensive methods to control weeds when compared to the other alternatives. Although the use of herbicides to control invasive species would be minimized under Alternative F, the long-term activity restrictions and additional management practices within the Greater Sage-Grouse PHMAs ACEC would result in greater beneficial impacts to the control of invasive species than under alternatives A, C, and D.

Fish and Wildlife Resources

Certain types of management that restricts surface-disturbing activities and other resource uses would, generally, provide habitat protection for fish, wildlife, special status species, and wild horses. Table 4-22 provides an overview of these selected protective management actions by important habitat types where they would occur for each alternative. This table is intended to provide a comparative overview comparison of the alternatives. Further discussion of the effects of these and other management actions for each fish and wildlife habitat types is provided in the proceeding sections. Impacts to special status species appear in sections 4.4.7 through 4.4.9, and impacts to wild horses appear in Section 4.4.10.

Table 4-22. Summary of Protective Management by Alternative for Selected Fish, Wildlife, and Special Status Species

	Alternative	Big Game Crucial Winter Range (acres)	Fish-bearing Streams (miles)	Greater Sage-Grouse Key/PHMA ¹ (acres)

4.4.5 Fish and Wildlife Resources – Fish

Wyoming state and federal resource management agencies manage aquatic species (including fish) in the Planning Area. The WGFD has statutory responsibility to protect all aquatic wildlife and is responsible for regulating the sport and commercial take of all fish in the Planning Area. The BLM manages the habitat on BLM-administered lands that supports both game and nongame fish species where they are found, and BLM management indirectly affects all aquatic species both upstream and downstream of BLM-administered lands. This analysis describes the potential impacts to fish habitat on BLM-administered lands.

Adverse impacts result from management actions that degrade fish habitat, including impacts to riparian/wetland habitat, changes in water quality (e.g., temperature, chemistry, etc.), or decreases in water quantity (e.g., natural flow regime) in the Planning Area. Beneficial impacts are those that improve or preserve riparian/wetland habitats and water quality or quantity by maintaining natural flow regimes.

Both natural events and human activities that result in changes to or stressors on habitat components such as vegetation, water quality, or water quantity may result in direct and indirect impacts to fish resources. Direct impacts include management actions that cause onsite disturbances to fish habitat. In addition, management actions that impact recreational access by the public to fish resources would be a direct impact to this resource. Indirect impacts include management actions that result in changes in water quality and quantity that subsequently affect fish. Actions that increase the transport of sediment to and through streams or increase deposition in streams are also considered indirect impacts.

4.4.5.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Activities that cause substantial disturbance to soils and vegetation may adversely affect water quality and quantity, which adversely affects fisheries habitats.
- Surface disturbances accelerate runoff and sediment delivery to stream channels, which alters streamflows and reduces habitat quality for fish that require clear water, moderated streamflows, deep pools, and clean substrates.
- Increased sedimentation adversely affects most fish species in the Planning Area. This analysis, therefore, focuses on the degree of surface disturbance anticipated under each alternative.
- The potential for sedimentation of streams and rivers is minimized through using BMPs.
- The health of fisheries in the Planning Area is directly related to the overall health and functional capabilities of riparian/wetland resources, which in turn reflect watershed health.
- As riparian systems adjust in response to the removal of vegetation or changes in hydrologic conditions, the availability of habitats required to fulfill the life history requirements of fish populations is likely to be affected.

4.4.5.2 Summary of Impacts by Alternative

The principal impacts to fish result from management that increases surface disturbance, resulting in sedimentation and other adverse impacts to water quality and quantity in fish-bearing streams. Increased sediment in fish habitat (streams, rivers, and reservoirs) decreases the potential for fish to

naturally reproduce, fills in pools, leads to channel degradation, decreases light penetration and productivity, alters fish community composition, and increases stream temperature. Alternative C places the fewest restrictions on surface-disturbing activities and has the greatest potential to adversely affect fish habitat, followed by alternatives A, D, F, B, and E. Alternatives D and F are projected to result in greater surface disturbance than Alternative A, but contain more additional reclamation requirements that may limit erosion to a greater degree and, therefore, mitigate adverse impacts to fish habitat. Alternatives B and E would result in the greatest direct beneficial impacts to fisheries through proactive management (e.g., watershed improvement projects), followed by alternatives D and F, A, and C.

4.4.5.3 Detailed Analysis of Alternatives

Potential impacts to fish habitat generally occur in relation to water quality and water quantity as these characteristics directly affect the ability of fish habitat to sustain fish. The analysis below is structured by these headings to identify management that would result in impacts to these characteristics of aquatic habitats. Section 4.1.4 *Water* includes additional detail on potential impacts to water quality and quantity from implementing alternatives. Section 4.4.3 *Vegetation – Riparian/Wetland Resources* describes impacts to riparian/wetland habitat that may also affect fish habitat.

Impacts Common to All Alternatives

The principle impacts to fish habitat result from management actions that affect water quality and quantity. These impacts would be similar under all alternatives, but the degree and intensity of impacts vary by alternative based on restrictions, allocations, projected activity, and other management, as described for each alternative. See *Impacts Common to All Alternatives* in Section 4.1.4 *Water* for a detailed analysis of impacts to surface water quality and quantity. See Section 4.1.3 *Soils* and Appendix V for a more detailed description of the methods used to predict the erosion rates that appear below.

Water Quality

Under all alternatives, fish habitat would be affected by management actions that alter water quality through sedimentation and related degradation from surface-disturbing activities, water temperature changes, water chemistry changes, and riparian area management and restoration.

Increased sediment in fish habitat (streams, rivers, and reservoirs) decreases the potential for fish to naturally reproduce, fills in pools, leads to channel degradation, decreases light penetration and productivity, alters fish community composition, and increases stream temperature. Activities that increase surface runoff can erode stream banks, altering riparian habitat and reducing the quality of in-stream habitat for fish. Under all alternatives, seeps, springs, wet meadows, and riparian vegetation would be maintained in a functional and diverse condition for young greater sage-grouse, resulting in indirect benefits to fish habitat by limiting the alteration of riparian habitat and increasing the quality of in-stream habitat for fish. Changes in aquatic habitats could lead fish to alter their uses of the stream, moving to different areas for feeding and spawning, or eliminate their ability to survive, depending on habitat conditions.

As noted in Section 4.1.4 *Water*, concentrated herbivory may contribute to soil compaction and damage to the vegetative cover and soil crust, thus increasing surface water runoff, erosion, and sedimentation. Fishbearing streams do not flow through the McCullough Peaks or Fifteenmile HMAs under any alternative, so adverse impacts from wild horses would be minimal under all alternatives.

Water Quantity

Water quantity is primarily affected by activities that alter water runoff and water discharge. In areas with little vegetation, less rainfall infiltrates the soil and therefore more runoff may reach stream systems. Greater runoff can cause accelerated erosion and increased sediment loading in streams and rivers. Impervious surfaces and compacted soils may result in higher volumes of water reaching stream systems in shorter time periods, thus increasing flow rate, flood frequency, and erosion. Stream bank disturbance could impact fish habitat by creating bank instability, which could alter flow and destroy pool-riffle formations needed for fish survival.

Produced water from conventional and CBNG wells is sometimes discharged to the surface, contributing additional flows into the surface water system. These discharges can alter the timing, location, and volume of local streamflow patterns. In the Planning Area, produced water discharges, although overall beneficial to stream habitat, result in both beneficial and adverse impacts. Particularly during periods of low flow and spawning, aquatic species may be affected by the amount of produced water discharged to the surface. Produced water discharge can increase flow rates and erosion in stream channels, contributing to sedimentation. BLM policies and BMPs, required as COA, minimize and mitigate, to the extent possible, erosion from produced water surface discharge. Produced water is also generally hotter than naturally occurring surface water, and contains dissolved compounds that can be toxic to fish. Downstream from the discharge point, cooled produced water that has released some of its dissolved chemical components can have a beneficial impact on stream habitat.

Under all alternatives, abnormally incised drainages in lost riparian functioning systems would be restored to raise water tables and increase water storage within greater sage-grouse habitat. In addition, riparian and wetlands areas within greater sage-grouse habitats would be restored. These management actions would benefit fish habitat by decreasing runoff, erosion, and sedimentation and by increasing water quantity and quality.

Alternative A

Surface Disturbance

Surface disturbance results in adverse impacts to fish habitat by increasing soil erosion and sedimentation that degrades water quality. Alternative A is anticipated to have short-term (136,253 acres) and long-term (15,646 acres) surface disturbance over the life of the plan (Table 4-1) causing erosion rates of 567,492 and 25,065 tons per year, respectively, that would contribute to sedimentation. Surface-disturbing activities are prohibited within 500 feet of surface water or riparian/wetland areas to minimize potential water quality impacts. Relative to the other alternatives, Alternative A includes the second fewest restrictions on activities that remove vegetation and compact soils, resulting in more storm water runoff entering streams.

Resource Uses

Under Alternative A, 4,130,352 acres are available for locatable mineral entry, 3,877,232 acres are open for oil and gas leasing, and 3,974,564 acres are open to mineral materials disposal. Alternative A closes areas encompassing 46 miles of fishbearing streams to locatable mineral entry (Table 4-22). There would be some oil and gas development in areas that drain into fishbearing streams, although there are 35 miles of fishbearing streams in areas closed to oil and gas development under Alternative A (Table 4-22). This alternative is anticipated to result in the development of 1,184 new federal wells, and produced water may impact fish habitat by changing flow regimes and contributing to sedimentation.

Under Alternative A, the BLM limits motorized vehicle use to existing roads and trails on 2,137,574 acres. Motorized vehicle use is likely to contribute to sedimentation in areas where existing roads and trails are in close proximity to, or cross, rivers and streams. Allowing off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations may result in new roads and trails that would impact fish where they cross rivers or streams or increase sedimentation. Alternative A closes 68,115 acres to motorized vehicle use and limits it to designated roads and trails in The Rivers SRMA and in areas with fragile soils, reducing adverse impacts from erosion and sedimentation.

Recreation sites (e.g., campgrounds, day use areas) are developed as demand warrants under Alternative A. Campground and recreational facility development in riparian/wetland areas can degrade water quality by removing vegetation and increasing erosion and sedimentation. The increased angler access provided by recreation facilities near water courses can also directly impact fish habitat (e.g., trampling of banks and stream bottoms, accidental fuel/chemical spills). Alternative A provides for and emphasizes opportunities for recreational access to rivers and streams, potentially causing adverse impacts to fish habitat.

Forest management under Alternative A allows for the third highest degree of vegetative treatment, including clear cuts, precommercial thinning, woodland treatments in all woodland types, and prescribed fire, that could contribute to soil disturbance and sedimentation in streams and rivers in the short term. However, Alternative A uses treatments and timber harvests to improve forest health; most of these treatments may decrease the probability of stand replacing wildfires that can cause erosion and sedimentation, and therefore benefit fisheries in the long term.

Special Designations

Special designations under Alternative A that protect riparian habitat and water quality by restricting surface-disturbing activities include the Carter Mountain, Five Springs Falls, and Upper Owl Creek ACECs, in total encompassing 44 miles of fish-bearing streams (Table 4-22). Under this alternative, water impoundments, major diversions, or hydroelectric power facilities are prohibited on all WSR eligible waterway segments. These segments are closed to mineral materials disposal; however, many remain open to mineral leasing and the associated adverse impacts to water quality and quantity. This management in special designations would mostly result in beneficial impacts to fish habitat; however, there also may be an adverse impact because NWSRS management under Alternative A may limit native species restoration activities.

Resources

Alternative A uses treatments and timber harvests to improve forest health; most of these treatments may decrease the probability of stand replacing wildfires that can cause erosion and sedimentation, and result in beneficial impacts to fish habitat in the long term. Riparian/wetland areas are managed to meet or make progress towards meeting PFC under Alternative A, providing long-term benefits to water quality. The prohibition of surface-disturbing activities within 500 feet of riparian/wetland areas provides beneficial impacts to fish habitat by reducing sedimentation into streams and reducing stream bank degradation. Alternative A does not fence wetlands or riparian areas to meet resource objectives, leaving these areas vulnerable to potential impacts from other resource uses or activities and potential degradation of fish habitat.

Proactive Management

Direct beneficial impacts to fish as a result of proactive management under Alternative A result from encouraging reservoir design to establish minimum pools sufficient to maintain viable fisheries,

managing intermittent streams and restoring streams and fisheries habitat on a case-by-case basis, and managing fisheries habitat to improve and enhance its value (e.g., vegetation planting and installing sediment and erosion control structures).

Alternative B

Surface Disturbance

Impacts on fish habitat from surface disturbance would be similar to those described under Alternative A, although to a lesser degree due to decreased surface disturbance. Management under Alternative B would result in less surface disturbance over the short term (73,940 acres) and long term (10,893 acres) resulting in approximately 46 percent and 31 percent less erosion than Alternative A in the short and long term, respectively. Compared to Alternative A, fewer opportunities exist for surface-disturbing activities, including oil and gas and ROW development in areas that contain fishbearing streams (Table 4-22). More areas are designated as having NSO and CSU restrictions along perennial streams, riparian areas, and waterbodies under this alternative. Alternative B prohibits surface-disturbing activities and surface occupancy within ¼ mile of Blue Ribbon or Red Ribbon streams, providing the greatest beneficial impact to water quality and fish habitat compared to the other alternatives. Alternative B includes more restrictions on activities that remove vegetation and compact soils than Alternative A, which would result in less adverse impacts to fish habitat due to increased runoff.

Resource Uses

Minerals development under Alternative B would result in less adverse impacts to fish habitat from sedimentation and other potential impacts to water quality than Alternative A. This alternative closes more area to locatable minerals and oil and gas development containing fishbearing streams (80 and 122 miles, respectively). Alternative B prohibits new surface discharge of produced water, which would limit beneficial impacts to stream habitat, but also potential adverse impacts from altered flow regimes and water chemical properties.

With more areas closed or limited to designated roads and trails, and less area limited to existing roads and trails, Alternative B would result in more adverse impacts from motorized vehicle use to water quality, compared to Alternative A. Prohibiting off-road motorized vehicle use for big game retrieval in areas with limited travel designations would limit adverse impacts to fish from new trail and road proliferation that may impair water quality. Heavily eroded or washed out roads, if alternative routes exist, are closed and reclaimed and all channel crossings are photo point monitored, providing long-term beneficial impacts to water quality. Recreation sites (e.g., campgrounds, day use areas) are developed as demand warrants under Alternative B. However, opportunities for recreational access to some rivers and streams, such as the Laddie Creek and Paint Rock Creek areas, are expanded under this alternative, augmenting potential adverse impacts to fish habitat in these areas.

Forest management actions under Alternative B primarily utilize natural processes to meet forest health goals over commercial thinning or harvesting practices, prohibit clear cuts, and retain old growth forest areas over a 30-year period in HUC Level 4 sub-basins, unless altered by natural processes. Forest management under Alternative B may result in fewer acres of short-term adverse impacts to fish habitat due to sedimentation than Alternative A, but also may result in the greatest risk of wildfire that may degrade fish habitat.

Special Designations

Management in special designations under Alternative B would result in more beneficial impacts to fish habitat compared to Alternative A. Special designations that protect riparian habitat and water quality by restricting surface-disturbing activities include the expanded Carter Mountain, Five Springs Falls, and Upper Owl Creek ACECs, and the proposed Chapman Bench, Clarks Fork Canyon, Rattlesnake Mountain, and Sheep Mountain ACECs, including a total of 78 miles of fishbearing streams (Table 4-22). Under Alternative B, all WSR eligible waterway segments are recommended as suitable for inclusion in the NWSRS. These segments are **withdrawn from** locatable mineral entry, and **closed to** mineral leasing, geophysical exploration, and all surface-disturbing activities, providing greater protection for water quality and fish habitat for these segments, compared to Alternative A. However, there also may be an adverse impact because NWSRS management under Alternative B may limit native species restoration activities, similar to Alternative A.

Resources

The BLM manages riparian/wetland areas toward achieving DPC and stabilizes watershed improvement projects to prevent the release of stored sediment if projects no longer meet resource needs, providing greater long-term benefits to fish habitat compared to Alternative A.

Alternative B maintains natural flow regimes in streams supporting fish, providing greater beneficial impacts to water quantity compared to Alternative A. Fencing of wetlands and riparian areas reduces potential bank degradation and sedimentation from other activities and resources uses, resulting in greater indirect beneficial impacts to fish than Alternative A.

Proactive Management

Direct beneficial impacts to fish as a result of proactive management under Alternative B result from restoring important stream segments for fish habitat on 10 lotic miles and 80 lentic acres. Alternative B not only improves existing fish habitat on BLM-administered land, but implements management practices to acquire, develop, and maintain new water sources. Alternative B requires mitigation that includes minimum pool depths and adequate public access routes for new impoundment construction on BLM-administered land, and designs and retrofits culverts to allow fish passage. Overall, Alternative B includes more proactive management to protect and restore fish habitat than Alternative A.

Alternative C

Surface Disturbance

Impacts to fish habitat from surface disturbance would be similar to those described under Alternative A, although to a greater degree due to increased surface disturbance. Management under Alternative C would result in 245,642 acres of short-term surface disturbance and 41,485 acres of long-term surface disturbance (Table 4-1) resulting in 80 percent and 165 percent more erosion in the short and long term, respectively, than Alternative A. Alternative C provides less restriction on surface-disturbing activities and minerals development, potentially affecting more miles of fishbearing streams, and would cause the greatest impacts to water quality compared to the other alternatives.

Resource Uses

Alternative C may result in the greatest amount of change to surface water quantity because the BLM projects the most new federal wells (1,304) and fewer miles of fishbearing streams are in areas closed to minerals development (Table 4-22). Under this alternative, the BLM may not maintain natural flows but

encourages water development projects with adequate and required in-stream flow features to maintain and support fish habitat values. The BLM also uses produced water – in accordance with federal, state, and local laws and regulations – to enhance fish habitat.

With the least area closed (9,274 acres), and the most area open (14,830 acres) to motorized vehicle use, Alternative C is anticipated to result in the greatest adverse impacts from OHV use to water quality compared to the other alternatives. Allowing off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations would result in impacts similar to Alternative A. Allowing motorized vehicle use on existing roads and trails in The Rivers SRMA would cause greater adverse impacts to fish habitat in this area than the other alternatives. Stabilizing heavily eroded or washed out roads and trails would cause greater short-term surface disturbance and potential sedimentation than the other alternatives. The water quality impacts from recreational development under this alternative are similar to Alternative A. The BLM would not emphasize opportunities for recreational access to certain rivers and streams under this alternative, limiting potential adverse impacts to fish habitat from recreational use. The BLM manages livestock grazing to optimize commodity production while meeting rangeland health standards, not to provide for the enhancement of other resources, and allows the placement of salt, mineral, or forage supplements to maximize livestock use, regardless of proximity to riparian/wetland areas, resulting in the greatest potential impact to water quality under this alternative.

Forest management actions under Alternative C generally prioritize resource use over forest health, although Alternative C provides for retaining old growth forests, similar to Alternative B. Logging, timbering, salvage, and silviculture techniques are used to maintain a desirable forest condition that is determined primarily by commercial or economic objectives. Alternative C allows clear cuts up to 100 acres, which would result in greater adverse impacts to water quality than under alternatives A and B.

Special Designations

Spanish Point Karst (designated under all alternatives) is the only ACEC that benefits water quality by restricting surface-disturbing activities and pesticide application; the only other ACEC designated under Alternative C, Brown/Howe Dinosaur Area, is managed to mitigate surface-disturbing activities, but generally allows mineral development and other types of surface-disturbing activities. Under this alternative, none of the WSR eligible waterway segments are recommended as suitable for inclusion in the NWSRS; these areas would be released to other uses and no special management actions would be applied. Under Alternative C, special designations do not provide any substantial beneficial impact to surface water quality or fisheries habitat.

Resources

Riparian/wetland areas are managed to achieve PFC, similar to Alternative A; however, Alternative C emphasizes those areas functioning at-risk with a downward trend or in nonfunctioning condition. Alternative C would provide fewer benefits to fish habitat than Alternative B because watershed improvement projects would be stabilized on a case-by-case basis. In addition, Alternative C has the most potential to adversely impact fish habitat because it would allow surface-disturbing activities in riparian/wetland areas and flood plains on a case-by-case basis. Allowing these types of activities could cause bank degradation, sedimentation, and changes to water quality.

Encouraging water developments that enhance adequate in-stream flow would result in beneficial impacts to fish habitat under Alternative C; however, these impacts may be less than alternatives A and B. Fencing of springs and their associated wetlands reduces bank degradation and sedimentation in site-specific areas, resulting in indirect beneficial impacts to fish habitat in those areas and potentially

downstream of those areas. These beneficial impacts are anticipated to be less than alternatives B and D, but greater than Alternative A.

Proactive Management

The direct beneficial impacts to fish from proactive management under Alternative C are less than under the other alternatives. Restoration efforts of stream segments and fisheries habitat are the same as Alternative A. In general, Alternative C only manages to improve fish habitat or maintain viable fisheries in accordance with required law or policy, while some management actions under alternatives A and D and all management actions under Alternative B surpasses these requirements.

Alternative D

Surface Disturbance

Impacts to fish habitat from surface disturbance would be similar to those described under Alternative A. Alternative D is projected to result in slightly more short-term surface disturbance (Table 4-1) that is estimated to result in a 3 percent and 17 percent increase in erosion in the short and long term, respectively. However, reclamation practices under this alternative, as they are more stringent than those under Alternative A, may limit soil erosion to a greater degree resulting in fewer adverse impacts to fishbearing streams. Additionally, Alternative D provides more restrictions on surface-disturbing activities and minerals development that could affect fishbearing streams than Alternative A.

Resource Uses

Minerals development under Alternative D would result in similar adverse impacts to fish habitat as under Alternative A, but to a greater degree. Alternative D closes more area to oil and gas development that drains into fishbearing streams than Alternative A, but less area to locatable minerals development. Since a greater amount of surface disturbance is projected to result from locatable minerals development, Alternative D may result in greater adverse impacts to fish habitat from minerals development than Alternative A. Alternative D is anticipated to develop fewer new federal wells than alternatives A and C, but more than Alternative B with proportional adverse impacts to water quantity that may affect fish habitat.

Travel and transportation management under Alternative D would result in less adverse impacts than alternatives A and C, but more than Alternative B. Motorized vehicle use under Alternative D would result in less adverse impacts than Alternative A, because the BLM closes a similar amount of acreage to motorized vehicle use but limits 34 percent more area to designated roads and trails. More lands are open to cross-country motorized travel, but these areas are not in close proximity to fish habitat and would not result in direct adverse impacts. Restricting off-road motorized and mechanized travel for big game retrieval to within 300 feet of established roads provided there is no resource damage and no new routes are created would result in less adverse impacts to fish habitat than Alternative A. Potential adverse impacts from recreational access to fish habitat, such as the Paint Rock, Laddie, and Canyon Creeks and the North and South Forks of the Shoshone River would result in similar adverse impacts to alternatives A and B, but to a greater degree. Impacts to fish habitat from recreational development and livestock grazing management under Alternative D would be similar to those under Alternative A.

Forest management actions under Alternative D would result in impacts similar to Alternative A, except for allowing clear cuts up to 100 acres, which would result in adverse impacts similar to Alternative C.

Special Designations

Special designations under Alternative D would result in similar beneficial impacts as those under Alternative A, but to a greater degree from closing the Upper Owl Creek and Five Springs Falls ACECs to oil and gas leasing. Designating the Clarks Fork Canyon ACEC would result in beneficial impacts by protecting additional fish habitat under Alternative D. By not recommending any of the WSR eligible waterway segments as suitable for inclusion in the NWSRS, Alternative D would result in fewer beneficial impacts from fish habitat protection afforded by this special designation under alternatives A and B; however, Alternative D would result in fewer limitations to native species restoration activities.

Resources

Riparian/wetland resources management under Alternative D would result in similar beneficial impacts to those under Alternative A, but to a greater degree. More adverse impacts may result to fish habitat by encouraging the maintenance of natural flow regimes only in prioritized streams; however, developing watershed improvement practices similar to those under Alternative B plus applying BMPs in cooperation with stakeholders would result in greater beneficial impacts than under Alternative A. Fencing reservoirs and riparian areas would result in similar beneficial impacts as those under Alternative B. Surface-disturbance restrictions around surface waters and riparian/wetland areas would result in similar beneficial impacts to those under Alternative A.

Proactive Management

Direct beneficial impacts to fish as a result of proactive management under Alternative D would be similar to those under Alternative A, although to a greater extent. Avoiding surface-disturbing activities within ¼ mile of perennial surface waters, riparian/wetland areas, and WGFD-rated Blue Ribbon or Red Ribbon fisheries (trout streams of national or statewide importance) would likely result in greater beneficial impacts than alternatives A and C. Managing perennial streams to become fish habitat, restoring important stream segments for fisheries habitat on a priority basis, encouraging minimum pool management in existing reservoirs, and designing or retrofitting culverts to allow fish passage on a priority basis would result in beneficial impacts similar to, or greater than, those under Alternative A.

Alternative E

Surface Disturbance

Impacts on fish habitat from surface disturbance would be similar to Alternative B, although to a slightly lesser degree due to decreased surface disturbance. Management under Alternative E would result in less surface disturbance over the short term (71,829 acres) and long term (10,676 acres), resulting in approximately 32 percent and 31 percent less erosion than Alternative A, and 3 percent and 2 percent less erosion than Alternative B in the short and long term, respectively. Alternative E places the greatest restrictions on surface-disturbing activities, including mineral and ROW development in areas that contain fish-bearing streams (Table 4-22), and would therefore result in the least sediment-bearing runoff and the least adverse impacts to fish habitat, compared to the other alternatives.

Resource Uses

Resource uses under Alternative E would result in the least adverse impacts to fish habitat from sedimentation and other potential impacts to water quality. Impacts from resource uses would be similar to Alternative B, but less adverse due to closure of the proposed Greater Sage-Grouse Key Habitat Areas ACEC to locatable mineral entry, mineral materials disposal, renewable energy development, and ROW development. Surface disturbances would be limited to one disturbance per

640 acres and less than 3 percent of the greater sage-grouse Key Habitat Areas, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. These limitations on surface disturbance would reduce erosion rates and sedimentation to adjacent waterways.

Alternative E closes the most miles of fish-bearing streams to locatable mineral entry and ROW development (103 miles and 93 miles respectively). In areas where the proposed Greater Sage-Grouse Key Habitat Areas ACEC overlaps forest and woodland areas, adverse impacts resulting from forest management actions may be reduced due to the greater limitations on surface disturbance. In areas outside the proposed Greater Sage-Grouse Key Habitat Areas ACEC, management of resource uses and the resulting impacts would be consistent with Alternative B.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land within greater sage-grouse Key Habitat Areas that would be designated as an ACEC. Additional limitations on surface-disturbing activities associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC would reduce impacts to fish in comparison with Alternative B and would result in the most beneficial impacts to fish habitat compared to the other alternatives. ACECs designated under Alternative E would encompass 72 miles of fish-bearing streams. All other impacts to fish from special designations outside the Greater Sage-Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Resources

Riparian/wetland area management and watershed improvement practices under Alternative E are generally the same as Alternative B and would provide the same beneficial impacts to fish habitat as Alternative B. Alternative E would also manage the proposed Greater Sage-Grouse Key Habitat Areas ACEC to restore sagebrush steppe habitat using native plants, which may result in indirect beneficial impacts for adjacent fish habitats by reducing erosion in the watershed.

Proactive Management

Proactive management of fish habitat under Alternative E is generally the same as Alternative B, and beneficial impacts to fish would be the same as Alternative B.

Alternative F

Surface Disturbance

Adverse impacts to fish habitat from surface disturbance would be similar to but less than alternatives D and A. Management under Alternative F would result in less surface disturbance over the short term (137,064 acres) and long term (17,663 acres), resulting in approximately 2 percent less erosion than Alternative D in both the short and long terms. Management practices relating to surface disturbance would be the same as Alternative D, except within areas of the proposed Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). In this ACEC, the BLM manages the density of disturbance to not exceed an average of one disruptive activity location per 640 acres and cover less than 3 percent of the greater sage-grouse PHMAs, compared to a larger allowable disturbance of 5 percent in greater sage-grouse PHMAs (1,232,583 acres) under Alternative D.

Resource Uses

Resource uses under Alternative F would result in slightly less adverse impacts to fish habitat than Alternative D and similar adverse impacts as Alternative A, but to a greater degree. This alternative

closes a larger area of federal mineral estate to oil and gas leasing as Alternative D and also applies a NSO stipulation within 0.6 mile of occupied sage-grouse leks within greater sage-grouse PHMAs. However, Alternative F limits surface disturbances to one per 640 acres and 3 percent or less of the Wyoming Density and Disturbance Calculation Tool (DDCT) analysis area, compared to 5 percent under Alternative D, which would afford greater protection for fish habitat within the Greater Sage-Grouse PHMAs ACEC. As a result, Alternative F is anticipated to develop fewer new federal wells than alternatives A, C, and D, but more than alternatives B and E with proportional adverse impacts to water quantity that may affect fish habitat.

In the Greater Sage-Grouse PHMAs ACEC, the number of new roads from ROW development and user-pioneered roads would be greater under Alternative F than alternatives A, B, and E, but less than would occur under alternatives C and D. In areas where the proposed ACEC overlaps forest and woodland areas, adverse impacts resulting from forest management actions may be reduced due to the greater limitations on surface disturbance. Overall, Alternative F would result in less adverse impacts than alternatives A, C, and D, but more than alternatives B and E. Impacts to fish from resource uses outside the ACEC would be the same as Alternative D.

Special Designations

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. Under this alternative, special designations would encompass 69 miles of streams. The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative F would result in greater protection for fish habitat than alternatives A, C, and D, but fewer than under alternatives B and E.

Resources

Management for riparian/wetland areas and watershed improvement projects under Alternative F would be the same as Alternative D, and the benefits to fish habitat would be the same as Alternative D. Alternative F would also manage the proposed Greater Sage-Grouse PHMAs ACEC to restore sagebrush steppe habitat to predisturbance conditions using native plants. Restoration of these habitats may result in indirect beneficial impacts for adjacent fish habitats by reducing erosion in the watershed.

Proactive Management

Proactive management of fish habitat under Alternative F is generally the same as Alternative D, and beneficial impacts to fish would be the same as Alternative D.

4.4.6 Fish and Wildlife Resources – Wildlife

Adverse impacts to wildlife include removal, degradation, or fragmentation of wildlife habitats. Beneficial impacts include actions that conserve or improve habitats, such as big game crucial winter range or nest sites.

Direct impacts to wildlife would result from loss of habitats or from immediate loss of life. Wildlife can be directly disturbed by human activities (e.g., motorized vehicle use, recreation), potentially causing wildlife to abandon a nest site or home range. Disturbance during sensitive periods (i.e., winter, nesting) may adversely impact wildlife populations. The impact from disturbances may be short-term, where the population may be displaced or shift its activities, or long-term, where the population may permanently abandon its home range, threatening its viability. Habitat loss and fragmentation can

result from vegetation treatments, fire and fuels management, mineral exploration and development, construction and maintenance of roads and trails, and development of wind-energy facilities.

Indirect impacts to wildlife result from changing habitat characteristics or habitat quality that affect wildlife. Surface-disturbing activities and other actions that remove vegetation and disturb soil can alter habitat quality. Indirect impacts to wildlife also result from actions that alter habitats to make them unsuitable for future habitation by wildlife species.

4.4.6.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- The BLM, in cooperation with state and other federal wildlife agencies, is responsible for managing habitat (e.g., quality, suitability, usability), whereas state and federal wildlife management agencies (e.g., WGFD, USFWS) have primary authority for overseeing management of wildlife populations. Therefore, this analysis primarily relies on vegetation changes and loss of habitat use due to disruptive activities to estimate impacts to wildlife habitats.
- For each alternative, changes to vegetation types, either in quantity, quality, or increased fragmentation, are compared to baseline conditions. Adverse and beneficial impacts to vegetation types (i.e., wildlife habitats) are assumed to have a corresponding adverse or beneficial impact on wildlife species.
- Disturbance impacts to wildlife are evaluated by comparison to current management practices in the Planning Area; increased protection in time or space are beneficial, whereas reduced protection result in adverse impacts.
- Disturbance during sensitive periods adversely affects wildlife.
- Habitat fragmentation and associated declines in habitat quality have been identified as principal causes for declines in wildlife populations and distribution in a variety of habitat types and spatial scales (WGFD 2010b); therefore, this analysis assumes that habitat fragmentation through the creation of roads, fences, pipelines, and other disturbances would result in impacts to wildlife species proportional to the scale and type of fragmentation anticipated to occur.
- Prescribed fire, where historical fire regimes occurred, is a tool used to manage vegetative communities and generally results in short-term adverse impacts with long-term beneficial impacts to wildlife species and habitats, and in some cases to forage productivity and availability. Certain species and habitats; however, may experience long-term adverse impacts from prescribed fire (e.g., sagebrush obligate species from prescribed fire in sagebrush habitat [Beck et al. 2011]).
- Forest management actions replicating natural historical disturbance regimes and managing wildlife habitats instead of, or in addition to, managing forest products are anticipated to benefit wildlife habitats. In contrast to actions that would maximize saw log production by managing for more marketable tree species, forest management actions would be managing for a diversity of tree species with both structural and age diversity.
- In general, management actions aimed at benefitting specific wildlife species are likely to benefit other species that utilize similar habitat types, rely on the target species as a food source, or receive benefits through other interspecies interactions. Exceptions to this assumption are noted accordingly.

- Alternatives with a larger number of acres of wetlands developed or protected will exhibit a greater benefit to waterfowl and other riparian/wetland wildlife species when compared to alternatives with smaller acreage of wetlands developed or protected.
- Alternatives providing more protection of water sources beneficial to wildlife are anticipated to have the greatest benefit to wildlife.
- Surface disturbance generally causes adverse impacts to wildlife habitats. Lesser amounts of surface disturbance in wildlife habitats have a corresponding lesser adverse impact to wildlife compared to more surface disturbance. The extent of adverse impacts due to surface disturbance depends on the precipitation zone.
- Prohibiting surface disturbance or occupancy is more restrictive and provides more protection for wildlife than avoiding surface disturbance or occupancy.
- The more surface disturbance that occurs on steep slopes or on highly erosive soils, the greater the potential for adverse impacts to wildlife habitats. Adverse impacts from surface disturbance also increase in areas that receive less precipitation.
- The higher the road density and the frequency of use in the Planning Area, the greater the potential to degrade adjacent wildlife habitat quality in the Planning Area.
- The more area used by OHVs and the higher the density of motorized vehicle use, the greater adverse impacts are anticipated to wildlife habitats.
- The BLM utilizes the best available information, management and conservation plans, and other research and related directives, as appropriate, to guide wildlife habitat management on BLM-administered lands.
- The quality and quantity of seasonal ranges and migration corridors are generally considered to be the limiting factors on big game populations in the Planning Area. The ability of these areas to support populations is a factor in determining population levels.
- Natural variability in wildlife health, population levels, and habitat conditions would continue. Periods of mild or severe weather as well as outbreaks of wildlife disease or insects/diseases that impact habitat (e.g., bark beetle, blister rust, mistletoe, and bleeding rust) may impact wildlife population levels.
- Wildlife habitats being protected are generally in desired natural condition and those being managed are being managed toward a more desirable condition.
- Habitat vegetation that trends away from natural vegetation condition (due to increase in invasive species), similarly trends away from natural wildlife species composition.

4.4.6.2 Summary of Impacts by Alternative

The principal adverse impacts to wildlife result from surface disturbance related habitat loss and fragmentation; the principal beneficial impacts to wildlife result from management that restricts surface-disturbing activities in known or potential wildlife habitat and disruptive activities (e.g., motorized vehicle use, recreation) that can cause the abandonment of nest site or home ranges. Based on the actions and uses allowed, alternatives ranked in order of increasing potential adverse impacts and decreasing beneficial impacts to the wildlife categories presented in this section are E, B, F, D, A, and C. Alternatives B and E include the most management to minimize wildlife habitat loss and fragmentation, such as closing areas to oil and gas leasing, followed by F, D, A, and C. Alternative C allows the most surface disturbance and resulting habitat degradation and loss, followed by alternatives A, D, F, B, and E. With the exception of limiting wind-energy development and ROW authorizations to a

greater extent than Alternative A, Alternative C has the fewest measures with which to control habitat loss and fragmentation, followed by A, D, F, B, and E. Alternative E designates the most ACECs, and similar to Alternative B, manages all lands with wilderness characteristics to maintain their wilderness characteristics (476,349 acres), resulting in beneficial impacts to wildlife over a large area; Alternative F manages 49,396 acres of lands with wilderness characteristics to maintain their wilderness characteristics. Alternative C does not restrict surface-disturbing activities in most sensitive areas and has few actions to improve habitat quality. Alternatives E and B place the most restrictions on motorized vehicle use during crucial wildlife periods, followed by alternatives F, D, A, and C. Under alternatives B and E, restricting motorized vehicle use and surface-disturbing activities in the Absaroka Front Management Area provides the greatest beneficial impacts to wildlife species, especially big game and predators. Less restrictive management is applied to the Absaroka Front Management Area under the other alternatives; however, alternatives D and F apply a MLP within the Absaroka Front and Big Horn Front MLP analysis areas that places CSU and TLS stipulations on oil and gas-related surface disturbances. As a result, alternatives D and F would provide more protection for big game in these areas than under alternatives A and C. Under Alternative C, the area is managed consistent with other resource objectives, with the exception of limiting motorized vehicle use to designated roads and trails with seasonal limitations. The area is not managed as a Management Area under Alternative A. Alternatives E and F limit motor vehicle use to designated roads and trails within the proposed greater sage-grouse ACECs, which are comprised by Key and PHMAs, respectively.

The spread of invasive species adversely affects wildlife by displacing native vegetation and altering ecosystem function. Alternative E would slow the spread of invasive species the most because it is projected to involve the least amount of surface disturbance and has the most stringent reclamation requirements, followed by alternatives B, F, D, A, and C. Vegetation treatments under Alternative C would result in the greatest amount of short-term surface disturbance, but if habitat loss and displacement of wildlife is temporary, this alternative may result in the greatest long-term benefit to wildlife by restoring fire adapted habitat and reducing the risk of catastrophic wildfire, followed by Alternative D. Alternatives B and E would result in the least short-term disturbance to wildlife from prescribed fire and fuels treatment, but also would result in the greatest risk of large wildfires that would alter wildlife habitat, followed by alternatives A, F, D, and C.

Alternative E includes the most improvements to habitat quality, provides for more measures to restrict activities that can damage soils and habitats, reserves the most forage for big game on crucial winter range, and sets aside the most land for ACECs with emphasis to benefit wildlife resources followed by alternatives B, F, D, A, and C (Table 4-22). Alternative C has minimal guidance to protect or improve habitat quality, and no ACECs are designated to conserve wildlife habitat. Alternatives D and F would result in similar habitat improvement actions in riparian/wetland areas as Alternative C, but these alternatives place greater restrictions on surface-disturbing activities in these areas than alternatives A and C and apply an NSO restriction on all wetlands greater than 20 acres, limiting potential adverse impacts from long-term surface disturbance to a greater extent. In general, alternatives D and F have similar measures to protect and improve habitat quality in grassland and shrubland communities as under alternatives B and E; however, under alternatives D and F, fewer ACECs are designated that would beneficially affect wildlife such as big game (Table 4-22). Forest management under alternatives D and F would cause impacts similar to Alternative A, except that allowing larger clear cuts may result in habitat loss for some species that prefer closed canopies. Seasonal restrictions on surface-disturbing activities around active raptor nests would affect the most forested habitat under alternatives B and E, followed by alternatives A, D and F, and C. In addition, alternatives B and E provide year-round CSU stipulations to protect approximately 47,651 acres of forested habitat. Alternative E provides the most protection

from surface-disturbing activities for big game on crucial winter range, followed by alternatives B, F, D, A, and C (Table 4-22).

4.4.6.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Surface Disturbance

The precise location of surface disturbance in the Planning Area resulting from implementation of the alternatives cannot be determined. Surface disturbance would occur in a variety of vegetation types all used as wildlife habitat by wildlife. Therefore, the BLM projects that the extent of impacts to wildlife from surface disturbance would generally relate to the amount of surface disturbance in the Planning Area. These activities will be evaluated further during project-specific NEPA evaluations before project authorization. As acreages of surface disturbance and human activity levels increase, the quality and quantity of wildlife habitats would decrease. Long-term surface disturbance accounts for reclamation of some lands following short-term disturbance. Although reclamation restores habitats, thereby reducing long-term surface-disturbance acreage, the location of permanent facilities (e.g., roads, well pads, etc.) adjacent to reclaimed areas may reduce the utility of reclaimed habitats. For example, the higher the density of permanent facilities in an area, the more a habitat is fragmented and the more adverse impacts anticipated for wildlife. In addition, reclaimed areas are more vulnerable to establishment of invasive species and would not initially provide the same level of habitat function, forage, or cover that the original vegetation provided. The timing and type of reclamation is also anticipated to result in impacts to wildlife.

As discussed in Chapter 3, habitat fragmentation occurs when a contiguous habitat is intersected, divided, or segmented by surface disturbance. Fragmentation causes a reduction in usable ranges and the isolation of smaller, less mobile species; a loss of genetic integrity in species or populations; and an increase in abundance of habitat generalists characteristic of disturbed environments (i.e., competitors, predators, and parasites) (Harris 1984). As disturbance reduces the size of contiguous habitat patches, density dependency thresholds of suitable habitats for species may be met, which ultimately may decrease population size and increase disease frequency.

Resource Uses

The principle impacts to wildlife species (especially big game) from minerals development in the Planning Area would be the reduction in usable wildlife habitat and disruption of migration corridors that link seasonal ranges. In areas with continuous surface disturbance, the adverse impacts would be greater.

Impacts from locatable minerals development would include displacement of wildlife from developed areas and avoidance of a larger area around the development because of human presence and noise. Increased bentonite mining, and potentially gypsum mining, along with difficulty in shrub reclamation in the 5- to 9-inch precipitation zone would result in a reduction of sagebrush habitat across all alternatives. Salable minerals extraction would result in short-term, direct impacts to wildlife and associated habitat. Impacts would include displacement and disturbance of animals, removal of vegetation, and loss of habitat. The level of impacts would depend on the size of the salable minerals area and the importance of the altered habitat to wildlife.

Oil and gas development would result in adverse impacts to wildlife habitat. As the number of wells, roads, and facilities increase, habitats in and near well fields may degrade due to invasive species spread

and fragmentation. Due to prolonged reclamation time, oil and gas development in the 5- to 9-inch precipitation zone may result in long-term impacts from habitat removal and fragmentation. Animals that remain in the affected zones are subjected to increased physiological stress. This avoidance and stress response impairs habitat function by reducing the capability of wildlife to use the habitat effectively. In addition, physical or psychological barriers lead to fragmentation of habitats, further limiting the availability of suitable habitat. An area of intensive activity or construction becomes a barrier when animals cannot or will not cross it to access otherwise suitable habitat. These impacts are especially problematic when they occur within limiting habitat components such as crucial winter ranges and reproductive habitats (WGFD 2009b). Studies have shown that actions involving increased human presence have adversely impacted wildlife populations such as mule deer and elk (Freddy et al. 1986; Phillips and Alldredge 2000; Shively et al. 2005). In human-dominated landscapes, human factors have been shown to have a greater effect on elk behavior than natural predators or other environmental factors, including decreased feeding times associated with closer proximity to roads and the adoption of a more vigilant behavioral mode in response to road traffic volumes of at least one vehicle every two hours (Ciuti et al. 2012).

Many sand and gravel areas are associated with riverine and alluvial plains; their development would impact these areas. The vegetative communities associated with these areas would be affected by the extraction of salable minerals. Salable mineral extraction may lower the water table, resulting in the potential loss of cottonwood communities typically associated with these minerals. Nesting birds such as great blue herons, bald eagles, and habitat for numerous waterfowl and migratory birds, and big game during the winter, depend on these communities.

Due to the projected surface disturbance and difficulty in reclamation, especially in arid areas, invasive species would continue to spread under all alternatives. Management actions may prevent the reoccurrence and spread of invasive and noxious weeds to maintain the native vegetative species that provide wildlife forage and habitat. Certain species of noxious weeds are poisonous and potentially fatal to some wildlife species. Prevention and treatment of invasive species would maintain or improve plant community health, thereby benefitting wildlife. Surface disturbance, new road construction, off-road motorized vehicle use, and livestock and wildlife grazing contribute to the spread of invasive species.

Impacts on wildlife from land use authorizations (including ROWs) would depend on (1) the location of the authorizations, and (2) the success of reclamation and mitigation of disturbed lands. Impacts to wildlife habitat would vary with the specific type and location of the requested ROW. There would be short-term impacts from the construction of pipelines, buried fiber-optic lines, and other subsurface actions. However, proper reclamation would restore some level of habitat function in these areas. Depending on the locations of these actions and the long timeframes required for some disturbed sites to return to pre-disturbance vegetation cover, some impacts would be long-term. Aboveground ROW actions, such as communication sites, powerlines, and wind turbines would have long-term impacts. These types of permanent structures are particularly hazardous to avian wildlife because of the potential for collision or electrocution (Erickson et al. 2005).

Unless otherwise specified, motorized vehicle use is limited to existing roads and trails on BLM-administered land. Existing roads and trails may be maintained for continued access. CTTM plans address maintenance of roads, ways, and trails at a site-specific level. Limiting motorized travel to existing roads and trails would result in beneficial impacts to multiple wildlife species by enhancing and increasing security areas where roads are sparse or nonexistent.

Motorized vehicle use management that result in increased human presence would have a localized impact on wildlife. Impacts would include increased displacement of wildlife, increased stress during important time periods (e.g., winter, nesting), and degradation of habitats. Motorized vehicle use may

alter the seasonal use patterns of many wildlife species. The use of motorized over-snow travel on winter range may lead to wildlife disturbance, causing additional stress. New roads created from OHV use would result in disturbance to wildlife in areas that normally do not contain human presence and habitat degradation through vegetation loss. Vehicle-wildlife collisions may increase in areas of high wildlife use and high human activity. Closure and reclamation of unnecessary roads would reduce fragmentation and restore habitat integrity while reducing the potential for wildlife disturbance.

Recreational activities (e.g., hiking, biking, camping, hunting, sightseeing) that result in increased human presence would cause localized impacts to wildlife. These activities would result in increased human presence, which may cause habitat degradation or wildlife disturbance (e.g., dispersal or avoidance). Human disturbance of big game may result in increased energy costs for the alerted animal, either from stress (preparation for flight [i.e., locomotion]) or from flight itself. An animal that has fled or is displaced incurs additional costs through loss of food intake and potential displacement to lower quality habitat. The cumulative energy costs of frequent disturbances may affect survival or reproductive success, especially during seasonally sensitive periods (e.g., winter, breeding, nesting, and early brood-rearing). Phillips and Alldredge (2000) and Shively et al. (2005) demonstrated a 30 percent reduction in elk calf recruitment from an activity as benign as simulated recreational hiking imposed during the calving season. If recreational activities were performed on noncrucial habitats or during seasons when sensitive wildlife species are not present and in compliance with recreation management actions, impacts would be minimal.

Livestock and wild horse grazing may impact wildlife habitat due to competition for forage and habitat use and alteration. Intensive use along stock driveways can cause near-complete removal of vegetation and compaction of soils; and if unfettered, may no longer provide forage or shelter for wildlife. When improper grazing occurs during the late or post-growing season, residual vegetation that could be available on big game winter ranges may be removed. This may also affect the availability of nesting cover for some birds the following spring. Impacts to bird species can be widely varied and grazing may result in positive, negative, or no changes to different species (Bock et al. 1993, Derner et al. 2009). Certain grazing disturbances can enhance forage and habitat for wildlife and may result in increased palatability of forage (Anderson and Scherzinger 1975, Severson and Urness 1994).

Wyoming Guidelines for Livestock Grazing Management and other appropriate BMPs would enhance rangeland health, improve forage for livestock, and meet other multiple use objectives. Appropriate grazing management with an emphasis on *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N), especially in the 5- to 9-inch precipitation zone where rangeland health is sensitive to grazing timing and intensity, will be required in all cases and would be beneficial to wildlife species.

Special Designations

Special designations that conserve vegetation and restrict surface-disturbing and other activities that adversely impact special status wildlife species, such as mineral development, motorized vehicle use, and ROW development would result in beneficial impacts by preventing disruptive activities in sensitive habitats, and limiting habitat loss, fragmentation, and degradation. Under all alternatives, WSAs are managed for naturalness, outstanding opportunities for solitude, and primitive and unconfined recreation according to BLM Manual 6330 (BLM 2012a), and loss or alteration of wildlife habitat would be minimized in these areas. WSAs would benefit wildlife and their habitats by restricting surface-disturbing and other disruptive activities and preserving wilderness characteristics. Conversely, managing WSAs requires the use of natural processes to the extent possible and generally does not allow surface-disturbing activities designed to benefit wildlife habitat, such as vegetation treatments;

WSAs may, therefore, result in adverse impacts to wildlife habitat that would benefit from such treatments. ACECs also benefit wildlife species by restricting surface-disturbing and other activities. The Spanish Point Karst ACEC, designated under all alternatives, is likely to result in beneficial impacts to special status bat species by restricting resource uses and activities that may impact roost habitat. Further analysis is provided in the discussions for each special designation according to the alternative.

Wildlife are likely to react to management and allowed uses by altering their behavior (e.g., changing migration routes or dispersal patterns). Restricting resource uses and activities in special designations and various management areas on BLM-administered land will have uncertain impacts to private lands from wildlife. Wildlife may leave private lands if BLM-administered lands provide more suitable habitat. However, if habitat protection on BLM-administered lands is sufficient to foster increases in wildlife populations, greater numbers may disperse to private lands.

Resources

All alternatives provide some degree of protection to streams, wells, springs, or other water sources by prohibiting or managing surface disturbance within varying distances from water sources. Those alternatives providing the greatest protection of water sources beneficial to wildlife species are anticipated to have the greatest benefit. Wildlife species that use water sources and riparian/wetland habitats in the Planning Area benefit from management actions common to all alternatives that promote the development and enhancement of water sources. The management of riparian/wetland areas to meet PFC and the *Wyoming Standards for Healthy Rangelands* (Appendix N) would improve habitat conditions for various wildlife species. Areas managed to higher standards (e.g., DPC), would result in additional benefits to wildlife.

Prescribed fire and wildfire would have both short-term and long-term impacts to wildlife. Short-term impacts include displacement from habitats, potential disturbance or loss of life for small game and ground nesting birds, and removal of vegetation and forage. The BLM generally conducts prescribed fires outside of the nesting season (depending on elevation, approximately April 15th through July 15th), which would limit direct impacts to nesting birds. Any fire would cause some loss of less-mobile wildlife and not able to avoid the path of the fire. Fire line construction, use of heavy equipment, and other fire suppression activities would damage or destroy vegetation and habitat for wildlife. Timely rehabilitation of these activities is important to maintaining the quality of wildlife habitats. If rehabilitation is not completed, fire suppression activities can cause erosion or the potential spread of invasive species, which results in long-term adverse impacts to wildlife habitat.

Over the long term, fire would generally improve habitat conditions for most wildlife species. Fire can improve the quality of wildlife habitat conditions by releasing soil nutrients, reducing fuel load, or setting back species such as trees that may be encroaching on other habitats such as grasslands and shrublands. Fire would reduce dense understory that has mixed values for various species of wildlife. In vegetative climax communities, fire would return the vegetative community to an earlier stage of succession, increasing forage and cover for a greater diversity of wildlife. Fire can remove excess dead and dying vegetation, reduce hiding cover for prey species and potential thermal cover in the winter months. However, post-fire log and limb fall would increase horizontal cover and may produce snags important for nesting birds in the long term. The extent of impacts to wildlife from fire depends on the extent of change in habitat structure and species composition the fire causes. Resident and migratory bird species would be directly affected by loss of habitat from wildland fires. The duration of habitat loss would depend on the types of vegetation removed and the fire severity.

Forest management practices would change the seral stage of the affected stands. Many forest management practices are designed to alter or set back the seral stage of the forest community. These

activities may increase wildlife species diversity and richness, depending on different species' habitat requirements. Properly mitigated commercial forest management may improve big game habitat in the long term by improving forest age class diversity and distribution, edge effect, and forage community diversity. Conversely, commercial forest management may take important habitat components (e.g., snags, dead and down components, and the largest trees) out of the ecosystem and result in adverse impacts to species that depend on these components. Amphibians, reptiles, and other smaller animals depend on these habitat components for survival, while species such as the snowshoe hare are generally harmed through precommercial thinning practices (USFS 2005b). Properly mitigated commercial forest management would result in beneficial impacts to wildlife species that depend on diverse forest seral stages; however, such treatments may also put stands in a stable state where the forest structure does not mimic natural conditions in untreated parcels. Impacts to wildlife from forest management depend on the type of stand – mostly adverse impacts occur in spruce and subalpine fir stands, while mostly beneficial impacts would occur in aspen, Douglas-fir, and ponderosa pine stands. Habitat loss and fragmentation would be long-term adverse impacts from forest management; displacement of animals, noise disturbance, and increased vehicle traffic would be short-term adverse impacts.

Under all alternatives, the BLM constrains wild horse population numbers to the initial appropriate management level in existing HMAs (Map 45), such that their existing effect to wildlife habitat and populations would be sustained at the current level. Maintaining horse populations at initial appropriate management levels can still result in adverse impacts to wildlife habitat and populations. Wild horses graze areas in the McCullough Peaks and Fifteenmile HMAs on a year-round basis, competing with wildlife directly for some forage species and access to water.

Management actions for cultural and paleontological resources would provide varying degrees of habitat protection by minimizing vegetation loss and erosion and by restricting surface-disturbing activities. If public interpretation facilities generate increased human presence during sensitive seasonal periods (e.g., breeding, nesting, or migration) wildlife could be disturbed.

Proactive Management

Wildlife habitat management would prevent or reduce impacts to wildlife species from surface-disturbing and other disruptive activities through implementing mitigation and BMPs, such as timing stipulations and designations of spatial buffers. These stipulations would provide some mitigation for loss of habitat function or habitat value for wildlife species.

Proactive management actions common to all alternatives that would benefit wildlife by conserving or improving habitat quality or reducing the likelihood of disturbance include prohibiting surface-disturbing and disruptive activities in the Bighorn River HMP/RAMP tracts and the BLM-administered tracts in Yellowtail Wildlife Habitat Management Area and applying an NSO restriction as appropriate; maintaining or improving important wildlife habitats through vegetative manipulations, habitat improvement projects, livestock grazing strategies and the application of the *Wyoming Guidelines for Managing Sagebrush Communities with Emphasis on Fire Management* (Wyoming Interagency Vegetation Committee 2002) and the *Wyoming BLM Standard Mitigation Guidelines for Surface-Disturbing and Disruptive Activities* (Appendix H); and continuing to use the existing West Slope, Bighorn River, and Absaroka Front HMPs, which contain numerous management actions for wildlife habitat enhancement.

Alternative A

Surface Disturbance – Alternative A

Alternative A would result in 136,253 acres of short-term surface disturbance that may degrade wildlife habitat and 15,646 acres of long-term surface disturbance that may result in habitat loss (Table 4-1). Minerals development, fire and fuels management, and silviculture treatments are the largest sources of short-term disturbance, with minerals development being the largest source of long-term disturbance. Alternative A requires that all surface-disturbing activities are analyzed for suitability and impacts and that vegetation cover is reestablished in disturbed areas within 5 years of initial seeding. These management actions would increase the probability of successful reclamation so that disturbed areas can return to suitable habitat in the long term. Heavily eroded or washed out roads are stabilized on a case-by-case basis, but not closed or reclaimed to return to wildlife habitat. Overall, the projected surface disturbance under Alternative A would result in adverse impacts to wildlife habitats, while associated reclamation practices would help to mitigate these impacts.

Resource Uses – Alternative A

Minerals development would be the greatest contributor to habitat loss and fragmentation. Under Alternative A, 4,130,352 acres are available for locatable mineral entry, which would result in approximately 10,000 acres of long-term disturbance and habitat loss (Appendix T). Under Alternative A, the BLM places constraints on oil and gas leasing and expects the development of up to 1,184 new federal wells. The adverse impacts to wildlife from oil and gas development would be proportional to the actual number of new wells and the imposed constraints.

In general, land acquisition or disposal actions would be performed considering land tenure adjustment criteria with the goal that the exchange, acquisition, or disposal would increase the public benefits of BLM-administered resources, including wildlife resources. Any acquisition of nonfederal surface land that includes high value habitat may result in beneficial impacts to wildlife habitat by allowing for mitigation or restrictions for surface-disturbing and disruptive activities to maintain or enhance the habitat under BLM management. Any disposal of BLM-administered land that contains high value habitat would typically be avoided as this may result in adverse impacts by increasing the potential for development without any required mitigation under BLM authority, and increased human presence would increase disturbance to wildlife utilizing the area. All land tenure actions would be analyzed on a site-specific basis, using a public process, to determine public interest before making a decision. Consolidating land ownership through land tenure adjustments would increase the manageability of lands and result in more contiguous blocks of habitat, which would result in beneficial impacts to wildlife. Under Alternative A, 115,905 acres are identified for disposal by sale, exchange, or other methods, with exchange being the preferred method.

Routing linear ROWs (e.g., pipelines, powerlines, roads) where impacts would be least disturbing would help to minimize fragmentation of sensitive habitats. Routing decisions would be determined with site-specific NEPA analyses before making decisions, and where possible, new utilities would be placed in existing ROW corridors. However, habitat fragmentation would still occur as more ROWs are sited and developed or as an existing ROW corridor is expanded. Under Alternative A, the BLM manages 61,147 acres as ROW exclusion areas, which occur in big game crucial winter range, and greater sage-grouse Key Habitat Areas (Table 4-22), limiting adverse impacts to sensitive wildlife habitat.

Allowing wind-energy development throughout the Planning Area would create collision hazards for bats, greater sage-grouse, and other avian species. Large wind-energy fields also result in surface disturbance, which would permanently change the habitat structure of the wildlife inhabitants. The

number of anticipated wind-energy developments is similar under all alternatives (Appendix T), with the location of wind-energy facilities likely to vary across alternatives. Alternative A considers the development of wind-energy facilities on a case-by-case basis consistent with the Wind Energy Programmatic EIS Record of Decision (ROD), which provides guidance to consider micro-siting alternatives, but not broader habitat avoidance efforts, when assessing the impacts of proposed facilities. Based on the lack of general guidelines for siting wind-energy projects outside wildlife habitat or avian concentration areas that would be most affected by new turbines, wind-energy development may result in adverse impacts to wildlife under this alternative, though ROW management would limit these impacts.

Motorized vehicle use restrictions would limit the potential for the proliferation of unauthorized trails and related habitat degradation and wildlife disturbance. Limiting motorized vehicle use to designated roads and trails (797,077 acres) and closing areas to motorized vehicle use (68,115 acres) would help to protect wildlife from human-caused disturbances or to sustain habitat integrity and water quality by preventing vegetation loss or soil erosion and compaction. Permitting off-road motorized vehicle use for big game retrieval and access to dispersed campsites in areas with limited travel designations would increase the likelihood of wildlife disturbance and trail proliferation that may degrade and fragment habitat. Overall, motorized vehicle use with restrictions under Alternative A would result in adverse impacts to wildlife.

Recreational facilities may disturb habitat during construction and lead to increased human presence that can cause avoidance behavior in wildlife and subsequent displacement. Under Alternative A, the BLM develops or upgrades recreation sites (i.e., camping sites, interpretive educational areas, day use areas) and the associated amenities and facilities if demand warrants and enhances opportunities for primitive recreation. Alternative A would result in 350 acres of surface disturbance from recreational site development; the increase in human presence and impact to wildlife would be proportional to the amount of surface disturbance.

Managing livestock grazing systems to limit forage competition between livestock and wildlife for forbs, shrubs, and other desirable plants would aid in wildlife survival at crucial times of the year. Limiting forage competition would be particularly important in the spring, when enhanced nutrition is essential following the demands on body reserves during the winter, and the fall, when high nutrient forage is more limited and animals are trying to build fat reserves (Vavra 1992). Livestock grazing can also affect residual grass cover for bird nests and forb diversity to benefit fledglings. Under Alternative A, the BLM manages livestock grazing to provide for protection or enhancement of other resource values and closes several areas, such as the Bighorn River tracts, to grazing. Alternative A prohibits the placement of forage supplements within ¼ mile of water or riparian/wetland habitats to limit potential adverse impacts from concentrated livestock grazing.

Special Designations – Alternative A

A detailed description of the beneficial impacts to wildlife from special designations, where most applicable, is included below. Special designations under Alternative A that would directly benefit wildlife species by conserving habitat include the Carter Mountain and Upper Owl Creek ACECs. ACECs designated under this alternative encompass 35,681 acres of big game crucial winter range (Table 4-22). Managing WSR eligible waterway segments to protect their free-flowing conditions and outstandingly remarkable values (ORVs) would beneficially impact riparian habitat for various wildlife species.

Resources – Alternative A

Under Alternative A, the BLM utilizes wildland fire to restore fire-adapted ecosystems and to reduce hazardous fuels. Alternative A would result in approximately 70,000 acres of surface disturbance from prescribed fire and mechanical fuels treatment (Appendix T). These management actions would cause short-term adverse impacts to wildlife through temporary habitat loss and disturbance, but rapid recovery of forage and enhanced palatability would benefit wildlife even in the first few years post fire. A greater long-term benefit from preventing catastrophic fire that may lead to extensive habitat loss would outweigh the short-term impacts. Alternative A would result in long-term beneficial impacts to wildlife from fire and fuels management.

Forest management actions may impact feeding, breeding, and sheltering of raptors and other forest-dependent species. Habitat fragmentation and degradation, increased human presence, and habitat access by competitor species that normally cannot use these areas may all impact these species, depending on whether the action is a harvest or thinning, where the access roads are constructed, the type of equipment used, and the rate of habitat rehabilitation. Under Alternative A, the BLM performs commercial forest management in a manner that protects and benefits, watershed, wildlife, and riparian/wetland habitat values with forest health as a primary concern. Properly mitigated commercial forest management would benefit wildlife by diversifying forest seral stages. The BLM restricts clear cuts to no more than 900 feet in any direction in important seasonal wildlife habitat and closes timber access roads on a case-by-case basis. Forest management under Alternative A would result in adverse impacts to wildlife that depends on old growth trees, snags, and downed trees, but also long-term beneficial impacts by reducing hazardous fuels, diversifying stands, and closing certain timber access roads, which ultimately improves habitat for wildlife.

Vegetation treatments may disturb wildlife and result in displacement in the short term, but in the long term, these treatments would benefit wildlife by improving habitat and controlling the spread of invasive species. Under Alternative A, the BLM manages at least 600,000 acres toward DPC objectives that would benefit wildlife and treats 2,000 acres to remove or control the spread of invasive species. The amount of invasive species spread, where seeds or plants are present, would be proportional with the total amount of surface disturbance. Alternative A requires livestock flushing on a case-by-case basis, which may decrease the potential spread of invasive species, especially in grasslands and shrublands.

The BLM manages riparian/wetland areas to meet PFC under all alternatives including Alternative A. Although wildlife habitat would be improved with this management action, because the PFC assessment methodology does not incorporate the habitat requirements of wildlife, additional management would be necessary to ensure that habitats provide conditions suitable to meet the life history requirements of various wildlife species. Alternative A prohibits surface-disturbing activities within 500 feet of water and riparian/wetland areas, which would benefit wildlife by conserving vegetation and valuable habitat for multiple species.

Proactive Management – Alternative A

Proactive management measures that would benefit wildlife are described in detail below. Proactive management actions implemented on a case-by-case basis under Alternative A include determining wildlife seasonal protections for surface-disturbing and disruptive activities related to the maintenance and operation (including production) of developed projects, addressing traditional migration and travel corridors, and determining the appropriate DPC to manage vegetation in crucial winter range. Beneficial impacts to wildlife would result from these actions under Alternative A.

Big Game – Alternative A

As identified in Chapter 3, big game in the Planning Area face certain challenges such as poor habitat conditions, habitat fragmentation, disease, increased development and urbanization, hunter access, and impacts to key forage species from livestock and wild horse grazing. Big game crucial winter range is more sensitive to forest management, road construction, and vegetative change than other seasonal habitats. Since crucial winter range is considered the “limiting factor” to these big game populations, modifications to habitat suitability can impact species survivability and viability (e.g., higher winter mortality, reduced reproductive success), ultimately leading to reductions in population size. This impact would be intensified in areas where crucial winter range is in degraded or poor condition.

Alternative A would result in 27,356 acres of surface disturbance due to minerals development and new road construction, which would result in correlated adverse impacts to big game, relative to the other alternatives. Although Alternative A applies a TLS stipulation to avoid surface-disturbing activities in big game crucial winter range, disturbance is allowed in these areas. Big game have exhibited sensitivity to human activity and disturbance. Mule deer exhibit a stress response to disturbances associated with noise and activity up to 0.29 mile from the source (Freddy et al. 1986). Allowing surface disturbance, including wind-energy development, in big game crucial winter range is likely to disturb and displace species such as mule deer in the short term. The WGFD estimates there would be adverse impacts to pronghorn from oil and gas development on at least 170 acres surrounding each well pad (WGFD 2009b). The greater mobility and adaptability of these species to human activity and disturbed areas would prevent long-term population impacts. However, it is feasible that big game behavior or populations may be altered in the long term at some level of development. Alternative A withdraws approximately 3 percent of big game crucial winter range to locatable mineral entry and closes 6 percent of big game crucial winter range to oil and gas development (Table 4-22), limiting adverse impacts in these areas. Alternative A also closes a small portion of big game crucial winter range to livestock grazing (Table 4-22), increasing forage availability in these areas.

Alternative A does not restrict motorized vehicle use to designated roads and trails in big game crucial winter range, which may adversely affect big game by increasing human access and the probability of disturbance. The use of all-terrain vehicles in elk habitat has been shown to exceed any other human land-use type in triggering increased vigilance in elk (Ciuti et al. 2012). Opening areas to over-snow travel on a case-by-case basis is likely to benefit big game by restricting access to areas of big game crucial winter range. As a result of other resource concerns, 24,921 acres and 28,153 acres of big game crucial winter range are managed as closed or seasonally restricted for motorized travel respectively. In these areas, the probability of vehicle caused disturbance would be lower.

Special designations would result in beneficial impacts to big game where they overlap big game habitat (Table 4-22) and restrict resource uses and activities that degrade big game habitat or can potentially disturb big game (e.g., oil and gas development and motorized vehicle use). Alternative A designates the Carter Mountain and Upper Owl Creek ACECs, which contain big game habitat and restrict motorized vehicle use and minerals development.

Proactive management actions under Alternative A result in multiple beneficial impacts to big game by conserving habitat values from potential impacts from oil and gas development (Freddy et al. 1986, WGFD 2009b) and potential forage competition from livestock (Vavra 1992). Alternative A applies a TLS to avoid surface-disturbing and disruptive activities in big game crucial winter range (1,324,371 acres) from November 15 through April 30 and a CSU stipulation for big game migration corridors, narrow ridges, overlapping big game crucial winter range. Alternative A prohibits the following actions unless adverse impacts can be avoided or mitigated: domestic sheep grazing on pronghorn crucial winter

range, and water development for livestock in elk crucial winter range. The BLM restores 25 to 200 acres of aspen stands per year until 2,000 to 4,000 acres are under management under Alternative A, which would especially benefit moose and deer that prefer woody vegetation as forage.

Trophy Game – Alternative A

Black bears are most affected by management actions in forest and woodland habitats, which generally are not focused on providing habitat for this species. Management actions under Alternative A that would minimize adverse impacts to this species by conserving habitat values include forest management in a manner that protects and benefits watershed, wildlife, and riparian/wetland habitat values and restricting clear cuts to no more than 300 yards in any direction in important seasonal wildlife habitats.

As cougars are typically found in remote, rugged areas, motorized vehicle use restrictions in WSAs under this alternative would minimize potential adverse impacts to this species (USGS 2007). Although no specific management actions for cougars are identified, cougars would experience impacts similar to mule deer, as cougars generally utilize similar habitats as mule deer—their primary prey.

Furbearing Animals – Alternative A

No specific management actions for furbearing animals exist, but other management actions would affect these species. Badger, bobcat, and weasel are habitat generalists and actions in a variety of habitats would affect these mammals. Impacts to various vegetation types can be found throughout this section. Because there would be as adverse and beneficial impacts to these vegetation types, these wildlife species would experience similar adverse and beneficial impacts.

Under Alternative A, no specific management actions aimed at maintaining old growth forests and woodlands exist to promote habitat for furbearing animals such as the American marten and weasel, although any activities proposed are addressed at the site-specific level before harvest decisions. Alternative A does restore 25 to 200 acres of aspen stands per year, which would benefit the American marten.

Several furbearing species (i.e., beaver, mink, and muskrat) are most affected by management actions that impact riparian/wetland habitat or water availability. Impacts to these species are similar to the impacts discussed below in the *Nongame (Migratory Birds)* section for species that use riparian/wetland habitat. The BLM manages riparian/wetland areas to meet PFC or to make progress toward meeting PFC under all alternatives including Alternative A, which would improve habitat suitability for wildlife.

Predatory Animals – Alternative A

The BLM does not perform any specific habitat management activities for predatory animals. Regardless, predatory animals will be affected by BLM management actions for wildlife habitats. These animals are largely habitat generalists and actions in a variety of habitat types would affect these animals. Impacts to various vegetation types can be found throughout this section. Some predatory animals (i.e., coyote and red fox) are highly mobile and would be affected by management actions pertaining to motorized vehicle use and projected new road development (USGS 2007) (Appendix T). In addition, predatory animals are vulnerable to motorized vehicle disturbance and collisions.

Small Game – Alternative A

There are no specific management actions for small game under Alternative A, but other biological resources management actions would affect these species. Habitat fragmentation is an issue for small game populations because they tend to be especially disadvantaged by isolation (Temple 1985). Projected surface disturbance from minerals development and new road construction, second highest

under Alternative A (Appendix T), would fragment small game habitat. Cottontail rabbits are habitat generalists and a variety of actions in all habitat types would affect rabbits. Snowshoe hare and red squirrel inhabit forests and woodlands. Allowing precommercial thinning in overstocked areas and regenerated timber sale areas under Alternative A may cause adverse impacts to snowshoe hares (USFS 2005b). Conversely, performing woodland treatments in aspen stands and regenerating 2,000 to 4,000 acres of aspen stands would benefit snowshoe hare by improving or creating more habitat. The northern flying squirrel occurs most commonly in riparian forests. The *Nongame (Migratory Birds)* section describes impacts to these habitats.

Game Birds – Alternative A

The BLM identifies modifying livestock grazing management, prescribed burning, installing water developments, and building roost structures (i.e., structures that provide protection from predators) as methods for improving habitats for upland game birds (BLM 1992b). Under Alternative A, there are no specific management actions for game birds that utilize grassland. Actions in grassland habitats, such as surface-disturbing activities, reclamation, invasive species control, and livestock and wildlife grazing, would affect these species. Adverse impact to game birds in grasslands under Alternative A would be proportional to overall surface disturbance (Table 4-1). Management actions in their preferred vegetation types would affect other game birds. Pheasants generally prefer habitat associated with riparian areas along river and stream corridors. Actions in forested areas and grass or sagebrush habitats would affect ruffed grouse and blue grouse. Actions in river bottoms, pine forests, and foothills habitats would affect wild turkeys. *Nongame (Migratory Birds)* describes impacts to these habitats.

Waterfowl – Alternative A

Although there are no specific management actions for waterfowl, other biological resource management actions, particularly those pertaining to water and riparian/wetland habitats would affect these species. The BLM manages riparian/wetland areas to meet PFC or to make progress toward meeting PFC under all alternatives, but does not consider wildlife life history requirements when managing vegetation. As a result of livestock grazing management practices and existing wild horse numbers in HMAs, some riparian zones on public land adjacent to streams, small reservoirs, and ponds have been trampled. Alternative A closes Bighorn River tracts to livestock grazing and prohibits forage supplements within ¼ mile of water or riparian/wetland areas, which would minimize adverse impacts to waterfowl habitat from livestock grazing in these areas. The BLM can use produced water to develop and enhance waterfowl habitats under Alternative A, which would benefit these species.

Nongame (Raptors) – Alternative A

The BLM identifies declining habitat quantity and quality as the major causes of decreases in raptor populations (BLM 1992c). Buffer zones around active nests minimize disturbance impacts to raptors in the Planning Area. Under Alternative A, the BLM applies a TLS to prohibit any activity or surface-disturbing activity within ¼ mile of raptor nests from February 1 through July 31; ultimately protecting 337,662 acres surrounding raptor nests. Protective buffers help to minimize, but cannot completely prevent, impacts to raptors because most species are mobile beyond these buffers. The impact from habitat degradation and loss would be proportional to surface disturbance (Appendix T).

Wind-energy facilities can be a source of mortality for raptors because raptors can collide with wind tower blades. High mortality may result if wind towers are placed along a migration path or in nesting areas. Wind-energy facilities also result in habitat loss and human disturbance through construction and maintenance of wind towers and associated facilities. Alternative A manages the location of wind-energy facilities throughout the Planning Area on a case-by-case basis.

Nongame (Migratory Birds) – Alternative A

The BLM (BLM 1992c) states that viable nongame bird populations and biological diversity can be promoted by improving livestock management, prescribed burning, removal of invasive species, seeding, and erosion control. These actions are managed under Alternative A; however, prescribed burning is limited and the spread of invasive species is expected to continue under all alternatives, including Alternative A.

Wind-energy facilities may adversely affect all migratory birds, as discussed for nongame raptors. Wind-energy facilities, and other linear features (e.g., roads, utility corridors), fragment habitat. Fragmentation creates habitat edges, where studies have indicated that the success of nongame bird nests decline (Paton 1994). Livestock grazing management can affect nongame bird habitat. Inadequate livestock grazing management results in adverse impacts to riparian/wetland habitat (Belsky et al. 1999), adversely affecting nongame birds in these areas (Taylor 1986). Likewise, heavy grazing reduces nongame bird species richness in grassland and shrubland habitat (BLM 1978). However, light to moderate intensity livestock grazing can increase plant species diversity (Manier and Hobbs 2007), which may beneficially impact nongame birds in grassland and shrubland communities.

Because of the diversity of bird species and habitat requirements, the descriptions of impacts are categorized under the following habitat guilds listed below: Forest and Woodland Species, Mountain Shrub Species, Sagebrush and Desert Shrub Species, Grassland Species, and Riparian/wetland Species.

Forest and Woodland Species – Alternative A requires forest management in a manner that protects and benefits watershed, wildlife, and riparian/wetland habitat values. Refer to Section 4.4.1 *Vegetation – Forests, Woodlands, and Forest Products* and Table 4-21 for a description of management actions and BLM-authorized activities that would impact forests or woodlands and would similarly affect migratory bird habitat in these areas. Allowing clear cuts up to a 900-foot radius would adversely impact migratory bird species that prefer closed canopies by reducing potential nest sites and fragmenting habitat; however, other species preferring open canopies or forest edges would benefit. The creation of early successional habitat, as a result of clear cuts or wildland fire, can result in replacement of a mature forest bird community with a young forest bird community (Thompson III et al. 1993). There is evidence that the juxtaposition of different aged stands, which creates increased amounts of edge in a forest, may have an adverse impact by reducing the reproductive success of migratory birds (Thompson III et al. 1993). Alternative A allows harvest of some old-growth forests and allows salvage of dead stands with appropriate levels of snag retention to benefit wildlife following site-specific review under NEPA. Overall, forest management practices under Alternative A would result in long-term beneficial impacts to migratory birds in forest and woodland habitats that would outweigh the short-term adverse impacts.

Mountain Shrub Species – Under Alternative A, the BLM manages mountain shrub communities toward DPC objectives that emphasize watershed protection, and livestock grazing. This management action would improve habitat conditions for migratory birds that depend on mountain shrub habitats in these areas. Adverse impacts to mountain shrub communities would result from surface disturbance and invasive species spread, and would be proportional to projected surface disturbance.

Sagebrush and Desert Shrub Species – Species that utilize or depend on sagebrush habitats would generally benefit from management actions for greater sage-grouse, as discussed in Section 4.4.9 *Special Status Species – Wildlife*. Alternative A applies a CSU restriction for ¼ mile around occupied greater sage-grouse leks and a TLS for nesting or early brood-rearing habitats within 2 miles of occupied greater sage-grouse leks. Because the breeding season and habitat of greater sage-grouse and migratory birds tend to coincide, many species of migratory birds benefit from this restriction.

Under Alternative A, the BLM manages salt desert shrub and basin grassland/shrub communities toward DPC objectives to emphasize watershed protection and livestock grazing. Surface-disturbing activities may result in habitat loss and fragmentation and reduced habitat quality, especially in the 5- to 9-inch precipitation zone due to the difficulty of successful reclamation and the potential spread of invasive species. Refer to Section 4.4.1 *Vegetation – Grassland and Shrubland Communities* and Table 4-21 for a description of management actions and BLM-authorized activities that would impact shrubland communities and would similarly affect migratory birds habitat in these areas.

Grassland Species – These species would be affected by actions in grassland habitats, such as surface-disturbing activities, reclamation, invasive species control, and livestock and wildlife grazing. Under Alternative A, the BLM manages foothills-mountain grassland/shrub and basin grassland/shrub communities toward DPC objectives to emphasize watershed protection and livestock grazing. Livestock grazing practices, though managed in accordance with the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming*, may not create the vegetation heterogeneity necessary to increase habitat suitability for migratory birds (Derner et al. 2009). However, habitat quality would be maintained in these areas to benefit migratory birds that depend on these habitats. Refer to Section 4.4.2 *Vegetation – Grassland and Shrubland Communities* and Table 4-21 for a discussion of management actions and BLM-authorized activities that would impact grasslands and would similarly affect migratory bird habitat in these areas. Due to its projected long-term surface disturbance and reclamation requirements, Alternative A would result in habitat loss and degradation in grasslands.

Riparian/Wetland Species – There are no specific management actions for migratory birds that use riparian/wetland habitats. However, other biological resource management actions, particularly those pertaining to water and riparian/wetland habitats, such as surface disturbance restrictions, livestock grazing and riparian area management, and special designations would affect these species. Refer to Section 4.4.3 *Vegetation – Riparian/Wetland Resources* and Table 4-21 for a description of management actions and BLM-authorized activities that would impact wetlands and riparian areas and would similarly affect migratory bird habitat in these areas.

Nongame (Mammals) – Alternative A

Although there are no specific management actions for nongame mammals, other biological resource management actions would affect these species. Nongame mammals are found in a variety of habitats and are affected by management actions in the preferred vegetation type of each species. Impacts to the various vegetation types are described above for nongame migratory birds and are expected to similarly impact nongame mammals.

Although bats can utilize a variety of habitats, caves and abandoned mines are important features for most species. Bats that use caves for roosting, maternity colonies, or hibernation may be affected by recreational caving and surface-disturbing activities near caves, cliffs, or other rock features. Habitat alteration and modification, loss of roosting habitat, and toxic chemicals are threats to bat species in the Planning Area (Keinath 2004; Gruver and Keinath 2006; and Luce and Keinath 2007). Generally, the BLM manages natural caves to meet recreational demand while conserving cave resources and allows activity in abandoned mine land (AML) sites on a case-by-case basis under Alternative A. The Little Mountain ACEC designated under Alternative A would conserve important habitat used by bats, and the use of heavy equipment is restricted over important caves and cave passages in the Little Mountain ACEC to minimize disturbance. Pesticides (specifically insecticides) can result in direct bat mortality, adversely affect reproduction, and reduce the insect prey base (Keinath 2004; Gruver and Keinath 2006; and Luce and Keinath 2007). Aerial application of insecticides under Alternative A may result in direct and

indirect adverse impacts to bats as these species are at risk from poisoning by insecticides due to their diet, high metabolic rates, high rate of food intake, and high rate of fat mobilization.

There are 71,333 acres of identified “badlands/rock outcrop” on BLM-administered land in the Planning Area that may contain potential bat habitats. These areas include the Medicine Lodge and Trapper Creek WSAs, where motorized vehicle use is limited to designated roads and trails under Alternative A, reducing the potential for wildlife disturbance in these areas. No specific management actions for abandoned mines exist under Alternative A. Wind-energy development would affect bats similar to migratory birds. Overall, Alternative A would limit adverse impacts to bats by protecting cave resources and conserving potential bat habitat.

Nongame (Reptiles and Amphibians) – Alternative A

Implementing and/or stipulating appropriate management guidelines in *Habitat Management Guidelines for Amphibians and Reptiles of the Northwestern U.S. and Canada, PARC Technical Publication HMG-4* (Pilliod and Wind 2008), and similar future guidance for activities that may impact amphibian/reptile habitat will benefit amphibians and reptiles by preventing, minimizing, or mitigating adverse impacts to these species. Retaining riparian vegetation when removing sediment from reservoirs would also benefit amphibian and reptile species such as aquatic turtles and amphibians in these areas by preserving their habitat. Biological resource management actions in other habitats also would affect reptiles and amphibians. Snakes occur in a variety of habitat types, while lizards typically occur in the drier habitats, particularly those with rock outcrops and cliffs. Impacts of management actions to these habitat types are discussed throughout this section.

Alternative B

Surface Disturbance – Alternative B

Alternative B would result in approximately 73,940 acres of short-term surface disturbance that may degrade wildlife habitat and 10,893 acres of long-term surface disturbance that may result in habitat loss (Table 4-1). Minerals development, fire and fuels management, and silviculture treatments are the largest sources of short-term disturbance, with minerals development being the largest source of long-term disturbance. Alternative B requires that all surface-disturbing activities are analyzed by mapping soils to a series level, collecting soils samples for analysis, and evaluating erosion conditions. This alternative also requires reclamation plans before disturbance, topsoil salvage, and establishing 50 percent of pre-disturbance vegetative cover within three growing seasons and 80 percent pre-disturbance cover within 5 years of initial seeding. These management actions would result in a higher probability of successful reclamation, compared to Alternative A, so that disturbed areas can return to suitable wildlife habitat in the long term. Alternative B requires the stabilization of all heavily eroded or washed out roads, and closes and reclaims these routes if alternative roads and trails are available. Overall, the projected surface disturbance and associated reclamation practices under Alternative B would result in less short- and long-term adverse impacts to wildlife compared to Alternative A.

Resource Uses – Alternative B

Minerals development would be the greatest contributor to habitat loss and fragmentation. Alternative B makes fewer acres available for locatable mineral entry than Alternative A, and is projected to result in approximately 5,000 acres of long-term disturbance that would cause habitat loss (Appendix T). Alternative B also places more constraints on oil and gas leasing for which 502 new federal wells are projected. Alternative B would result in less adverse impacts to wildlife from minerals development, relative to Alternative A.

Impacts to wildlife habitat from lands and realty management actions would be similar to those described under Alternative A. Under Alternative B, there would be more emphasis on retaining and acquiring lands in the Absaroka Front and certain ACECs. All acquisitions would be from willing sellers, and while increased acres have been identified, there is no certainty of acquisitions.

Under Alternative B, the BLM would manage more land as ROW exclusion areas (225,447 acres) compared to Alternative A, including 105,158 acres of big game crucial winter range (Table 4-22). The ROW exclusion areas identified under this alternative would reduce powerline occurrences and lower the risk of raptor electrocution. Alternative B would result in a greater consolidation of ROWs that would cause less habitat fragmentation and would result in the least adverse impacts to wildlife, relative to Alternative A.

Under Alternative B, the BLM avoids locating wind-energy projects in big game crucial winter range. Alternative B provides more Planning Area-wide guidance for the location of wind-energy project development resulting in the least adverse impact to wildlife, compared to Alternative A.

CTTM designations would limit the potential for the proliferation of unauthorized trails and related habitat degradation and wildlife disturbance. Under Alternative B, the BLM closes more area (170,253 acres) to motorized vehicle use and restricts motorized vehicle use to designated roads and trails over more area (2,416,378 acres) than Alternative A. These restrictions would enhance the protection of wildlife from human-caused disturbances and sustain habitat integrity and water quality by preventing vegetation loss or soil erosion and compaction. Overall, motorized vehicle use with restrictions under Alternative B would result in less adverse impacts to wildlife, relative to Alternative A.

Under Alternative B, the BLM does not develop or upgrade recreation sites unless otherwise called for in an SRMA or RMZ. Alternative B would result in more surface disturbance from recreational site development than Alternative A (Appendix T); the increase in human presence and impact to wildlife would be proportional.

Under Alternative B, the Planning Area is open to livestock grazing where it does not conflict with other resource management objectives. Crucial winter range for elk and bighorn sheep—to prevent forage competition and possible displacement (Scolvin et al. 1968; Coe et al. 2004; Stewart et al. 2002)—and greater sage-grouse Key Habitat Areas are closed to livestock grazing and pronghorn crucial winter range is closed to new domestic sheep grazing. The BLM apportions additional sustained yield forage for wildlife, which would have greater beneficial impacts to wildlife, compared to Alternative A, by reducing the potential for competition with livestock (Vavra 1992 and Scolvin et al. 1968).

Special Designations – Alternative B

A detailed description of the beneficial impacts to wildlife from special designations is included below. Special designations under Alternative B that would directly benefit wildlife species by conserving habitat include the Carter Mountain and Upper Owl Creek ACECs and their expansions, the Little Mountain ACEC expansion, and the Chapman Bench, Clarks Fork Canyon, Rattlesnake Mountain, and Sheep Mountain ACECs. Additionally, the Absaroka Front Management Area would be managed to protect and enhance wildlife habitat under Alternative B. Managing WSR suitable waterway segments to protect their free-flowing conditions and ORVs would result in similar beneficial impacts as those under Alternative A, but to a greater degree as Alternative B applies greater protective measures around these segments to protect riparian habitat.

Resources – Alternative B

Under Alternative B, the BLM utilizes wildland fire and other vegetation treatments to restore fire-adapted ecosystems and to reduce hazardous fuels. Alternative B would result in approximately 25,000

acres of prescribed fire and mechanical fuels treatment (Appendix T). These management actions would cause fewer short-term adverse impacts to wildlife through temporary habitat loss and disturbance than Alternative A, but fewer long-term benefits because more area would remain in FRCC 2 and 3, more susceptible to catastrophic fire, and ultimately less fire adapted habitat would be restored. Based on the amount of vegetation treatment, Alternative B would result in less long-term beneficial impacts to wildlife from fire and fuels management than Alternative A, as in certain habitats fire is documented to improve the palatability of wildlife forage and provide age class diversity to habitats (BLM 2007f).

Under Alternative B, the BLM prohibits clear cuts and performs forest management only where natural processes are unable to accomplish forest health goals. Roads not required for other existing uses are closed, which would reduce human presence and the risk of unplanned ignitions in forestlands in the short term, and augment habitat and reduce habitat fragmentation in the long term. Forest management practices under Alternative B would result in less short-term adverse impact to wildlife from disturbance and displacement than Alternative A. Wildlife in spruce and subalpine fir stands would experience mostly beneficial impacts from prohibiting commercial forest management to let natural processes determine forest structure, while species in aspen, Douglas-fir, and ponderosa pine stands would mostly experience adverse impacts due to the lack of fuels reduction and stand diversification. Closing timber access roads would benefit wildlife species in all types of forest.

Under Alternative B, the BLM manages to achieve or make progress towards the reference state plant community based on ESDs, and manages large, contiguous blocks of land by maintaining or enhancing important plant communities. The amount of invasive species spread would be proportional to the total amount of surface disturbance (Table 4-1) in areas where invasive species seeds or plants are present. Alternative B would treat far less acreage to remove or control the spread of invasive species than Alternative A. Alternative B allows the authorized officer to require livestock flushing for 72 hours, which would reduce the potential for invasive species spread to a greater extent than Alternative A. The lesser extent of vegetation treatments under Alternative B would result in less short-term adverse impact to wildlife than Alternative A from disturbance, but less long-term beneficial impacts by enhancing habitat conditions and controlling the spread of invasive species.

The BLM manages all riparian/wetland areas to meet DPC under Alternative B. This management would ensure to the greatest extent, compared to the other alternatives, that riparian/wetland habitats provide conditions suitable to meet the life history requirements of various wildlife species. Alternative B prohibits surface-disturbing activities within ¼ mile of water and riparian/wetland areas and applies an NSO restriction on wetland areas greater than 40 acres, limiting habitat loss and fragmentation in these areas and benefiting wildlife that depend on these areas to a greater extent than under Alternative A.

Proactive Management – Alternative B

Proactive management actions under Alternative B include applying wildlife seasonal protections for surface-disturbing and disruptive activities related to the maintenance and operation (including production) of a developed project when the actions are determined to be detrimental, identifying and preserving traditional migration and travel corridors for big game and migratory birds, and managing vegetation in areas identified as habitat for special status species and big game crucial winter range to the most beneficial DPC while considering the habitat needs of other species. Based on their emphasis on implementation for both habitat protection and enhancement, proactive management actions under Alternative B would result in more beneficial impacts to wildlife, compared to Alternative A.

Big Game – Alternative B

Alternative B prohibits surface-disturbing activities and applies an NSO restriction in big game crucial winter range. The BLM avoids locating wind projects in big game crucial winter range. After Alternative E, Alternative B withdraws the greatest area in big game crucial winter range to locatable minerals and closes the largest area to oil and gas development (Table 4-22). Overall, restrictions on surface-disturbing activities and motorized vehicle use under Alternative B would result in the less adverse impacts to big game than Alternative A.

Alternative B places more restrictions on motorized vehicle use in comparison to Alternative A and prohibits over-snow vehicle use in big game crucial winter range. These actions would provide additional protection from human disturbance of wildlife compared to Alternative A. Under Alternative B, 54,273 acres and 606,233 acres of big game crucial winter range are managed as closed or seasonally restricted for motorized travel respectively. Special designations would result in beneficial impacts to big game where they overlap big game habitat and restrict resource uses that degrade big game habitat or may disturb big game (e.g., oil and gas development and motorized vehicle use).

Alternative B expands the Carter Mountain, Upper Owl Creek, and Little Mountain ACECs that contain important big game habitats, migration corridors, and bighorn sheep populations, and ACECs designated under Alternative B encompass more big game crucial winter habitat than Alternative A (Table 4-22). In addition to restrictions that exist under Alternative A, the Carter Mountain and Little Mountain expansion is closed to oil and gas leasing and withdrawn from locatable mineral entry. The Chapman Bench, Rattlesnake Mountain, and Sheep Mountain ACECs are also designated under Alternative B, which all contain important big game habitat and restrict motorized vehicle use and/or minerals development. Managing all lands with wilderness characteristics specifically to preserve their wilderness characteristics, and the associated restrictions on resource uses and activities, would benefit big game, as 188,101 acres of crucial winter range lie within these lands (Table 4-22).

Proactive management actions under Alternative B result in multiple, primarily beneficial impacts to big game by conserving habitat values from potential impacts due to oil and gas development, reducing competition from livestock, and minimizing human-caused wildlife disturbance. Alternative B prohibits surface-disturbing and disruptive activities in big game crucial winter range (1,324,371 acres) and closes the Absaroka Front Management Area to mineral leasing, geophysical exploration, and motorized vehicle use in certain areas. The BLM limits motorized vehicle use to designated roads and trails with seasonal closures in big game crucial winter range. Alternative B prohibits domestic sheep grazing on pronghorn crucial winter range, and livestock grazing on crucial winter range for elk and bighorn sheep (Table 4-22) to increase forage availability, reduce forage competition and prevent possible displacement of these wildlife populations (Scolvin et al. 1968; Coe et al. 2004; Stewart et al. 2002). Furthermore, prohibiting water developments for livestock in elk crucial winter range unless no adverse impacts to wildlife can be demonstrated reduces the probability of concentrated livestock areas that may compact soil, damage vegetation, and increase the chance of invasive species spread. Conversely, closing elk habitat to livestock grazing entirely removes this resource use as a potential management tool to improve habitat through enhancing forage palatability and may result in adverse impacts to elk in these areas (Frisina 1992; Anderson and Scherzinger 1975).

The BLM restores 100 acres of aspen stands per year over the life of the plan under Alternative B (for a total restoration similar to that of Alternative A), which would especially benefit moose and deer that use habitats with woody vegetation for forage. All of these actions protect habitat for big game and reduce habitat fragmentation and disruptive activities.

Due to the adverse impacts from projected surface disturbance and motorized vehicle use, and the beneficial impacts from proactive management actions and special designations under this alternative, Alternative B would result in less adverse impacts to big game, compared to Alternative A.

Trophy Game – Alternative B

Black bears are most affected by management actions in forest and woodland habitats. Management actions under Alternative B that minimize adverse impacts to this species by preserving habitat values include forest management, when natural processes cannot achieve forest health goals, and prohibiting clear cuts.

As cougars are typically found in remote, rugged areas, the motorized vehicle use restrictions in WSAs under Alternative B would minimize potential adverse impacts to this species the most in these areas, compared to Alternative A (USGS 2007). Under Alternative B, the BLM also manages all lands with wilderness characteristics specifically to preserve their wilderness characteristics, and restricts minerals development and motorized vehicle use in these areas. Alternative B would benefit cougars to a greater extent than Alternative A by reducing the potential of human disturbance in remote areas and providing more beneficial impacts to big game, including mule deer.

Furbearing Animals – Alternative B

Forest management actions under Alternative B maintain old growth forests and woodlands, which would benefit the American marten. Several furbearing mammal species (i.e., badger, beaver, mink, and muskrat) are most affected by management actions that impact riparian/wetland habitat or water availability. Impacts to these species are similar to those described below in the *Nongame (Migratory Birds)* section that use riparian/wetland habitat. Under Alternative B, the BLM manages all riparian/wetland areas to meet DPC, ensuring consideration of habitat requirements for wildlife. Alternative B would result in fewer new oil and gas wells than Alternative A, and therefore may result in less adverse impacts to furbearing mammal species from altering water availability.

Predatory Animals – Alternative B

Alternative B actions that would benefit different vegetative types in the Planning Area are anticipated to benefit habitat generalists, such as predatory animals. Motorized vehicle restrictions and projected new road development under Alternative B are expected to cause less adverse impacts to predatory animals such as the coyote and red fox than Alternative A.

Small Game – Alternative B

Alternative B actions benefiting forests, woodlands, riparian areas, and other habitat types would proportionally benefit the habitat generalist cottontail rabbit, and more habitat-specific species, such as the snowshoe hare and red squirrel. Preventing precommercial thinning except for fuels treatment would benefit snowshoe hare (USFS 2005b), as would regenerating aspen stands for wildlife values. Management actions to retain old growth forests in HUC Level 4 sub-basins would beneficially impact red squirrels by conserving their habitat.

Game Birds – Alternative B

Under Alternative B, management actions that enhance grassland and shrubland habitat, manage toward DPC in riparian/wetland areas, and control invasive species spread in shrub and grassland communities would provide greater benefits to greater sage-grouse, chukar, and gray partridge, compared to Alternative A. Alternative B actions benefiting forests, woodlands, riparian areas, and other habitat types would proportionately benefit other game birds, such as the ruffed grouse, blue

grouse, wild turkey, and pheasant that prefer these habitat types. Impacts to these habitats are discussed below under *Nongame (Migratory Birds)*. Late brood-rearing greater sage-grouse would benefit from alpine habitat conserved in the Carter Mountain and Owl Creek ACECs designated and expanded under Alternative B.

Waterfowl – Alternative B

Although there are no specific management actions for waterfowl, other biological resource management actions, particularly those pertaining to water and riparian/wetland habitats, would affect these species. Under Alternative B, the BLM would manage all riparian/wetland areas to meet DPC with consideration of habitat requirements for wildlife. Alternative B prohibits forage supplements within ½ mile of water or riparian/wetland areas, which would further minimize adverse impacts to these areas from livestock grazing, compared to Alternative A. Under Alternative B, the BLM would not use produced water to develop and enhance waterfowl habitats, resulting in less area of suitable habitat for waterfowl and less beneficial impact from produced water than under Alternative A. However, the risk of high water temperature or impaired water quality adversely affecting waterfowl would be less under Alternative B.

Nongame (Raptors) – Alternative B

Under Alternative B, the BLM applies a TLS to prohibit any activity or surface-disturbing activity within 1 mile of raptor nests from February 1 through July 31 or until young birds have fledged and a year-round CSU to protect the actual nest site from disturbance. The protective buffers around raptor nest sites under Alternative B (569,218 acres) are larger than under Alternative A and would minimize adverse impacts to raptors more than under that alternative. Avoiding locating wind-energy projects in raptor concentration areas would minimize the potential for collision mortality and displacement.

Nongame (Migratory Birds) – Alternative B

Alternative B management actions pertaining to minerals development and motorized vehicle use restrictions; wind-energy development; forest management; management of sagebrush, grassland, and riparian/wetland habitats toward DPC; invasive species control; and fire management would result in the greater beneficial impacts to nongame migratory birds, compared to Alternative A. Although the short-term impacts from prescribed fire and fuels treatments would be less under Alternative B, the increased risk of catastrophic fire that may completely destroy woodland and sagebrush habitat would be greater than under Alternative A.

Designated under Alternative B, the Chapman Bench, Rattlesnake Mountain, and Sheep Mountain ACECs conserve migratory bird nesting habitat.

Forest and Woodland Species – Alternative B closes more area in forests and woodlands to oil and gas development and withdraws more area from locatable mineral development than Alternative A (Table 4-21). This alternative prohibits clear cuts and performs forest management only when natural processes cannot achieve forest health goals. BLM actions for silviculture treatments, forest products, and fuels reduction under this alternative would result in less short-term disturbance than Alternative A, but also pose greater risk for catastrophic fire. Planting conifer areas exposed by wildfire if they do not regenerate naturally within 20 years would result in a longer time before habitat is restored, compared to the other alternatives, but retaining old-growth forests and requiring with appropriate levels of snag retention during salvage would benefit wildlife. Overall, forest management practices under Alternative B would result in less short-term impacts than Alternative A, but the long-term adverse impacts posed by the risk of wildfire would be greater.

Mountain Shrub Species – Under Alternative B, the BLM manages mountain shrub communities to achieve or make progress towards the reference state plant community based on ESDs—which would provide greater benefit to migratory birds, compared to Alternative A—by enhancing habitat in these areas. Designating the Rattlesnake Mountain and Sheep Mountain ACECs would conserve mountain shrub habitat from disturbance.

Sagebrush and Desert Shrub Species – Species that utilize or depend on sagebrush habitats would generally benefit from management actions for greater sage-grouse as discussed in Section 4.4.9 *Special Status Species – Wildlife*. Alternative B applies larger buffers around greater sage-grouse leks and in nesting or early brood-rearing habitats to conserve sagebrush habitat than Alternative A. Under Alternative B, the BLM manages salt desert shrub and basin grassland/shrub communities to achieve the reference state plant community, based on the ESD for the site. Alternative B would result in less surface disturbance that may result in habitat loss than Alternative A, especially in the 5- to 9-inch precipitation zone, and has more stringent requirements for reclamation, which would result in less impacts to migratory birds that depend on sagebrush and desert shrub habitats.

Grassland Species – Actions in grassland habitats, such as surface-disturbing activities, reclamation, invasive species control, and livestock and wildlife grazing would affect these species. Under Alternative B, the BLM would manage grasslands communities to achieve or make progress towards the reference state plant community, which would provide the greatest benefit, compared to the other alternatives, by enhancing habitat for migratory birds in these areas. However, closing crucial winter range for elk and bighorn sheep and greater sage-grouse Key Habitat Areas to livestock grazing would limit the use of livestock grazing as a tool where it may create vegetation heterogeneity that enhances habitat for grassland migratory birds (Derner et al. 2009). Refer to Section 4.4.2 *Vegetation – Grassland and Shrubland Communities* and Table 4-21 for a discussion of management actions and BLM-authorized activities that would impact grasslands and would similarly affect migratory bird habitat in these areas. Due to its projected long-term surface disturbance and reclamation requirements, Alternative B would result in less habitat loss and degradation in grasslands compared to Alternative A.

Riparian/Wetland Species – The restrictions on minerals development and other surface-disturbing activities in riparian/wetland areas and within WSR suitable waterway segments under Alternative B would result in similar beneficial impacts to those under Alternative A, but to a greater degree by further limiting degradation of riparian habitat. Refer to Section 4.4.3 *Vegetation – Riparian/Wetland Resources* and Table 4-21 for a description of management actions and BLM-authorized activities that would impact wetlands and riparian areas and would similarly affect migratory bird habitat in these areas. Based on these management practices, Alternative B would result in greater beneficial impacts to migratory birds that depend on riparian/wetland habitat than Alternative A.

Nongame (Mammals) – Alternative B

Although there are no specific management actions for nongame mammals, other biological resource management actions would affect these species. Nongame mammals are found in a variety of habitats and are affected by management actions in the preferred vegetation type of each species. Impacts to the various vegetation types are described above for nongame migratory birds and are expected to similarly impact nongame mammals.

Generally, the BLM places the greatest restrictions on surface-disturbing activities and motorized vehicle use to conserve cave resources under Alternative B. Activities are prohibited within ¼ mile of AMLs, which would reduce the opportunities for disturbances to bats in these areas. The BLM closes the Medicine Lodge and Trapper Creek WSAs to motorized vehicle use under Alternative B, minimizing human presence and the opportunities for wildlife disturbance in these areas. Little Mountain and

Clarks Fork Canyon ACECs designated under this alternative would protect bat habitat. Alternative B places more restrictions on the aerial applications of pesticides reducing potential adverse impacts to bat species relative to Alternative A. Wind-energy development would affect bats similar to migratory birds. Overall, Alternative B would result in greater beneficial impact to bats than Alternative A by protecting cave resources and conserving potential bat habitat.

Nongame (Reptiles and Amphibians) – Alternative B

The impacts to reptiles and amphibians under Alternative B would be similar to those under Alternative A, although to a lesser extent. Alternative B similarly applies management guidelines identified in *Habitat Management Guidelines for Amphibians and Reptiles of the Northwestern U.S. and Canada, PARC Technical Publication HMG-4* (Pilliod and Wind 2008). The adverse impact to these animals would be correlated with surface disturbance (Appendix T) and beneficial impacts would result from habitat conservation and enhancement measures described throughout this section. Alternative B applies a larger buffer around riparian/wetland areas to prohibit surface-disturbing activities, which would benefit amphibians and reptiles such as aquatic turtles in these habitats. Alternative B would result in less adverse impact to reptiles and amphibians than Alternative A.

Alternative C

Surface Disturbance – Alternative C

Alternative C would result in approximately 245,642 acres of short-term surface disturbance that may degrade wildlife habitat and 41,485 acres of long-term surface disturbance that may result in habitat loss and fragmentation (Table 4-1). Minerals development, fire and fuels management, and silviculture treatments are the largest sources of short-term disturbance, with minerals development also being the largest source of long-term disturbance. Alternative C requires that all surface-disturbing activities are analyzed by mapping, collecting, and evaluating soil on a case-by-case basis and that reclamation plans and topsoil salvage are performed on a case-by-case basis. The BLM requires 30 percent desired vegetative cover within three growing seasons, but does not specify a long-term vegetative cover requirement. These management actions would result in the least probability of successful reclamation, compared to the other alternatives, so that disturbed areas would be less likely to return to suitable habitat in the long term. Under this alternative, stabilization, but not closure or reclamation, is required for all heavily eroded or washed out roads. Overall, the projected surface disturbance and associated reclamation practices under Alternative C would result in the greatest short- and long-term adverse impact to wildlife.

Resource Uses – Alternative C

Minerals development would be the greatest contributor to habitat loss and fragmentation. Alternative C makes the most acres available for locatable mineral entry of any alternative, and is projected to result in approximately 20,000 acres of long-term disturbance that could contribute to habitat loss and fragmentation (Appendix T). Alternative C also places the least constraints on oil and gas leasing for which 1,304 new federal wells are projected. Alternative C would result in the greatest adverse impacts to wildlife from minerals development, relative to the other alternatives.

Impacts to wildlife habitat from lands and realty management actions under Alternative C would be similar to those described under Alternative A, however, more area is identified for disposal (including disposal with restrictions and disposal for specific uses) than under the other alternatives.

Under Alternative C, the BLM manages the least land as ROW exclusion areas (7,586 acres), including 936 acres in big game crucial winter range. Alternative C would result in the least consolidation of ROWs and the greatest habitat fragmentation. ROWs under Alternative C would result in the greatest adverse impact to wildlife, relative to the other alternatives.

Under Alternative C, the BLM allows wind-energy projects in big game crucial winter range, raptor concentration areas, and greater sage-grouse nesting, brood-rearing, and winter concentration areas on a case-by-case basis. Alternative C provides more Planning Area-wide guidance for wind-energy project locations and turbines than Alternative A, but allows for their construction in wildlife habitat that may be sensitive to impacts. Wind-energy development under Alternative C would result in the second-greatest impact to wildlife, compared to the other alternatives.

CTTM designations would limit the potential for the proliferation of unauthorized trails and related habitat degradation and wildlife disturbance. Under Alternative C, the BLM closes the least area (9,274 acres) and opens the most area (14,830 acres) to motorized vehicle use, which would result in the greatest potential for human-caused disturbances, vegetation loss, and soil erosion and compaction. Permitting off-road motorized vehicle use for big game retrieval and access to dispersed campsites would result in impacts similar to those under Alternative A. Overall, motorized travel designations under Alternative C would result in less adverse impact to wildlife than Alternative A, due to the larger area with seasonal restrictions.

Under Alternative C, the BLM develops or upgrades recreation sites (i.e., camping sites, interpretive educational areas, day use areas) and the associated amenities and facilities if demand warrants. Alternative C would result in the greatest amount of surface disturbance from recreational site development and OHV play areas; the increase in human presence and impacts to wildlife would be proportional.

Under Alternative C, the BLM closes a similar amount of acreage to livestock grazing as under Alternative A, but manages livestock grazing to optimize commodity production while meeting rangeland health standards. Alternative C allows the placement of forage supplements to maximize livestock use, regardless of habitat sensitivity to potential vegetation impacts. As cattle are more likely to concentrate around forage supplements (Bailey et al. 2001), their placement may increase the impact of livestock grazing on vegetation and soil in these areas that may impact wildlife. The potential for adverse impacts to wildlife from livestock grazing would be greatest under Alternative C.

Special Designations – Alternative C

As only two ACECs are designated under Alternative C (neither of which is proposed to protect wildlife values), this alternative would result in the smallest beneficial impact to wildlife habitat from special designations (Table 4-22). Alternative C does not recommend WSR eligible waterway segments as suitable for inclusion in the NWSRS and, therefore, would not protect riparian habitat in these areas to benefit wildlife as under alternatives A and B. Alternative C also places the least restrictions on motorized vehicle use in WSAs, which would result in the greatest potential for human disturbance of wildlife in these remote areas.

Resources – Alternative C

Under Alternative C, the BLM utilizes wildland fire and other vegetation treatments to restore fire-adapted ecosystems, to enhance forage for commodity production, and to reduce hazardous fuels. Alternative C would result in approximately 140,000 acres of surface disturbance from prescribed fire and mechanical fuels treatment (Appendix T). These management actions would cause the greatest short-term adverse impact to wildlife through temporary habitat loss, fragmentation, and disturbance,

compared to the other alternatives, but would potentially result in the greatest long-term benefit from preventing catastrophic fire and restoring fire adapted habitat. Alternative C would potentially result in the greatest long-term beneficial impact to wildlife from fire and fuels management if management practices consider wildlife habitat needs.

Under Alternative C, the BLM allows forest management in areas classified as commercial forestland without specific regard for wildlife habitat values and allows clear cuts up to 100 acres, which is a larger area than allowed under Alternative A. Not retaining appropriate numbers of snags in salvage operations would adversely impact amphibians, reptiles, birds, and other small animals that depend on snags and downed wood for habitat. Forest management under Alternative C would result in the potential for altered forest structure that does not mimic natural conditions, which would adversely impact wildlife. The BLM allows spur roads to remain open to meet other resource objectives or for new recreational purposes, which would result in short-term adverse impacts from increased human presence and the risk of unplanned ignitions in forestlands, and long-term adverse impacts from habitat loss and fragmentation. Forest management practices under Alternative C would result in the greatest short-term impact to wildlife from disturbance, displacement, and habitat loss. Alternative C may also result in the greatest long-term beneficial impact to species in aspen, Douglas-fir, and ponderosa pine stands by reducing hazardous fuels, if short-term impacts do not result in permanent habitat loss or displacement and forest structure is not substantially altered from natural conditions.

Under Alternative C, the BLM manages toward achieving the *Wyoming Standards for Healthy Rangelands* (Appendix N) and performs habitat enhancement vegetation treatments in sagebrush communities as opportunities and funding allow, consistent with Wyoming Governor's EO 2011-5. The amount of invasive species spread, where invasive seeds or plants are present, would be proportional with the total amount of surface disturbance (Appendix T), and limited by vegetation treatments to remove or control invasive species spread on 4,000 acres. The BLM does not require livestock flushing under Alternative C, which increases the likelihood of invasive species spread that would degrade wildlife habitat, especially in grasslands and shrublands. The greater projected vegetation treatments and prescribed fire under Alternative C would result in the greatest short-term impact to wildlife. Despite treatment measures, surface disturbance and the associated establishment of invasive species would degrade the most habitat and result in the greatest adverse impact to wildlife under Alternative C due to the projected surface disturbance. Long-term benefits to wildlife would be realized only if vegetation management practices consider wildlife habitat needs along with other resource objectives.

The BLM manages all riparian/wetland areas to meet PFC under Alternative C without considerations for wildlife life history requirements. Alternative C allows surface-disturbing activities in flood plains or riparian/wetland areas on a case-by-case basis, which would potentially result in the greatest adverse impact to wildlife species in these areas from habitat degradation or loss.

Proactive Management – Alternative C

Proactive management measures that would result in beneficial impacts to wildlife are described in detail below. Proactive management actions under Alternative C include identifying and developing management for traditional migration and travel corridors for big game and migratory birds and managing vegetation in areas identified as habitat for special status species, or crucial winter range, for big game to the DPC that benefits all grazing/browsing animals. Proactive management actions under Alternative C would result in the fewest beneficial impacts to wildlife, compared to the other alternatives.

Big Game – Alternative C

Alternative C exempts Oil and Gas Management Areas (260,460 BLM-administered surface acres) and ROW corridors (133,184 acres) from discretionary wildlife seasonal stipulations. The BLM allows wind-energy development in big game crucial winter range on a case-by-case basis. Alternative C would result in the greatest acres of surface disturbance due to minerals development and new road construction, which would result in proportional adverse impacts to big game, relative to the other alternatives. Alternative C closes motorized vehicle use on the smallest acreage of big game crucial winter range (7,437 acres) and seasonally restricts travel on the second smallest area of big game crucial winter range (28,552 acres). These less prohibitive restrictions on surface-disturbing activities would result in the greatest adverse impact to big game, compared to the other alternatives, but the seasonal restrictions on motorized vehicle use under Alternative C would limit adverse impacts to big game more than under Alternative A. The areas closed to livestock grazing under Alternative C are similar to those under Alternative A. Special designations under Alternative C would protect the least amount of big game crucial winter range from surface-disturbing activities (Table 4-22).

Proactive management actions under Alternative C result in the fewest beneficial impacts to big game by providing less habitat protection to potential impacts from oil and gas development and competition from livestock due to prioritizing livestock forage allocation over wildlife. The BLM limits motorized vehicle use to designated roads and trails with seasonal closures in the Absaroka Front Management Area to minimize big game disturbance; however, big game crucial winter range is afforded the least protection from surface-disturbing activities and potential disturbance under Alternative C (Table 4-22). Proactive management actions would result in the fewest beneficial impacts to big game under this alternative.

Due to the adverse impacts from projected surface disturbance and motorized vehicle use, and fewer beneficial impacts from proactive management actions and special designations under this alternative, Alternative C would result in the greatest adverse impact to big game, compared to the other alternatives.

Trophy Game – Alternative C

Black bears are most affected by management actions in forest and woodland habitats. Forest management practices under Alternative C result in the greatest short-term adverse impact to black bears from disturbance and displacement, but may result in the greatest long-term benefit, if displacement is not permanent, by improving stand diversity and preventing catastrophic wildfires.

Alternative C places fewer restrictions on motorized vehicle use in WSAs than alternatives A or B, which would result in the greatest potential for human-caused disturbance of cougars in these areas. Management actions affecting big game would have similar impacts on cougars.

Furbearing Animals – Alternative C

The BLM manages forestland under Alternative C for more forest production, resulting in a greater amount of activity that would disturb and displace wildlife. However, old growth forest areas are retained at appropriate locations and distribution levels, which would benefit the American marten in these areas.

Under Alternative C, the BLM manages all riparian/wetland areas to meet PFC without consideration of habitat requirements for wildlife. Alternative C would result in the most new oil and gas wells, and therefore may result in the greatest adverse impact to furbearing mammal species by contributing to the depletion of these rivers. Habitat degradation and loss would be greatest in riparian/wetland areas

under Alternative C, and therefore would result in the greatest adverse impact to furbearing animals in these areas.

Predatory Animals – Alternative C

Alternative C actions that would impact different vegetative types in the Planning Area are anticipated to impact habitat generalists, such as predatory animals. Motorized vehicle use restrictions and new road development under Alternative C are expected to cause the greatest adverse impacts to predatory animals such as the coyote and red fox (USGS 2007).

Small Game – Alternative C

Alternative C actions affecting forests, woodlands, riparian areas, and other habitat types would have proportionate impacts on generalists like cottontail rabbits, as well as more habitat-specific species, such as the snowshoe hare, red squirrel, and flying squirrel. Precommercial thinning practices under Alternative C would result in similar adverse impacts to snowshoe hare, yet to a greater extent, than under Alternative A. Alternative C would result in no beneficial impacts from regenerating aspen stands, as is so under alternatives A and B.

Game Birds – Alternative C

Alternative C would result in the greatest potential habitat loss and spread of invasive species in shrubland and grassland communities due to surface disturbance and the greatest potential habitat loss and degradation of riparian/wetland areas due to surface disturbance and concentrated livestock grazing. Alternative C actions affecting forests, woodlands, riparian areas, and other habitat types would have proportionate impacts on other game birds, such as the ruffed grouse, blue grouse, wild turkey, and pheasant that prefer these habitat types. Impacts to these habitats are discussed below under *Nongame (Migratory Birds)*. Alternative C would result in the greatest adverse impact to game birds. Although using produced water to enhance wildlife habitat may beneficially impact some game bird species, Alternative C would result in the greatest adverse impact to game birds from habitat loss in shrubland and grassland communities and potential habitat degradation in riparian/wetland areas.

Waterfowl – Alternative C

Although there are no specific management actions for waterfowl, other biological resource management actions, particularly those pertaining to water and riparian/wetland habitats, would affect these species. Under Alternative C, the BLM would manage all riparian/wetland areas to meet PFC without consideration of wildlife life history requirements. Alternative C would result in a greater impact from concentrated livestock grazing than the other alternatives, because the BLM would place forage supplements to maximize usage without regard for sensitive habitat. Similar to Alternative A, Alternative C uses produced water to develop and enhance waterfowl habitats in accordance with federal, state, and local laws and regulations, which would have beneficial impacts to waterfowl.

Nongame (Raptors) – Alternative C

Under Alternative C, the BLM applies a TLS to avoid disruptive or surface-disturbing activity within ¼ mile of active raptor nests during specific species nesting periods, or until young birds have fledged. The protective buffers around raptor nest sites under Alternative C (47,651 acres) are the smallest and do not prohibit disruptive activities, which would result in the greatest potential adverse impacts to raptors compared to the other alternatives.

Allowing wind-energy projects in raptor concentration areas on a case-by-case basis would result in greater potential adverse impacts from displacement and collisions than alternatives B and D, but less than Alternative A.

Nongame (Migratory Birds) – Alternative C

Alternative C actions pertaining to minerals development and motorized vehicle use restrictions; wind-energy development; forest management; management of sagebrush, grassland, and riparian/wetland habitats; invasive species control; and fire management would result in the greatest impact to nongame migratory birds. Alternative C would result in the greatest short-term adverse impacts to these species from prescribed fire and fuels treatments; however, the risk of catastrophic fire would be smallest under this alternative.

Alternative C does not designate any ACECs specially designed to protect wildlife values, such as migratory bird nesting habitat.

Forest and Woodland Species – Alternative C withdraws the least area in forests and woodlands to locatable mineral development, closes the smallest area to oil and gas development, allows for the most disturbance in forests and woodlands from silviculture and fuels treatments, and permits the largest clear cuts. Under this alternative, the BLM restores forests exposed by wildfire in the shortest time period and retains old-growth forests, but not snags used by migratory birds for nest sites. Refer to Section 4.4.1 *Vegetation – Forests, Woodlands, and Forest Products* and Table 4-21 for a description of management actions and BLM-authorized activities that would impact forests or woodlands and would similarly affect migratory bird habitat in these areas. Overall, forest management practices under Alternative C would result in the greatest short-term impacts from habitat loss, disturbance, and displacement, but the long-term adverse impacts posed by the risk of wildfire are reduced under this alternative.

Mountain Shrub Species – Under Alternative C, the BLM manages mountain shrub communities toward achieving the *Wyoming Standards for Healthy Rangelands* (Appendix N), which would result in less habitat enhancement, compared to the other alternatives, to benefit migratory birds in these areas.

Sagebrush and Desert Shrub Species – Species that utilize or depend on sagebrush habitats would generally benefit from management actions for greater sage-grouse as discussed in Section 4.4.9 *Special Status Species – Wildlife*. Alternative C applies the smallest buffers around greater sage-grouse leks and in nesting or early brood-rearing habitats. Under this alternative, the BLM manages salt desert shrub and basin grassland/shrub communities toward achieving the *Wyoming Standards for Healthy Rangelands*, which would result in less habitat enhancement, compared to the other alternatives, to benefit migratory birds in these areas. Alternative C would result in the most surface disturbance that may result in habitat loss, especially in the 5- to 9-inch precipitation zone, and has the least stringent requirements for reclamation. The associated loss of habitat and potential spread of invasive species would result in the greatest adverse impact to migratory birds that depend on sagebrush and desert shrub communities.

Grassland Species – Actions such as surface-disturbing activities, reclamation, invasive species control, and livestock and wildlife grazing in grassland habitats would affect these species. Under Alternative C, the BLM would manage foothills-mountain grassland/shrub and basin grassland/shrub communities to achieve *Wyoming Standards for Healthy Rangelands*, which would result in the fewest beneficial impacts to migratory birds from habitat enhancement in grassland communities. Focusing livestock grazing practices on commodity production would not likely create heterogeneous vegetative cover to enhance habitat for grassland migratory birds (Derner et al. 2009). Due to its projected long-term

surface disturbance and reclamation requirements, Alternative C would result in the most habitat loss and degradation in grasslands compared to the other alternatives.

Riparian/Wetland Species – Under Alternative C, the BLM allows surface-disturbing activities in flood plains and riparian/wetland areas as well as the placement of forage supplements to maximize usage, without regard for habitat degradation. Alternative C does not recommend WSR eligible waterway segments as suitable for inclusion in the NWSRS and, therefore, would not result in additional beneficial impacts to riparian habitat for migratory birds. Based on these management practices and the potential water depletion due to oil and gas development, Alternative C would result in the fewest beneficial impacts to migratory birds that depend on riparian/wetland habitat.

Nongame (Mammals) – Alternative C

Although there are no specific management actions for nongame mammals, other biological resource management actions would affect these species. Nongame mammals are found in a variety of habitats and are affected by management actions in the preferred vegetation type of each species. Impacts to the various vegetation types are described above for nongame migratory birds and are expected to similarly impact nongame mammals.

Generally, the BLM places the least restrictions on surface-disturbing activities and motorized vehicle use to protect cave resources under Alternative C, and manages known caves for recreational opportunities. Activities are allowed in AMLs, creating opportunities for bat disturbance in these areas. The BLM allows motorized vehicle use on designated roads and trails in the Medicine Lodge and Trapper Creek WSAs under Alternative C, increasing human presence and the opportunities for wildlife disturbance in these areas. There are no ACECs designated under Alternative C that would conserve bat habitat. Restrictions on the aerial applications of pesticides would be more than alternatives A and D, but less than Alternative B, with correlated impacts to bat species. Wind-energy development would impact bats similar to migratory birds. Overall, Alternative C would result in the fewest beneficial impacts to bats by protecting cave resources and conserving potential bat habitat.

Nongame (Reptiles and Amphibians) – Alternative C

Based on implementation of management guidelines identified in *Habitat Management Guidelines for Amphibians and Reptiles of the Northwestern U.S. and Canada*, PARC Technical Publication HMG-4 (Pilliod and Wind 2008) on a case-by-case basis, the projected surface disturbance under Alternative C (Appendix T), and the allowance of surface-disturbing activities in riparian/wetland areas, Alternative C would result in the greatest adverse impact to reptiles and amphibians, compared to the other alternatives.

Alternative D

Surface Disturbance – Alternative D

Alternative D would result in similar short- and long-term surface disturbance as Alternative A, with proportional impacts to wildlife from all surface-disturbing activities in various resource programs. To minimize long-term habitat loss from surface disturbance, Alternative D imposes greater erosion prevention measures and reclamation requirements to disturbed areas than Alternative A. Alternative D requires reclamation plans, stipulations, or measures before surface disturbance, the reestablishment of healthy native or DPCs based on pre-disturbance species composition, and the use of temporary protective surface treatments, such as weed-free mulch, to facilitate reclamation. Overall, the projected

surface disturbance under Alternative D is slightly more than under Alternative A, but the impacts to wildlife habitat would be mitigated to a greater extent.

Resource Uses – Alternative D

Alternative D withdraws less area to locatable minerals entry than Alternative A, but closes more area to oil and gas development in sensitive wildlife habitat such as big game crucial winter range (Table 4-22). Therefore, minerals development under Alternative D would result in less adverse impact to wildlife than under alternatives A and C, but more than under Alternative B.

Impacts to wildlife habitat from lands and realty management actions under Alternative D would be similar to those under Alternative A; however, less area is identified for general disposal than alternatives A and C.

Under Alternative D, the BLM would manage more lands as ROW exclusion areas than under Alternative C, of which 9,213 acres are in big game crucial winter range (Table 4-22). ROWs under Alternative D would result in more adverse impacts than under Alternative B, but less than under alternatives A and C, based on the total acreage managed as ROW avoidance or exclusion areas.

Renewable energy development under Alternative D would result in impacts similar to those under Alternative C, although to a lesser extent because the BLM avoids wind-energy projects in big game crucial winter range and raptor concentration areas, and avoids wind-energy development in greater sage-grouse PHMAs subject to specific exception criteria. Renewable energy development under Alternative D would result in more adverse impacts to wildlife habitat than under Alternative B, but less than under alternatives A and C.

Alternative D limits motorized vehicle use to designated roads and trails in more area than alternatives A and C and closes a similar amount of acreage as Alternative A to motorized vehicle use, protecting more wildlife habitat in the Planning Area than these alternatives. Permitting off-road big game retrieval would result in impacts similar to those under Alternative A, but to a lesser extent because off-road travel is limited to 300 feet from established roads. Overall, CTTM under Alternative D would cause more adverse impacts to wildlife than under Alternative B, but less than under alternatives A and C.

Impacts to wildlife from recreational site development and livestock grazing management would be similar to those under Alternative A.

Special Designations – Alternative D

Beneficial impacts to wildlife from special designations under Alternative D would be similar to those under Alternative A, but to a greater extent. Greater minerals development restrictions and ROW stipulations in the Carter Mountain, Five Springs Falls, Little Mountain, and Upper Owl Creek ACECs, and designating the Clarks Fork Canyon and Sheep Mountain ACECs would result in greater protective measures for wildlife habitat than Alternative A. Similar to Alternative C, Alternative D does not recommend WSR eligible waterway segments as suitable for inclusion in the NWSRS, resulting in no additional beneficial impacts to wildlife by preserving riparian habitat.

Resources – Alternative D

Overall, impacts to wildlife from fire and fuels management and forest, woodlands, and forest products management under Alternative D would be similar to those under Alternative A. Allowing larger areas to be clear cut would result in more habitat loss for wildlife species that prefer closed canopies; however, maintaining the structure and composition of old growth stands would benefit wildlife species that use this habitat type, such as the American marten.

Beneficial impacts to wildlife from grassland and shrubland community management under Alternative D would be similar to those under Alternative B, although to a lesser extent. Under Alternative D, the BLM would manage some areas under for a higher plant community state or phase (based on state and transition models in ESDs) on a case-by-case basis where site-specific management objectives determine that a higher plant community state or phase is desirable, resulting in fewer beneficial impact to wildlife habitat than under Alternative B. However, the BLM would treat more area for invasive species than Alternative B, providing greater long-term beneficial impact to wildlife by preventing the spread of invasive species that may degrade wildlife habitat. Livestock flushing practices would result in similar beneficial impacts as those under Alternative A.

The management of riparian/wetland vegetation under Alternative D would result in similar beneficial impacts as those under Alternative C, but to a greater extent. Managing streams with unique recreational or fishery values to obtain DFC may increase habitat values in these areas more than under Alternative C, but additional management would be necessary to ensure that habitat meets life history requirements for various wildlife species. Alternative D applies more stipulations to surface-disturbing activities near riparian/wetland areas than Alternative C, limiting adverse impacts from surface disturbance, and applies an NSO restriction on all wetlands greater than 20 acres, protecting the most wetland habitat compared to the other alternatives. Overall, beneficial impacts to riparian/wetland habitat for wildlife under Alternative D would be greater than under alternatives A and C, but less than under Alternative B.

Proactive Management – Alternative D

Proactive management measures that would benefit wildlife are described in detail below. Similar to Alternative A, the BLM modifies identified hazard fences in accordance with wildlife needs, prohibits domestic sheep grazing on pronghorn crucial winter range unless adverse impacts can be mitigated, and addresses traditional migration and travel corridors for big game wildlife species and migratory birds on a case-by-case basis under Alternative D. However, Alternative D also requires the use of recent policy and guidance to identify hazard fences and prohibits surface-disturbing activities within 0.5 mile of big game migration corridors in the Big Horn Front MLP Analysis Area, which could increase beneficial impacts to wildlife relative to Alternative A. Similar to Alternative B, the BLM pursues land tenure adjustment authorities for the acquisition of, and interest in, lands for the improved management of important wildlife habitat and applies minerals development restrictions, although to a lesser extent, in the Absaroka Front Management Area. Similar to Alternative C, the BLM performs habitat enhancement vegetation treatments in sagebrush communities as opportunities and funding allow, consistent with Wyoming Governor's EO 2011-5, uses produced water to develop and enhance wildlife habitat, and exempts Oil and Gas Management Areas from discretionary wildlife seasonal stipulations. Overall, proactive wildlife management actions under Alternative D would result in greater beneficial impacts to wildlife than under alternatives A and C, but less than under Alternative B.

Big Game – Alternative D

Alternative D exempts Oil and Gas Management Areas (190,891 BLM-administered surface acres) from discretionary wildlife seasonal stipulations similarly to Alternative C. However, Alternative D does not exempt ROW corridors from seasonal stipulations and avoids wind-energy projects in big game crucial winter range, raptor concentration areas, and greater sage-grouse PHMAs (subject to exception criteria), resulting in less adverse impacts than Alternative C. Impacts from minerals development and new road construction under Alternative D would be less than those under Alternative A because of the additional restrictions applied to the Absaroka Front (253,112 acres) and Big Horn Front (379,308 acres) MLP analysis areas, which include CSU stipulations that limit the location, timing, and amount of surface

oil and gas-related surface disturbances to protect big game. Within Zone 1 of the Absaroka Front MLP Analysis Area (Map 35), Alternative D requires minimum lease sizes and places limitations on the density and total acreage of oil and gas-related surface disturbance per lease. Areas outside elk crucial winter range require a minimum lease size of 640 acres and a maximum of one oil and gas-related facility that does not exceed 32 acres of surface disturbance per lease, whereas areas inside elk crucial winter range require a minimum lease size of 1,280 acres and a maximum of one oil and gas-related facility that does not exceed 64 acres of surface disturbance per lease. Similar restrictions are applied in Zone 3, with the application of specific CSU and TLS stipulations to protect forest vegetation types and recreation settings for hunting. Although Zone 2 is generally available for oil and gas leasing, it is only offered as 2 parcels requiring a Master Development Plan to minimize impacts to big game. These stipulations would have beneficial impacts on big game that utilize the Absaroka Front MLP Analysis Area, particularly elk, by decreasing the density of roads, well pads, and other infrastructure that cause habitat fragmentation as well as the level of human activity in this area. Areas with higher densities of development and higher frequencies of human activity have been correlated with lower use by elk and mule deer (Sawyer and Nielson 2005; Sawyer et al. 2006).

Alternative D also applies a NSO restriction within ½-mile of big game migration corridors within the Big Horn Front MLP Analysis Area, which would result in similar adverse impacts as Alternative B. The application of CSU and TLS stipulations, minimum lease size requirements (1,280 acres), and limitations on the density (one location per lease) and total acreage of oil and gas-related surface disturbance (64 acres per lease), would result in similar beneficial impacts to big game as described for elk crucial winter range within Zone 1 of the Absaroka Front MLP Analysis Area.

Given the generally low to very low potential for oil and gas development (99 percent of the Absaroka Front area and the entire Big Horn Front area are characterized by low to very low potential) and redundancies with restrictions from the management of other resources and resource uses within these MLP analysis areas, the level of impacts is not anticipated to vary greatly by alternative. Overall, the application of MLPs to the Absaroka Front and Big Horn Front MLP analysis areas could result in more beneficial impacts to big game than under alternatives A and C, which apply less extensive TLS and/or CSU restrictions in big game crucial winter range and migration routes. However, anticipated impacts are likely to be less beneficial than under Alternative B, which closes the entirety of the Absaroka Front MLP Analysis Area to mineral leasing and applies NSO restrictions to big game crucial winter range in the Big Horn Front MLP Analysis Area.

Similar to Alternative B, seasonal wildlife protections discussed above would also apply to project maintenance and operation (including production) activities. Potential adverse impacts from this management would be the same as described under that alternative.

As a result of other resource concerns, 18,450 acres and 28,627 acres of big game crucial winter range are managed as closed or seasonally restricted for motorized travel, respectively. Based on these acreages, impacts to big game from potential disturbance would be second-least under Alternative D. Overall, impacts to big game from motorized vehicle use would be less than under alternatives A and C, but more than under Alternative B.

Special designations under Alternative D would protect more big game crucial winter range than under alternatives A and C, but less than under Alternative B. The BLM designates the Sheep Mountain ACEC and manages the Chapman Bench Management Area with additional resource use restrictions that would benefit big game. Designating the Carter Mountain, Upper Owl Creek, and Little Mountain ACECs would result in similar beneficial impacts to those under Alternative A.

Proactive management actions under Alternative D would result in similar beneficial impacts to big game as under Alternative A, but to a greater extent. The BLM would apply various restrictions and stipulations on minerals development in the Absaroka Front Management Area (130,872 BLM-administered surface acres) that would benefit big game more than alternatives A and C. The BLM avoids wind-energy projects in big game crucial winter range under Alternative D as well, minimizing the potential for disturbance and displacement. Allowing the temporary closures of designated roads in big game crucial winter range would limit adverse impacts to big game due to disturbance from motorized travel.

Trophy Game – Alternative D

Adverse impacts to black bears under Alternative D would be similar to those under Alternative A, but to a greater extent as clear cuts are allowed up to 100 acres. Alternative D places more restrictions on motorized vehicle use in WSAs than alternatives A and C, but less than Alternative B, resulting in proportional adverse impacts to cougars from potential disturbance. Managing lands with wilderness characteristics consistent with other resource objectives would result in similar impacts to alternatives A and C. Based on big game management actions, the beneficial impact to cougars under Alternative D would be less than under Alternative B, but greater than under alternatives A and C.

Furbearing Animals – Alternative D

Based on forest management actions, beneficial impacts to furbearing animals under Alternative D would be similar to those under Alternative A, but to a greater extent. Based on projected surface disturbance, reclamation and restoration practices, and vegetation management, habitat generalists such as the badger, bobcat, and weasel would be adversely impacted under Alternative D more than under Alternative B, but less than under alternatives A and C. Management actions in old growth stands under Alternative D would benefit the American marten similarly to Alternative B, but restoring aspen stands only when opportunities and funding allow would result in less beneficial impact than alternatives A and B for the American marten and other furbearing mammals in this habitat. Furbearing species most affected by management actions that impact riparian/wetland habitat or water availability (badger, beaver, mink, and muskrat) would be beneficially affected less than under Alternative B, but more than under alternatives A and C.

Predatory Animals – Alternative D

Alternative D actions that would impact different vegetative types in the Planning Area are anticipated to impact habitat generalists such as predatory animals. Motorized vehicle use restrictions and new road development under Alternative D are expected to cause less adverse impacts to predatory animals, such as the coyote and red fox, than under alternatives A and C, but more than under Alternative B.

Small Game – Alternative D

Alternative D actions affecting forests, woodlands, riparian areas, and other habitat types would have proportionate impacts on the habitat generalists like cottontail rabbits, as well as more habitat-specific species, such as the snowshoe hare, red squirrel, and flying squirrel. Precommercial thinning practices under Alternative D would result in similar adverse impacts to snowshoe hare as under Alternative C, with the potential for limited beneficial impacts to this species from aspen restoration, if opportunities and funding allow.

Game Birds – Alternative D

Alternative D would result in less habitat loss and less potential for invasive species spread in shrubland and grassland communities than alternatives A and C (Table 4-21), with correlated impacts to game

birds. Alternative D actions affecting forests, woodlands, riparian areas, and other habitat types would have proportionate impacts on other game birds, such as the ruffed grouse, blue grouse, wild turkey, and pheasant that prefer these habitat types. Impacts to these habitats are discussed below under *Nongame (Migratory Birds)*. Using produced water to develop and enhance wildlife habitat may beneficially impact some game bird species if the created habitat is suitable.

Waterfowl – Alternative D

Although there are no specific management actions for waterfowl, other biological resource management actions, particularly those pertaining to water and riparian/wetland habitats, would affect these species. Riparian/wetland management actions under Alternative D would result in less beneficial impacts to waterfowl than under alternatives A and B, but more than under Alternative C. Prohibiting forage supplements within ¼ mile of water, wetlands, or riparian areas and applying an NSO restriction to wetland areas larger than 20 acres would result in beneficial impacts similar to Alternative B, but to a greater extent. Special designations under Alternative D, including the Sheep Mountain ACEC, would restrict resource uses and activities, conserving migratory bird habitat. Using produced water to develop and enhance wildlife habitat may beneficially affect some game bird species if water quality is not impacted and the created habitat is suitable.

Nongame (Raptors) – Alternative D

Alternative D would result in more adverse impacts to raptors than Alternative B, but less than alternatives A and C. Although Alternative D seasonally protects less area (47,561 acres) around active raptor nests than Alternative A, it applies a year-round CSU stipulation to protect raptor nest sites and avoids wind-energy development in raptor concentration areas.

Nongame (Migratory Birds) – Alternative D

Alternative D management actions pertaining to minerals development and motorized vehicle use restrictions, wind-energy development, vegetation management, invasive species control, fire and fuels management, and special designations would result in more beneficial impacts to migratory birds than alternatives A and C, but less than Alternative B. The Chapman Bench Management Area and Sheep Mountain ACEC, designated under Alternative D, would conserve migratory bird nesting habitat.

Forest and Woodland Species – Management actions in forest and woodland habitat under Alternative D are similar to those under Alternative A and would, therefore, result in impacts to forest and woodland migratory bird species similar to Alternative A. Alternative D closes more area in forests and woodlands to minerals development than alternatives A and C, but less than Alternative B. Protecting old growth stands and leaving appropriate levels of snag retention to be used by migratory birds as nest sites would result in similar beneficial impacts to those under Alternative B. Alternative D allows larger clear-cuts than Alternative A, which would result in a greater beneficial impact for migratory bird species preferring open habitat but may reduce the reproductive success of some migratory bird species (Thompson III et al. 1993).

Mountain Shrub Species – Under Alternative D, potentially managing some mountain shrub communities for a higher plant community state or phase (based on state and transition models in ESDs) where site-specific management objectives determine that a higher plant community state or phase is desirable would result in similar beneficial impacts, although to a lesser extent, than under Alternative B. Designating the Sheep Mountain ACEC would restrict resource uses and activities that may disturb or displace migratory birds, benefitting mountain shrub species in this area.

Sagebrush and Desert Shrub Species – Species that utilize or depend on sagebrush habitats would generally benefit from management actions for greater sage-grouse as discussed in Section 4.4.9 *Special Status Species – Wildlife*. Alternative D applies more resource use and activity restrictions in greater sage-grouse habitat than alternatives A and C, with proportional limitations in adverse impacts to migratory birds in sagebrush habitat. Based on the restrictions on minerals development in sagebrush and desert shrub habitat (Table 4-21) and the reclamation requirements under Alternative D, this alternative is likely to result in fewer adverse impacts to migratory birds in these habitats than under alternatives A and C, but more than under Alternative B.

Grassland Species – Based on projected surface disturbance and management actions to restrict resource uses and activities in grassland habitat, vegetation management actions, reclamation practices, invasive species control, and livestock grazing management, Alternative D would result in less habitat loss and degradation in grasslands than alternatives A and C, but more than Alternative B, affecting migratory birds proportionately. Allowing livestock grazing in areas closed to grazing as a tool to maintain or improve resource conditions may beneficially impact migratory birds in these areas, if grazing practices create vegetation heterogeneity to benefit these species (Derner et al. 2009).

Riparian/Wetland Species – Vegetation management practices and the management of WSR eligible waterways under Alternative D would result in similar impacts to migratory birds as those under Alternative C, but migratory birds may benefit more from managing certain riparian areas to obtain DFC and prohibiting livestock forage supplements within riparian/wetland areas. Alternative D would also restrict surface-disturbing activities in more wetland areas. Overall, Alternative D would result in more adverse impacts to migratory birds in riparian/wetland habitat than Alternative B, but less than alternatives A and C.

Nongame (Mammals) – Alternative D

Although there are no specific management actions for nongame mammals, other biological resource management actions would affect these species. Nongame mammals are found in a variety of habitats and are affected by management actions in the preferred vegetation type of each species. Impacts to the various vegetation types are described above for nongame migratory birds and are expected to similarly impact nongame mammals. Special designations and restrictions around AMLs under Alternative D would result in similar beneficial impacts to bat species as Alternative B, although to a lesser extent. However, Alternative D proactively minimizes the potential for adverse impacts to bat species from White Nose Syndrome by implementing the decontamination protocol under BLM IM 2010-181 or the National White Nose Syndrome protocol. Adverse impacts from aerial pesticide application would be similar to Alternative A. Wind-energy development would affect bats similar to migratory birds.

Nongame (Reptiles and Amphibians) – Alternative D

Impacts to reptiles and amphibians under Alternative D would be similar to those under Alternative C, although to a lesser extent. Greater surface-disturbance restrictions in riparian/wetland areas than under Alternative C, avoiding reservoir work during amphibian mating and metamorphosis periods, and retaining riparian vegetation to benefit habitat values when cleaning or removing sediment from reservoirs would limit adverse impacts to reptiles and amphibians.

Alternative E

Surface Disturbance – Alternative E

Alternative E would result in approximately 71,829 acres of short-term surface disturbance that may degrade wildlife habitat and 10,676 acres of long-term surface disturbance that may result in habitat loss (Table 4-1), the least of any alternative. Management practices relating to surface disturbance would be the same as Alternative B, except for areas within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). In this ACEC, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) to not exceed one disturbance per 640 acres and cover less than 3 percent of the greater sage-grouse Key Habitat Areas, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. When compared to the other alternatives, the potential for short- and long-term adverse impacts to wildlife would be the least for the surface-disturbing activities of Alternative E.

Resource Uses – Alternative E

Compared to the other alternatives, the restrictions on surface disturbance and conservation measures of Alternative E would provide the greatest protection of wildlife by limiting minerals development and disposal on the largest acreage. Management for resource uses would be the same as Alternative B, except for the Greater Sage-Grouse Key Habitat Areas ACEC, which is closed to mineral materials disposal and withdrawn from mineral entry under Alternative E. Retention of all lands within the proposed Greater Sage-Grouse Key Habitat Areas ACEC would result in beneficial impacts to wildlife by allowing for mitigation or restrictions for surface-disturbing and disruptive activities to maintain high value habitat. Alternative E identifies 24,042 acres for disposal, the same as Alternative B, but fewer acres than alternatives D and F, A, and C, respectively.

ROW management under Alternative E would result in the fewest adverse impacts to wildlife, relative to the other alternatives. Under Alternative E, the BLM would manage more land as ROW exclusion areas (1,322,879 acres) than any other alternatives, including 1,232,583 acres in greater sage-grouse Key Habitat Areas (Table 4-22). In comparison to Alternative B, the additional ROW exclusion areas identified under this alternative would result in a lower risk of raptor electrocutions and greater consolidation of ROWs that would cause less habitat fragmentation. Alternative E also identifies the most acres as renewable energy exclusion areas (1,954,204 acres) in comparison to the other alternatives, which would further reduce habitat fragmentation and loss, as well as collision hazards for avian species.

Management for other resource uses outside of the Greater Sage Grouse Key Habitat Areas ACEC and associated impacts to wildlife would be the same as Alternative B. Alternative E requires that Special Recreation Permits in the proposed Greater Sage-Grouse Key Habitat Areas ACEC have neutral or beneficial effects to sage-grouse habitat, which would reduce the potential for disruptive activities in these areas.

Special Designations – Alternative E

The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative E would result in additional protections for wildlife in comparison to the other alternatives. Specifically, the closure of the proposed Greater Sage-Grouse Key Habitat Areas ACEC to mineral materials disposal, renewable energy development, ROW development, and withdrawal from locatable mineral entry would result in the greatest beneficial impacts to wildlife compared to the other alternatives. Other impacts to wildlife from special designations outside of the Greater Sage-Grouse Key Habitat Areas ACEC would be same as Alternative B.

Resources – Alternative E

The BLM would use similar wildland fire and other vegetation treatments to restore fire-adapted ecosystems and to reduce hazardous fuels as under Alternative B; however, treatments would be designed and implemented with a greater emphasis on protection of sagebrush ecosystems within the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Therefore, management actions within these areas are likely to be more beneficial for sagebrush obligate species as well as other wildlife, such as pronghorn, that rely on sagebrush steppe communities for habitat. Similar beneficial impacts to these species would result from habitat restoration and invasive species management actions, which also emphasize sage-grouse habitat objectives within the proposed Greater Sage-Grouse Key Habitat Areas ACEC.

Impacts to wildlife resulting from management actions for resource protection outside the Greater Sage-Grouse Key Habitat Areas ACEC would be same as Alternative B. In areas where the proposed ACEC overlaps forest and woodland areas, adverse impacts resulting from forest management actions may be reduced due to the greater limitations on surface disturbance.

Proactive Management – Alternative E

Wildlife management under Alternative E is generally the same as Alternative B, and the beneficial impacts would be the same as Alternative B. However, areas in the Greater Sage-Grouse Key Habitat Areas ACEC would provide the greatest benefits to sage-grouse and other species that use sagebrush habitat compared to the other alternatives.

Big Game – Alternative E

Impacts to big game would be the same as Alternative B, except to a lesser extent where big game crucial winter range overlaps the proposed Greater Sage-Grouse Key Habitat Areas ACEC due to additional constraints on resource uses that create surface disturbance in these areas. Alternative E withdraws the greatest area in big game crucial winter range to locatable minerals development (652,927 acres) and would result in the least surface disturbance in comparison to the other alternatives, and would therefore result in the least adverse impacts to big game. Designation of the proposed Greater Sage-Grouse Key Habitat Areas ACEC excludes renewable energy and ROW development over greater areas of big game crucial winter range than the other alternatives (Table 4-22).

Alternative E would designate the most acres of ACEC that overlap big game crucial winter range (665,963 acres), resulting in more beneficial impacts than any other alternative.

Management of invasive species and fire and fuels under Alternative E would result in more beneficial impacts to big game species in the short term from reduced surface-disturbing and disruptive fuels treatments in the Greater Sage-Grouse Key Habitat Areas ACEC, but may potentially result in adverse long-term impacts from more intense wildfires and reduced ability to treat invasive species due to restrictions on fuel management and herbicide use.

As a result of these additional restrictions on resources uses within the proposed Greater Sage-Grouse Key Habitat Areas ACEC, Alternative E would result in the least adverse impact to big game of any alternative.

Trophy Game – Alternative E

Black bears are most affected by management actions in forest and woodland habitats. Alternative E would designate the most acres of ACEC that overlap forest and woodland habitats (129,888 acres),

Fish and Wildlife Resources – Wildlife

resulting in less adverse impacts than any other alternative. Limitations on surface disturbance and disruptive activities within the Greater Sage-Grouse Key Habitat Areas ACEC would result in less adverse impacts where black bear habitat is overlapped by the ACEC.

Other impacts to trophy game outside of the Greater Sage-Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Furbearing Animals – Alternative E

Impacts to furbearing animals would be the same as Alternative B, but with fewer adverse impacts in areas where the proposed Greater Sage-Grouse Key Habitat Areas ACEC overlaps the habitats of furbearing animals due to greater limitations on surface disturbance and disruptive activities in these areas compared to other alternatives. Alternative E would designate the most acres of ACECs that overlap forest and woodland habitats (129,888 acres) and riparian/wetland areas (11,040 acres), which would benefit the American marten and furbearing mammal species that use riparian/wetland habitats (i.e., badger, beaver, mink, and muskrat). Other impacts to furbearing animals outside of the Greater Sage-Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Predatory Animals – Alternative E

Impacts to predatory animals would be the same as Alternative B, but with fewer adverse impacts due to limitations on surface disturbance and disruptive activities within the Greater Sage-Grouse Key Habitat Areas ACEC, which covers 1,232,583 acres and overlaps various habitats used by predatory animals, which are typically habitat generalists. Other impacts to predatory animals outside of the Greater Sage-Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Small Game – Alternative E

Impacts to small game animals would be the same as Alternative B, but with fewer adverse impacts where the Greater Sage-Grouse Key Habitat Areas ACEC overlaps forests, woodlands, riparian/wetland areas, and other habitat types used by small game habitat generalists due to additional limitations on surface disturbance and disruptive activities.

Game Birds – Alternative E

Alternative E would designate the most acres as ACECs (1,438,802 acres), which would benefit habitats used by game birds throughout the Planning Area. Under Alternative E, management actions to reduce surface disturbance and control invasive species spread in shrub and grassland communities through special designations would provide the greatest benefit to greater sage-grouse, chukar, and gray partridge, compared to the other alternatives. Impacts to small game birds outside the Greater Sage-Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Waterfowl – Alternative E

Alternative E would designate the most acres of ACECs that overlap riparian/wetland areas (11,040 acres), which would result in fewer impacts to waterfowl due to greater restrictions on surface disturbance and disruptive activities when compared to the other alternatives. Impacts to waterfowl outside of the Greater Sage-Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Nongame (Raptors) – Alternative E

Protective buffers around raptor nest sites would be the same as Alternative B, which would minimize adverse impacts to raptors more than any other alternative. However, Alternative E would exclude wind

energy from the largest area (1,945,204 acres), which would minimize the potential for collision mortality and displacement to the greatest extent among the alternatives.

Nongame (Migratory Birds) – Alternative E

Impacts to migratory birds would be the same as Alternative B across much of the Planning Area, except in areas overlapped by the proposed Greater Sage-Grouse Key Habitat Areas ACEC. In the Greater Sage-Grouse Key Habitat Areas ACEC, additional limitations on surface disturbance and disruptive activities, as well as management that protects and restores sagebrush habitat, would provide additional beneficial impacts to migratory birds. Beneficial impacts from ACECs designated under Alternative E would affect the greatest proportion of habitats used by migratory birds when compared to the other alternatives, as indicated by the following acres of overlap with ACECs:

- Forests and woodlands – 129,888 acres
- Grasslands – 10,112 acres
- Nonnative annual brome – 23,950 acres
- Riparian – 11,040 acres
- Sagebrush – 900,827 acres
- Salt desert – 329,465 acres

Nongame (Mammals) – Alternative E

Impacts to nongame mammals would be similar to those discussed for migratory birds above, as they are found in a variety of habitats and are affected by management actions in the preferred vegetation type of each species.

Alternative E would exclude wind-energy development from more acres throughout the Planning Area than any other alternative (1,954,204 acres), which would result in the least collision hazards for bats. All other impacts to nongame mammals would be consistent with Alternative B.

Nongame (Reptiles and Amphibians) – Alternative E

Alternative E would result in the least surface disturbance of any alternative, and would therefore result in the least adverse impacts to reptiles and amphibians. Alternative E would therefore result in less adverse impacts to reptiles and amphibians than Alternative A, and similar impacts to Alternative B, but to a lesser degree.

Alternative F

Surface Disturbance – Alternative F

Alternative F would result in 137,064 acres of short-term and 17,663 acres of long-term surface disturbance. Impacts to wildlife from surface disturbance under Alternative F are projected to be greater than under alternatives A, B, and E, but less than under alternatives C and D. Management practices relating to surface disturbance would be the same as Alternative D, except within areas of the proposed Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). Additional restrictive management actions, including greater erosion prevention measures and reclamation requirements provided in a larger area under Alternative F, mitigate impacts to wildlife habitat to a greater extent than alternatives A and D.

Resource Uses – Alternative F

Resource uses under Alternative F would result in fewer adverse impacts to wildlife habitat than Alternative D and slightly greater adverse impacts than Alternative A. This alternative closes more federal mineral estate to oil and gas leasing than alternatives A and D. Similar to Alternative D, this alternative applies a NSO stipulation within 0.6 mile of occupied sage-grouse leks within greater sage-grouse PHMAs. However, Alternative F limits surface disturbances to one per 640 acres and 3 percent or less of the Wyoming Density and Disturbance Calculation Tool (DDCT) analysis area, compared to 5 percent under Alternative D. As a result, Alternative F is anticipated to develop fewer new federal wells than alternatives A, C, and D, but more than alternatives B and E with proportional adverse impacts to wildlife.

Alternative F would require seasonal restrictions on construction of aboveground powerlines or the use of buried powerlines in the proposed Greater Sage-Grouse PHMAs ACEC, which would reduce adverse impacts on wildlife. Alternative F would also limit motorized vehicle use to designated roads and trails and exclude renewable energy development over a greater area than Alternative D, resulting in less adverse impacts than alternatives A, C, and D, but more than alternatives B and E.

Impacts to wildlife from resource uses outside the proposed Greater Sage-Grouse PHMAs ACEC would be the same as Alternative D. Similar to Alternative E, Alternative F requires that Special Recreation Permits in the proposed Greater Sage-Grouse PHMAs ACEC have neutral or beneficial effects to sage-grouse habitat, which would reduce the potential for disruptive activities in these areas.

Special Designations – Alternative F

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative F would result in greater protection for wildlife habitat than alternatives A, C, and D, but fewer than under alternatives B and E.

Resources – Alternative F

Impacts to wildlife from management actions to protect resources would be generally the same as Alternative D; however, the BLM would apply specific management actions for habitat restoration, invasive species management, and fire and fuels management that prioritize the protection of greater sage-grouse populations and habitat in the proposed Greater Sage-Grouse PHMAs ACEC. Therefore, management actions within these areas are likely to be more beneficial for sage-grouse and other sagebrush obligate species than under Alternative D.

Proactive Management – Alternative F

Wildlife management under Alternative F is generally the same as Alternative D, and the beneficial impacts to wildlife would be the same as Alternative D. However, areas in the Greater Sage-Grouse PHMAs ACEC would provide greater benefits to sage-grouse and other species that use sagebrush habitat than alternatives A, C, and D, but less than alternatives B and E.

Big Game – Alternative F

Impacts to big game would be similar to Alternative D, but with fewer adverse impacts where the proposed Greater Sage-Grouse PHMAs ACEC overlaps big game crucial winter range areas due to additional constraints on resource uses in these areas. Specifically, Alternative F places greater limitations on ROW development, renewable energy, and motor vehicle use in greater sage-grouse

PHMAs. In areas where the Greater Sage-Grouse PHMAs ACEC overlaps Oil and Gas Management Areas, the ACEC management would apply, resulting in fewer impacts to big game under Alternative F than alternatives A, C, and D.

ACECs designated under Alternative F would protect 634,085 acres of big game crucial winter range, which is more than under alternatives A, C, and D, but less than alternatives B and E. Like Alternative D, Alternative F applies additional restrictions to the Absaroka Front (253,112) and Big Horn Front (379,308) MLP analysis areas, including CSU stipulations that limit the location, timing, and amount of surface oil and gas-related surface disturbances to protect big game.

Other impacts to big game outside of the Greater Sage-Grouse PHMAs ACEC would be the same as Alternative D.

Trophy Game – Alternative F

Black bears are most affected by management actions in forest and woodland habitats. Alternative F would designate the second-most acres of ACEC that overlap forest and woodland habitats (107,354 acres), resulting in fewer adverse impacts to black bears than alternatives A, B, C, and D. Alternative F would limit motorized vehicles to designated roads and trails on a total of 1,820,427 acres, resulting in fewer potential adverse impacts to cougars than under alternatives A, C, and D, but greater than under alternatives B and E.

Other impacts to trophy game would be the same as Alternative D.

Furbearing Animals – Alternative F

Impacts to furbearing animals would be the same as Alternative B, but with fewer adverse impacts in areas where the proposed Greater Sage-Grouse PHMAs ACEC overlaps the habitats of furbearing animals due to additional limitations on surface disturbance and disruptive activities in these areas. Based on projected surface disturbance, reclamation and restoration practices, and vegetation management, habitat generalists such as the badger, bobcat, and weasel would be adversely impacted under Alternative F more than under alternatives B and E, less than under alternatives A and C, and similar to Alternative D. Alternative F would designate the most second-most acres of ACECs that overlap forest and woodland habitats (107,354 acres) and riparian/wetland areas (8,497 acres), which would benefit the American marten and furbearing mammal species that use riparian/wetland habitats (i.e., badger, beaver, mink, and muskrat). Other impacts to furbearing animals would be the same as Alternative D.

Predatory Animals – Alternative F

Impacts to predatory animals under Alternative F would be the same as Alternative D except in areas where the Greater Sage-Grouse PHMAs ACEC overlaps various habitats used by predatory animals due to additional motorized vehicle use restrictions and projected new road development under Alternative F. Therefore, Alternative F would result in fewer adverse impacts to predatory animals than alternatives A, C, and D, but more than under alternatives B and E.

Small Game – Alternative F

Impacts to small game animals would be similar to Alternative D, but with fewer adverse impacts due to limitations on surface disturbance and disruptive activities where the proposed Greater Sage-Grouse PHMAs ACEC overlaps forests, woodlands, riparian/wetland areas, and other habitat types used by small game habitat generalists. Other impacts to small game outside greater sage-grouse PHMAs would be the same as Alternative D.

Game Birds – Alternative F

Alternative F would result in less habitat loss and less potential for invasive species spread in shrubland and grassland communities than alternatives A, C, and D (Table 4-22), with correlated impacts to game birds. Impacts to game birds would be similar to Alternative D, but with less adverse impacts due to limitations on surface disturbance and disruptive activities where the proposed Greater Sage-Grouse PHMAs ACEC overlaps forests, woodlands, riparian/wetland areas, and other habitat types.

Proportionate impacts would occur on other game birds, such as the ruffed grouse, blue grouse, wild turkey, and pheasant that prefer these habitat types. Impacts to these habitats are discussed below under *Nongame (Migratory Birds)*. Impacts to game birds outside the Greater Sage-Grouse PHMAs ACEC would be the same as Alternative D.

Waterfowl – Alternative F

Impacts to waterfowl would be similar to Alternative D, but with fewer adverse impacts in areas where the proposed Greater Sage-Grouse PHMAs ACEC overlaps riparian/wetland areas. ACECs under Alternative F would overlap the second-most acres of riparian/wetland areas (8,497 acres), which would result in fewer adverse impacts to waterfowl due to greater restrictions on surface disturbance and disruptive activities. Other impacts to waterfowl would be the same as Alternative D.

Nongame (Raptors) – Alternative F

Under Alternative F, impacts to raptors would be the same as Alternative D, except in areas where the proposed Greater Sage-Grouse PHMAs ACEC overlaps habitat used by raptors. In addition to providing a protective buffer around nesting sites, Alternative F would implement additional restrictions on surface disturbance in the Greater Sage-Grouse PHMAs ACEC and would provide more beneficial impacts to raptors than alternatives A, C, and D, but less than alternatives B and E.

Nongame (Migratory Birds) – Alternative F

Impacts to migratory birds would be the same as Alternative D, except in areas overlapped by the proposed Greater Sage-Grouse PHMAs ACEC. Additional limitations on surface disturbance and disruptive activities, including motorized vehicle use, as well as management that protects and restores sagebrush habitat, would provide additional beneficial impacts to migratory birds when compared to Alternative D. Beneficial impacts from the designation of this ACEC would be similar to Alternative D, but to a lesser degree due to the fewer restrictions and protective management actions implemented under Alternative F.

Beneficial impacts from ACECs designated under Alternative F would be the greatest in the following habitats used by migratory birds proportionally, as indicated by the following acres of overlap:

- Forests and woodlands – 107,354 acres
- Grasslands – 11,830 acres
- Nonnative annual brome – 33,714 acres
- Riparian – 8,497 acres
- Sagebrush – 809,728 acres
- Salt desert – 200,131 acres

Nongame (Mammals) – Alternative F

Impacts to nongame mammals would be similar to those discussed for migratory birds above, as they are found in a variety of habitats and are affected by management actions in the preferred vegetation type of each species. Other impacts to nongame mammals would be same as Alternative D.

Nongame (Reptiles and Amphibians) – Alternative F

Impacts to reptiles and amphibians under Alternative F would be similar to alternatives C and D, although to a lesser extent due to limitation on surface disturbance and disruptive activities in areas where the proposed Greater Sage-Grouse PHMAs ACEC overlaps riparian/wetland areas. Impacts to reptiles and amphibians in areas outside the Greater Sage-Grouse PHMAs ACEC would be consistent with Alternative D.

Special Status Species

4.4.7 Special Status Species – Plants

Adverse impacts are those that contribute to the decline in abundance or distribution of BLM special status plant species. Beneficial impacts to BLM special status plant species consist of activities that protect habitat or reduce the risk of harm to these species. An increase in BLM special status plant species numbers over time in response to an enhanced habitat or the increased viability of species is considered a beneficial impact.

For this analysis, direct impacts to BLM special status plant species are those actions resulting in damage to or loss of individual BLM special status plants, fragmentation of habitat, loss of habitat quality, loss of pollinators, and loss of soil seed banks. Direct impacts may result from surface-disturbing activities, trampling, herbivory, fire, and herbicide application. Indirect impacts to BLM special status plant species are those actions that aid or compromise the protection of these species. There may be indirect impacts to potential habitats for BLM special status plant species when actions change the habitats in a way that make them unsuitable for future colonization.

For this analysis, short-term impacts to BLM special status plant species include those activities that contribute to the decline in abundance or distribution of a species within 5 years of when the activity occurs. Long-term impacts to BLM special status plants take more than 5 years to manifest on the surface.

The Final Biological Assessment that accompanies this document can be viewed on the Bighorn Basin RMP Revision Project website (<http://www.blm.gov/wy/st/en/programs/Planning/rmps/bighorn.html>) provides additional analysis of potential impacts to Ute ladies'-tresses (a threatened species under the ESA) under the proposed alternatives.

4.4.7.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Where resources overlap, management actions associated with protecting wildlife habitats and cultural resources directly benefit BLM special status plant species.
- Unless specifically designed to enhance BLM special status plant species habitat, surface-disturbing activities or invasive species treatments in BLM special status plant habitat would adversely affect BLM special status plant species.

- As more monitoring and survey data become available, it is possible that additional populations of existing BLM special status plants and unique plant communities might be found.
- The total amount of new surface disturbance allowed by an alternative is an index of potential impacts to BLM special status plants. Success of reclamation measures prescribed as a condition of development is unknown, and could either overestimate or underestimate the potential impact of surface disturbance on BLM special status plant populations.
- The existing provisions in place to protect BLM special status plant species populations are carried out and conditional monitoring is performed (e.g., grazing and surface disturbance reclamation) to ensure BLM special status plant species populations are not jeopardized.
- Management actions that preclude or restrict development, including those not specifically aimed at conserving BLM special status plant species, are assumed to benefit BLM special status plant species where populations overlap with management action boundaries.
- Because the densities and locations of BLM special status plant species in the Planning Area are not entirely known and because the locations of potential actions under the different alternatives also are not known, impact analyses are based on the amount of vegetation and soil disturbed, the threats identified for BLM special status plant species in Chapter 3, and the level of restrictions placed on BLM actions that could adversely impact BLM special status plant species.
- Consultation with the USFWS and following conservation measures identified in the BA for all listed and sensitive species for the BLM *Final Vegetation Treatments Using Herbicides on Bureau of Land Management Lands in 17 Western States Programmatic EIS* (BLM 2007b) are anticipated to mitigate most impacts to BLM special status plant species.
- Actions that reduce the threat of establishment or spread of invasive species directly benefit BLM special status plant species. IM 2006-073 (BLM 2006c) establishes policy and guidance for use of certified weed-free seed and mulch in restoration projects on public lands.

4.4.7.2 Summary of Impacts by Alternative

The principal adverse impacts to BLM special status plant species result from management that increases surface disturbance and habitat fragmentation; the principal beneficial impacts include management that increases restrictions in known or potential BLM special status plant species habitat. Based on the acreage of surface disturbance, the potential for habitat fragmentation, and proactive management actions and special designations to protect BLM special status plant species, alternatives with the least to most potential adverse impacts to BLM special status plant species are alternatives E, B, F, D, A, and C. Alternative E would result in the least surface disturbance and habitat fragmentation, followed by alternatives B, A, F, D, and C. However, alternatives D and F contain management actions to minimize habitat fragmentation that alternatives A and C do not contain. Alternatives B and E include the most provisions to protect sensitive soils and riparian/wetland areas for the benefit of BLM special status plants, followed by alternatives D and F, A, and C. Restrictions on motorized vehicle use, especially restricting motorized cross-country travel, would reduce adverse impacts to BLM special status plant species the most under Alternative E, followed by alternatives B, F, D, A, and C.

4.4.7.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Various surface-disturbing activities, including mineral exploration and development and the associated roads, ROWs, and corridors, can directly affect individuals, populations, and habitats for BLM special status plant species. Recreational use, collection of plants, fire, as well as livestock, wild horse, and native ungulate grazing may remove or trample vegetation and disturb soil, resulting in adverse impacts to BLM special status plant species. Surface-disturbing activities also can indirectly affect BLM special status plant species by contributing to soil erosion and transporting invasive species into BLM special status plant species habitats. The spread of invasive species could adversely affect BLM special status plants due to the limited size and distribution of these sensitive plants. Surface disturbance also can result in habitat fragmentation, which can isolate populations of BLM special status plant species. Populations of BLM special status plant species typically have a patchy distribution across the landscape, and eliminating one or more populations can prevent gene flow among populations if residual populations are too far apart for sufficient cross-pollination. Habitat fragmentation would be a long-term impact to BLM special status plant species. Implementing the *Wyoming Mitigation Guidelines for Surface-disturbing and Disruptive Activities* (Appendix H) and the *Wyoming BLM Reclamation Policy* (BLM 2012b) minimizes adverse impacts from surface disturbance.

Several BLM special status plant species (e.g., Shoshonea, Absaroka beardstongue, Evert's waferparsnip, Wyoming tansymustard, limber pine, whitebark pine) occur in inaccessible areas, rugged terrain, or on unstable slopes in the Planning Area. As a result, there are fewer threats to these species and the anticipated adverse impacts from surface-disturbing activities are minimal. Management actions that restrict surface disturbance on unstable slopes would result in beneficial impacts to these species. For BLM special status plant species in riparian/wetland areas (e.g., Ute ladies'-tresses, persistent sepal yellowcress), management actions that limit activity in these areas are anticipated to benefit these species by reducing direct impacts from trampling, mining, and recreational activities. Meeting PFC across all alternatives improves habitat for Ute ladies'-tresses and persistent sepal yellowcress.

Livestock grazing may result in both adverse and beneficial impacts to BLM special status plants depending on grazing intensity, timing/season of grazing, range conditions, and precipitation regimes. Livestock grazing may maintain or create habitat for BLM special status plant species by reducing competition. However, livestock grazing may result in direct mortality through trampling, herbivory, and general site degradation (e.g., soil compaction, erosion). Livestock grazing in areas of Ute ladies'-tresses could benefit this BLM special status plant species as long as grazing occurs outside the flowering period. Adverse impacts to Williams' spring-parsley and Hyattville milkvetch from livestock grazing are not anticipated, as cattle and sheep are not known to graze on these plants. Under all alternatives, adherence to *Wyoming Standards for Healthy Rangelands* (Appendix N) would help to limit impacts to BLM special status plant species. Potential adverse impacts from wild horse grazing would be limited to HMAs and would be similar under all alternatives as the initial appropriate management level for the HMAs would remain the same.

Travel and transportation management may adversely affect BLM special status plant species if motorized travel is allowed in areas with these species. Motorized vehicle use disturbs soil and removes vegetation resulting in adverse impacts to BLM special status species plant habitat. The generation of dust from motorized vehicle travel on roads next to BLM special status plant species could affect plant development, growth, reproduction and overall population survival if there are only a few individual

Special Status Species – Plants

plants in the area. Invasive species are more likely to spread along trails and roads and may out compete BLM special status plant species.

Management in special designations (e.g., ACECs) ultimately protects special status plant species by avoiding or prohibiting surface-disturbing activities in these areas. These designations may increase the interest, popularity, and use of these areas, resulting in increased potential for disturbance and removal of BLM special status plant species and the spread of invasive species.

Some management actions generally benefit all BLM special status plant species. For example, management to control invasive species may benefit BLM special status plants by reducing competition for available habitat. Management actions that protect erosive soils, riparian areas, and steep slopes are beneficial to most BLM special status plant species. Beneficial impacts are anticipated for BLM special status plant species where protection of visual and cultural resources, fish and wildlife habitat, and vegetation overlap with suitable habitat for these species. Requirements for surveys of BLM special status plant species prior to authorization of surface-disturbing activities would reduce impacts to these species by avoiding populations if they are found. In addition, these surveys may identify new locations of BLM special status plant species, thereby increasing knowledge of these species. The BLM would also consult with stakeholders in the permitting process to design projects in a manner that would minimize or avoid potential adverse effects to BLM special status plant species.

Alternative A

Surface Disturbance

Surface-disturbing activities such as energy and mineral development, road construction, and other mechanized disturbance could cause adverse impacts to known BLM special status species plant populations and potential habitats, and undocumented populations. These activities fragment habitats, potentially isolating populations of BLM special status plants. Reclamation mitigates short-term impacts of surface disturbance by minimizing soil erosion and the establishment of invasive species. However, even with reclamation, surface-disturbing activities can have long-term adverse impacts to BLM special status plants through changes in the plant community structure or encroachment of invasive species. Under Alternative A, BLM actions are projected to result in 136,253 acres of short-term surface disturbance on BLM-administered land and 15,646 acres in the long term over the life of the plan (Table 4-1). Maintenance of healthy soil conditions enhances the viability, vigor, and abundance of BLM special status plant species.

Resource Uses

Assuming exploration and development of minerals will continue in the Planning Area and potentially increase for some minerals, the potential for adverse impacts to special status plants will increase proportionately. Alternative A has the second-most acreage open to oil and gas leasing subject to the terms and conditions of the standard lease form and the second-to-least acreage open with major constraints. Required pre-disturbance surveys, mitigation, and reclamation will minimize impacts from mineral development.

The spread of invasive species may adversely affect special status plant species, which are limited in size and distribution. However, due to management of invasive species, the BLM anticipates that adverse impacts from invasive species would be minimal, with cheatgrass being the species with the most potential to adversely impact special status plant species. Management of invasive species could directly benefit special status plants by eliminating direct competition and maintaining habitat health and diversity. In particular, eradication of invasive species in riparian areas (e.g., Tamarisk, Russian

olive) benefits Ute ladies'-tresses and persistent sepal yellowcress. Under Alternative A, aerial application of pesticides is allowed on a case-by-case basis and livestock flushing is required on a case-by-case basis. Livestock flushing minimizes the transport of invasive species in fecal material onto or within BLM-administered lands.

The development of ROWs may result in habitat fragmentation and degradation resulting in adverse impacts to special status plants. The development and use of linear ROWs can also lead to an increase in the spread of invasive species resulting in adverse impacts to special status plants. ROWs concentrated in a corridor tend to localize or confine disturbance to a smaller area and reduce disturbance in areas identified as sensitive. Under Alternative A the BLM manages 61,147 acres as ROW exclusion areas, limiting adverse impacts.

Motorized vehicle use may adversely affect habitat for special status plants. Alternative A has the greatest acreage limited to existing roads and trails and the second least acreage closed to motorized vehicle use in the Planning Area. Invasive species are more likely to spread to areas with roads and trails used by motorized vehicles. Permitting off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations would result in soil disturbance, vegetation removal, and transport of invasive species. Motorized vehicle use is a threat to Rocky Mountain twinpod, Hyattville milkvetch, and Dubois milkvetch (Mills and Fertig 2000b; Fertig 2001; Fertig 2000a), and is anticipated to indirectly and adversely impact known and unknown populations of special status plant species under Alternative A.

Under Alternative A, the Planning Area is open to livestock grazing, except in areas specifically closed including Bighorn River tracts, campgrounds, and exclosures. While trampling and herbivory from livestock grazing may result in direct adverse impacts to special status plant species, Alternative A manages livestock grazing to protect or enhance other resource values, minimizing adverse impacts. In addition, by instituting a ¼-mile buffer around riparian/wetland areas for placement of salt, mineral, or forage supplements, Alternative A minimizes adverse impacts to Ute ladies'-tresses and persistent sepal yellowcress.

Special Designations

Two existing ACECs that include special status species as their value of concern are Five Springs Falls and Upper Owl Creek, although other ACECs may also include BLM special status plant species. Protecting special status plants in these areas directly benefits the species known to occur there. Management of the Five Springs Falls ACEC and Upper Owl Creek ACEC includes NSO restrictions for leasable minerals, resulting in beneficial impacts to special status plants. While Upper Owl Creek ACEC is open to ROW authorizations, a detailed activity plan must be developed and approved before any surface-disturbing activity in the ACEC, which may minimize adverse impacts to special status plant species.

No WSRs are currently designated in the Planning Area; however, twenty waterways meet the WSR eligibility criteria. Management of these waterways to protect their ORVs and their free-flowing conditions, results in beneficial impacts to Ute ladies'-tresses and persistent sepal yellowcress by minimizing disturbances to riparian/wetland habitat.

Resources

Soil compaction and erosion may result in indirect adverse and long-term impacts to special status plant species. Several special status plant species occur in areas with sparse vegetative cover, on steep slopes, and in rocky areas; therefore, management actions that limit activities in these areas and protect the integrity of the soils in the area, are anticipated to have beneficial impacts to these species.

Special Status Species – Plants

Alternative A does not require reclamation plans, although it reestablishes vegetation cover on disturbed soils within 5 years of initial seeding.

Changes in water management that reduce the periodicity of flooding may impact Ute ladies'-tresses and persistent sepal yellowcress (Heidel 2007, Handley and Heidel 2008). Alternative A encourages the maintenance of natural flow regimes for streams supporting fisheries, but does not require it, which could adversely impact Ute ladies'-tresses and persistent sepal yellowcress.

Wildland fires may affect special status plant species by temporarily removing vegetation, changing plant community composition, and inhibiting plant succession. If special status plants depend on a specific seral stage or associative plants, a wildland fire could upset the ecological balance that supports a sensitive plant's habitat or plant community. Wildland fire also may enhance habitat for special status plants and be a catalyst for their reestablishment and proliferation. Habitat degradation from invasion of Utah juniper due to fire suppression has been identified as a threat to Hyattville milkvetch (Fertig and Welp 2001). Alternative A utilizes wildland fires to restore fire-adapted ecosystems, which could benefit Hyattville milkvetch.

Alternative A manages all riparian/wetland areas to meet or make progress toward meeting PFC, but does not prioritize those not meeting PFC. Under Alternative A, the 500-foot buffer for surface-disturbing activities around riparian/wetland areas would reduce adverse impacts to special status plants in these areas. The buffer reduces the potential for direct removal of special status plants, sedimentation, and the potential for invasive species establishment, which have indirect adverse impacts to special status plant species.

Where restrictions of surface-disturbing activities are implemented for fish and wildlife habitats, special status plant habitats could be improved and adverse impacts to these species minimized. Alternative A institutes a TLS in big game crucial winter range and a CSU stipulation for big game migration corridors, and narrow ridges. Alternative A manages habitat, on a case-by-case basis, for the appropriate DPC based on the presence of special status species, potentially benefitting BLM special status plants in the long term.

Proactive Management

Under Alternative A, proactive management actions implemented include reviewing actions, use authorizations, rangeland improvement projects, invasive species treatments, and fire suppression effects for potential impacts to BLM special status plant species before performing these tasks. For all these tasks, avoidance, minimization and/or compensation measures are implemented on a case-by-case basis. These reviews are anticipated to benefit BLM special status plant species. Alternative A does not identify any buffer around BLM special status plant species for placement of forage supplements; however, mitigations to avoid BLM special status plant species are routinely applied at the site-specific activity level when appropriate.

Alternative B

Surface Disturbance

Under Alternative B, BLM actions are projected to result in 73,940 acres of short-term surface disturbance to BLM-administered land and 10,893 acres of long-term surface disturbance over the life of the plan (Table 4-1). In addition to causing less surface disturbance than Alternative A, Alternative B reduces the potential for habitat fragmentation by maintaining large, contiguous blocks of native plant communities. The restrictions on habitat fragmentation and fewer disturbed acres relative to

Alternative A are anticipated to indirectly benefit BLM special status plant species by protecting potential habitats, minimizing the spread of invasive species, and minimizing soil erosion.

Resource Uses

Under Alternative B, approximately 2,464,754 acres are closed to oil and gas leasing, approximately 9.5 times more acreage than under Alternative A. While required mitigation and reclamation under all alternatives minimizes adverse impacts from mineral development, Alternative B results in fewer adverse impacts to BLM special status plant species than Alternative A due to the greater acreage closed to oil and gas leasing.

Invasive species spread would result in similar potential adverse impacts to those under Alternative A, but to a lesser extent. The BLM treats less acreage to eradicate or control the spread of invasive species under Alternative B; however, this alternative would cause less surface disturbance and the BLM employs greater measures to return disturbed areas to native vegetation communities, leaving less area vulnerable to invasive species establishment. Allowing the aerial application of pesticides within ½ mile of riparian/wetland areas to manage riparian weed species would beneficially impact the Ute ladies'-tresses and persistent sepal yellowcress. Overall, management of invasive species under Alternative B would have less adverse impacts to BLM special status plant species, compared to Alternative A.

Alternative B designates more area (225,447 acres) as exclusion areas for ROWs and corridors resulting in more beneficial impacts to BLM special status plants than Alternative A by minimizing habitat fragmentation and degradation.

Under Alternative B, adverse impacts to BLM special status plant species from motorized vehicle use are anticipated to be less than Alternative A because Alternative B has more acreage closed to motorized vehicle use, less acreage limited to existing roads and trails, and more acreage limited to designated roads and trails. Prohibiting off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations would also reduce the impacts from this action described under Alternative B. The anticipated soil disturbance, vegetation removal, and transport of invasive species under Alternative B are expected to produce less indirect and adverse impacts to unknown populations of BLM special status plant species compared to Alternative A.

Livestock grazing is more limited under Alternative B than under Alternative A, as approximately 270,834 acres of crucial winter range for elk and bighorn sheep and 1,229,612 acres of greater sage-grouse Key Habitat Areas are closed to livestock grazing. Closing more acres to livestock grazing would result in less potential adverse impact to BLM special status plant species from trampling and herbivory. Additionally, Alternative B prohibits forage supplements within ½ mile of BLM special status plant species populations to minimize adverse impacts from livestock grazing. Expanding the McCullough Peaks HMA boundary may increase the extent of adverse impacts from wild horse grazing, but maintaining the initial appropriate management level for wild horses would not change the intensity of impacts. Alternative B would result in greater beneficial impacts to Ute ladies'-tresses and persistent sepal yellowcress than Alternative A because of the larger buffer around riparian/wetland areas with respect to placement of forage supplements. In addition, Alternative B places more emphasis on meeting the rangeland health standards and maximizing multiple use benefits. More effective monitoring, management, and implementation of some grazing systems may benefit BLM special status plant species under Alternative B.

Special Designations

In addition to carrying forward the Five Springs Falls and Upper Owl Creek ACECs that emphasize protection of BLM special status plant species, Alternative B expands the existing Upper Owl Creek,

Special Status Species – Plants

Carter Mountain, and Little Mountain ACECs, and proposes designating Clarks Fork Canyon, Rattlesnake Mountain, and Sheep Mountain ACECs, all of which support BLM special status plant populations. Other ACECs under Alternative B may include BLM special status plant species as well. Designating these additional ACECs minimizes adverse impacts to the BLM special status plant populations within the boundaries of the ACECs because managing these areas helps protect these populations. This alternative provides more opportunities to maintain BLM special status plant habitats in special designations.

Alternative B manages 20 waterways as suitable for inclusion in the NWSRS, which includes approximately 27,317 acres in the Planning Area. This alternative prohibits surface-disturbing activities on BLM-administered lands in the WSR suitable waterways, withdraws the segments from appropriation under the mining laws, closes the areas to geophysical exploration, and manages the segments as ROW exclusion areas. This type of management protects the values of the segments more than under Alternative A; therefore, the anticipated beneficial impacts to BLM special status plant species under Alternative B are more than under Alternative A.

Resources

Alternative B includes additional protective measures for soils compared to Alternative A. Reclamation plans are developed and approved before starting any surface-disturbing activities, areas are reclaimed based on pre-existing plant communities, and inventories and mapping of soils to determine erosion and degree of soil stability are completed. By understanding the soils better, the BLM can institute required BMPs that will be most effective in each area, thereby potentially reducing erosion, and minimizing adverse impacts to BLM special status plant species. The anticipated level of soil erosion and compaction are expected to be less under Alternative B than under Alternative A.

While Alternative A may fence springs and reservoirs to meet resource objectives, Alternative B may also fence riparian/wetland areas as necessary, potentially increasing the beneficial impacts to BLM special status plant species in these habitats. In addition, Alternative B maintains natural flow regimes for streams supporting fisheries. This is important to Ute ladies'-tresses and persistent sepal yellowcress, which depend on periodic flooding events during their life-cycles.

Under Alternative B, the BLM utilizes wildland fire and other vegetation treatments to restore fire-adapted ecosystems, which could result in the same or fewer beneficial impacts to Hyattville milkvetch than Alternative A because Alternative B relies mostly on natural processes, and less on active restoration. Wildland fire and other vegetation treatments could be used to reduce the invasion of Utah juniper into Hyattville milkvetch habitat.

Alternative B is anticipated to result in greater beneficial impacts to BLM special status plants in riparian/wetland habitats than Alternative A because Alternative B manages these habitats to achieve DPC, prioritizes those areas not meeting PFC, and increases the buffer prohibiting surface-disturbing activities around riparian/wetland habitats to ¼ mile. Through these management actions, the potential for direct removal of BLM special status plants, sedimentation, and spread of invasive plants is less than under Alternative A. In addition, Alternative B applies an NSO restriction to wetlands larger than 40 acres.

Alternative B provides more protections to big game crucial winter range areas by establishing the Absaroka Front Management Area and applying an NSO restriction to these ranges and areas elsewhere, and prohibiting surface disturbance within ½ mile of migration corridors. These restrictions result in beneficial impacts to BLM special status plants in these areas, by reducing removal and trampling of these species. Because the restrictions are NSO, the beneficial impacts are anticipated to be greater than under Alternative A.

Proactive Management

Alternative B includes more restrictions for the protection of special status plant species habitat and provides more protection to known populations of BLM special status plants compared to Alternative A. Range improvement projects are not allowed within ½ mile of known BLM special status plant species, forage supplements are prohibited within ½ mile of BLM special status plants, aerial applications of pesticides are prohibited within 1 mile of BLM special status plants, and surveys are required in potential BLM special status plant habitats before approving any project. The increased buffers and required surveys compared to Alternative A aid in habitat protection and potential expansion of BLM special status plant populations.

Alternative C

Surface Disturbance

Under Alternative C, BLM actions are projected to result in 245,642 acres of short-term surface disturbance on BLM-administered land and 41,485 acres of surface disturbance in the long term over the life of the plan, the greatest acreage of all alternatives (and more than double the acreage of Alternative A) (Table 4-1). Similar to Alternative A, Alternative C increases the potential for habitat fragmentation by not maintaining large, contiguous blocks of native plant communities. By having fewer restrictions on habitat fragmentation and disturbing more acres than alternatives A, B, and D, Alternative C is anticipated to indirectly benefit BLM special status plant species less than the other alternatives. The spread of invasive species and extent of soil erosion would be greatest under Alternative C.

Resource Uses

Alternative C has the greatest acreage open to oil and gas development subject to standard constraints, the fourth greatest acreage subject to moderate constraints, the least acreage subject to major constraints, and the least acreage closed to oil and gas development. While required mitigation and reclamation under all alternatives minimizes adverse impacts from mineral development, Alternative C could result in the greatest adverse impacts to BLM special status plant species due to implementing the least restrictions to these activities.

Under Alternative C, implementing a ½-mile buffer around BLM special status plant species prohibiting aerial herbicide application may result in less adverse impacts from invasive species management to Ute ladies'-tresses and persistent sepal yellowcress than under alternatives A and D (under which aerial application is permitted), but more than Alternative B (under which the BLM implements a 1-mile buffer). Alternative C allows exceptions to this buffer to manage riparian weed species, which could benefit Ute ladies'-tresses and persistent sepal yellowcress in the long term. Under Alternative C, impacts from transport of invasive species by livestock are anticipated to be greater than any other alternative, as flushing of livestock is not required.

Under Alternative C, adverse impacts to BLM special status plant species from OHV use are anticipated to be the greatest of all the alternatives because Alternative C has the least acreage closed to motorized vehicle use, the second greatest acreage limited to existing roads and trails, the second least acreage limited to designated roads and trails, and the greatest acreage open. Permitting off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations would result in impacts similar to those described for Alternative A, but to a greater extent by allowing the creation of new travel routes. The anticipated soil disturbance, vegetation removal, and transport of

Special Status Species – Plants

invasive species under Alternative C are expected to produce the most indirect and adverse impacts to unknown populations of BLM special status plant species compared to other alternatives.

Similar to alternatives A and D, livestock grazing is closed on Bighorn River tracts, campgrounds, and exclosures. Alternative C may result in greater adverse impacts to Ute ladies'-tresses and persistent sepal yellowcress than alternatives A, B, and D by allowing placement of forage supplements in riparian/wetland areas. Alternative C (and Alternative D) allows the placement of forage supplements after considering the location of BLM special status plant species, which may increase the risk of herbivory and trampling. In addition, Alternative C places more emphasis on livestock forage availability while meeting multiple use objectives. Overall, adverse impacts to BLM special status plants from livestock grazing management under Alternative C are anticipated to be similar to alternatives A and D and greater than Alternative B.

Special Designations

Under Alternative C, only the existing Brown/Howe Dinosaur Area and Spanish Point Karst ACECs are carried forward and no new ACECs are designated. No BLM special status plant species are known to occur in either ACEC. Therefore, beneficial impacts to special status plants from designation and management of ACECs would be the least under Alternative C.

Under Alternative C, does not recommend any WSR eligible waterway segments as suitable for inclusion in the NWSRS. By releasing these areas for other uses to be managed in accordance with adjacent BLM-administered lands, the potential for adverse impacts to Ute ladies'-tresses and persistent sepal yellowcress is greater than alternatives A and B.

Resources

Alternative C includes additional protective measures for soils compared to Alternative A, so that reclamation plans are developed on a case-by-case basis and 30 percent desired vegetative cover is required within three growing seasons. The anticipated level of soil erosion and compaction are expected to be similar to Alternative A.

While Alternative A may fence springs and reservoirs, Alternative C may fence springs and their associated wetland areas, potentially increasing the beneficial impacts to BLM special status plant species in these habitats. Alternative C manages for adequate in-stream flow to support riparian and fisheries values, which may provide fewer beneficial impacts than maintaining natural flow regimes as under alternatives A, B, and D. Because Alternative C only implements BMPs on permitted activity plans to reduce sediment loading in streams and river segments, it would have fewer beneficial impacts to BLM special status plant species than alternatives A, B, and D.

Under Alternative C, the BLM utilizes wildland fire and other vegetation treatments to restore fire-adapted ecosystems, similar to Alternative B, except that under Alternative C active restoration is used, which may create a greater beneficial impact than natural processes alone. This may result in more beneficial impacts to Hyattville milkvetch than Alternative A. Wildland fire and other vegetation treatments could be used to reduce the invasion of Utah juniper into Hyattville milkvetch habitat.

Alternative C may result in similar beneficial impacts to BLM special status plants in riparian/wetland habitats as Alternative A because both alternatives manage these habitats to meet PFC. In addition, Alternative C prioritizes areas functioning at-risk with a downward trend and areas in a nonfunctioning condition. However, Alternative C allows surface-disturbing activities in riparian/wetland areas on a case-by-case basis, potentially increasing adverse impacts to BLM special status plants in these areas. Through these management actions, the potential for direct removal of BLM special status plants,

sedimentation, and spread of invasive plants is greater than under alternatives A, B, and D. Similar to Alternative A, Alternative C does not apply an NSO restriction to wetland areas greater than 40 acres.

Alternative C provides fewer protections to big game crucial winter range, and migration corridors than alternatives A, B, and D. By allowing activities in these areas, Alternative C results in the fewest beneficial impacts to BLM special status plants in these areas because these species may be removed or trampled.

Proactive Management

Alternative C sets aside the least amount of land of any alternative for areas that have management actions to benefit BLM special status plant species. Similar to Alternative B, buffers and restrictions for other resources and surface-disturbing activities around BLM special status plant species will likely provide indirect beneficial impacts to habitats for special status plants. Range improvement projects are not allowed within ½ mile of known BLM special status plant species, forage supplements are prohibited within 300 feet of BLM special status plants, and aerial applications of pesticides are prohibited within ½ mile of BLM special status plants, but surveys are only required in potential habitats for federally listed, proposed, or candidate species before approving any project. The increased buffers and requirement of some surveys compared to Alternative A aid in habitat protection and the potential expansion of the special status plant populations.

Alternative D

Surface Disturbance

Under Alternative D, BLM actions are projected to result in 140,175 acres of short-term surface disturbance on BLM-administered land and 18,306 acres of surface disturbance over the life of the plan, the second most acreage compared to the other alternatives. However, similar to Alternative B, Alternative D reduces the potential for habitat fragmentation by maintaining large, contiguous blocks of native plant communities. Although the BLM allows the use of nonnative seeds that may slow the reestablishment of native plant communities, reclamation practices under Alternative D, would mitigate short-term impacts of surface disturbance more than under Alternative A. Overall, surface disturbance under Alternative D would result in impacts similar to those under Alternative A.

Resource Uses

Alternative D has approximately 911,814 acres open to oil and gas leasing subject to the terms and conditions of the standard lease form, approximately one-fifth of the acreage under Alternative A, and has almost two times more acreage closed to oil and gas leasing than under Alternative A. Minerals development under Alternative D would result in fewer adverse impacts to BLM special status plant species than under alternatives A and C, but more than under Alternative B.

Adverse impacts from management of invasive species under Alternative D would be similar to those under Alternative A. Alternative D results in more surface disturbance than Alternative A, leaving more areas vulnerable to invasive species spread, but employs more measures to restore vegetation in disturbed areas and places more restrictions on motorized travel that can spread invasive species.

Alternative D manages 20,345 fewer acres as ROW exclusion areas than Alternative A, but 1,467,719 more acres as ROW avoidance areas, which would result in more beneficial impacts to special status plant species than under alternatives A and C, but less than under Alternative B.

Under Alternative D, adverse impacts to BLM special status plant species from motorized vehicle use would be more than under alternatives A and B, but less than under Alternative C; Alternative D closes

Special Status Species – Plants

or limits motorized vehicle use on fewer acres than alternatives A and B, but is more restrictive than Alternative C. Restricting off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations to within 300 feet of established roads would limit the adverse impacts described under Alternative A.

Impacts from livestock grazing management under Alternative D would be similar to those under Alternative A. Allowing the use of livestock grazing, even in closed areas, as a tool to improve resource conditions may beneficially affect BLM special status plant species if grazing is used to enhance native plant communities.

Special Designations

Special designations under Alternative D would result in similar beneficial impacts as those under Alternative B, but to a lesser extent. Alternative D carries forward the Five Springs Falls, Upper Owl Creek, Carter Mountain, and Little Mountain ACECs, and proposes designating the Clarks Fork Canyon and Sheep Mountain ACECs. Alternative D would designate more acreage in ACECs than alternatives A and C, but less than Alternative B. Not recommending WSR eligible waterway segments as suitable for inclusion in the NWSRS would result in similar potential adverse impacts as those under Alternative C.

Resources

Alternative D includes additional protective measures for soils compared to alternatives A and C, but less than Alternative B. Alternative D requires reclamation plans, stipulations, or measures before authorized surface-disturbing activities and develops reclamation plans in coordination with stakeholders. The anticipated level of soil erosion and compaction are expected to be less under Alternative D than under alternatives A and C, but more than under Alternative B.

Similar to Alternative A, Alternative D does not require the maintenance of natural flow regimes for streams supporting fisheries, which would result in similar adverse impacts. Developing watershed improvement projects and fencing springs, wetlands, reservoirs, and riparian areas to meet resource objectives would result in similar beneficial impacts to those under Alternative B.

Fire and fuels management under Alternative D would result in impacts to BLM special status plant species similar to those under Alternative A.

Alternative D would result in beneficial impacts to BLM special status plant species in riparian/wetland habitats similar to Alternative A, but to a greater extent because the BLM manages areas with unique fisheries or recreational value toward achieving DFC. Management toward DFC is assumed to exceed the requirements of managing toward PFC and would therefore result in improved functioning and healthier riparian/wetland areas. Avoiding surface-disturbing activities within ¼ mile of riparian/wetland areas would reduce adverse impacts to BLM special status plant species in these areas similarly to Alternative A. Alternative D also applies an NSO on wetlands greater than 20 acres, resulting in similar beneficial impacts as those under Alternative B, but to a greater extent.

Alternative D provides similar beneficial impacts as those under Alternative B by establishing the Absaroka Front Management Area, but to a lesser extent. Alternative D restricts mineral development in this area less than Alternative B—by using a mix of CSU, TLS, NSO, and closed to leasing restrictions—but more than Alternative C and Alternative A (under which this management area is not recognized). Potential adverse impacts to special status plant species from wild horse grazing under Alternative D would be similar to those described under Alternative B.

Proactive Management

Alternative D avoids range improvement projects that may concentrate herbivory within ¼ mile of BLM special status plant species, unless the project is determined not to adversely impact that population; allows the placement of forage supplements after considering their proximity to BLM special status plant species; implements avoidance, minimization and/or compensation measures for projects and activities in coordination with surface owners on split-estate; avoids aerial applications of herbicides within ½ mile of BLM special status plant species; and allows the application of fire suppression chemicals within ¼ mile of known/documented populations of BLM special status plant species with consent of the authorized officer. Overall, these measures would result in more beneficial impacts to BLM special status plant species than alternatives A and C, but less than Alternative B.

Alternative E

Surface Disturbance

Under Alternative E, BLM actions are projected to result in 71,829 acres of short-term surface disturbance to BLM-administered land and 10,691 acres of long-term surface disturbance over the life of the plan, the least acreage of all alternatives (Table 4-1). Management practices relating to surface disturbance would be the same as Alternative B, except for areas within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). In this ACEC, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) to not exceed one disturbance per 640 acres and cover less than 3 percent of the greater sage-grouse Key Habitat Areas, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. This additional restriction on anthropogenic disturbances would reduce effects from surface disturbance to a greater degree than described under Alternative B. Similar to Alternative B, but to a greater degree, Alternative E would reduce the potential for habitat fragmentation by maintaining large, contiguous blocks of native plant communities which would indirectly benefit BLM special status plant species by protecting potential habitats, minimizing the spread of invasive species, and minimizing soil erosion.

Resource Uses

Compared to the other alternatives, Alternative E would close the most acreage to mineral development and disposal while also placing additional limitations on surface disturbance within the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Therefore, Alternative E would result in the fewest adverse impacts to special status species plants from minerals development. Although alternatives B and E apply similar management actions to eradicate or control the spread of invasive species, the potential for invasive species spread would be reduced under Alternative E due to less surface disturbance. Additional management actions to protect sage-grouse habitat from invasive species under Alternative E would indirectly benefit special status plant species whose habitat overlaps the proposed Greater Sage-Grouse Key Habitat Areas ACEC; however, restrictions on herbicide applications in the ACEC could reduce the ability to control infestations.

Impacts resulting from travel management under Alternative E would be the same as Alternative B and would benefit special status plant species by placing the most limitations on and closures to motorized vehicle use of any alternative.

Alternative E designates the greatest acreage (1,322,879 acres) as exclusion areas for ROWs and corridors, substantially more than any other alternative due to the designation of the proposed Greater Sage-Grouse Key Habitat Areas ACEC as a ROW exclusion area, which would result in the greatest beneficial impacts to BLM special status plants by minimizing habitat fragmentation and degradation.

Special Status Species – Plants

Impacts to special status plant species from other resource uses would be the same as Alternative B.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land within greater sage-grouse Key Habitat Areas that would be designated as an ACEC. The relative size and additional restrictions on surface-disturbing activities and resource uses in the proposed Greater Sage-Grouse Key Habitat Areas ACEC would result in the most beneficial impacts to special status plant species in comparison to the other alternatives. Impacts to special status plant species from special designations in areas outside the proposed Greater Sage-Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Resources

The resource management of Alternative E and additional management practices to protect and restore sagebrush habitats within the proposed Greater Sage Grouse Key Habitat Areas ACEC would provide the most beneficial impacts to special status plant species by reducing surface disturbance, soil erosion, and compaction in the largest area when compared to the other alternatives. Impacts on special status species plants from other management actions to protect resources would be the same as Alternative B for areas outside of the Greater Sage-Grouse Key Habitat Areas ACEC.

Proactive Management

Proactive management for the protection of special status plant species habitats and known populations would be generally the same as Alternative B. However, the greatest indirect beneficial impacts to special status plant species may result from the management to protect and restore sagebrush habitats within the proposed Greater Sage-Grouse Key Habitat Areas ACEC.

Alternative F

Surface Disturbance

Under Alternative F, BLM actions are projected to result in 137,064 acres of short-term and 17,663 acres of long-term surface disturbance, the third most acreage compared to the other alternatives. However, similar to alternatives B and E, Alternative F reduces the potential for habitat fragmentation by maintaining large, contiguous blocks of native plant communities. Overall, surface disturbance under Alternative F would result in impacts similar to Alternative A and slightly less adverse than Alternative D due to reduced surface disturbance from additional management practices that would reduce the total acreage of surface disturbance in 1,116,698 acres of the Greater Sage-Grouse PHMAs ACEC.

Resource Uses

Minerals development under this alternative would result in fewer adverse impacts to special status plant species than Alternative D due to greater limitations on surface disturbance and additional restrictions placed on minerals development in the Greater Sage-Grouse PHMAs ACEC. Minerals development under Alternative F would therefore result in fewer adverse impacts to BLM special status plant species than under alternatives A, C, and D, but more than under alternatives B and E.

Adverse impacts from management of invasive species would be slightly less than under Alternative D due to management actions within the proposed Greater Sage-Grouse PHMAs ACEC that reduce surface disturbance, place greater restrictions on motorized vehicle travel, and prioritize the health and restoration of sagebrush habitats. However, similar to Alternative E, restrictions on herbicide applications in the ACEC could reduce the ability to control infestations.

Alternative F manages 92,932 more acres as ROW exclusion areas than Alternative D and requires seasonal restrictions on construction of aboveground powerlines or the use of buried powerlines within the proposed Greater Sage-Grouse PHMAs ACEC. Alternative F manages more acres as ROW avoidance areas than does Alternative A. ROW management under this alternative would result in fewer adverse impacts to special status plant species than under alternatives A, C, and D, but more than under Alternative B.

Under Alternative F, adverse impacts to BLM special status plant species from motorized vehicle use would be more than under alternatives B and E, but less than under alternatives A, C, and D, because Alternative F limits motorized vehicle use to designated roads and trails over a greater area.

Impacts from livestock grazing would be similar to alternatives A and D, but with greater potential for indirect beneficial impacts within the proposed Greater Sage-Grouse PHMAs ACEC, which would be managed to protect and restore native sagebrush habitat.

Special Designations

The relative size and additional restrictions on surface-disturbing activities and resource uses in special designations areas under Alternative F would result in greater protections for special status plant species in comparison to alternatives A, C, and D, but fewer than under alternatives E and F. Specifically, additional constraints on oil and gas leasing, motorized vehicle use, and renewable energy development in the proposed Greater Sage-Grouse PHMAs ACEC would reduce surface disturbances and result in fewer adverse impacts to special status plant species than Alternative D. Impacts to special status plant species from special designations in areas outside the proposed Greater Sage-Grouse PHMAs ACEC would be the same as Alternative D.

Resources

Decreased surface disturbance under this alternative would reduce soil erosion and compaction to a greater extent than Alternative D, increasing less adverse impacts to special status plant species. Similar to Alternative E, management actions for habitat restoration, invasive species management, and fire and fuels management that emphasize the conservation and restoration of sagebrush habitats would provide additional benefits to special status plant species within the proposed Greater Sage-Grouse PHMAs ACEC. Impacts on special status plant species from other management actions to protect resources would be the same as Alternative D.

Proactive Management

Management actions under Alternative F for habitat restoration, invasive species management, fire and fuels management, and livestock grazing that prioritize the conservation of native sagebrush habitats within the proposed Greater Sage-Grouse PHMAs ACEC would provide greater protection for special status plant species than alternatives A and C, similar impacts to Alternative D, and fewer beneficial impacts than alternatives B and E. Management of areas outside of the Greater Sage-Grouse PHMAs ACEC and associated impacts to special status plant species would be the same as Alternative D.

4.4.8 Special Status Species – Fish

Adverse impacts are those that degrade water quality (e.g., temperature, chemistry, etc.) in the Planning Area, particularly where there are special status fish species. Beneficial impacts are those that improve and/or preserve water quality and quantity in these areas. Direct impacts are similar to those identified in Section 4.4.5 *Fish and Wildlife Resources – Fish* and include onsite disturbances to fish habitat, while indirect impacts result from changes in water quality and quantity.

For this analysis, short-term impacts to special status fish species include those activities that contribute to the decline in abundance or distribution of a species within 5 years of when the activity occurs. Long-term impacts to special status fish are those that require more than 5 years to manifest, such as efforts to improve habitat over time or remove competitive nonnative species.

In general, management actions that affect fish would also affect special status fish species. Section 4.4.5 *Fish and Wildlife Resources – Fish* provides a detailed analysis of direct and indirect management actions that impact fish. This section focuses on the potential impacts of the alternatives to special status fish species habitat (including habitat of the Yellowstone cutthroat trout, a BLM sensitive species), proactive management that could beneficially impact these species, and potential impacts to federally listed species downstream of the Planning Area.

4.4.8.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Water consumption in the Bighorn River and the Clarks Fork of the Yellowstone River watersheds may adversely affect surface water quantity in the larger Yellowstone River and Missouri River ecosystem.
- Production water from CBNG drilling that is low in salts and other chemicals that may be detrimental to aquatic life forms is assumed to have negligible influence on surface water quantity and quality in the Bighorn River and the Clarks Fork of the Yellowstone River watersheds due to the low likelihood that CBNG activities would occur at high levels in the Bighorn Basin. However, if CBNG activities are located near important habitat for special status fish species, it can be assumed there will be adverse impacts.
- In cooperation with WGF, the BLM would continue to manage species listed on BLM Wyoming State Director's Sensitive Species List in accordance with BLM manual 6840 (BLM 2001b).
- USFWS would have jurisdiction over the management of threatened and endangered fish and wildlife populations.

4.4.8.2 Summary of Impacts by Alternative

Impacts to special status fish species are generally the same as those for fish, although the beneficial impacts to these species would tend to be greater because of additional protective management for special status species under all alternatives. The principal impacts to fish result from management that increases surface disturbance, resulting in sedimentation and other adverse impacts to water quality and quantity in waterways containing special status species. Increased sediment in fish habitat (streams, rivers, and reservoirs) decreases the potential for fish to naturally reproduce, fills in pools, leads to channel degradation, decreases light penetration and productivity, alters fish community composition, and increases stream temperature. Alternative C places the fewest restrictions on surface-disturbing activities and has the greatest potential to contribute sediment to surface waters in the Bighorn, Shoshone, and Clarks Fork of the Yellowstone rivers, resulting in the greatest potential adverse impact on water quality in Yellowstone cutthroat trout and other special status species fish habitat. Alternative C is projected to result in the highest number of new federal wells (Appendix T), which may result in the greatest water depletion and, therefore, the greatest adverse impact to water quantity in these rivers, followed by alternatives A, D, F, B, and E. Alternatives D and F are projected to result in greater surface disturbance than Alternative A, but contain additional reclamation requirements that may limit erosion to a greater degree and, therefore, mitigate adverse impacts to fish habitat.

Alternatives B and E would result in the greatest beneficial impacts to special status fish species habitat from more definitive proactive management actions and more stringent reclamation requirements relative to the other alternatives. Alternatives B, D, E, and F would provide long-term beneficial impacts by pursuing restoration of Yellowstone cutthroat trout to its native waters in the Planning Area.

4.4.8.3 Detailed Analysis of Alternatives

Allowable uses and management actions with potential to degrade water quality in the Bighorn and Clarks Fork of the Yellowstone Rivers and their tributaries could directly affect special status fish species in the Planning Area and indirectly impact federally listed fish in the Yellowstone River. The types of impacts projected to affect water quality and quantity in these watersheds are anticipated to be common to all alternatives and, therefore, are discussed in the following section. A detailed discussion of the anticipated impacts to fish from changes in water quality and quantity is included in Section 4.4.5 *Fish and Wildlife Resources – Fish*. This section focuses on the direct impacts to special status fish species habitat from proactive management, which varies by alternative.

Impacts Common to All Alternatives

The potential for management to result in adverse impacts to special status fish species is primarily a function of impacts to surface water quality and quantity. Reduced water flow in the Yellowstone River can lead to adverse impacts to the ecosystems that support special status fish species. Increased sediment in the Bighorn and Clarks Fork of the Yellowstone Rivers may contribute to sedimentation in the Yellowstone River.

Water Quality

Water quality is affected by surface-disturbing activities and associated soil erosion, particularly on soils highly susceptible to water erosion that contribute to sedimentation. Sedimentation reduces the quality of in stream habitat for most fish by filling in pools, reducing thermal recovery areas, and covering stream bottoms with a more uniform layer of sediment, which smothers eggs and alevin, thereby reducing fish reproduction rates. Appendix T provides data regarding surface-disturbance acreage and reasonable foreseeable actions related to development by alternative. Principle impacts from surface-disturbing activities would result from removing vegetation and disturbing soil, thereby increasing the potential for offsite erosion and sediment delivery into the Bighorn and Clarks Fork of the Yellowstone Rivers and their tributaries. Other actions, including concentration of livestock, fire and fuels management, OHV use, and reclamation of disturbed areas are anticipated to remove or reduce vegetation and disturb soil, but are expected to have less potential to degrade water quality in the Bighorn and Clarks Fork of the Yellowstone watersheds and therefore less potential to impact fish downstream. See Section 4.1.4 *Water* for more information regarding potential impacts to surface water quality.

Spanish Point Karst (designated under all alternatives) is the only ACEC that benefits water quality by restricting surface-disturbing activities and pesticide application in this area. WSAs contain 0.7 miles of occupied Yellowstone cutthroat trout habitat, and the restrictions on resource uses and activities to maintain their wilderness characteristics may result in indirect beneficial impacts to special status fish species under all of the alternatives.

Water Quantity

Water used for well construction and completion may reduce the amount of water available for use in the Bighorn and Clarks Fork of the Yellowstone Rivers, and therefore in the Yellowstone River

downstream of the Planning Area as well. Produced water from oil and gas wells may alter flow regimes and water quantity in streams containing special status fish species. See Section 4.4.5 *Fish and Wildlife Resources – Fish* for a description of the impacts from produced water. Produced water from CBNG drilling is assumed to have a negligible influence on surface water quantity and quality in the Bighorn River and the Clarks Fork of the Yellowstone River watersheds. See Section 4.1.4 *Water* for more information regarding potential impacts to surface water quantity.

Alternative A

Surface Disturbance

The BLM projects 15,646 acres of long-term surface disturbance from BLM-authorized actions under Alternative A (Table 4-1) resulting in an estimated erosion rate of 25,065 tons per year (Appendix V). Surface-disturbing activities remove vegetation and disturb soil, thereby increasing the potential for offsite erosion and sediment delivery to the Bighorn, Shoshone, and Clarks Fork of the Yellowstone rivers, among the waterways in the Planning Area that drain into the Yellowstone River. Sedimentation fills in pools and covers stream bottoms with a more uniform layer of sediment that adversely affects special status fish species. Surface-disturbing activities would reduce water quality and degrade Yellowstone cutthroat trout and other special status fish species habitat in the Planning Area. The greater the surface disturbance, the greater potential for adverse impacts to special status fish species.

Resource Uses

Under Alternative A, 4,130,352 acres are available for locatable mineral entry, 1,354,593 acres are open with standard constraints for oil and gas leasing, and 3,974,564 acres are open to mineral materials disposal. This alternative would develop an estimated 1,184 new federal wells. Alternative A closes 68,115 acres to motorized vehicle use and limits motorized vehicle use to designated roads and trails in areas with fragile soils, limiting vehicle-caused soil disturbance and resulting contributions to sediment loads. Adverse impacts to special status fish species from sedimentation due to surface disturbance and erosion, depleted water quantity due to mineral development, and altered flow regimes due to soil compaction and produced water discharge would occur but would be mitigated under Alternative A.

Special Designations

Alternative A designates three ACECs, containing 9.8 miles of occupied Yellowstone cutthroat trout habitat that would benefit special status fish species by restricting surface-disturbing activities in these areas and reducing the likelihood of sedimentation in the associated watersheds. Managing all 20 WSR eligible waterways, containing 3.1 miles of Yellowstone cutthroat trout habitat, would result in beneficial impacts to special status fish species habitat relative to the other alternatives by restricting resource uses and activities to maintain the free-flowing conditions of these waterways. However, WSR eligible waterway segment management may prevent construction of fish barriers to protect special status fish species habitat, if the natural free-flowing conditions of the stream would be impaired by these actions.

Resources

Under Alternative A, the BLM requires the stabilization of existing watershed improvement projects where they have failed to promote/enhance/improve watershed stability, and routinely seeds, or requires permittees and operators to seed, disturbed areas with native plant species to reestablish vegetation cover over disturbed soils within 5 years. These actions would beneficially impact special status species fishbearing streams by reducing sedimentation. Alternative A implements watershed

improvement practices from Wyoming’s Bighorn Basin water quality plans and encourages natural flow regimes in streams supporting fisheries in compliance with the state’s water laws, providing potential indirect beneficial impacts to special status fish species. Surface discharge under Alternative A may have adverse impacts if produced water degrades water quality in special status fish species inhabited streams and rivers. Alternative A places restrictions on surface-disturbing activities around riparian/wetland areas. Forest management under Alternative A allows for 30,000 acres of treatment that could contribute to soil disturbance and sedimentation in the short term, but may have beneficial impacts by preventing stand-replacing wildfires, which may cause much more sedimentation, in the long term. Overall, resource management actions under Alternative A would result in beneficial impacts to special status fish species.

Proactive Management

Proactive management actions that have direct beneficial impacts to special status fish under Alternative A include restoring stream segments for fisheries habitat, constructing barriers to prevent nonnative fish from colonizing habitat occupied by native fish species, and introducing special status fish species to waters outside of their historic range on a case-by-case basis. Additional long-term beneficial impacts may result from considering restoring Yellowstone cutthroat trout to its native waters in the Planning Area. Prohibiting surface-disturbing activities within 500 feet of surface water and/or riparian habitat except when impacts can be mitigated would limit direct adverse impacts to special status fish species habitat.

Alternative B

Surface Disturbance

Impacts to special status fish species would be similar to those described under Alternative A, although to a lesser extent. Surface disturbance under Alternative B (Table 4-1) would result in a 31 percent decrease in long-term erosion (Appendix V) from the baseline condition, which would reduce adverse impacts to special status fish species.

Resource Uses

Compared to Alternative A, Alternative B allows fewer opportunities for resource use that result in surface disturbance and more restrictions are placed on mineral and ROW development, motorized vehicle use, and livestock grazing. Therefore, Alternative B less potential to result in adverse impacts to special status fish species due to resource uses that can affect water quality or quantity than Alternative A.

Special Designations

The special designations under Alternative B would have greater beneficial impacts to special status fish species than Alternative A. Alternative B expands three ACECs (Carter Mountain, Five Springs Falls, and Upper Owl Creek) and designates four new ACECs (Chapman Bench, Clarks Fork Canyon, Rattlesnake Mountain, and Sheep Mountain) that restrict surface-disturbing activities. The Clarks Fork Canyon ACEC protects a large portion of Clarks Fork of the Yellowstone watershed from the adverse impacts of surface-disturbing activities and mineral development, resulting in the greatest direct beneficial impacts to special status fish species in the Yellowstone River. ACECs encompass 42.7 miles of Yellowstone cutthroat trout habitat. Managing all 20 WSR suitable waterways would result in similar impacts to those under Alternative A. Additionally, managing all lands with wilderness characteristics specifically to preserve their wilderness characteristics and restricting resource uses and activities in these areas to

Special Status Species – Fish

protect wilderness characteristics may beneficially impact 8.8 miles of Yellowstone cutthroat trout habitat under this alternative.

Resources

Similarly to Alternative A, Alternative B stabilizes watershed improvement projects if they are no longer meeting resource objectives to prevent the release of stored sediment. Alternative B provides greater short-term beneficial impacts to special status fish species habitat than Alternative A by requiring more immediate and precisely defined vegetation reestablishment goals in disturbed areas, thereby preventing potential sedimentation. Alternative B also creates greater beneficial impacts than Alternative A by developing watershed improvement practices, which all activity plans and permitted activities include, in cooperation with local governments. The BLM manages forests and woodlands through natural processes under Alternative B, as opposed to mechanical treatments emphasized under Alternative A, likely resulting in less surface disturbance and impacts to water quality in the short term. However, if maintained stand density results in high intensity wildfires, long-term adverse impacts to water quality and flow regimes may result. Alternative B manages all riparian/wetland areas to achieve DPC, increasing the potential for long-term beneficial impacts to special status fish species habitat, relative to Alternative A.

Proactive Management

Proactive management actions under Alternative B would result in greater direct beneficial impacts to special status fish compared to Alternative A. This alternative restores important fisheries habitat on 3 miles of streams, constructs nonnative fish barriers except in WSR suitable waterway segments, removes barriers or constructs fish passageways to enable native fish to occupy all suitable habitats, pursues restoring Yellowstone cutthroat trout to all its original waters, and introduces special status fish species outside their historic range, if environmentally feasible, in coordination with WGFD and other stakeholders.

Alternative C

Surface Disturbance

Adverse impacts to special status fish species from surface disturbance would be greatest under Alternative C. Surface disturbance under Alternative C would be the highest of the alternatives (Table 4-1), resulting in a 165 percent increase in long-term erosion (Appendix V) compared to Alternative A and, therefore, the greatest adverse impact to special status fish species.

Resource Uses

Alternative C provides the least restriction on resource use, especially surface-disturbing activities such as minerals development, having the greatest potential adverse impact on special status fish species by altering water quantity and quality. The BLM manages livestock grazing to optimize commodity production while meeting rangeland health standards, not to enhance other resource values, resulting in the greatest potential adverse impacts to special status fish species from riparian/wetland area degradation and vegetation removal that can impact water quality and quantity.

Special Designations

Other than the Spanish Point Karst ACEC, the Brown/Howe Dinosaur Area ACEC is the only ACEC designated under Alternative C; this ACEC may have a beneficial impact by preventing sedimentation in waterways as surface-disturbing activities must be mitigated, but management of the ACEC generally

allows mineral development and other types of surface-disturbing activities that may affect water quality. ACECs under this alternative contain only 0.2 miles of Yellowstone cutthroat trout habitat. In addition, Alternative C does not recommend any WSR eligible waterway segments as suitable for inclusion in the NWSRS. Under Alternative C, special designations do not provide any substantial beneficial impact to surface water quality or fisheries habitat, and therefore this alternative has the least potential to beneficially impact special status fish species.

Resources

Alternative C only stabilizes watershed improvement projects if they are not meeting resource objectives, on a case-by-case basis. Alternative C applies less stringent restoration requirements than Alternative B to limit soil erosion in disturbed areas. The BLM does not implement watershed improvement plans (BMPs are relied on to mitigate adverse impacts) under Alternative C, providing the least potential beneficial impacts to special status fish species compared to the other alternatives. Forest management treatments emphasize commercial and economic objectives, resulting in the greatest potential impacts to water quality, compared to the other alternatives.

Proactive Management

The proactive management actions that result in direct beneficial impacts to special status fish under Alternative C are similar to those under Alternative A, except that the BLM only restores stream segments with special status fish species on a case-by-case basis and does not construct nonnative fish barriers. Alternative C provides the fewest beneficial impacts to special status fish species from proactive management compared to the other alternatives.

Alternative D

Surface Disturbance

Impacts to special status fish species from surface disturbance would be similar to those described under Alternative A. The projected surface disturbance is slightly more under Alternative D—estimated to result in a 17 percent increase in long-term erosion compared to Alternative A (Appendix V)—but reclamation and restoration practices are likely to limit erosion and sedimentation more than under Alternative A.

Resource Uses

Alternative D allows fewer opportunities for resource use that can result in surface disturbance than Alternative C. The BLM places more restrictions on minerals, ROWs, and motorized vehicle use under Alternative D than under alternatives A and C. Livestock grazing management under Alternative D would result in impacts similar to those under Alternative A. Overall, Alternative D has more potential to result in adverse impacts to special status fish species than Alternative B, but less than alternatives A and C.

Special Designations

Special designations under Alternative D would have a greater beneficial impact to special status fish species than under alternatives A and C, but less than under Alternative B. Alternative D designates the Clarks Fork, PETM, and Sheep Mountain ACECs in addition to the ACECs designated under Alternative A, containing 10.7 miles of Yellowstone cutthroat trout habitat, and applies additional resource use restrictions in the Chapman Bench Management Area to minimize impacts to special status species. Alternative D does not manage any lands with wilderness characteristics specifically to preserve their

Special Status Species – Fish

wilderness characteristics or recommend any WSR eligible waterway segments as suitable for inclusion in the NWSRS, which would result in fewer beneficial impacts on special status fish species in these areas than Alternative B. Special status fish species habitat would not be protected to the same degree in these areas as under alternatives A and B. However, the BLM could construct fish barriers on these waterways to prevent the spread of nonnative fish species that may adversely impact special status fish species.

Resources

Management actions to stabilize watershed improvement projects and reestablish vegetation in disturbed areas under Alternative D would result in similar beneficial impacts to those under Alternative A, but to a greater extent. Watershed improvement practices would result in similar beneficial impacts to those under Alternative B. Forest management would result in impacts similar to those under Alternative A, but there would be more potential adverse impacts from allowing clear cutting, similar to Alternative C. Management of riparian/wetland resources under Alternative D would be similar to Alternative C. However, managing streams with unique fishery values to meet DFC would result in greater beneficial impacts to special status fish species in these areas. Under Alternative D, the BLM would place more restrictions on surface-disturbing activities near riparian/wetland areas, which would limit impacts to a greater extent. Overall, resource management under Alternative D would result in more beneficial impacts to special status fish species than alternatives A and C, but fewer than Alternative B.

Proactive Management

Proactive management actions under Alternative D would result in similar beneficial impacts to special status fish species as under Alternative B, but to a lesser extent because the BLM would perform similar management actions, but on a priority basis. Surface-disturbance restrictions would limit direct adverse impacts to special status fish species habitat similarly to Alternative A. Pursuing the restoration of Yellowstone cutthroat trout to historically occupied watersheds would result in similar beneficial impacts to those under Alternative B.

Alternative E

Surface Disturbance

Management practices relating to surface disturbance would be the same as Alternative B, except for areas within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). In this ACEC, the BLM manages anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) to not exceed one disturbance per 640 acres and cover less than 3 percent of the greater sage-grouse Key Habitat Areas, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. This additional restriction on anthropogenic disturbances would reduce effects from surface disturbance to a greater degree than described under Alternative B. Under Alternative E, management actions in the Greater Sage-Grouse Key Habitat Areas ACEC would result in the least surface disturbance of any alternative (Table 4-1). In comparison to alternatives A and B, this alternative would respectively result in 32 percent and 2 percent reductions in long-term erosion (Appendix V) and, therefore, the least adverse impact to special status fish species.

Resource Uses

Restrictions on resource uses under this alternative would be generally the same as Alternative B, with additional restrictions and closures to mineral development, renewable energy development, livestock

grazing, and ROW development within the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Impacts resulting from travel management under Alternative E would be the same as Alternative B and would benefit special status fish species by placing the most limitations on and closures to motorized vehicle use of any alternative. When compared to the other alternatives, Alternative E has the least potential to result in adverse impacts to special status fish species due to management practices for resource uses that provide the most improvement to water quality and quantity by increasing infiltration rates and reducing future erosion and sedimentation sources.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of an additional 1,232,583 acres of BLM-administered land in Greater Sage-Grouse Key Habitat Areas ACEC. The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative E would provide the greatest protection for special status fish species through additional protection for surface water quality and quantity. Additional designation of ACECs under this alternative would result in beneficial impacts to approximately 16 miles of Yellowstone cutthroat trout habitat, which would result in greater beneficial impacts than any other alternative.

Resources

Impacts to special status fish species from management actions for resource protection would be similar to Alternative B, but with slightly greater beneficial impacts due to reduced surface disturbance and erosion within the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Habitat restoration, invasive species management, and fire and fuels management within this ACEC would prioritize the conservation and restoration of native sagebrush habitats, with potential beneficial indirect effects to adjacent fish habitats.

Proactive Management

Impacts to special status fish species from proactive management, including fish habitat restoration activities, would be the same as Alternative B.

Alternative F

Surface Disturbance

Impacts to special status fish species from surface disturbance would be similar to Alternative D, although to a lesser extent. Management actions associated with the designation of the Greater Sage-Grouse PHMAs ACEC would result in slightly less surface disturbance than Alternative D. Although Alternative F would result in a 13 percent increase in long-term erosion compared to Alternative A (Appendix V), reclamation and restoration practices under alternatives D and F are likely to limit erosion and sedimentation more than Alternative A.

Resource Uses

Impacts from resource uses under Alternative F would be generally similar to those under Alternative D, except in the proposed Greater Sage-Grouse PHMAs ACEC. Alternative F would place additional restrictions on renewable energy development, ROW development, and motorized vehicle use in the proposed Greater Sage-Grouse PHMAs ACEC, reducing surface disturbance and associated runoff and sedimentation to nearby waterways, compared to Alternative D. Overall, Alternative F has more potential to result in adverse impacts to special status fish species than alternatives B and E, but less than alternatives A, C, and D.

Special Designations

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in Greater Sage-Grouse PHMAs ACEC. Additional restrictions on renewable energy development, ROW development, and motorized vehicle travel within the proposed Greater Sage-Grouse PHMAs ACEC would result in slightly lower impacts to special status fish species in comparison with Alternative D due to reduced impacts from erosion. Designation of ACECs under this alternative would result in beneficial impacts to Yellowstone cutthroat trout habitat. Overall, special designations under Alternative F would result in more adverse impacts to special status fish species than alternatives B and E, but less adverse impacts than alternatives A, C, and D.

Resources

Management actions for resource protection and related impacts to special status fish species would be the same as Alternative D, with slightly greater beneficial impacts in the proposed Greater Sage-Grouse PHMAs ACEC due to reduced surface disturbance and erosion rates. Similar to Alternative E, habitat restoration, invasive species management, and fire and fuels management within this ACEC would prioritize the conservation and restoration of native sagebrush habitats, with potential beneficial indirect effects to adjacent fish habitats.

Proactive Management

Impacts to special status fish species from proactive management would be the same as Alternative D.

4.4.9 Special Status Species – Wildlife

Direct impacts to special status wildlife species result from the direct loss of important habitat or a key habitat feature, such as a nest site or lek area, or from the immediate loss of life. Human activities can directly disturb special status wildlife, potentially causing nest, lek, or home range abandonment. Disturbance during sensitive periods (e.g., winter and breeding) leads to lower recruitment rates and higher mortalities, which results in adverse impacts to special status wildlife species.

Discussed in detail in the introduction to Biological Resources in this chapter and in Chapter 3, habitat loss and fragmentation result in adverse impacts to special status wildlife species. Habitat loss generally results in direct impacts to the individual or population that is immediately affected. The impacts of habitat fragmentation, however, operate indirectly through mechanisms such as population isolation (Saunders et al. 1991); edge effects, such as increased nest predation and parasitism (Paton 1994; Faaborg et al. 1995); encroachment of invasive species; and disruption of migration patterns.

Special status wildlife experience indirect impacts through changes in habitat characteristics or quality, which ultimately can change migration patterns, habitat use, carrying capacity, and long-term population viability. Indirect impacts to habitats for special status wildlife species can also occur when specific actions change habitat to make it unsuitable. Disturbance impacts can range from short-term displacement and shifts in activities to long-term abandonment of home range (Miller et al. 1998; Warmoloy et al. 1988; Connelly et al. 2000).

For the purpose of this analysis, short-term impacts (up to 5 years) to special status wildlife are those activities that an individual or species respond to immediately, but do not impact the population viability of the species. Long-term impacts (more than 5 years) are those that cause an individual or species to permanently abandon an area, or that alter the population viability and survival of the species. Examples of beneficial long-term impacts include restoration of habitat structure or health, or enhancement of forage base to improve populations of special status wildlife species over time.

This section also describes the environmental consequences associated with the impacts to greater sage-grouse and its habitat from activities carried out in conformance with this RMP, in addition to BLM management actions. In undertaking BLM management actions, and consistent with valid existing rights and applicable law, in authorizing third party actions that result in habitat loss and degradation in PHMA, the BLM will require mitigation that provides a net conservation gain to the species including accounting for any uncertainty associated with the effectiveness of such mitigation. In addition, to help implement this RMP, a Western Association of Fish and Wildlife Agencies (WAFWA) Management Zone Regional Mitigation Strategy (per Appendix Y) will be developed within one year of the issuance of the ROD. The strategy will elaborate on the components identified in Chapter 2 (avoidance, minimization, compensation, additionality, timeliness, and durability), and will be considered by the BLM for management actions and third party actions that result in habitat loss and degradation. The implementation of a Regional Mitigation Strategy will benefit greater sage-grouse, the public, and land-users by providing a reduction in threats, increased public transparency and confidence, and a predictable permit process for land-use authorization applicants.

The Final Biological Assessment that accompanies this document can be viewed on the Bighorn Basin RMP Revision Project website (<http://www.blm.gov/wy/st/en/programs/Planning/rmps/bighorn.html>) provides additional analysis of potential impacts to federally listed threatened, endangered, candidate, or proposed species under the proposed alternatives. Special status wildlife species addressed in the Biological Assessment are the black-footed ferret, Canada lynx, gray wolf, greater sage-grouse, grizzly bear, and mountain plover.

4.4.9.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Impacts to special status wildlife species are based primarily on potential impacts to habitats managed by the BLM.
- Precise quantitative estimates of impacts generally are not possible because the exact locations of future actions are unknown, population data for special status wildlife species are often lacking other environmental variables, or habitat types affected by surface-disturbing activities cannot be predicted.
- The more habitat available for a species, the greater the benefit to the targeted species.
- Prohibiting all surface-disturbing and disruptive activities in greater sage-grouse seasonal habitats is more beneficial to greater sage-grouse than avoiding these activities, as avoidance provides discretion for each proposed activity and applies mitigations, where prohibition precludes all activity.
- Within historical fire regimes, prescribed fire is used to manage vegetative communities and can result in short-term adverse impacts with long-term beneficial impacts to wildlife, certain desirable wildlife habitats, and in some cases to forage productivity and availability.
- Measures to protect one species generally result in long-term benefits to other species in that habitat.
- Because of the migratory nature and relative mobility of some special status wildlife species (e.g., waterfowl, migratory birds, and raptors), these species are affected by actions on non BLM-administered land more so than other species. In the case of migratory species, impacts to winter and migration habitats could adversely impact the viability of some species. Winter and

migration habitats are assumed to be at least as important to long-term viability of these species as breeding and nesting habitats.

- Removal of sagebrush habitat will have a long-term adverse impact on sagebrush obligate species in the 5- to 9-inch precipitation zone.
- The USFWS may designate additional wildlife species as threatened and endangered as additional data are collected and evaluated. These species would be managed in accordance with the ESA and as directed by decisions in the alternatives.

4.4.9.2 Summary of Impacts by Alternative

Impacts to special status wildlife species are generally the same as those for wildlife and include habitat loss and fragmentation (adverse impacts) from surface disturbances and protection of habitat through management that increases restrictions in known or potential habitat (beneficial impacts). Overall, Alternative E is projected to result in the least surface disturbance and would have the least potential to cause habitat loss and fragmentation in the short- and long-term, followed by alternatives B, A, F, D, and C. Alternatives B and E provide the greatest beneficial impacts to special status wildlife habitats by including the most proactive actions to restore and enhance habitats. Except for seasonal motorized vehicle restrictions in the Absaroka Front Management Area, Alternative C would have the greatest adverse impacts to wildlife habitats and, therefore, the fewest beneficial impacts for special status wildlife species. Alternatives A, D, and F would be similar in terms of surface disturbance, though the mitigation and reclamation requirements under alternatives D and F may lead to fewer impacts than Alternative A. Alternatives B and E, and to a lesser extent alternatives D and F, benefit special status wildlife species by protecting large areas of contiguous native habitats in the Absaroka Front Management Area, ACECs, and lands with wilderness characteristics managed to maintain their wilderness characteristics; alternatives A and C would protect fewer large blocks of contiguous habitat. Alternatives C, D, and F exempt Oil and Gas Management Areas (430,674 BLM-administered surface acres under Alternative C and 348,617 BLM-administered surface acres under alternatives D and F) from seasonal wildlife restrictions (with the exception of the areas overlapped by the proposed Greater Sage-grouse PHMAs ACEC under Alternative F), resulting in adverse impacts to special status wildlife species.

Livestock grazing management under Alternative C would adversely affect grizzly bears and gray wolves the most, followed by alternatives A, D and F, and B and E. Gray wolves would benefit more from forest, woodland, and forest products management under alternatives A, D, and F, and less under alternatives B, C, and E. Timber harvesting practices, old-growth stand retention, surface-disturbance restrictions around raptor nests, and snag retention under alternatives B and E would result in the most beneficial impacts to Canada lynx, followed by alternatives D and F, A, and C.

Alternative E protects the largest area of greater sage-grouse leks, nesting and early brood-rearing habitats, and winter concentration areas, followed by alternatives B, F, D, A, and C. Alternative E, and to a lesser extent Alternative B, places comparatively greater restrictions on resource uses and activities in greater sage-grouse Key Habitat Areas. Alternatives D and F also apply protective management for greater sage-grouse, although to a lesser extent than Alternative E, in PHMAs. Similar to alternatives E and F, Alternative D applies adaptive management principles to identify when changes in management may be needed in order to continue meeting greater sage-grouse conservation objectives. Although livestock grazing in greater sage-grouse habitat can have both adverse and beneficial impacts (e.g., alternatives D and F allow livestock grazing to improve greater sage-grouse habitat), the more restrictive management under alternatives B and E would be the most beneficial to this species. Other sagebrush-dependent species (e.g., Brewer's sparrow, sage sparrow, and sage thrasher) are anticipated to benefit

the most from protective management actions for greater sage-grouse under Alternative E, followed by alternatives B, F, D, A, and C. Chapter 3 provides a discussion of identified threats to greater sage-grouse while Table 4-23 provides a comparison of management actions across the range of alternatives and summarizes impacts for each threat.

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
General Limitations on Surface Disturbance and/or Disruptive Activities in Greater Sage-Grouse Habitat					
MANAGEMENT SUMMARY					
<p>Apply a CSU stipulation for discretionary actions to prohibit surface-disturbing and disruptive activities within 0.25 miles of occupied leks.</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities in nesting and early brood-rearing habitats within 2 miles of occupied leks or other nesting and brood-rearing habitat (March 15 to July 15; February 1 to July 31).</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities in winter concentration areas from November 15 to March 14.</p>	<p>Prohibit surface-disturbing and disruptive activities within 0.6 miles of occupied leks.</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities in nesting and early brood-rearing habitats within 3 miles of occupied leks or other nesting and brood-rearing habitat (February 1 to July 31).</p> <p>Avoid surface-disturbing and disruptive activities in winter concentration areas from November 15 to March 14.</p> <p>Anthropogenic disturbance must not exceed one disturbance per 640 acres and must cover less than 5 percent of priority habitat regardless of ownership.</p>	<p>Apply a CSU stipulation for discretionary actions to prohibit surface-disturbing and disruptive activities within 0.25 miles of all occupied leks.</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities in nesting and early brood-rearing habitats within 2 miles of occupied leks or other nesting and brood-rearing habitat (March 15 to July 15).</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities in winter concentration areas from November 15 to March 14.</p> <p>Exempt Oil and Gas Management Areas and ROW corridors from discretionary wildlife seasonal stipulations.</p>	<p>Prohibit surface-disturbing and disruptive activities within 0.6 miles of occupied leks inside priority habitat and within 0.25 miles of occupied leks outside priority habitat.</p> <p>In priority habitat, apply a TLS to restrict disruptive activity within 0.6 miles of occupied leks and prohibit or restrict surface-disturbing and disruptive activities in nesting and early brood-rearing habitat from March 15 to June 30.</p> <p>Outside priority habitat, apply a TLS to restrict disruptive activity within 0.25 miles of occupied leks and prohibit or restrict surface-disturbing and disruptive activities in nesting and early brood-rearing habitat within 2 miles of occupied leks from March 15 to June 30.</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities within winter concentration areas from November 15 to March 14.</p> <p>Limit the density of disturbance in priority habitat to 5 percent of the DDCT analysis area.</p>	<p>Prohibit surface-disturbing and disruptive activities within 0.6 miles of occupied leks.</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities in nesting and early brood-rearing habitats within 3 miles of occupied leks or other nesting and brood-rearing habitat (February 1 to July 31).</p> <p>Avoid surface-disturbing and disruptive activities in winter concentration areas from November 15 to March 14.</p> <p>Anthropogenic disturbance must not exceed one disturbance per 640 acres and must cover less than 3 percent of priority habitat regardless of ownership.</p>	<p>Prohibit surface-disturbing and disruptive activities within 0.6 miles of occupied leks inside priority habitat and within 0.25 miles of occupied leks outside priority habitat.</p> <p>In priority habitat, apply a TLS to restrict disruptive activity within 0.6 miles of occupied leks and prohibit or restrict surface-disturbing and disruptive activities in nesting and early brood-rearing habitat from March 15 to June 30.</p> <p>Outside priority habitat, apply a TLS to restrict disruptive activity within 0.25 miles of occupied leks and prohibit or restrict surface-disturbing and disruptive activities in nesting and early brood-rearing habitat within 2 miles of occupied leks from March 15 to June 30.</p> <p>Apply a TLS to avoid surface-disturbing and disruptive activities within winter concentration areas from November 15 to March 14.</p> <p>Anthropogenic disturbance must not exceed one disturbance per 640 acres and must cover less than 3 percent of the DDCT analysis area within priority habitat.</p>

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<p>Impact Summary: Limitations on surface disturbance and disruptive activities in proximity to greater sage-grouse leks and within seasonal habitats under alternatives E and F would protect the greatest overall area, particularly through the inclusion of additional areas outside of priority habitat, followed by alternatives B, D, A, and C. Limitations on the density of surface-disturbance within priority habitats would vary based on the delineation of the DDCT analysis area for a given project, but alternatives E and F would generally allow less cumulative disturbance (3 percent) than alternatives B and D (5 percent) within priority habitat.</p>					
<p>Threat – Sagebrush Elimination</p>					
<p>MANAGEMENT SUMMARY</p>					
<p>No specific management provided for conducting habitat enhancement vegetation treatments in sagebrush communities.</p>	<p>Conduct habitat enhancement vegetation treatments on at least 200 acres per year in sagebrush communities.</p>	<p>Conduct habitat enhancement vegetation treatments within sagebrush communities as opportunities and funding allow.</p>	<p>Conduct habitat enhancement vegetation treatments within sagebrush communities as opportunities and funding allow, designing treatments to maintain or improve sagebrush habitat in stands with less than 15 percent cover. Treatments that reduce sagebrush canopy cover to less than 15 percent may be allowed if sufficient canopy cover is maintained in adjacent areas.</p>	<p>Conduct habitat enhancement vegetation treatments on at least 200 acres per year in sagebrush communities. Do not reduce sagebrush canopy cover to less than 15 percent unless required to meet greater sage-grouse conservation objectives or provide strategic habitat protection. Restore native (or desirable) plants and create landscape patterns that most benefit greater sage-grouse using the reference state of the appropriate ESD. Avoid sagebrush reduction/treatments to increase livestock or big game forage in occupied habitat.</p>	<p>Conduct habitat enhancement vegetation treatments within sagebrush communities as opportunities and funding allow, designing treatments to maintain or improve sagebrush habitat in stands with less than 15 percent cover. Do not reduce sagebrush canopy cover to less than 15 percent unless required to meet greater sage-grouse conservation objectives or provide strategic habitat protection. Manage areas for a higher plant community state or phase (based on state and transition models in ESDs) on a case-by-case basis to achieve sage-grouse seasonal habitat objectives. Avoid sagebrush reduction/treatments to increase livestock or big game forage in occupied habitat.</p>
<p>Impact Summary: All alternatives would reduce sagebrush elimination by managing to maintain suitable canopy cover and understory diversity in greater sage-grouse nesting habitat and existing nonnative grass seedings with less than 5 percent canopy cover. Beneficial impacts from the restoration of non-functioning riparian systems and brood-rearing habitat in riparian/wetland areas would also be common to all alternatives. Requiring habitat enhancement vegetation treatments to maintain or improve sagebrush stands with less than 15 percent canopy cover under alternatives D, E, and F could reduce habitat fragmentation and habitat loss to a greater extent than the other alternatives; however, exceptions allowed under Alternative D could result in greater sagebrush elimination in certain areas. Requiring the treatment of 200 acres of sagebrush communities annually, at minimum, would help to ensure ongoing maintenance and restoration of greater sage-grouse habitat over the life of the plan under alternatives B and E. By managing sagebrush communities toward appropriate ESDs, alternatives E and F may provide more comprehensive targets for and measures of treatment success than canopy coverage alone. Alternatives E and F also avoid sagebrush reduction/treatments designed to increase forage for other uses, which would help to maintain the integrity of occupied habitat. Overall, alternatives E and F include the most proactive measures for reducing sagebrush elimination through vegetation treatments and are most likely to achieve the RMP objectives of increasing connectivity of occupied greater sage-grouse habitats and maintaining at least 70 percent of lands capable of producing sagebrush with 10 to 30 percent sagebrush canopy cover in priority habitat.</p>					

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Threat – Fire					
MANAGEMENT SUMMARY					
No specific management provided for fire and fuels in sagebrush communities.	No specific management provided for fire and fuels in sagebrush communities.	No specific management provided for fire and fuels in sagebrush communities.	Treatments that reduce sagebrush canopy cover to less than 15 percent may be allowed if sufficient canopy cover is maintained in adjacent areas.	Do not reduce sagebrush canopy cover to less than 15 percent unless required to meet greater sage-grouse conservation objectives or provide strategic habitat protection. Use fire to treat sagebrush in less than 12-inch precipitation zones only after exhausting all other feasible treatment options. Design fuels management projects in priority sage-grouse habitat to strategically and effectively reduce wildfire threats over the greatest area.	Do not reduce sagebrush canopy cover to less than 15 percent unless required to meet greater sage-grouse conservation objectives or provide strategic habitat protection. Use fire to treat sagebrush in less than 12-inch precipitation zones only after exhausting all other feasible treatment options. Design fuels management projects in priority sage-grouse habitat to strategically and effectively reduce wildfire threats over the greatest area.
<p>Impact Summary: All alternatives require suppression of fires threatening greater sage-grouse habitat and only allow the use of prescribed fire if demonstrated to meet greater sage-grouse conservation objectives through NEPA analysis. Prohibiting fuels treatments that reduce sagebrush canopy cover to less than 15 percent under alternatives E and F could reduce habitat fragmentation and habitat loss to a greater extent than the other alternatives. Alternative D also applies a 15 percent sagebrush canopy cover requirement, but allows exceptions that may result in greater habitat loss in certain areas. In contrast, Alternative E and F only allow exceptions to provide strategic habitat protection or conserve habitat quality for greater sage-grouse. Alternatives E and F restrict the use of fire to treat sagebrush in low-precipitation zones and design fuels management projects to strategically reduce wildfire threats over the greatest area in priority greater sage-grouse habitat; this management would require careful coordination of proposed prescribed fires and fuels treatments with greater sage-grouse conservation objectives, but is unlikely impede the use of these tools to reduce the risk of catastrophic wildland fires. Overall, the management of fires and fuels treatments under alternatives E and F is likely to result in the most beneficial impacts and achieve the RMP objective of protecting greater sage-grouse habitat through fuels treatments. Alternatives A, B, and C contain no specific management for fire and fuels in sagebrush communities.</p>					

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Threat – Conifer Encroachment					
MANAGEMENT SUMMARY					
Manage conifer encroachment to improve wildlife habitat and forest health conditions.	Manage conifer encroachment to improve wildlife habitat and forest health conditions.	Manage conifer encroachment to enhance livestock grazing.	Manage conifer encroachment to improve wildlife habitat and forest health conditions as well as make progress toward potential natural communities, as determined by the site’s ESD.	Manage conifer encroachment to improve wildlife habitat and forest health conditions.	Manage conifer encroachment to improve wildlife habitat and forest health conditions.
<p>Impact Summary: All alternatives require removal of conifers encroaching into sagebrush habitat, with priority given to areas closest to occupied leks. More long-term benefits may be achieved by reintroducing fire regimes that would limit conifer encroachment in sagebrush habitat; this management is also common to all alternatives. Managing conifer encroachment to improve wildlife habitat conditions under all alternatives except Alternative C is likely result in beneficial impacts to the greater sage-grouse, for which habitat conservation is a management high priority. Although Alternative C would protect sagebrush habitat from conifer encroachment, managing these areas to enhance livestock grazing without consideration for wildlife habitat conditions under this alternative is likely to result in the least beneficial impacts to greater sage-grouse. Alternative D may result in the most beneficial impacts of all the alternatives by managing areas treated for conifer encroachment toward more comprehensive vegetation community goals (i.e., ESDs) than conifer elimination alone.</p>					
Threat – Weed and Annual Grass Invasion					
MANAGEMENT SUMMARY					
No specific management provided for invasive, nonnative plant species in greater sage-grouse habitat. Require livestock flushing at the discretion of the authorized officer.	No specific management provided for invasive, nonnative plant species in greater sage-grouse habitat; however, this alternative manages to maintain contiguous blocks of native plant communities and minimize fragmentation, while allowing for other resource uses. Implement a 72-hour livestock flushing protocol at the discretion of the authorized officer.	No specific management provided for invasive, nonnative plant species in greater sage-grouse habitat. Do not require livestock flushing.	No specific management provided for invasive, nonnative plant species in greater sage-grouse habitat; however, this alternative manages to maintain contiguous blocks of native plant communities and minimize fragmentation, while allowing for other resource uses. Require livestock flushing at the discretion of the authorized officer.	Restrict activities in greater sage-grouse habitat that facilitate the spread of invasive plants. Implement a 72-hour livestock flushing protocol at the discretion of the authorized officer and require vehicle washing. Use native seeds and plants to restore greater sage-grouse habitat to its ESD potential in areas that have been disturbed or invaded by nonnative plants. If sagebrush reduction/treatments are conducted, create plans to restore high-quality habitat in areas with invasive species and minimize the use of herbicides. Monitor and control invasive vegetation post-treatment.	Require livestock flushing at the discretion of the authorized officer and require vehicle washing. Use native seeds and plants to restore greater sage-grouse habitat to a higher plant community state or phase (based on state and transition models in ESDs) in areas that have been disturbed or invaded by nonnative plants. If sagebrush reduction/treatments are conducted, create plans to restore high-quality habitat in areas with invasive species and minimize the use of herbicides. Monitor and control invasive vegetation post-treatment. Consider potential changes in climate when selecting native

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
				Design post emergency stabilization and rehabilitation management to ensure long-term persistence of seeded or pre-burn native plants. Allocate native seeds for future use and consider potential changes in climate when selecting native post-fire seedlings.	post-fire seedlings.
<p>Impact Summary: Developing an invasive species and pest management plan and coordinating with local counties and other stakeholders on invasive plant species management in accordance with current guidance could reduce the potential for invasive species establishment and spread in greater sage-grouse habitats under all alternatives. In addition, all alternatives manage to promote the growth and persistence of native plants that would provide seasonal food and concealment for greater sage-grouse. All alternatives except Alternative C may require livestock flushing, which would reduce the potential for weed spread in greater sage-grouse habitat. Specific time requirements for livestock flushing under alternatives B and E and vehicle washing requirements under alternatives E and F could further reduce opportunities for weed spread. Although alternatives B and D do not include specific management for invasive, nonnative plant species in greater sage-grouse habitat, these alternatives may result in beneficial impacts through efforts to maintain contiguous blocks of native plant communities. Alternatives E and F include similar management requirements for maintaining and monitoring native plant communities in greater sage-grouse habitat; however, Alternative E also manages to restore these habitats to their full ESD potential, conducts post fire rehabilitation to ensure persistence of native plants, and proactively reserves native seeds for future use, which may result in more beneficial impacts than any other alternative.</p>					
<p>Threat – Mining</p>					
<p>MANAGEMENT SUMMARY</p>					
No specific management provided for mining in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures to mining established to protect other resources and resources uses would apply.	No specific management provided for mining in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures to mining established to protect other resources and resources uses would apply.	No specific management provided for mining in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures to mining established to protect other resources and resources uses would apply.	In priority habitat, allow only one energy or mining facility per 640 acres. The cumulative value of existing and proposed disturbance must not exceed 5 percent of habitat.	Pursue a withdrawal from appropriation under the mining laws and close priority habitat to mineral material disposals. Make existing claims within this area subject to validity exams or buyout and consider applying seasonal restrictions. Restore salable mineral pits no longer in use. Seek to acquire subsurface mineral rights to conserve or restore greater sage-grouse habitat.	Consider applying seasonal restrictions to mining activities in priority habitat. Restore salable mineral pits no longer in use. Seek to acquire subsurface mineral rights to conserve or restore greater sage-grouse habitat.
<p>Impact Summary: Priority habitat is considered unsuitable for coal mining pursuant to federal regulations under all alternatives. All alternatives also require that disturbance of springs and riparian areas is minimized during mining activities, which would help to maintain suitable water sources and brooding habitat for greater sage-grouse. The BLM may pursue a withdrawal from appropriation under the mining laws for locatable minerals in special status species habitats under any alternative, but only proposes to do so under Alternative E. Limitations on the density of disturbance in priority habitats under Alternative D would minimize cumulative impacts from mining and other disturbances. The withdrawal of priority habitat to locatable mineral entry and closure to mineral material disposals would make Alternative E most effective in reducing adverse impacts from mining in greater sage-grouse habitat on BLM-administered lands.</p>					

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Threat – Energy Development					
MANAGEMENT SUMMARY					
<p>No specific management provided for energy development in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures to energy development established to protect other resources and resources uses would apply.</p>	<p>Avoid wind energy projects in nesting, brood-rearing, and winter habitat areas. Priority habitat is closed to mineral leasing. Apply a NSO restriction to mineral leasing within a 0.6-mile radius of all occupied leks and within winter concentration areas. Wells must not disturb more than 15 acres within a 640-acre section and the cumulative value of existing and proposed disturbance must not exceed 5 percent of habitat within the section.</p>	<p>Allow wind energy projects in greater sage-grouse nesting, brood-rearing, and winter habitat areas. No specific management provided for mineral leasing in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures to energy development established to protect other resources and resources uses would apply.</p>	<p>Avoid wind energy projects in priority habitat. Inside priority habitat, apply a NSO restriction to mineral leasing within a 0.6-mile radius of occupied greater sage-grouse leks. Outside priority habitat, apply a NSO restriction to mineral leasing within a 0.25 miles of occupied leks. In priority habitat, allow an average of one energy or mining facility per 640 acres. The cumulative value of existing and proposed disturbance must not exceed 5 percent of habitat.</p>	<p>Avoid wind energy projects in nesting, brood-rearing, and winter habitat areas. Priority habitat is closed to mineral leasing. Apply a NSO restriction to mineral leasing within a 0.6-mile radius of all occupied greater sage-grouse leks and within winter concentration areas. Apply NSO conditions of approval on existing leases to the extent feasible within greater sage-grouse priority habitat. Limit proposed surface disturbance to 3 percent for an area when permitting APDs on existing leases that are not yet developed. Close priority habitat to geophysical exploration.</p>	<p>Avoid wind energy projects in priority habitat. Inside priority habitat, apply a NSO restriction to mineral leasing within a 0.6-mile radius of occupied leks. Outside priority habitat, apply a NSO restriction to mineral leasing within a 0.25 miles of occupied leks. Apply NSO conditions of approval on existing leases to the extent feasible within priority habitat. Limit proposed surface disturbance to 3 percent for an area when permitting APDs on existing leases that are not yet developed and require a minimum lease size of 640 contiguous acres. Allow geophysical exploration in priority habitat if appropriately mitigated.</p>
<p>Impact Summary: Surface disturbing and disruptive activities associated with energy development would be subject to general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures to energy development established to protect other resources, to varying degrees, under all alternatives. All alternatives with the exception of alternatives A and C avoid wind energy projects in greater sage-grouse priority or seasonal habitats, which would likely require projects to be located and designed to minimize impacts. Alternative C could result in the most adverse impacts by specifically allowing wind energy development in seasonal habitats. Neither Alternative A nor Alternative C include specific management for mineral leasing in greater sage-grouse habitat. NSO restrictions applied to greater sage-grouse leks under alternatives B, D, E, and F may reduce disturbances and disruptive activities that could contribute to declines in lek attendance or lek abandonment; however, Alternatives B and E close priority habitat to mineral leasing and apply larger protective lek buffers outside of priority habitat, which would eliminate the potential for new oil and gas related disturbances across a large portion of the Planning Area and provide more protection to areas outside of priority habitat than the other alternatives. Limitations on the density of disturbance in priority habitat under alternatives B and D would minimize cumulative impacts from mining and other disturbances. Alternatives E and F have the greatest potential to reduce impacts in areas already leased for mineral development by applying NSO conditions of approval, when feasible, to the existing leases and limiting surface disturbance to 3 percent of the lease area in greater sage-grouse priority habitat. Overall, Alternative E is likely to be most effective in minimizing impacts from energy development and meeting the RMP objective to mitigate adverse impacts to greater sage-grouse from fluid mineral development on BLM-administered lands.</p>					

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Threat – Infrastructure					
MANAGEMENT SUMMARY					
<p>No specific management provided for infrastructure development in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures or restrictions on infrastructure development to protect other resources and resources uses would apply.</p>	<p>Manage areas within a 0.6 miles of all occupied leks as ROW exclusion areas. Manage priority habitat as a ROW avoidance area. No specific management provided for new road construction in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures or restrictions on road construction to protect other resources and resources uses would apply.</p>	<p>No specific management provided for infrastructure development in greater sage-grouse habitat; however, general restrictions on surface-disturbing and disruptive activities for greater sage-grouse and overlapping closures or restrictions on infrastructure development to protect other resources and resources uses would apply.</p>	<p>Manage priority habitat as a ROW avoidance area. In priority habitat, avoid locating new collector roads within 1.9 miles and other new roads within 0.6 miles of occupied leks. Construct roads to minimum design standards need for production activities. In priority habitat, co-locate major overhead powerlines within 0.5 miles of an existing 115 kV or greater powerline or within a designated corridor. Distribution lines may be authorized when effectively mitigated.</p>	<p>Manage priority habitat as a ROW avoidance area. Manage areas within a 0.6 miles of all occupied leks as ROW exclusion areas. Prohibit new road construction within 4 miles of occupied leks, and avoid new road construction in occupied habitat. Allow only below ground ROWs within designated ROW corridors. Co-locate new ROWs associated with valid existing rights within existing ROWs or where impacts to greater sage-grouse are minimized. Remove, bury, or modify existing powerlines and require burial of new ROWs in designated ROW corridors within priority greater sage-grouse habitat. Use existing roads or realignments to access valid existing rights when feasible, otherwise build new roads to the minimum design standards necessary.</p>	<p>Manage priority habitat as ROW avoidance areas. Locate new primary and secondary roads greater than 1.9 miles from the perimeter of occupied leks in priority habitat. Consider alternatives that would locate new tertiary roads greater than 0.6 miles from occupied leks. Allow only below ground ROWs within designated ROW corridors. Remove, bury, or modify existing powerlines and require burial of new ROWs in designated ROW corridors within priority greater sage-grouse habitat. Construct new transmission lines between July 1 and March 14 (or between July 1 and November 30 in mapped winter concentration areas) and within 0.5 miles on either side of existing 115 kV or larger transmission lines. Use existing roads to access valid existing rights when feasible, otherwise build new roads to the minimum design standards necessary.</p>
<p>Impact Summary: Alternatives B, D, E, and F manage greater sage-grouse priority habitats as ROW avoidance areas; however, Alternatives B and E would generally be most effective in protecting occupied leks from infrastructure development by excluding ROW development within 0.6 miles of these areas. Alternatives D, E, and F include requirements to co-locate new powerline ROWs, which would generally confine new disturbances to areas with lower habitat value. Alternatives E and F also require burial of ROWs within designated ROW corridors and would remove or modify existing powerlines in priority habitat, which could reduce habitat fragmentation and potential risks of collision and predation. Seasonal limitations on the construction of transmission lines under alternatives D and F would minimize disruption of greater sage-grouse during sensitive periods. Designing roads to minimum standards necessary is a common requirement of alternatives D, E, and F that would reduce the overall level of disturbance from new road development in priority greater sage-grouse habitats. Alternatives D, E, and F avoid or prohibit the development of new roads in close proximity to greater sage-grouse leks. Alternative B would reduce the</p>

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<p>potential for habitat fragmentation, disruptions, and vehicle strikes associated with road development to the greatest extent by prohibiting new road construction within 4 miles of occupied leks. Alternatives A and C provide no specific management for infrastructure development in greater sage-grouse habitats and the potential for adverse effects from infrastructure development are greatest under these alternatives. Overall, alternatives E and F are likely to result in the least adverse impacts to greater sage-grouse from infrastructure development.</p>					
<p>Threat – Grazing</p>					
<p>MANAGEMENT SUMMARY</p>					
<p><i>Common to All Alternatives:</i> Prioritize the processing of grazing permits/leases in priority habitat.</p> <p><i>Common to All Alternatives:</i> Manage livestock grazing to achieve the Wyoming Standards for Rangeland Health.</p> <p><i>Common to All Alternatives:</i> NEPA analysis for renewals and modifications of livestock grazing permits/leases that fall within priority habitat may consider Greater Sage-grouse Habitat Conservation Objectives and management considerations, Land Health Standards (43 CFR 4180.2), ecological site potential, and/or local variability. Renewals and modifications will also include one or more defined responses that will allow the authorizing officer to make adjustments to livestock grazing that have already been subjected to NEPA analysis.</p> <p><i>Common to All Alternatives:</i> Require new fences in priority habitat to be located in a manner that minimizes disturbance and that the visibility of existing fences be increased where documented strikes are a problem.</p>	<p>Close priority habitat to livestock grazing.</p> <p>Prohibit new livestock water development in greater sage-grouse nesting habitat.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>No specific management prescribed for livestock grazing in greater sage-grouse habitat.</p> <p>Allow new livestock water development in greater sage-grouse nesting habitat.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>Prioritize allotments in priority habitat for field checks to ensure compliance with grazing permits.</p> <p>Allow new livestock water development in greater sage-grouse nesting habitat when impacts can be mitigated.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>Close priority habitat to livestock grazing.</p> <p>Prohibit new livestock water development in greater sage-grouse nesting habitat.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>Allow livestock grazing in priority habitat.</p> <p>Prioritize the completion of rangeland health assessment in priority habitat and develop specific objectives to achieve greater sage-grouse habitat objectives.</p> <p>Reduce grazing in important seasonal habitats for greater sage-grouse.</p> <p>Allow new livestock water development in greater sage-grouse nesting habitat when impacts can be mitigated.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
No additional specific management prescribed for livestock grazing or new livestock water developments in greater sage-grouse habitat.					
<p>Impact Summary: Alternatives B and E close priority habitat to livestock grazing outright and prohibit the new livestock water developments, which would eliminate potential adverse impacts from loss of herbaceous cover due to overgrazing, invasive species spread, loss or degradation of water sources, or drowning hazards. Although Alternative F allows livestock grazing in priority habitat, it includes a number of mitigation and monitoring requirements to help ensure that livestock grazing activities are aligned with greater sage-grouse habitat objectives. Proper livestock grazing is likely to be compatible with greater sage-grouse conservation objectives under all alternatives; however, prohibitions on livestock grazing under alternatives B, E and F are likely to be most effective in reducing threats to greater sage-grouse.</p>					
<p>Threat – Recreation</p>					
<p>MANAGEMENT SUMMARY</p>					
<p><i>Common to All Alternatives:</i> Motorized vehicle use on BLM-administered land is limited to existing roads and trails on an interim basis until completion of travel management planning. Designation changes from “limited to existing roads and trails” to “limited to designated roads and trails” upon the completion of a travel management plan.</p> <p>No specific management prescribed for motorized vehicle use or other recreational activities in greater sage-grouse habitat; however, overlapping closures or restrictions based on other resources and resources uses would apply.</p>	<p>Motorized vehicle use is limited to designated roads and trails in priority habitat with a seasonal closure from February 1 to July 31.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>No specific management prescribed for motorized vehicle use or other recreational activities in greater sage-grouse habitat; however, overlapping closures or restrictions based on other resources and resources uses would apply.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>No specific management prescribed for motorized vehicle use or other recreational activities in greater sage-grouse habitat; however, overlapping closures or restrictions based on other resources and resources uses would apply.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>Motorized vehicle use is limited to designated roads and trails in priority habitat with a seasonal closure from February 1 to July 31.</p> <p>Only authorize SRPs that have neutral or beneficial effects to greater sage-grouse in priority habitat.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>	<p>Only authorize SRPs that have neutral or beneficial effects to greater sage-grouse in priority habitat.</p> <p>See also <i>Common to All Alternatives</i> management under Alternative A.</p>
<p>Impact Summary: Seasonal limitations on motorized vehicle use in greater sage-grouse priority habitat under alternatives B and E would reduce the risk of collisions and disturbance from off-trail use. Alternatives E and F only authorize SRPs that would occur in locations or during times that would not result in adverse impacts on greater sage-grouse. Based on these restrictions, Alternative E is anticipated to result in the fewest adverse impacts on greater sage-grouse from recreation. Alternatives A, C, and D do not include specific management for recreation in greater sage-grouse habitat.</p>					

Table 4-23. Key Management Actions and Their Effectiveness in Reducing Threats to Greater Sage-Grouse (Continued)

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
---------------	---------------	---------------	---------------	---------------	---------------

Notes:

- a) Management actions summarized in this table have been adapted from Table 2-9, Detailed Alternatives. In some cases, descriptions in this table have been generalized for ease of comparison. Please refer to Table 2-9 for a full description of management actions.
- b) Threats were identified from the Final Report on Greater Sage-Grouse Conservation Objectives (COT Report – USFWS 2013a).
- c) Alternatives B and E generally contain management for greater sage-grouse Key Habitat Areas, while D and F contain management for PHMAs. For ease of comparison and due to the similarity of these habitat areas, the term “priority habitat” is used throughout the table.
- d) The summaries contained above focus on greater sage-grouse specific management most relevant to each threat; however, there would also be influence from overlapping management for other resources and resource uses.
- e) For discretionary actions, the BLM may choose to apply required design features and/or mitigation not included in this table on a case-by-case basis.

Alternatives B and E protect the largest area around active raptor nests (including a year-round CSU stipulation around all nests) and would be the most beneficial to these species, followed by alternatives A; D and F; and C. Alternative C restricts activities that may potentially disturb raptor nesting sites (including a TLS stipulation of 0.25-mile around nests). Adverse impacts to bald eagles from surface disturbance would be greatest under Alternative C, followed by alternatives A, D and F, and B and E. Impacts from recreation in riparian/wetland areas to this species would be greatest under Alternative A, followed by alternatives B and E, D and F, and C. Proactive management actions in the Chapman Bench area under alternatives B, D, E, and F would beneficially affect the mountain plover and long-billed curlew. Livestock grazing and vegetation management under Alternative C is most beneficial to the mountain plover when compared to the other alternatives, while adverse impacts to prairie dogs under this alternative would result in adverse impacts to the mountain plover as well.

4.4.9.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

The types of projected impacts to special status wildlife species under the various alternatives are similar to the impacts described in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*. Therefore, this section includes only instances where impacts are different from those described for wildlife.

Authorized activities for resource uses may disturb special status wildlife species by causing displacement or excessive stress during critical life stages. Management actions and allowable uses under all alternatives would involve habitat loss, degradation, reclamation, protection, enhancement, and fragmentation. However, the intensity of impacts would vary by alternative. Refer to Appendix T for projected short- and long-term surface disturbance from BLM actions.

Resource Uses

Oil and gas development may result in adverse impacts to special status species, including the greater sage-grouse, under all alternatives. Increased bentonite mining, and potentially gypsum mining, along with the difficult nature of shrub reclamation in the 5- to 9-inch precipitation zone would result in adverse impacts to special status wildlife species in sagebrush habitat under all alternatives. However, under all alternatives, adverse impacts would be lessened through implementation of the Wyoming BLM Standard Mitigation Guidelines for Surface-Disturbing and Disruptive Activities (Appendix H) and BMPs (Appendix L).

Subject to valid existing rights, the BLM would prioritize leasing and authorizing development of fluid mineral resources in greater sage-grouse habitat areas in the following order: 1) outside of PHMAs and GHMAs, 2) non-habitat areas inside of PHMAs and GHMAs, and 3) least suitable habitat areas inside of PHMAs and GHMAs. Where adverse effects to greater sage-grouse populations or habitat are anticipated, the BLM would work with the project proponent in developing an APD to avoid, reduce and mitigate adverse impacts to the extent compatible with lessees' rights to drill and produce fluid mineral resources.

Avoiding the aerial application of pesticides, though minimizing drift into non-target areas in greater sage-grouse habitat, may result in adverse impacts in some situations because ground application can be a greater disturbance to greater sage-grouse. Avoiding pesticide application in greater sage-grouse breeding habitat during the brood-rearing season may preclude beneficial impacts if pesticides are necessary to control pests that would substantially reduce forage cover (e.g., grasshoppers). Conversely, pesticide application to reduce pests such as grasshoppers may result in adverse impacts to young birds by decreasing food availability.

Special status bird, raptor, and bat species can collide with wind-energy and utility infrastructure, causing a direct adverse impact due to mortality and displacement. Projected renewable energy development is the same for all alternatives (Appendix T), requiring the placement of these structures to minimize impacts. Large wind-energy fields involve surface disturbance, which could permanently change the habitat structure for the wildlife inhabitants.

Livestock grazing can alter special status wildlife species habitat resulting in adverse or beneficial impacts. Livestock grazing at the appropriate intensity and timing can be beneficial to grassland and shrubland habitats and the associated special status wildlife species, such as greater sage-grouse. In allotments where grazing by wild horses or livestock removes nest or brood cover, reduces the production of annual forbs, or restricts access to water, impacts to special status wildlife species, such as greater sage-grouse, would be adverse. Potential adverse impacts to greater sage-grouse from livestock grazing would be minimized under all alternatives by managing to achieve the Wyoming Standards for Rangeland Health. In addition, prioritizing grazing permits/leases in PHMAs to investigate if modification is needed prior to renewal would help to reduce the potential for the continuation of livestock grazing management in priority greater sage-grouse habitat that is degrading habitat.

All alternatives manage land tenure adjustments with a goal of preserving important resource values (including habitat for special status species). Maintaining lands in federal ownership would continue BLM review and authorization of discretionary activities that could adversely affect special status species and facilitate more consistent management across a species' range than may be feasible in areas that contain a patchwork of landownership.

Under all alternatives, PHMAs and GHMAs are subject to temporary closures to motorized vehicle use at the discretion of the authorized officer to prevent adverse impacts to greater sage-grouse. These closures would result in short-term beneficial impacts on greater sage-grouse and other sagebrush obligate species by reducing disruptive activity and risk of vehicle strikes.

Special Designations

Special designations that restrict surface-disturbing activities and resource uses that adversely affect special status wildlife species, such as mineral development, motorized vehicle use, and ROW development provide beneficial impacts to these species. Under all alternatives, WSAs are managed for naturalness, outstanding opportunities for solitude, and primitive and unconfined recreation. These special designations provide multiple beneficial impacts by restricting activities and resource uses that degrade habitat and disturb special status wildlife species. The Spanish Point Karst ACEC, designated regardless of the alternative, would limit adverse impacts to special status bat species in this area.

Resources

Similar to livestock grazing, fire and fuels management can alter special status wildlife species habitat, resulting in adverse and beneficial impacts. Replicating historical fire regimes in grassland, shrubland, and forest and woodland habitats, although potentially resulting in adverse impacts to special status wildlife species in the short term, can prevent catastrophic wildfires likely to cause more adverse impacts, but only in areas where cheatgrass has not become prevalent and annual precipitation is sufficient to restore burned areas (e.g., above 12 to 14 inches annually). Wildland fire is used to restore fire-adapted ecosystems and in the long term improves forest health for many wildlife species such as mule deer and elk that summer and winter in these habitats. This in turn benefits special status wildlife species such as grizzly bears and gray wolves, which are predators of big game. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for a more detailed description of resource uses that impact wildlife.

Special Status Species – Wildlife

Special status wildlife species are anticipated to benefit both directly and indirectly where restrictions are implemented that conserve different habitat types from surface-disturbing and wildlife-disturbing activities. For example, managing riparian/wetland areas to meet PFC improves habitat conditions for various special status wildlife species that inhabit these areas. Conservation of sagebrush habitat will not only benefit greater sage-grouse, it will benefit other sagebrush-dependent species such as the sage thrasher and sage sparrow.

Proactive Management Actions

Select management actions and allowable uses are anticipated to benefit special status wildlife species by promoting individual species and their habitats or by restricting or altering activities of other resource programs (e.g., mineral development, motorized vehicle use, and fire and fuels management). Collectively, this section describes these actions as proactive management actions, which include restricting certain types of development, managing habitat fragmentation, and developing and protecting water sources and associated habitats for special status wildlife species in cooperation with the WGFD.

Under all alternatives, implementing, where appropriate, conservation measures, terms and conditions, and appropriate BMPs and reasonable and prudent measures in existing state programmatic biological opinions for the bald eagle, Canada lynx, gray wolf, black-footed ferret, and grizzly bear would minimize and mitigate adverse impacts from resource uses and activities. Biological opinions are available on the project website at <http://www.blm.gov/wy/st/en/programs/Planning/rmps/bighorn.html>.

The greater sage-grouse is a BLM sensitive species known to occur in the Planning Area. Numerous management actions common to all alternatives from the *BLM National Sage-grouse Habitat Conservation Strategy* that would beneficially affect the greater sage-grouse by protecting and enhancing its habitat include: insecticide and pesticide restrictions, water source maintenance and protection, riparian/wetland area restoration, and vegetation treatments. All alternatives apply a protective buffer to restrict surface-disturbing activities around occupied greater sage-grouse leks and nesting and early brood-rearing habitat, providing beneficial impacts to greater sage-grouse and other sagebrush obligate species by protecting undisturbed sagebrush steppe habitats from potential mineral, industrial, and recreational facility development. The prioritization and removal of conifers encroaching into sagebrush habitats would benefit greater sage-grouse and other sagebrush obligate species by reducing habitat loss.

All alternatives apply a protective buffer around all active raptor nests, benefitting special status raptor species and other special status wildlife species that share this habitat. Applying measures, such as seasonal timing limitations, project design modifications, pre-disturbance surveys, and buffers, to avoid taking migratory birds under all alternatives would have beneficial impacts on migratory birds by avoiding disturbance during occupancy periods and minimizing habitat loss.

The impacts to special status wildlife species are described under individual alternatives in terms of anticipated surface disturbance; the potential impacts from other resource uses, special designations and resource program actions; and proactive management followed by a more detailed description of impacts.

Alternative A

Surface Disturbance – Alternative A

In general, the impacts to special status wildlife species from surface disturbance parallel the impacts to all wildlife. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for a general discussion of these

impacts. This section emphasizes what are likely to be the greatest impacts from surface disturbance to special status wildlife species.

Estimated short- and long-term surface disturbance from BLM actions in the Planning Area under Alternative A (Table 4-1) would result in loss, degradation, and fragmentation of sagebrush habitat. Loss of grassland and shrubland habitat will directly affect special status species that depend on these habitats. Surface disturbance, when it increases erosion and sedimentation, can also result in adverse impacts to special status wildlife species that depend on riparian/wetland habitats. Riparian/wetland habitat degradation due to surface disturbance is anticipated under Alternative A, which may result in adverse impacts to special status wildlife species inhabiting those areas.

Resource Uses – Alternative A

Minerals development would result in adverse impacts to special status wildlife species under Alternative A. Specifically, studies have identified mineral and oil and gas development as a potential cause of declining greater sage-grouse populations (Wyoming Sage-grouse Working Group 2003). Minerals development would result in 13,770 acres of long-term surface disturbance in grassland and shrubland communities under Alternative A that may result in habitat loss. Noise from mineral facilities operations, especially oil and gas facilities can also impact special status bird species relying on aural cues such as the greater sage-grouse. Alternative A is projected to result in 1,184 new federal oil and gas wells that would result in adverse impacts from habitat loss and noise disturbance.

Surface disturbance related to powerlines under Alternative A would be approximately 338 acres. Powerlines can directly affect raptor species through electrocution and current policy requires mitigating construction methods to avoid electrocution, when permitted on BLM-administered lands. Wind-energy development can also directly affect raptors and other birds through collisions and displacement, and indirectly through habitat fragmentation. Although renewable energy development across all alternatives is anticipated to be equal, Alternative A does not exclude wind-energy developments on any part of the Planning Area and the projected impacts to special status bird species from this resource use is greatest under this alternative.

Alternative A would limit impacts to special status wildlife species by closing 68,115 acres, including threatened and endangered species habitat, to motorized vehicle use that can disturb special status species. Projected surface disturbance from roads totals 1,966 acres in the short term and 983 acres in the long term under Alternative A, contributing to habitat loss and potentially forming barriers that fragment habitat for some special status wildlife species (Appendix T).

Livestock grazing under Alternative A is generally managed to provide for protection or enhancement of other resource values (e.g., wildlife). The BLM prohibits forage supplements within ¼ mile of riparian/wetland areas to avoid adverse impacts to this habitat. Special status wildlife species categories potentially affected by livestock and wild horse grazing include trophy game, game birds, nongame mammals, migratory birds, and amphibians.

Special Designations – Alternative A

Under Alternative A, the BLM designates the Five Springs Falls and Upper Owl Creek ACECs, which have special status species as a value of concern. Additionally, Alternative A restricts certain resource uses and activities within WSR eligible waterway segments, which would beneficially impact special status species that use riparian habitat. Special designations would limit adverse impacts to special status wildlife species under Alternative A.

Special Status Species – Wildlife

Resources – Alternative A

The impacts of resource management to special status wildlife species are addressed more specifically below. An overview of resource management as it applies to special status wildlife species habitat is included here under each alternative.

Fire and fuels management is likely to cause similar impacts to special status wildlife species across all alternatives. Under Alternative A, wildland fire is used to restore fire-adapted ecosystems and to reduce hazardous fuels, likely resulting in long-term beneficial impacts to all special status wildlife species, except in areas with lower precipitation, where wildland fire is not expected to enhance grassland or shrubland habitats.

Currently, the BLM manages invasive species primarily through cooperative efforts with county Pest Control Districts. Recent permitted activities under APDs, or ROWs, require weed treatment by the APD or ROW holder. Weeds have spread on public lands in developed oil and gas fields, along roads and pipelines, and with increasing recreational use. In general, Alternative A allows for expansion of these resource uses and is predicted to continue the spread of invasive species. The spread of invasive species is anticipated to degrade sagebrush and riparian/wetland habitats most acutely, and result in adverse impacts to special status wildlife species that depend on these habitats in the long term.

Forest management under Alternative A pursues some measures anticipated to disturb special status wildlife species and degrade/destroy habitat. These activities include precommercial thinning, woodland treatments, prescribed burns, timber harvest, and clear cutting limited to 300 yards in any direction. However, timber harvesting performed in a manner that protects and benefits wildlife would limit disturbance and reduce fuel loads to lower the risk of wildfire, providing long-term benefits. Special status wildlife species categories directly affected by forest management include raptors, mammals, and bats.

Under Alternative A, the BLM manages grassland and shrubland communities on a small portion of the Planning Area for watershed protection and livestock grazing without any specific management actions for improving these habitats for wildlife. Reclamation of grassland and shrubland vegetation, especially in lower precipitation zones, would minimize long-term impacts to special status wildlife species that depend on these habitats. Under Alternative A, the BLM reclaims disturbed areas by routinely seeding, or requiring permittees and operators to seed, these areas with native seed mixes without specific requirements regarding topsoil salvage, temporary protective surface treatments, or reclamation plans. Special status wildlife species categories directly affected by grassland and shrubland management and reclamation include the greater sage-grouse, raptors, migratory birds, and nongame mammals.

Alternative A provides riparian/wetland communities the third most protection, compared to other alternatives. All riparian/wetland areas are managed to meet, or make progress toward meeting, PFC. Special status wildlife species categories directly affected by riparian/wetland management and protection include raptors, migratory birds, mammals, and amphibians.

Proactive Management – Alternative A

In general, proactive management under Alternative A provides benefits and mitigates adverse impacts to special status wildlife species. Impacts due to proactive management, and other impacts, are described in detail under each special status wildlife species category below.

Trophy Game – Alternative A

The BLM implements, as appropriate, various measures from the existing state programmatic biological opinion for the grizzly bear to minimize adverse impacts to this species under all alternatives. Other

measures included in Alternative A that may provide beneficial impacts to grizzly bear habitat include big game crucial winter range and migration corridor seasonal closures and restrictions, seasonal surface-disturbance restrictions around raptor nests, protection of elk calving areas, and limitations of geophysical operations and other surface disturbances around greater sage-grouse leks, all of which may occur in grizzly bear habitat.

Livestock grazing management is likely to result in adverse impacts to grizzly bears as a result of accidental or illegal take (e.g., a herder shooting a bear attacking livestock) or bear removal by the WGFD due to livestock depredation. Conflicts have been more prevalent on sheep allotments and more difficult to resolve without phasing out sheep grazing (BLM 2005f). Under Alternative A, the Planning Area is open to livestock grazing except for Bighorn River tracts, campgrounds, and exclosures, which may result in adverse impacts to grizzly bears where livestock grazes in grizzly bear habitat.

Predatory Animals – Alternative A

Under Alternative A, there are no specific management actions for gray wolves; however, management actions that protect the habitat gray wolves and their prey (primarily elk) utilize are anticipated to benefit gray wolves in the Planning Area. Management actions limiting human activities, ROW development such as roads, and habitat fragmentation also will benefit gray wolves. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more detail on impacts to big game.

Under Alternative A, harvesting timber in a manner that protects and benefits wildlife habitat values would beneficially impact gray wolves by creating of patchwork pattern of forest stands that will enhance forage used by elk and other big game (BLM 2004f). However, new roads created for timber management may disturb and displace gray wolves with more human access. Closing spur roads after completion of timber management would limit these impacts.

Under Alternative A, management actions that may directly or indirectly minimize impacts to gray wolves include prescribed burns to enhance big game forage and seasonally prohibiting surface-disturbing activities around active raptor nests. Alternative A also applies a CSU stipulation for big game migration corridors, indirectly benefitting gray wolves. These restrictions benefit gray wolves only where their habitats, or their prey's habitats, overlap.

Game Birds (Greater Sage-Grouse) – Alternative A

See Table 4-23 for a summary of management actions and impacts under Alternative A specific to greater sage-grouse. A detailed discussion follows in the sections below.

Alternative A applies a CSU stipulation to prohibit surface-disturbing and disruptive activities within a ¼ mile of occupied greater sage-grouse leks and a TLS to avoid such activities in nesting and early brood-rearing habitats within a 2-mile radius of the perimeter of the occupied greater sage-grouse leks (834,543 acres), in identified greater sage-grouse nesting and brood-rearing habitat outside the 2 mile buffer (626,564 acres), and in winter concentration areas (172,809 acres). Such management would reduce the potential for adverse impacts to greater sage-grouse by limiting the potential for ROW and mineral development directly adjacent to occupied leks year round, while providing additional restrictions during sensitive nesting and early brood-rearing periods. However, Braun (2002) indicates that adverse impacts to greater sage-grouse can occur within ¼- or ½-mile buffers and accordingly recommends no surface disturbance within 3 miles of occupied leks. Therefore, Alternative A would still allow development at distances where declines in lek attendance or lek abandonment could occur. Combined with the lack of an overall management strategy to address landscape-level threats to sagebrush habitat from human and natural activities, Alternative A is anticipated to result in adverse impacts to greater sage-grouse in the short and long term.

Leasable mineral development could result in adverse impacts to greater sage-grouse and their habitat through changes to habitat components, habitat fragmentation, and noise and other disruptions. This could potentially reduce survivability and breeding of affected populations. Specific risks to greater sage-grouse from oil and gas development include elevated mortality due to collisions with structures and vehicles, risk of West Nile virus due to increased mosquito habitat from holding ponds, stress, disturbance of birds that may force them into suboptimal habitats with elevated predation rates (resulting in a decline in habitat suitability), and direct habitat loss (Walker et al. 2007). Holloran et al. (2010) found that male greater sage-grouse yearlings were 4.6 times more likely to establish leks outside compared to inside areas with oil and gas infrastructure, and yearling female avoidance responses indicated a loss of functional nesting habitats within 3,000 feet of the infrastructure of natural gas fields. These results suggest that conventional oil and gas development adversely affects greater sage-grouse by excluding individuals from developed areas. Alternative A closes 41,120 acres of greater sage-grouse PHMAs to oil and gas development, which would limit these impacts (Table 4-22). However, adverse impacts could result in areas that are available for oil and gas development subject to the standard lease form or open seasonally. BLM authorization for permits to drill could include conditions of approval that would limit potential adverse impacts on greater sage-grouse on a case-by-case basis. However, unless such conditions of approval are applied in a coordinated and consistent manner across the Planning Area and connected habitats, they would not alleviate adverse impacts from oil and gas development.

The CSU restrictions and TLS stipulations for surface-disturbing and disruptive activities described above, as well as the designation of ROW avoidance areas, could reduce adverse impacts from the location of ROW and renewable energy facilities on BLM-administered land in greater sage-grouse seasonal habitats and around occupied leks. In areas where new ROWs or renewable energy projects are allowed, vegetation loss, habitat degradation, and invasion of exotic plant species could occur. New ROW development could fragment formerly intact habitat, severing greater sage-grouse travel routes to seasonal habitat areas. Disturbance and noise from human presence, vehicles, and equipment could cause greater sage-grouse to temporarily or permanently abandon the area. Habitat abandonment could lead to successful relocation if nearby habitat is available, while displacement to lower quality habitat could reduce survival or reproduction success due to physiological stress or lack of forage and cover (Blickley et al. 2012). High profile structures associated with certain renewable energy or ROW development or communication sites could serve as perches for raptors that prey on greater sage-grouse, while linear ROW disturbances could enhance access for predatory animals, such as foxes. Management that encourages the placement of new ROW and communication sites in or near previously disturbed areas could reduce the potential for adverse impacts to specific leks or habitats by concentrating development in previously disturbed areas less used by greater sage-grouse.

Prolonged fire suppression has allowed fuels to build up to the point that an unplanned wildfire is likely to be much larger and greater in intensity. Alternative A utilizes wildland fires to restore fire-adapted ecosystems and employs the full suite of available fuels treatment options (mechanical, chemical, and biological) across the landscape as needed to restore vegetative diversity and reduce the risk of unnatural fire within those ecosystems. Depending on the extent, location, severity of a fire, and seral vegetation type affected, fire management would have short-term to long-term adverse impacts on greater sage-grouse resulting from the direct removal or alteration of habitat and injury or death from fire or smoke inhalation or indirect effects including changes in species movement patterns and lek attendance in burned habitat and reduced population viability. In areas that are available for fuels treatments, changes in vegetation can result in adverse impacts on greater sage-grouse, such as direct habitat loss, habitat fragmentation, and disruption to species; however, it can also result in beneficial impacts, such as habitat restoration. In the short term, fuels treatments and prescribed fires may also introduce new human presence that is disruptive to greater sage-grouse, though the application of CSUs

and TLSs would reduce these adverse impacts by helping to limit the timing and location of these activities. Fire and fuels management actions that reset vegetation seral stage can increase susceptibility to invasion by undesirable plant species. Noxious and invasive weeds are often of lower value to wildlife, degrade wildlife habitat by reducing optimal cover or food, and change site-specific fire ecology in ways that result in the loss of shrub communities. Sagebrush-steppe communities are among the ecosystems most vulnerable to invasion and degradation by invasive plant species.

Although both wildfire and prescribed fire adversely affect habitat in the short term by removing vegetation and disturbing soil, the long-term beneficial effects of fire often outweigh the short-term adverse impacts. Over the short term, the plant community is changed dramatically by a fire, as taller and denser vegetation is replaced by a more open habitat. Additionally, fire can improve the quality of greater sage-grouse habitat by releasing soil nutrients, reducing fuel load, or setting back tree encroachment into shrubland or grassland habitats. The herbaceous and woody plants that establish following a burn provide abundant foliar tissue and seeds. These are more palatable for greater sage-grouse and encourage an influx of insects that provide valuable nourishment for greater sage-grouse chicks. As the area gradually recovers, however, many of the pre-fire components become reestablished, and the area again supports a healthy plant community. This cycle may take decades or centuries, depending on the dominant plant species. Alternatively, vegetation restoration might never occur if climatic conditions are no longer suitable for the former dominants.

Managing the large majority of BLM-administered lands as open to livestock grazing could alter greater sage-grouse habitats components in a manner that decreases the suitability and extent of greater sage-grouse habitats in the Planning Area (Wyoming Sage-grouse Working Group 2003). Although livestock grazing management has limited direct effects on sagebrush species, it affects the height and density of herbaceous material within sagebrush vegetation communities that provide cover for greater sage-grouse. However, livestock grazing management can maintain healthy rangeland conditions that are compatible with greater sage-grouse habitat requirements (i.e., nesting, brood-rearing, and summer habitat) when properly designed and monitored (Crawford et al. 2004). Managing the timing and intensity of grazing can promote desirable plant communities and annual management of the standing crop to provide cover for the greater sage-grouse (Wyoming Office of the Governor 2013). Monitoring is important to ensure grazing intensity and duration does not remove required herbaceous cover and litter important for maintaining greater sage-grouse habitats. Although rangeland productivity is improving in the Planning Area, the current focus of management and monitoring does not emphasize the protective cover of vegetation and litter required by greater sage-grouse. Therefore, management of livestock grazing under Alternative A may not improve the quality or quantity of habitats for greater sage-grouse, particularly given the other threats affecting the species.

Alternative A manages several HMAs for wild horses. In contrast to properly managed grazing livestock, year-long grazing by wild horses in HMAs holds little potential to improve habitat for greater sage-grouse due to inherent difficulties in managing wild horse distribution and forage utilization. However, population management that meets the established appropriate management level for wild horses in the HMAs could help maintain wild horse use in balance with habitat quality and quantity for greater sage-grouse.

Designing range improvement projects to meet multiple-use objectives and mitigate impacts to other resource values, and prohibiting the placement livestock supplements within ¼ mile of water, wetlands, riparian areas, reclaimed or reforested areas, or other areas determined by the authorized officer (which could include greater sage-grouse habitats) could reduce impacts to greater sage-grouse. Managing supplement placement could prevent trampling and degradation of greater sage-grouse habitat, particularly in riparian/wetland areas and late season brood rearing habitat. Supplements

would be placed in locations that both promote proper grazing distribution and prevent inappropriate livestock use on riparian habitat, minimizing soil compaction and damage to vegetation, and could decrease grazing pressure and competition for riparian vegetation. Water developments could also adversely affect greater sage-grouse habitat, particularly in nesting habitat and riparian areas, through reductions in forage, cover, or possible nest trampling due to increased distribution of animals. However, implementation of the Wyoming Standards for Healthy Rangelands on BLM-administered lands could ensure that habitat is not degraded by over-use of livestock.

Modifying identified hazard fences and requiring analysis and construction of new fences in accordance with appropriate wildlife needs and the *BLM Fencing Handbook 1741-1* would generally beneficially affect greater sage-grouse. Fences can affect greater sage-grouse by creating travel barriers, altering distribution patterns, increasing stress and energy loss, and causing injury or death from entanglement or collisions. Modifying or constructing fences to BLM standards could reduce impacts to greater sage-grouse by decreasing the chances of collision or entanglement if the fences were fitted with anti-collision markers. Studies in Wyoming show that fence markers can reduce sage-grouse mortality from wire fence collision by 70 to 83 percent (Christiansen 2009, Stevens et al. 2012). Where fences were constructed with anti-collision standards for special status species, greater sage-grouse could be less likely to be injured or perish due to fence impacts. Where fences are constructed with perch inhibitors for raptors, greater sage-grouse would be less likely to be subject to hunting from predatory bird species. Removal of fences reduces threats of injury or death from impacts to fences, opens up travel corridors, and could allow access to additional forage and cover. Fences, regardless of their construction, can reduce potential adverse impacts from livestock trampling of cover and forage where they serve to exclude livestock from greater sage-grouse habitat.

Designating 25,680 acres as ACECs within greater sage-grouse Key Habitat Areas (Table 4-22) and managing all eligible WSRs to maintain their suitability for inclusion in the NWSRS would result in beneficial impacts to greater sage-grouse. The restrictions on resource uses and activities in these areas would limit the potential for habitat fragmentation and loss from development, and could limit stress from human presence in these areas during development. Conversely, these special designation areas could draw recreation and tourism, potentially increasing disruptions from human presence for recreational use.

Limiting motorized travel across the large majority of the Planning Area to existing roads and trails, until such time as travel management planning is complete and routes are either designated or closed, or designated as roads and trails could lessen impacts to greater sage-grouse from vehicle use. Route closures will not be determined until the travel management process is complete, but interim-management limiting cross-country travel and the construction of new roads and routes could prevent some adverse impacts to greater sage-grouse. Cross-country motorized vehicle use, which is allowed on a limited acreage under Alternative A, may create corridors that could be used by predatory animals and establish social trails that attract additional vehicle travel. Motorized vehicles could cause direct mortality of greater sage-grouse. Linear disturbances can create barriers to movement, fragmentation of habitat, and overall habitat loss for special status species. Vehicle travel may also cause vegetation loss, erosion, and the spread of invasive, non-native plant species.

Alternative A uses DPC to emphasize watershed protection, forestland health, and livestock grazing, and allows a wide variety of vegetation management techniques to achieve specific vegetation community objectives. Temporary disruptions from human activities and vegetation removal could displace greater sage-grouse into less desirable habitat and could increase competition for available resources with other species and habitat uses. However, because the BLM would design vegetation treatments to meet specific resource objectives (including habitat and cover for greater sage-grouse), the long-term benefits

from vegetation management could outweigh these short-term adverse impacts. Because this alternative does not manage specifically to maintain contiguous blocks of native vegetation communities, it may result in the fragmentation of habitat and may reduce the potential for habitat to meet all greater sage-grouse needs.

Although the extent of sagebrush habitat degradation from the presence of invasive plant species has not been quantified for the Planning Area, there is potential for these species to proliferate and substantially affect greater sage-grouse habitats (Wyoming Sage-grouse Working Group 2003). Therefore, the anticipated continued expansion and spread of invasive species under Alternative A would result in adverse impacts to greater sage-grouse and sagebrush habitats.

Managing conifer encroachment to improve wildlife habitat and forest health conditions, and removing encroaching conifer in sagebrush habitat, would benefit greater sage-grouse habitat over the long term. In addition to management that reintroduces wildland fire into historically fire-adapted ecosystems, treatment of conifer encroachment could limit the conversion of additional sagebrush-steppe to forest, and could create additional habitat for greater sage-grouse over the long term. In the short term, such treatments may also introduce adverse human presence that is disruptive to the birds, or provide areas that are suitable for expansion of invasive plant species.

Alternative A does not require project proponents to locate facilities or use equipment that reduces noise in proximity to greater sage-grouse leks. Noise above certain decibel levels may result in disturbance of greater sage-grouse, and studies have indicated that noise could adversely affect the communication abilities of strutting males (LaGory et al. 2001; Dantzker et al. 1999). Holloran (2005) and Blickley et al. (2012) suggest that noise emitted from drilling operations could reduce lek attendance by male and possibly female greater sage-grouse.

Where surface disturbances in greater sage-grouse habitat occur, application of the Wyoming BLM Reclamation Policy and requiring that reclamation achieve vegetation cover reestablishment within five years could reduce long-term adverse impacts. Although initial disturbance would result in habitat loss, reclamation activities could restore sagebrush habitat over the long term. Some areas of habitat, such as greater sage-grouse winter concentration areas, could be difficult to restore to original conditions due to the composition and size of sagebrush in these areas. Surface disturbance may also provide opportunities for invasive plant species (e.g., cheatgrass) to establish, making it difficult to restore sagebrush habitat with native species in some areas and achieve reclamation success.

Nongame (Raptors) – Alternative A

Special status raptor species would be affected by surface-disturbing activities, fire and fuels management, invasive species spread, motorized vehicle use, livestock grazing (Johnson and Horn 2008; Torre et al. 2007), and management actions for biological resources under Alternative A. The late winter, spring, and early summer periods, when courtship, nest construction, incubation, and early brooding periods occur, would be more sensitive to disturbance because adult raptors are more prone to abandon nests at these times (USFWS 2002).

Surface disturbance causes localized adverse impacts to raptor prey species by temporarily and permanently disturbing habitats for small mammals and birds. Under Alternative A, no activity or surface disturbance is allowed for up to a ¼-mile radius from any active raptor nest from February 1 through July 31 to prevent nest disturbance and abandonment. Surface-disturbing activities are restricted at known bald eagle nests and communal winter roosts, but not in terrestrial foraging habitats, and therefore may adversely impact bald eagles (BLM 2003b) and other special status raptor species. Bald eagles are also directly affected by impacts to riparian/wetland habitat. See Section 4.4.3

Vegetation – Riparian/Wetland Resources and the *Nongame (Migratory Birds)* section for likely impacts to bald eagles.

Constructing roads, powerlines, and other development facilities can contribute to loss and fragmentation of raptor habitats and ultimately impacts the diversity and abundance of raptor populations (USFWS 2002). For example, utility poles can provide perching and nesting structures for raptors, but also can result in mortality to raptors through collision and electrocution (APLIC and USFWS 2005); current policy requires mitigation be applied to construction design for power poles permitted on BLM-administered land. Wind-energy facilities can be a source of mortality for raptors if they collide with wind tower blades. High mortality could result if wind towers are placed along a migration path or in nesting habitat. Wind-energy facilities also could be a source of habitat loss and fragmentation, and human disturbance from construction and maintenance activities. The ROD for Wind Energy Development (BLM 2005e), which guides management under Alternative A, provides BMPs to minimize impacts to raptors, but lacks specific guidelines to avoid adverse impacts. Likewise, wind-energy development is considered on a case-by-case basis and no areas are excluded from wind-energy development under Alternative A, so the potential impacts to raptors are greatest under this alternative.

As recreational use is often concentrated in riparian areas, human activity in these areas may cause bald eagles to avoid or abandon otherwise suitable habitats (BLM 2003b). Developing or upgrading recreation sites and establishing day use facilities at Wardel and Harrington reservoirs would adversely impact bald eagles under Alternative A. Similarly, managing the Bighorn River SRMA to maximize recreation opportunities may also adversely impact bald eagles due to disturbances from recreationists.

Livestock grazing in riparian/wetland areas may indirectly contribute to adverse impacts on bald eagles if soil erosion, degradation of stream bank conditions, introduction of noxious weeds, and the reduction of viable cottonwood tree sapling recruitment result (BLM 2003b). Under Alternative A, the Bighorn River tracts are closed to livestock grazing, limiting adverse impacts to bald eagles in these areas.

Special status raptors are affected by wildlife-disturbing activities that contribute to habitat loss, fragmentation, and degradation. Such actions include, but are not limited to, clear-cutting, snag removal, industrial activities, and invasive species control. For example, clear-cutting directly impacts raptor habitat for those raptors (e.g., northern goshawk) that prefer closed canopies. Other raptor species, such as ferruginous hawks, may benefit from openings in the canopy when in pursuit of prey. Snag removal indirectly affects raptors by degrading habitat and reducing potential nest sites. Alternative A allows for clear cutting and timber salvage of dead stands, which would adversely impact raptors by reducing habitat and nest sites. In the long term, the continued spread of invasive species in the Planning Area, combined with the loss and fragmentation of raptor habitats by wind energy, mineral development, and associated infrastructure projected under Alternative A, are expected to have adverse impacts to special status raptor species.

Nongame (Migratory Birds) – Alternative A

Although impacts to migratory birds on their winter habitat are not subject to BLM management, impacts to breeding and nesting habitats from surface-disturbing activities, invasive species management, fire and fuels management, and management actions for biological resources on BLM-administered lands are anticipated for these species. Where possible, site-specific assessments and discretionary permit actions will mitigate these impacts. Surface disturbance is anticipated to have localized adverse impacts to breeding and nesting habitats for migratory birds. Habitat impacts from surface disturbance may include temporary and permanent loss of breeding and nesting habitats due primarily to mineral development. Fragmentation and degradation of habitats for migratory birds also are anticipated from surface-disturbing activities and associated development and the spread of invasive

species. In general, management actions and projected development under Alternative A are likely to result in adverse impacts to migratory birds from habitat loss, fragmentation, and degradation.

Because of the diverse species in the migratory bird category, the discussion below organizes these species into the following habitat guilds:

- Sagebrush and shrubland species: Brewer’s sparrow, loggerhead shrike, sage sparrow, and sage thrasher
- Grassland species: Baird’s sparrow, long-billed curlew, and mountain plover
- Riparian/wetland species: yellow-billed cuckoo, trumpeter swan, and white-faced ibis

Sagebrush and Shrubland Species – Similar to the greater sage-grouse, the Brewer’s sparrow, sage sparrow, and sage thrasher depend on sagebrush habitats, though they may use other shrubland types, particularly during the nonbreeding season. The loggerhead shrike uses a more diverse mix of shrubland and grassland types, including sagebrush. There are no proactive management actions specific to sagebrush and shrubland migratory birds under Alternative A, but measures to protect greater sage-grouse discussed under *Game Birds* would generally benefit other sagebrush and shrubland species. Adverse and beneficial impacts to sagebrush habitats discussed under *Surface Disturbance* and *Game Birds* apply to migratory birds that occur in similar habitats. Although precise habitat requirements may vary between certain sagebrush and shrubland species, restrictions on surface disturbance are likely to benefit the suite of species in areas where their ranges overlap.

Sagebrush and shrubland species may benefit from prescribed fire used to improve plant community health in shrubland communities, but only where healthy native vegetation and adequate annual precipitation (above 12 to 14 inches) are present. Any wildland fire occurrence in lower precipitation zones or where cheatgrass is present would likely reduce sagebrush and increase cheatgrass occupancy (Keeley 2006). In the long term, allowable uses resulting in habitat loss would adversely impact sagebrush and shrubland migratory birds, but management actions implemented under Alternative A would limit adverse impacts to these species.

Grassland Species – Grasslands make up less than 1 percent of the Planning Area. Under Alternative A, there are no management actions specific to special status migratory birds that utilize grasslands, other than the mountain plover. Refer to Section 4.4.2 *Vegetation – Grassland and Shrubland Communities* and Table 4-21 for a discussion of management actions and BLM-authorized activities that would impact grasslands and would similarly affect migratory bird habitat in these areas. Due to its projected long-term surface disturbance and reclamation requirements, Alternative A would result in habitat loss and degradation in grasslands.

Adverse impacts to the mountain plover would be minimized by implementing various conservation measures and BMPs under Alternative A. Mountain plovers are often found in association with prairie dog towns because they tend to prefer nesting areas with sparse vegetation cover, and therefore are affected by management actions for white-tailed prairie dogs (see *Nongame [Mammals]*). In addition, mountain plovers show a nesting preference to areas heavily grazed by livestock (BLM 2005g). Range management practices that favor uniform grass cover of taller grasses and a lack of bare patches reduce available mountain plover habitats (BLM 2005g). Although livestock grazing management under Alternative A could increase the availability of suitable mountain plover habitat, few beneficial impacts are anticipated because the Planning Area already has an abundance of naturally sparse habitats for mountain plover nesting.

Riparian/Wetland Species – Although there are no specific management actions for special status migratory birds that use riparian areas and wetlands, other biological resource management actions—

particularly those pertaining to water and riparian/wetland areas, such as surface disturbance restrictions, livestock grazing and riparian area management, and special designations—would affect these species. While most surface-disturbing activities will not occur in riparian/wetland areas, adverse impacts, to a limited extent, may occur due to erosion and increased sedimentation in streams. Prohibiting the placement of salt, mineral, or forage supplements would limit adverse impacts from concentrated livestock to riparian/wetland areas. Refer to Section 4.4.3 *Vegetation – Riparian/Wetland Resources* and Table 4-21 for a description of other management actions and BLM-authorized activities that would impact wetlands and riparian areas and would similarly affect migratory bird habitat in these areas.

Nongame (Mammals) – Alternative A

Surface-disturbing activities, invasive species control, fire and fuels management, and management actions for biological resources may result in impacts to special status nongame mammals. Surface disturbance would have localized adverse impacts to special status nongame mammal habitats, including temporary displacement, and would fragment and degrade special status nongame mammal habitat.

It is important to note that some special status nongame mammal species, especially bats, may use more than one habitat type (e.g., caves and forests/woodlands). However, because of the diverse species in the special status nongame mammal category, the discussion below organizes these species into the following habitat guilds:

- Sagebrush and Shrubland Species: white-tailed prairie dog and black-footed ferret
- Forest and Woodland Species: Canada lynx
- Cave Species: Townsend’s big-eared bat, spotted bat, and long-eared myotis

Sagebrush and Shrubland Species – Similar to the greater sage-grouse, special status nongame mammals in this category depend on sagebrush habitats or other shrubland types. Therefore, measures to protect greater sage-grouse as discussed under *Game Birds (Greater Sage-Grouse)* would generally benefit other sagebrush and shrubland species. Although precise habitat requirements may vary between certain sagebrush and shrubland species, restrictions on surface disturbance are likely to benefit the suite of species in areas where their ranges overlap. Likewise, adverse impacts to sagebrush habitats discussed for the greater sage-grouse would result in adverse impacts to these species. In the long term, actions implemented under Alternative A would benefit special status nongame mammals occupying sagebrush habitats in designated greater sage-grouse lek habitat buffers. Black-footed ferrets are associated with and depend on prairie dog colonies in the Planning Area. Due to the BLM’s use of conservation measures, terms and conditions, and BMPs, measurable adverse impacts from BLM actions to prairie dog populations are not anticipated under Alternative A.

Forest and Woodland Species – Canada lynx prefer coniferous forests and riparian areas. Under Alternative A, there are no specific management actions for Canada lynx; however, management actions that protect the Canada lynx habitats and their prey (primarily snowshoe hare) may result in beneficial impacts to Canada lynx. For example, prohibition of surface disturbance within ¼ mile of active raptor nests conserves Canada lynx habitats during the TLS where these habitats overlap but would not provide long-term protection to Canada lynx. Maintenance of forest stands with dense vegetative cover (i.e., prohibiting precommercial thinning) is important to maintaining snowshoe hare populations and therefore the presence of Canada lynx in the Planning Area (USFS 2005b). Logging, forest health management, and fire and fuels management in aspen and coniferous forests, in accordance with the Lynx Conservation Assessment Strategy, may result in short-term impacts to Canada lynx habitats by

reducing large woody debris that may reduce cover, eliminate den sites, reduce kitten survival, and reduce the availability of prey species (e.g., snowshoe hare and red squirrel) (BLM 2005h; USFS 2005b). However, over the long term, treatments may improve habitat for Canada lynx and its prey species by diversifying forest structure and reducing fuel loads. Alternative A does not address old growth forest areas in the Planning Area, but ensures an appropriate level of snag retention and harvests timber in a manner that protects wildlife habitat values, minimizing adverse impacts to the Canada lynx.

Cave Species – Although bats can utilize a variety of habitats including riparian and forest habitat, cave and karst habitat and abandoned mines are of importance for most species. Bats that use caves for roosting, maternity colonies, or hibernation could be affected by surface-disturbing activities near caves, cliffs, or other rock features. Abandoned mine closures and recreational caving have been identified as the two major threats to bat habitats (Priday and Luce 1995). Alternative A allows activities in AMLs on a case-by-case basis, resulting in the second highest potential adverse impacts to bat habitat. Management that increases recreation and access to caves may result in adverse impacts to bats. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* and Section 4.1.5 *Cave and Karst Resources* for impacts to bats and their habitat. Similarly to raptors, bats are likely to be adversely affected by wind-energy development.

Nongame (Amphibians) – Alternative A

Special status amphibian species in the Planning Area are associated with riparian, wetland, woodland, and forested habitat and are susceptible to impacts from habitat degradation and fragmentation, pollution, and modified hydrology. Beneficial impacts to these species are similar to the impacts described under *Nongame (Migratory Birds)* for this alternative. The Great Basin spadefoot toad may be affected by activities in sagebrush communities, where this species occurs. Beneficial impacts to the Columbia spotted frog are similar to those described for greater sage-grouse for this alternative. Accordingly, Alternative A is likely to result in mitigated adverse impacts to special status amphibian species. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more information on impacts to amphibians.

Alternative B

Surface Disturbance – Alternative B

Estimated short- and long-term surface disturbance from BLM actions in the Planning Area (Table 4-1) would result in less loss, degradation, and fragmentation of sagebrush habitat under Alternative B, relative to Alternative A. Erosion from surface disturbance would also result in less impacts to riparian/wetland habitats under Alternative B. Surface disturbance from roads totals 1,229 acres in the short term and 615 acres in the long term under Alternative B (Appendix T), forming fewer barriers to fragment habitat than Alternative A. Reclamation requirements are more stringent under Alternative B, likely resulting in the highest degree of surface disturbance mitigation, compared to Alternative A.

Resource Uses – Alternative B

Minerals development under Alternative B would result in similar adverse impacts to special status wildlife species as under Alternative A, but to a lesser extent. Alternative B has fewer acres open to mineral development, which would retain more shrubland and grassland habitat, compared to Alternative A. Alternative B is projected to result in 502 new federal oil and gas wells that would result in fewer adverse impacts from less habitat loss and noise disturbance than Alternative A.

Special Status Species – Wildlife

Alternative B places more restrictions on powerline development than Alternative A, which would reduce the potential risk of raptor electrocution. The BLM closes a portion of the Planning Area to wind-energy development (1,244,948 acres) and avoids raptor concentration areas and greater sage-grouse nesting, brood-rearing, and winter habitat. Powerline and wind-energy development under Alternative B would therefore impact special status species less than under Alternative A.

Compared to Alternative A, Alternative B closes more area to motorized vehicle use, which can disturb special status species, including threatened and endangered species habitat.

Livestock grazing under Alternative B is generally managed to meet multiple use objectives over solely livestock forage availability. Although livestock grazing would be restricted more under this alternative, this will not necessarily benefit special status species that depend on livestock grazing to increase range productivity and reduce vegetation height, such as the mountain plover. Alternative B prohibits forage supplements within ½ mile of riparian/wetland areas to minimize adverse impacts to this habitat. Special status wildlife species most likely affected by livestock grazing include greater sage-grouse, nongame mammals, migratory birds, and amphibians.

Special Designations – Alternative B

Three ACECs are expanded (Carter Mountain, Five Springs Falls, and Upper Owl Creek) and three new ACECs are designated (Chapman Bench, Clarks Fork Canyon, and Rattlesnake Mountain) with special status species values of concern under Alternative B, providing greater potential benefits to special status wildlife species than Alternative A. Alternative B manages WSR suitable waterway segments similarly to Alternative A, though places greater restrictions on resource uses and activities with proportional beneficial impacts to special status species in riparian habitat.

Resources – Alternative B

Fire and fuels management is likely to cause similar impacts to special status wildlife species across all alternatives. Under Alternative B, the BLM would use wildland fire to restore fire-adapted ecosystems and reduce hazardous fuels, likely resulting in long-term beneficial impacts to special status wildlife species in areas of higher precipitation. Due to the reliance on natural process before active restoration, achieving fire-adapted ecosystems is less likely under Alternative B. However, treatments are used in the WUI to protect structures from fire, potentially adversely affecting special status wildlife species in the short term if treatments require surface disturbance or alter vegetative cover, but benefitting them in the long term if treatments reduce the chance of catastrophic wildfire that could destroy greater expanses of habitat.

In general, Alternative B limits the expansion of resource uses, and therefore may result in less invasive species spread relative to Alternative A. Invasive species would therefore impact special status wildlife species less under Alternative B.

Forest management under Alternative B, by generally pursuing natural processes to meet forest health goals, would adversely impact special status wildlife species less than Alternative A from destroying or degrading habitat. Additionally, the BLM retains old growth forests, providing beneficial impacts to special status wildlife species, especially raptors and bats.

Grassland and shrubland management under Alternative B would provide greater potential beneficial impacts to special status wildlife species than Alternative A. Under Alternative B, the BLM manages grassland and shrubland communities to achieve or make progress towards the reference state plant community based on ESDs, and maintains and enhances important plant communities on large, contiguous blocks of land. These measures are likely to result in the greatest natural vegetation

diversity and slow the spread of invasive species, benefitting special status wildlife species, especially greater sage-grouse, nongame mammals, and migratory birds.

Alternative B provides more protection for riparian/wetland communities than Alternative A. All riparian/wetland areas are managed to achieve DPC, likely resulting in more diverse riparian/wetland habitat that will provide greater benefits to special status wildlife species.

The Absaroka Front Management Area, designated under Alternative B, provides additional habitat protection goals that would likely benefit special status wildlife species including migratory birds, raptors, bats, grizzly bears, and gray wolves that depend on upper-elevation shrub/grassland and forest habitats.

Proactive Management – Alternative B

In general, proactive management under Alternative B provides more benefits, and mitigates adverse impacts to special status wildlife species to a greater extent than Alternative A. Impacts due to proactive management, in addition to other impacts, are described in more detail under each special status wildlife species category below.

Trophy Game – Alternative B

The BLM implements, as appropriate, various measures from the existing state programmatic biological opinion for the grizzly bear to minimize adverse impacts to this species under Alternative B. Alternative B includes other measures, similar to Alternative A that may provide beneficial impacts to grizzly bear habitat. The closure of the Absaroka Front Management Area to various resource uses is also likely to result in beneficial impacts to grizzly bears by reducing activities that can potentially fragment habitat.

Alternative B closes elk and bighorn sheep crucial winter range and greater sage-grouse Key Habitat Areas to livestock grazing and prohibits domestic sheep grazing on pronghorn crucial winter range. These management actions would beneficially impact grizzly bears in areas where grazing prohibitions overlap with grizzly bear habitat by reducing the potential for conflict that may result in accidental or illegal take or WGFD removal.

Predatory Animals – Alternative B

Under Alternative B, there are no specific management actions for gray wolves; however, management actions that protect the habitat gray wolves and their prey (primarily elk) utilize may benefit gray wolves in the Planning Area. Management actions limiting human activities, ROW development such as roads, and habitat fragmentation also would benefit gray wolves. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more detail on impacts to big game.

Harvesting timber only where natural processes are unable to accomplish forest health goals would minimize short-term impacts from disturbance and displacement to gray wolves, but may result in less long-term beneficial impacts than Alternative A by limiting widespread diversification of forest stand structure. Closing timber management roads not required for existing uses would benefit gray wolves by reducing human access and habitat fragmentation.

Under Alternative B, management actions that minimize adverse impacts to gray wolves include habitat enhancement projects in sagebrush communities, aspen restoration, prohibiting livestock grazing, and seasonally prohibiting surface-disturbing activities around active raptor nests. These restrictions benefit gray wolves only where the habitats overlap. Under Alternative B, resource use restrictions in the Absaroka Front Management Area may be the most beneficial to big game, and therefore to gray wolves.

Game Birds (Greater Sage-Grouse) – Alternative B

See Table 4-23 for a summary of management actions and impacts under Alternative B specific to greater sage-grouse. A detailed discussion follows in the sections below.

Under Alternative B, estimated short- and long-term surface disturbance from BLM actions in the Planning Area would result in less loss, degradation, and fragmentation of sagebrush habitats than under Alternative A. In addition, Alternative B manages to maintain continuous blocks of native plant communities, such as sagebrush habitat. Alternative B prohibits surface-disturbing and disruptive activities (including ROWs) within 0.6 mile of occupied greater sage-grouse leks and limits anthropogenic disturbance to one location that, when combined with existing disturbances, comprises less than 5 percent of sagebrush habitat per 640-acre. Overall, Alternative B would result in less surface disturbance and habitat loss, degradation, and fragmentation and therefore less impact to greater sage-grouse than Alternative A.

Alternative B closes greater sage-grouse Key Habitat Areas (1,490,758 acres) to new mineral leasing, which would largely eliminate potential adverse impacts from oil and gas development including displacement, habitat abandonment, human presence and noise, and possible offsite impacts, including erosion, and spread of invasive, non-native plant species. Applying a NSO stipulation within 0.6 mile of occupied leks, including leks outside of Key Habitat Areas, would limit potential adverse impacts from oil and gas development (Holloran et al. 2010) to a greater extent than the CSU restriction applied within 0.25 miles of occupied leks under Alternative A. Stipulations on fluid mineral exploration and development under this alternative could reduce avoidance behavior and displacement of birds, loss of habitat, and mortality from collisions with structures or increased incidence of West Nile Virus. In addition, limiting disturbance from oil and gas wells to no more than 15 acres per 640-acre section could maintain a more contiguous, uninterrupted seasonal habitats for greater sage-grouse, thus facilitating greater habitat connectivity.

Alternative B excludes ROW development on 132,194 acres in greater sage-grouse Key Habitat Areas (Map 40; Table 4-22) year round and applies a TLS to avoid surface-disturbing and disruptive activities (including ROW development and other discretionary surface disturbing activities) in greater sage-grouse nesting and early brood-rearing habitat (310,749 acres) and within a 3-mile radius of the perimeter of occupied greater sage-grouse leks in those habitats (1,526,277 acres). Restricting ROW development in these areas would reduce the potential for the types of adverse impacts described under Alternative A (e.g., increased susceptibility to the establishment of nonnative, invasive plant species, habitat fragmentation, or increased predation potential), across these important habitats. As discussed in Alternative A, limiting disruptive activities and habitat disturbances within 3 miles of lek is recommended to maintain viable greater sage-grouse populations.

Alternative B uses wildland fire and other vegetation treatments to restore fire-adapted ecosystems in the Planning Area, and impacts on greater sage-grouse would be similar to those described under Alternative A. Establishing a natural fire regime in fire-adapted ecosystems and reducing fuel loads in the Planning Area may lower the risk of catastrophic fire in areas with sufficient native vegetation and precipitation over the long term. As discussed under Alternative A, however, short-term impacts on greater sage-grouse would occur where fires result in direct removal or alteration of habitat, injury or death from fire or smoke inhalation, or indirect effects including changes in species movement patterns and lek attendance in burned habitat. Although Alternative B would require careful coordination of proposed prescribed fires and fuels treatments with greater sage-grouse conservation objectives, but is unlikely impede the use of these tools to reduce the risk of catastrophic wildland fires. Greater reliance

on natural processes in wildland fire management could reduce disturbance from new human presence during fuels treatments, and would reduce short-term adverse impacts compared to Alternative A.

Under Alternative B, the BLM closes extensive areas to livestock grazing, including greater sage-grouse Key Habitat Areas (1,129,612 acres), which could have adverse and beneficial impacts, depending on site-specific range conditions and grazing practices. Poor livestock grazing management can have long-term, adverse impacts to greater sage-grouse by degrading habitat (WGFD and BLM 2007).

Approximately 154 of the 328 grazing allotments within the Planning Area, or portions of those allotments, were identified as not meeting one or more of the Wyoming Standards for Healthy Rangelands as of the most recent assessment and 213 allotments or portions of allotments in greater sage-grouse PHMAs (similar to Key Habitat Areas) have been identified for improvements in livestock management and range conditions (Appendix P). For Key Habitat Areas in which range conditions are not meeting the Wyoming Standards for Healthy Rangelands and livestock grazing is the cause, closing these areas may benefit greater sage-grouse by improving habitat conditions over long time periods (40 years or more) (Crawford et al. 2004). Within Key Habitat Areas, these closures would eliminate the potential for adverse impacts to greater sage-grouse due to loss of herbaceous cover from overgrazing, invasive weed spread by livestock, degradation of unfenced riparian areas and water sources from concentrated grazing and trampling, or drowning hazards posed by stock watering features.

On Wyoming big sagebrush sites with dense sagebrush and an understory of annual grasses, reductions in livestock grazing may hasten further habitat degradation if ungrazed fuel loads increase the chance of wildfires that kill sagebrush over large areas (Crawford et al. 2004). Appropriate grazing intensity and duration has been shown to maintain suitable greater sage-grouse habitat (WGFD and BLM 2007) and in some cases, light-to-moderate livestock grazing may improve greater sage-grouse habitat by increasing herbaceous vegetation in arid-to-semiarid areas (Holechek et al. 2006). Eliminating livestock grazing in areas where grazing has improved habitat conditions for greater-sage grouse could have adverse impacts.

The management of range improvements and supplements would result in similar impacts to those described under Alternative A. Like Alternative A, locating new fences in a manner that minimizes disturbance to greater sage-grouse habitat and increasing the visibility of existing fences would be beneficial to greater sage-grouse. Additional restrictions on the placement of supplements under Alternative B would reduce adverse impacts from concentrated grazing compared to Alternative A. Alternative B includes a larger supplement placement buffer (1/2 mile) around water, wetlands, riparian areas, reclaimed or reforested areas, or other areas determined by the authorized officer than does alternative A, reducing the potential for adverse impacts to soils and habitats in these areas. Impacts from the placement of water developments and other range improvement projects would be similar to those described under Alternative A.

The effects of wild horse grazing in HMAs would be similar to those under Alternative A.

Special designations under Alternative B would provide additional beneficial impacts to greater sage-grouse through the application of resource use restrictions over a larger area than under Alternative A. ACECs under Alternative B encompass 96,272 acres of greater sage-grouse Key Habitat Areas (Table 4-22), which would restrict resource uses and activities that could adversely impact greater sage-grouse.

Travel management under Alternative B would have similar adverse impacts to those described under Alternative A, though to a lesser extent due to additional restrictions. Alternative B limits travel in greater sage-grouse Key Habitat Areas to designated roads and trails with a seasonal closure during sensitive breeding and early brood-rearing periods (February 1 to July 31). This restriction would limit the potential for motorized vehicle related adverse impacts during periods when birds could be sensitive

Special Status Species – Wildlife

to human disruptions until travel management is aligned to greater sage-grouse conservation objectives through subsequent planning processes. Managing new road construction in and adjacent to greater sage-grouse habitat consistent with restrictions on surface-disturbing and disruptive activities would limit the creation of new roads near occupied leks, reducing the potential for new fragmentation, disruption, and direct habitat loss in these areas.

Managing to achieve or make progress towards reference state plant communities based on site ESD, and requiring that the appropriate functional structural plant groups be present would provide more comprehensive targets for and measures of vegetation treatment success compared to management under Alternative A. The use of ESDs in designing vegetation treatments in sage-grouse habitat would help to maintain vegetation health, soil stability, and productivity over the long-term, as well as reduce adverse impacts from the introduction and spread of invasive plant species that could alter or degrade the native landscape and cause greater sage-grouse to move from high quality habitat to areas of lower quality, less desirable habitat. Alternative B requires the treatment of at least 200 acres of sagebrush communities annually, which would ensure continued efforts to make progress toward ESDs in greater sage-grouse habitat over the life of the plan.

The management of conifer encroachment in sagebrush under Alternative B would be similar to management under Alternative A, and impacts would be similar to those described under that alternative. The greater reliance on natural process to manage forest and other habitats under this alternative could result in slower progress on addressing conifer encroachment under this alternative, though, conversely, the use of natural processes would also limit disruption due to human presence during treatment to a greater extent than management under Alternative A.

Although surface disturbance results in short-term habitat loss and damage, the reclamation requirements of Alternative B help maintain long-term habitat quality in all habitat types, including sagebrush. Interim and/or final reclamation of surface disturbance under Alternative B requires 50 percent vegetative cover within three growing seasons and 80 percent cover within 5 years. The BLM requires development of an appropriate reclamation plan before authorization of any surface-disturbing activity. In addition to requiring topsoil salvage and segregation for all surface-disturbing activities, Alternative B requires the reestablishment of healthy native plant communities based on preexisting composition in the area. These actions are anticipated to increase reclamation success and minimize the establishment of invasive weeds in comparison to Alternative A, resulting in fewer adverse impacts to greater sage-grouse habitats.

Limiting new sources of noise to levels of 10 dBA above ambient noise at the perimeter of leks from 6 PM to 8 AM during initiation of breeding would reduce adverse impacts to greater sage-grouse from noise generated by oil and gas facilities or other development.

Nongame (Raptors) – Alternative B

Surface-disturbing activities, renewable energy development, invasive species control, motorized vehicle use, livestock grazing (Johnson and Horn 2008; Torre et al. 2007; Jones 2000), and management actions for biological resources would adversely impact raptors less under Alternative B than under Alternative A. Compared to Alternative A, restrictions around raptor nests are more extensive under Alternative B and TLS are species-specific, resulting in fewer direct impacts to nesting raptors. Additionally, the BLM applies a seasonal 2-mile buffer to active ferruginous hawk nests and a year-round CSU stipulation to protect all raptor nest sites. Alternative B protects more BLM-administered surface surrounding raptor nests compared to Alternative A, resulting in greater beneficial impacts to special status raptor species. Alternative B is projected to result in fewer acres of surface disturbance and therefore will have less adverse impact on special status raptor terrestrial foraging habitat.

Alternative B would place more restrictions on powerline development than Alternative A, which would reduce the potential for adverse impacts to raptors due to electrocution. Wind-energy development is avoided in raptor concentration areas, and approximately 1,244,948 acres are renewable energy exclusion areas under Alternative B, thereby decreasing the potential to fragment habitats and directly impact raptors from collisions or displacement relative to Alternative A. The BLM prohibits clear cutting under Alternative B, and uses salvage operations, including appropriate levels of snag retention, to improve wildlife habitat. These actions would result in beneficial impacts by protecting and enhancing more habitat for those raptors that prefer closed canopy habitats, compared to Alternative A.

Alternative B would continue to improve rangeland productivity and slow the spread of invasive species to a greater extent than Alternative A. Overall, the restrictions to surface-disturbing activities, wind-energy development, and livestock grazing and proactive management to maintain native vegetation under Alternative B would protect more raptor habitats compared to Alternative A.

Allowing surface-disturbing activities in riparian/wetland areas would adversely impact bald eagles through displacement and habitat loss. Recreational activities would cause impacts similar to those under Alternative A for bald eagles, but to a lesser extent. Maintaining current facilities and not providing campsites at Wardel and Harrington reservoirs would cause fewer adverse impacts to bald eagles by limiting human activity in these areas. Impacts to bald eagles in the Bighorn River SRMA are likely to be less under Alternative B than under Alternative A, because managing the area to provide a “moderate” level of recreation experience would involve less intensive forms of recreation and less human activity.

Closing more acres to livestock grazing under Alternative B (1,984,211 acres) would result in less potential adverse impact to bald eagles from riparian habitat degradation than under Alternative A.

Nongame (Migratory Birds) – Alternative B

Under Alternative B, short- and long-term surface disturbance are anticipated to be less; therefore, associated adverse impacts to breeding and nesting habitats for migratory birds are anticipated to be less than under Alternative A. The impacts to migratory birds from wind-energy development under Alternative B would also be less than under Alternative A.

Sagebrush and Shrubland Species – Alternative B applies larger buffers around greater sage-grouse leks and in nesting or early brood-rearing habitats to conserve sagebrush habitat than under Alternative A (see Game Birds). Alternative B would result in less surface disturbance that may result in habitat loss and has more stringent requirements for reclamation, which would reduce impacts to migratory birds that depend on sagebrush and shrubland habitats relative to Alternative A.

Grassland Species – Actions in grassland habitat, such as surface-disturbing activities, reclamation, invasive species control, and livestock and wildlife grazing impact special status migratory bird species. BLM actions under Alternative B, including designation of the Chapman Bench ACEC, would result in less adverse impact to grassland habitat and would protect more grassland habitat from fragmentation than under Alternative A. Management actions for white-tailed prairie dogs (see *Nongame [Mammals]*) may affect the mountain plover and long-billed curlew, as these species nest in areas with sparse vegetation. Greater restrictions on livestock grazing under Alternative B may result in adverse impacts to mountain plover by reducing available mountain plover habitat (i.e., heavily grazed areas and areas with bare patches); however, managing areas to create preferred habitat for the mountain plover, would likely provide a net benefit to this species.

Riparian/Wetland Species – Although there are no specific management actions for special status migratory birds that use riparian areas and wetlands, other biological resource management actions—

Special Status Species – Wildlife

particularly those pertaining to water and riparian/wetland areas, such as surface disturbance restrictions, livestock grazing and riparian area management, and special designations—would affect these species. Overall, restrictions on surface disturbance, management of invasive species and livestock grazing, and managing riparian/wetland areas to achieve DPC under Alternative B would protect and enhance more riparian/wetland habitat and benefit special status migratory birds in the Planning Area more than under Alternative A.

Nongame (Mammals) – Alternative B

Surface-disturbing activities, invasive species control, fire and fuels management, livestock grazing management, and management actions for biological resources under Alternative B would result in less adverse impacts to special status nongame mammals than under Alternative A.

Sagebrush and Shrubland Species – Sagebrush and shrubland special status nongame mammal species would generally benefit from management actions limiting habitat fragmentation and surface disturbance in sagebrush and shrubland communities. Measures to protect and reduce potentially adverse impacts to greater sage-grouse, as discussed under *Game Birds*, benefit special status sagebrush and shrubland nongame mammal species. Decreased surface disturbance and less habitat fragmentation under Alternative B would limit adverse impacts to special status nongame mammal species more than Alternative A. In addition, an NSO restriction placed on prairie dog colonies suitable for black-footed ferret reintroduction and the Sage Creek Prairie Dog Town would benefit both species. Alternative B provides more overall beneficial impacts to these species compared to Alternative A.

Forest and Woodland Species – Under Alternative B, there are no specific management actions for Canada lynx; however, management actions that protect the habitats Canada lynx and their prey (primarily snowshoe hare) utilize are anticipated to result in beneficial impacts to Canada lynx. Under Alternative B, fewer short-term adverse impacts to Canada lynx would result from forest treatments; however, less stand diversification over the long term may result in less beneficial impacts to Canada lynx habitat and the habitats of its prey species. Prohibiting clear-cutting and precommercial thinning, except for fuels treatments, retains more woody debris than Alternative A to provide cover and den sites and enhance the availability of prey species. Alternative B retains old growth forest areas and, when possible, retains connectivity of existing or potential old growth areas, benefiting Canada lynx more than Alternative A. Alternative B would result in greater short-term beneficial impacts to Canada lynx habitats than Alternative A due to greater restrictions on surface-disturbing activities, but long-term habitat improvement, especially from fire and fuels management to prevent landscape-scale fires, may be limited.

Cave Species – Bats using caves for roosting, maternity colonies, or hibernation may be affected by surface-disturbing activities near caves, cliffs, or other rock features. The BLM closes caves during critical periods for bats and prohibits activities within ¼ mile of AML sites under Alternative B, providing more beneficial impacts than Alternative A. As renewable energy development is excluded in a large area, the potential impacts from wind-energy development to bats are less under Alternative B than Alternative A.

Nongame (Amphibians) – Alternative B

Potential impacts to special status amphibians are correlated with impacts to riparian/wetland habitats. The adverse impacts under Alternative B would be similar to those described for special status migratory birds that use riparian/wetland habitats and less than those under Alternative A. Potential adverse impacts to the Great Basin spadefoot toad would be proportional to impacts to sagebrush habitats and are anticipated to be similar to those described for special status migratory birds and greater sage-

grouse. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more information on impacts to amphibians.

Alternative C

Surface Disturbance – Alternative C

Under Alternative C, estimated short- and long-term surface disturbance from BLM actions in the Planning Area (Table 4-1) would result in the greatest loss, degradation, and fragmentation of sagebrush habitat compared to the other alternatives. Erosion from surface disturbance would cause the greatest impact to riparian/wetland habitats under Alternative C. Surface disturbance from roads totals 4,638 acres in the short term and 2,319 acres in the long term under Alternative C, potentially forming the most barriers to fragment habitat (Appendix T).

Resource Uses – Alternative C

Minerals development under Alternative C would result in similar adverse impacts to special status species as under Alternative A, but to a greater extent. Alternative C has the most acres open to mineral development, resulting in the greatest potential loss of special status wildlife species habitat, compared to the other alternatives. Alternative C is projected to result in 1,304 new federal oil and gas wells that would result in more adverse impacts from habitat loss and noise disturbance than Alternative A.

Alternative C would have the most powerline development, resulting in the greatest potential risk for raptor electrocution. The BLM closes a limited portion of the Planning Area to wind-energy development, and allows projects in special status raptor species and greater sage-grouse habitat on a case-by-case basis. The projected impact of wind-energy development to special status wildlife species would be less than Alternative A, but more than alternatives B and D.

Alternative C closes the least amount of land to motorized vehicle use and does not close threatened and endangered species habitat to this resource use. Alternative C is likely to result in the greatest disturbance of special status wildlife species from motorized vehicle use.

The BLM allows livestock grazing in the same areas under Alternative C as under Alternative A, but manages to optimize commodity production while meeting rangeland health standards, not to provide for the enhancement of other resource values. Livestock grazing is restricted the least under this alternative and is more likely to concentrate in riparian/wetland areas, causing the greatest impact to riparian/wetland special status wildlife species. Wild horse grazing in HMAs would also have similar adverse effects to Alternative A, as horses also congregate near water, adversely affecting riparian/wetland special status wildlife species.

Special Designations – Alternative C

Only two ACECs are designated under Alternative C and this alternative does not recommend any WSR eligible waterway segments as suitable for inclusion in the NWSRS and releases these waterways to other resource uses, resulting in no beneficial impacts to special status wildlife species.

Resources – Alternative C

Under Alternative C, the BLM uses wildland fire to restore fire-adapted ecosystems and reduce hazardous fuels, but also to enhance forage for commodity production, potentially benefitting special status wildlife species less than the other alternatives when restoration objectives conflict. However, treatments are used across the Planning Area to restore vegetative diversity and reduce the risk of

Special Status Species – Wildlife

unnatural fire, providing the greatest potential benefit to special status wildlife species from fire and fuels management.

In general, Alternative C allows for the greatest expansion of resource uses, and therefore would result in the greatest spread of invasive species, relative to the other alternatives. The impacts to special status wildlife species from invasive species would be the greatest under Alternative C.

Forest management under Alternative C is similar to Alternative A, but timber harvesting is performed with economic objectives as the primary concern with less regard for wildlife habitat values. The BLM allows larger clear cut areas with the associated adverse impacts described under Alternative A, but old growth forests are retained under Alternative C, directly benefitting Canada lynx and special status raptor and bat species. Although the impacts from forest management actions vary, in general, forest management under Alternative C would provide some beneficial impacts to special status wildlife species from old growth stand retention, but would also result in the greatest adverse impacts to special status wildlife species from timber harvest practices with less regard for wildlife habitat values.

Grassland and shrubland management under Alternative C would provide more beneficial impacts to special status wildlife species than Alternative A, but less than alternatives B and D. Under Alternative C, the BLM manages grassland and shrubland communities toward meeting the *Wyoming Standards for Healthy Rangelands* (Appendix N) with appropriate functional and structural plant groups. These measures are likely to result in a modest improvement in vegetation diversity, but are unlikely to slow the spread of invasive species. Reclamation requirements are more stringent than Alternative A, but less than alternatives B and D. Due to the larger amount of anticipated surface disturbance and invasive species spread under Alternative C, grassland and shrubland communities are likely to be lost or degraded the most under this alternative, affecting special status wildlife species proportionately.

Alternative C provides riparian/wetland communities the least protection compared to other alternatives. The BLM manages all riparian/wetland areas toward meeting PFC, but only prioritizes those in a nonfunctioning condition or with a downward trend. Alternative C is likely to result in the greatest amount of degraded riparian/wetland habitat.

Proactive Management – Alternative C

In general, proactive management under Alternative C provides fewer benefits and mitigates adverse impacts to special status wildlife species to a lesser extent than alternatives A, B, and D. Impacts due to proactive management, and other impacts, are described in detail under each special status wildlife species category below.

Trophy Game – Alternative C

Alternative C has the fewest seasonal closures and restrictions of big game winter ranges and migration corridors and the greatest potential for habitat fragmentation and disturbance to wildlife by exempting Oil and Gas Management Areas and ROW corridors from seasonal wildlife stipulations. Adverse impacts from livestock grazing under Alternative C would be similar to those under Alternative A, but to a greater extent from allowing domestic sheep grazing in more areas. Overall, adverse impacts to the grizzly bear are anticipated to be the greatest under Alternative C.

Predatory Animals – Alternative C

Under Alternative C, there are no specific management actions for gray wolves; however, management actions that protect the habitats gray wolves and their prey (primarily elk) utilize would benefit gray wolves in the Planning Area. Management actions limiting human activities, ROW development such as

roads, and habitat fragmentation also would benefit gray wolves. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more detail on impacts to big game.

Allowing the most timber harvesting (e.g., clear cutting up to 100 acres), mechanical fuels treatments, and prescribed burns under Alternative C would result in the greatest short-term adverse impacts to gray wolves from disturbance and displacement and less long-term beneficial impacts than under Alternative A from timber harvesting that does not protect habitat values. Additionally, allowing timber management roads to remain open for recreational use would adversely impact gray wolves by allowing more human access and potential disturbance, illegal hunting, and habitat fragmentation.

Under Alternative C, seasonal buffers prohibiting surface disturbance around active raptor nests are smaller in size than under alternatives A, B, and D. Alternative C results in the greatest amount of road development (2,319 acres of long-term disturbance) causing greater habitat fragmentation and risk of vehicle collisions than the other alternatives (Appendix T). Alternative C implements the same seasonal restrictions on big game crucial winter range with regards to surface disturbance, but exempts Oil and Gas Management Areas and ROW corridors and opens the Absaroka Front Management Area to mineral, renewable energy, and ROW developments, and motorized vehicle use. Based on more surface disturbance, more potential habitat fragmentation from roads, and a larger area open to cross-country motorized travel, Alternative C results in the fewest beneficial impacts to gray wolves, compared to the other alternatives.

Game Birds (Greater Sage-Grouse) – Alternative C

See Table 4-23 for a summary of management actions and impacts under Alternative C specific to greater sage-grouse. A detailed discussion follows in the sections below.

Estimated short- and long-term surface disturbance from BLM actions under Alternative C are greater than alternatives A, B, and D (Table 4-1), resulting in greater potential for loss, degradation, and fragmentation of sagebrush habitats. However, because Alternative C includes buffers around occupied leks and in nesting and early brood-rearing habitats similar to those under Alternative A, the potential for certain direct adverse impacts to greater sage-grouse and their habitats would be similar to that described under Alternative A. As under Alternative A, Alternative C does not include specific management to preserve large contiguous blocks of native vegetation communities, and therefore landscape-level adverse impacts to sagebrush habitat such as fragmentation and the loss of connectivity between leks and seasonal habitats could occur under this alternative.

Leasable mineral management under Alternative C would result in impacts similar to those described under Alternative A, except that Alternative C would waive certain timing limitations. Under Alternative C, Oil and Gas Management Areas and ROW corridors are exempt from discretionary wildlife timing limitations, which could result in adverse impacts to greater sage-grouse leks in these areas if development occurs during lekking, nesting, or other sensitive time periods. As a result, Alternative C could result in additional stress and displacement of birds into suboptimal habitats compared to Alternative A.

Depending on the placement of the development and supporting facilities, managing some areas as renewable energy exclusion areas (148,416 acres), may result in a reduction in adverse impacts compared to Alternative A. However, Alternative C specifically allows wind energy project in greater sage-grouse seasonal habitats, which could result in additional adverse impacts to greater sage-grouse through large-scale disturbance and disruptive activity during construction and ongoing adverse impacts from noise and habitat loss associated with wind turbines and facilities. Alternative C may therefore result in more adverse impacts to greater sage-grouse from renewable energy development in areas

outside of exclusion areas than Alternative A. Restrictions on the location of ROWs under Alternative C would result in impacts similar to management under Alternative A.

Wildland fire and fuels treatments under Alternative C are similar to those under Alternative A, and would result in similar short-term adverse and long-term beneficial impact to those described under that alternative.

Alternative C manages livestock grazing similar to Alternative A, and impacts to greater sage-grouse would generally be consistent with impacts under that alternative. However, because the BLM manages livestock grazing to optimize commodity production while meeting the Wyoming Standards for Healthy Rangelands, not to provide for the enhancement of other resources such as greater sage-grouse habitat, the extent of the beneficial impacts described under Alternative A could be reduced. In addition, Alternative C requires less stringent monitoring of rangeland conditions than management under Alternative A, or any of the other alternatives. Less frequent feedback on habitat conditions where livestock grazing and greater sage-grouse habitat overlap would be less effective in identifying areas in need of improvement and could delay the implementation of corrective actions. Compared to the other alternatives, Alternative C would increase the potential for disparities between habitat objectives and actual rangeland conditions, potentially reducing cover and forage for greater sage-grouse.

The management of range improvements and supplements under Alternative C is focused on achieving optimal conditions for livestock grazing and would limit the potential for beneficial impacts to greater sage-grouse compared to the other alternatives. As a result, the placement of these items may result in grazing patterns that reduce cover and forage in important greater sage-grouse habitats. The management of hazard fences under Alternative C is the same as under Alternative A, and beneficial impacts from reduced incidence of collision or entanglement would be the same as described under that alternative.

The effects of wild horse grazing in HMAs would be similar to those under Alternative A.

Special designations under Alternative C would provide fewer beneficial impacts to greater sage-grouse than the other alternatives. ACECs designated under this alternative encompass the least area of greater sage-grouse Key Habitat Areas (Table 4-22).

Travel management under Alternative C is generally consistent with Alternative A, and impacts would be similar to those described under that alternative. However, Alternative C could increase the potential for degradation of greater sage-grouse habitats in areas exempted from discretionary seasonal wildlife stipulations.

Management of vegetation communities would result in similar effects to those described under Alternative B. However, because Alternative C does not specifically manage sagebrush communities toward ESDs or establish annual acreage requirements for vegetation treatments in sagebrush habitat, the beneficial impacts described under Alternative B from these actions would not occur.

Managing conifer encroachment to enhance livestock grazing may reduce the beneficial impacts to greater sage-grouse anticipated to occur under alternatives A and B if livestock forage requirements and greater sage-grouse habitat requirements do not align. Management of conifer encroachment to maintain or restore rangeland under Alternative C may therefore result in less suitable habitat for greater sage-grouse than management under the other alternatives.

Alternative C requires the establishment of 30 percent desired vegetative cover within three growing seasons following disturbance, but has no other specific reclamation requirements unless required on a case-by-case basis through a site-specific reclamation plan. Alternative C applies the same requirements as Alternative A to establish vegetative cover in disturbed areas, but does not require revegetation with

native plant species; instead, the BLM would reestablish plant communities to increase commodity production or to meet other resource objectives. Alternative C, because it does not require seeding native species, would result in a reduced potential for beneficial impacts to greater sage-grouse from native habitat recovery. Overall, because surface disturbance and habitat loss, degradation, and fragmentation are greater than under the other alternatives and the reclamation requirements are comparable to Alternative A and less stringent than Alternative B, the associated adverse impacts to greater sage-grouse habitats from these activities would likely be greater than under Alternative C.

Limiting noise sources to 10 dBA above natural, ambient noise during the greater sage-grouse breeding season would result in impacts similar to those under Alternative B, but to a lesser extent. Overall, proactive management actions under Alternative C would limit adverse impacts to the greater sage-grouse less than the other alternatives.

Nongame (Raptors) – Alternative C

Surface-disturbing activities, fire and fuels management, invasive species control, motorized vehicle use, livestock grazing (Johnson and Horn 2008; Torre et al. 2007; Jones 2000), and management actions for biological resources would impact special status raptors more under Alternative C than under alternatives A, B, or D. Under Alternative C, restrictions around raptor nests (47,651 acres) are less extensive than the other alternatives. Though TLS are species specific as under Alternative B, the reduced buffer distance is likely to result in the greatest disturbance to raptor nests under Alternative C. Alternative C is projected to result in more surface disturbance than the other alternatives and, therefore, will have a greater adverse impact on bald eagle terrestrial foraging habitat.

The BLM projects the most powerline development under Alternative C, resulting in the greatest potential adverse impact to raptors from electrocution. The BLM allows wind-energy development in raptor concentration areas on a case-by-case basis, which may result in greater adverse impacts to raptors than alternatives B and D, but less than Alternative A. The BLM allows clear cuts up to 100 acres under this alternative, which would result in a greater adverse impact to raptors that prefer closed canopy habitat than under Alternative A. Forest salvage operations are performed where economically feasible without an appropriate level of snag retention, potentially adversely affecting raptors by degrading habitat; however, because Alternative C retains old growth forests, greater beneficial impacts would result under this alternative than under Alternative A.

Management actions for invasive species control under Alternative C would result in similar special status raptor habitat quality impacts as under Alternative A. Management actions for fire management under Alternative C may, more than the other alternatives in the long term, reduce the potential for catastrophic fire that would adversely impact special status raptor species habitat. Based on these actions, Alternative C would result in greater adverse impacts to special status raptor species habitats than the other alternatives.

Alternative C is anticipated to improve rangeland productivity primarily for livestock grazing, with less area closed to livestock grazing and less forage available for wildlife. Livestock grazing has been shown to reduce raptor prey in arid ecosystems and grasslands (Johnson and Horn 2008; Torre et al. 2007; Jones 2000). Livestock grazing management under Alternative C would result in similar adverse impacts to those under Alternative A, but to a greater extent.

Impacts from recreational use to bald eagles under Alternative C would be similar to Alternative A, but to a lesser extent. Managing lands along the Bighorn River for wildlife habitat, river health, and wildlife resources with less emphasis on recreation would result in fewer adverse impacts to bald eagles from human activity.

Nongame (Migratory Birds) – Alternative C

Under Alternative C, short- and long-term surface disturbance would be the greatest, resulting in the greatest adverse impacts to breeding and nesting habitats for special status migratory birds, compared to the other alternatives. The impacts from wind-energy development under Alternative C are likely to be similar to Alternative A, as projected development is the same across all alternatives and Alternative C manages the least acreage (148,416 acres) as renewable energy exclusion areas, compared to Alternative B.

Sagebrush and Shrubland Species – Measures that adversely affect the greater sage-grouse under Alternative C, as discussed under *Game Birds*, would result in similar impacts to other sagebrush and shrubland species. Alternative C would result in the greatest adverse impacts to these species.

Grassland Species – Actions such as surface-disturbing activities, reclamation, invasive species control, and wild horse and livestock grazing in grassland habitats would affect grassland special status migratory bird species. Alternative C would result in more fragmentation of grassland habitat compared to the other alternatives. Protective measures for the mountain plover are similar to Alternative B, but the larger amount of surface disturbance, especially the disturbance allowed in all prairie dog towns, may result in the greatest adverse impacts to nesting habitat for this species and the long-billed curlew. Although fewer restrictions on livestock grazing under Alternative A could increase the availability of suitable mountain plover habitat similar to Alternative A, few beneficial impacts are anticipated because the Planning Area already contains an abundance of naturally sparse habitats for mountain plover nesting.

Riparian/Wetland Species – Although no specific management actions for special status migratory birds utilizing riparian/wetland areas are identified under Alternative C, other biological resource management actions, particularly those pertaining to water and riparian/wetland habitats, would affect these species. Under Alternative C, actively managing less area for riparian habitat enhancement, allowing surface-disturbing activities in riparian/wetland areas on a case-by-case basis, and allowing the placement of forage supplements to maximize livestock use, regardless of proximity to riparian/wetland areas would result in the most adverse impacts to special status migratory birds that prefer these habitats.

Nongame (Mammals) – Alternative C

Surface-disturbing activities, invasive species control, fire and fuels management, livestock grazing management, and management actions for biological resources would impact special status nongame mammals. Long-term surface disturbance under Alternative C is the greatest compared to all alternatives, likely resulting in proportional adverse impacts to these species.

Sagebrush and Shrubland Species – Measures that adversely affect the greater sage-grouse under Alternative C, as discussed under *Game Birds*, would result in similar impacts to special status nongame mammals in sagebrush and shrubland communities. Alternative C would result in the greatest adverse impacts to sagebrush and shrubland nongame mammals from surface disturbance and livestock grazing and has the fewest measures to mitigate the adverse impacts of surface-disturbing activities to prairie dogs and the associated mountain plover habitat. Although more active fuels treatments to prevent large wildfires may provide a long-term benefit to sagebrush and shrubland nongame mammals, the amount of habitat destroyed from long-term surface disturbance is likely to outweigh this benefit.

Forest and Woodland Species – Under Alternative C, there are no specific management actions for Canada lynx; however, management actions that protect the habitats Canada lynx and their prey (primarily snowshoe hare) utilize would result in beneficial impacts to Canada lynx. Under Alternative C,

short-term impacts from silviculture and fuels treatments, in accordance with the Lynx Conservation Assessment Strategy, may temporarily result in impacts to Canada lynx; however, over the long term these treatments may improve Canada lynx habitat and the habitats of its prey species. Precommercial thinning and clear-cutting up to 100 acres would retain less woody debris than Alternative A, resulting in similar adverse impacts, but to a greater extent. However, retaining old growth forests and adopting connectivity of these areas where feasible would result in similar beneficial impacts to those under Alternative B. Smaller buffer areas around raptor nests and allowing surface-disturbing activities in riparian/wetland areas would result in more adverse impacts to Canada lynx from habitat destruction and potential disturbance. Overall, Alternative C would result in more adverse impacts to Canada lynx habitats than Alternative A due to less restrictions on surface-disturbing activities and more intensive timber harvesting methods.

Cave Species – Surface-disturbing activities near caves, cliffs, or other rock features may impact bats using caves for roosting, maternity colonies, or hibernation. Alternative C manages caves for recreational use, allows activities in AML areas, and does not close caves during critical periods for bats, resulting in the greatest potential adverse impact to bat species. Impacts to bats from wind-energy development under Alternative C would be similar to those under Alternative A.

Nongame (Amphibians) – Alternative C

Potential impacts to special status amphibian species would be correlated with impacts to riparian/wetland habitats. The adverse impacts under Alternative C are similar to those described for special status migratory birds that use riparian/wetland habitats and greater than under alternatives A, B, and D. Potential adverse impacts to the Great Basin spadefoot toad are correlated with impacts to sagebrush habitats and are anticipated to be similar to those described for special status migratory birds and greater sage-grouse; these impacts would be greater under Alternative C than under the other alternatives. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more information on impacts to amphibians.

Alternative D

Surface Disturbance – Alternative D

Estimated short- and long-term surface disturbance from BLM actions in the Planning Area (Table 4-1) under Alternative D would result in similar loss, degradation, and fragmentation of sagebrush habitat as under Alternative A. However, measures to limit erosion and reclaim and restore habitat implemented under Alternative D are likely to mitigate adverse impacts from surface disturbance more than under Alternative A.

Resource Uses – Alternative D

Minerals development under Alternative D would result in similar adverse impacts to special status wildlife species as under Alternative A, but to a lesser extent. Alternative D has the second most area available to locatable minerals entry, but the second least area open to oil and gas development, with more area closed than alternatives A and C in sagebrush habitat to limit impacts to greater sage-grouse. Alternative D is projected to result in 1,143 new federal wells that would impact special status wildlife species from habitat loss and noise disturbance more than Alternative B, but less than alternatives A and C.

The BLM projects that Alternative D would result in the same amount of powerline development as Alternative A with similar potential adverse impacts to raptors. Impacts from ROW and wind-energy

Special Status Species – Wildlife

development under Alternative D would result in more adverse impacts to special status wildlife species than under Alternative B, but less than under Alternative A.

Alternative D closes a similar amount of acreage as Alternative A to motorized vehicle use, and limits motorized vehicle use to designated roads and trails in the second-largest area, including essential and recovery habitat for threatened and endangered species. Adverse impacts from motorized vehicle use under Alternative D would be greater than under Alternative B, but less than under alternatives A and C.

Livestock grazing management under Alternative D would result in impacts similar to those under Alternative A. However, livestock grazing management under Alternative D may provide some benefits because the BLM uses livestock grazing management in certain areas, such as special status wildlife species habitat, to maintain or improve resource conditions.

Special Designations – Alternative D

Special designations under Alternative D would result in similar beneficial impacts as those under Alternative B, but to a lesser extent. Alternative D designates less area as ACECs, does not recommend any WSR eligible waterway segments as suitable for inclusion in the NWSRS and implements fewer restrictions on resource uses and activities to protect special status wildlife species habitat in these areas.

Resources – Alternative D

Impacts to special status wildlife species from fire and fuels management and forests, woodlands, and forest products management under Alternative D would be similar to those under Alternative A, except that by allowing larger areas to be clear cut under Alternative D, there would be more habitat loss for special status wildlife species that prefer closed canopies, such as certain raptors and Canada lynx. However, Alternative D includes management actions to retain old-growth forests that would benefit these species more than Alternative A.

Beneficial impacts to special status wildlife species from grassland and shrubland community management under Alternative D would be similar to those under Alternative B, although to a lesser extent. The BLM manages grassland and shrubland communities for a higher plant community state or phase (based on state and transition models in ESDs) where site-specific management objectives determine that a higher plant community state or phase is desirable, resulting in similar but fewer beneficial impacts to special status wildlife species habitat than Alternative B. However, Alternative D would treat more area for invasive species than Alternative B, providing greater long-term beneficial impact by preventing the spread of invasive species that may degrade special status wildlife species habitat. Livestock flushing practices would result in impacts to grassland and shrubland communities similar to those under Alternative A.

The management of riparian/wetland resources under Alternative D would result in similar beneficial impacts as those under Alternative C, but to a greater extent. Habitat would improve, but additional management would be necessary to ensure that habitat meets life history requirements for various special status wildlife species. Alternative D applies more restrictions to surface-disturbing activities near riparian/wetland areas than Alternative C, limiting adverse impacts from surface disturbance. Overall, beneficial impacts to riparian/wetland habitat for special status wildlife species under Alternative D would be greater than under alternatives A and C, but less than under Alternative B.

Proactive Management – Alternative D

In general, proactive management actions under Alternative D provide more benefits and mitigate adverse impacts to special status wildlife species to a greater extent than under alternatives A and C, but

less than under Alternative B. Impacts due to proactive management and other impacts are described in detail under each special status wildlife species category below.

Trophy Game – Alternative D

Alternative D exempts Oil and Gas Management Areas from discretionary big game seasonal stipulations, but applies more restrictions and seasonal closures in big game habitat, around active raptor nests, and in greater sage-grouse PHMAs than alternatives A and C that would limit adverse impacts to grizzly bear. Impacts from minerals development and new road construction under Alternative D would be less than those under Alternative A because of the additional restrictions applied to the Absaroka Front (253,112) and Big Horn Front (379,308) MLP analysis areas, which include CSU stipulations that limit the location, timing, and amount of oil and gas-related surface disturbances to protect big game.

Predatory Animals – Alternative D

Under Alternative D, there are no specific management actions for gray wolves; however, management actions that protect the habitats gray wolves and their prey (primarily elk) utilize would benefit gray wolves in the Planning Area. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more detail on impacts to big game. Management actions limiting human activities, ROW development such as roads, and habitat fragmentation under Alternative D would benefit gray wolves more than under alternatives A and C, but less than under Alternative B. Forests and woodlands management under Alternative D would result in impacts to gray wolves similar to those under Alternative A. Habitat enhancement in sagebrush and aspen habitats under Alternative D would result in limited beneficial impacts to gray wolves, similar to Alternative C.

Game Birds (Greater Sage-Grouse) – Alternative D

See Table 4-23 for a summary of management actions and impacts under Alternative D specific to greater sage-grouse. A detailed discussion follows in the sections below.

Estimated short- and long-term surface disturbance from BLM actions under Alternative D are similar to Alternative A, but oil and gas leasing in sagebrush habitat would be subject to greater restrictions (Table 4-21) and more closures in greater sage-grouse PHMAs (Table 4-22). Alternative D prohibits surface-disturbing and disruptive activities within 0.6-mile of occupied sage-grouse leks inside PHMAs and within a ¼ mile of occupied leks outside of PHMAs. Alternative D also applies an overall (cumulative) limit on the allowable density of disturbance to 5 percent of a proposed project's DDCT analysis area. Alternative D also applies TLSs to prohibit or restrict surface-disturbing and/or disruptive activities in and around occupied leks and early brood rearing and nesting habitat from March 15 to June 30. This management could prevent stress from noise and human presence during breeding, nesting, and early brood-rearing. These TLSs and their impacts would be similar to those under Alternative B, though they would be applied over a shorter period of time. Overall, resource use and activity restrictions under Alternative D would minimize impacts to greater sage-grouse in PHMAs more than alternatives A and C, but less than Alternative B. Outside of PHMAs, restrictions on resource uses and activities would result in similar beneficial impacts as under Alternative B, although to a lesser extent due to the decreased size of protective lek buffers.

Impacts to greater sage-grouse from mineral leasing under Alternative D would generally be more adverse than under Alternative B, but less adverse than under Alternative A. The Proposed RMP manages PHMAs as open to mineral leasing, but applies a NSO stipulation within 0.6 miles of occupied sage-grouse leks in PHMAs. In comparison, Alternative B closes all greater sage-grouse priority habitat to mineral leasing and applies larger protective buffers outside of priority habitat (0.6 mile versus 0.25

mile). Limiting energy or mining facilities to one location per 640 acres would have similar impacts as the requirement under Alternative B that oil and gas wells disturb no more than 15 acres within a 640-acre section by maintaining more contiguous, uninterrupted habitat within PHMAs, avoiding barriers to greater sage-grouse movement between habitat areas, and limiting human presence and other disruptive activities. Alternative D applies a cumulative five percent limit on disturbance from oil and gas development, which would result in similar impacts to those under Alternative B.

Alternative D manages PHMAs as avoidance areas for wind-energy and ROW development, which would provide similar protections to greater sage-grouse habitat as Alternative B. Alternative D manages the most area as wind-energy avoidance areas and the second-most area as wind-energy exclusion areas, potentially limiting adverse impacts to greater sage-grouse to a greater extent than alternatives A and C, but to a lesser extent than Alternative B. Because Alternative D allows the case-by-case placement of high profile structures in greater sage-grouse nesting habitat, management under this alternative could increase the potential for overhead predation from raptors or other predatory birds, or avoidance behavior of adjacent nesting habitat by greater sage-grouse. The application of TLSs, inside and outside of PHMAs, and a surface disturbance and disruption prohibition within 0.6 miles of occupied leks inside PHMAs would limit the potential for adverse disruption to greater sage-grouse during sensitive winter and lekking periods. Avoiding ROW authorizations in PHMAs and requiring co-location of new major overhead powerlines with 0.5 miles of existing 115 kV or greater powerlines or within designated corridors would also reduce the potential for adverse impacts by applying stipulations that ensure that the proposed development aligns with greater sage-grouse conservation objectives and confining development to less suitable habitat. More broadly, density limitations and other protective measures (such as consolidation of facilities and transmission) could reduce the impacts to greater sage-grouse from habitat loss, disturbance, fragmentation, predation, that result of linear and renewable energy development.

Fire and fuels management and potential adverse and beneficial impacts would be similar to those described under Alternative A.

Livestock grazing management would result in impacts similar to Alternative A, but would increase the potential for loss of herbaceous cover due to overgrazing, invasive species spread, and loss or degradation of water sources compared to Alternative B, which closes all priority habitat to livestock grazing. Unlike under the other alternatives, the prioritization of allotments within PHMAs for field checks would help ensure compliance with the terms and conditions of grazing permits in greater sage-grouse habitat. These checks could further reduce the potential for adverse impacts from livestock grazing to greater sage-grouse through early identification of potential issues in important habitat, allowing the BLM sufficient time to take corrective action where needed. In areas where livestock grazing is adversely affecting habitat or causing disruptions, considering whether public lands in voluntarily relinquished or abandoned permits or leases should remain available for livestock grazing or be used to support greater sage-grouse or other resource management objectives could allow the BLM to reduce adverse impacts to greater sage-grouse by eliminate future livestock grazing.

Impacts from managing range improvements would be similar to those described under Alternative A. Like Alternative A, modification of hazard fences and construction of new fences in accordance with the BLM Fencing Handbook would decrease the chances of entanglement and could prevent harm to greater sage-grouse. In addition, evaluating identified existing and new fences using other current and future updated guidance could allow the BLM to adapt management of potentially adverse fences on the landscape using the most recent science and approaches.

The effects of wild horse grazing in HMAs would be similar to those under Alternative A.

Lands and realty management under Alternative D would retain PHMAs and GHMAs under federal management unless disposal of these lands is shown to be consistent with greater sage-grouse conservation objectives, which would benefit the species by maintaining federal decision-making authority for mitigation or restrictions on surface-disturbing and disruptive activities. Though all alternatives would manage land tenure adjustments with a goal of preserving important resource values (including potentially greater sage-grouse habitats), managing specifically to maintain or provide a net conservation gain under this alternative could provide additional beneficial impacts compared to alternatives A, B, and C.

Special designations under Alternative D would protect the fourth-most area in greater sage-grouse PHMAs, providing more beneficial impacts to greater sage-grouse than alternatives A and C, but less than alternatives B, and E and F (which include greater sage-grouse focused ACECs).

Travel management under Alternative D would be the same as under Alternative C, and impacts would be the same as described under that alternative. However, because Alternative D avoids development of new roads near occupied leks, the potential for adverse effects to greater sage-grouse from future road construction or use would be reduced under this alternative. Road construction can create barriers to movement, fragmentation of habitat, and overall habitat loss. Vegetation loss, erosion, and the spread of invasive, non-native plant species may also occur during or following road construction. Human presence and vehicles may force special status species away from desired habitat to lower quality, less desirable habitat. Collisions with vehicles may also occur when roads are constructed within wildlife habitat. Road corridors are desirable areas for predatory animals, but these areas may be avoided by prey species which may move to less desirable habitat to avoid predation.

Impacts to greater sage-grouse habitat from vegetation treatments and management would be similar to under Alternative C. Impacts to habitat from managing for appropriate functional structural plant groups would be the same as Alternative C, though the direction to potentially manage some areas for a higher plant community state or phase to meet management objectives could allow additional site-specific adjustments to management regimes that would increase cover or other important habitat functions for greater sage-grouse. Alternative D management would limit reductions in sagebrush cover by avoiding treatments that reduce cover below 15 percent.

The management of conifer encroachment in sagebrush under Alternative D would be similar to management under alternatives A and B, but potentially more beneficial because Alternative D manages areas treated for conifer encroachment to toward comprehensive vegetation community goals, as determined through a site's ESD, that include a broader range of habitat suitability factors that could benefit greater sage-grouse.

Where surface disturbances in greater sage-grouse habitat do occur, application of the *Wyoming BLM Reclamation Policy* would establish similar reclamation requirements as Alternative A. In addition, requiring that interim and final reclamation begin at the earliest feasible time, and that successful final reclamation achieve a desired vegetative cover equal to or better than predisturbance site conditions could further reduce adverse impacts from surface disturbances compared to Alternative A and Alternative B. While initial disturbance would result in habitat loss, some sagebrush habitat could be restored over the long term; although some areas of habitat, such as greater sage-grouse winter habitat, could be difficult to restore to original conditions due to the composition and size of sagebrush in these areas. Surface disturbance may also provide opportunities for invasive plant species (e.g., cheatgrass) to establish, making it difficult to restore sagebrush habitat with native species in some areas.

Alternative D is unique from the other alternatives in its requirement that the BLM engage in collaborative management to develop appropriate conservation objectives, determine whether a causal

relationship exists between improper grazing and greater sage-grouse conservation objectives, and identify appropriate actions to achieve conservation objectives. This action could foster wider support for greater sage-grouse management strategies implemented by the BLM and result in the development of more effective conservation measures. Alternative D also monitors greater sage-grouse populations and habitat in relation to specific adaptive management triggers. Tripping identified hard and soft triggers, which are based on metrics such as the number of active leks and acres of available habitat, would prompt the BLM to investigate causal factors and adjust current management in order to continue meeting greater sage-grouse conservation objectives. Existing activities and authorizations with the potential to adversely impact greater sage-grouse may be curtailed or deferred during this time, as allowed by law.

Limiting noise sources to 10 dBA above natural, ambient noise during the greater sage-grouse breeding season would result in impacts similar to those under Alternative B, but to a greater extent because Alternative D extends the time period of the restriction.

Nongame (Raptors) – Alternative D

Surface-disturbing activities, fire and fuels management, invasive species spread, and livestock grazing (Johnson and Horn 2008; Torre et al. 2007; Jones 2000) under Alternative D would impact special status raptors more than under Alternative B, but less than under alternatives A and C. Seasonal restrictions on surface-disturbing activities around active raptor nests are species-specific in timing and more extensive than Alternative C. Alternative D also applies a year-round CSU stipulation with similar beneficial impacts as under Alternative B. Alternative D is projected to result in more surface disturbance than alternatives A and B, with impacts to special status raptor terrestrial foraging habitat similar to Alternative A.

Powerline and wind-energy development under Alternative D would result in similar adverse impacts to those under Alternative A, although to a greater extent, as Alternative D manages more land as ROW exclusion or avoidance areas.

Impacts to raptor terrestrial foraging areas from surface disturbance, fire and fuels management, invasive species control, and livestock grazing would be similar to impacts under Alternative A. Vegetation management in these habitats (managing some areas for a higher or lower plant community state or phase (based on state and transition models in ESDs) would result in more beneficial impacts than alternatives A and C, but less than Alternative B.

Riparian/wetland resources management and restrictions on surface-disturbing activities in these areas under Alternative D would result in less adverse impacts to bald eagles than under alternatives A and C, but greater than under Alternative B. Recreational development at Wardel and Harrington reservoirs under Alternative D result in impacts similar to those under Alternative A. Impacts from recreational use in the Bighorn River area would be similar to those under Alternative B, although to a lesser extent because under Alternative D, the BLM would manage the Bighorn River ERMA in the CYFO for resource protection, among other objectives, with less emphasis on recreation.

Nongame (Migratory Birds) – Alternative D

Projected short- and long-term surface disturbance under Alternative D would result in similar adverse impacts to migratory birds as those under Alternative A. Impacts to migratory birds from wind-energy development would be greater than Alternative B, but less than alternatives A and C.

Sagebrush and Shrubland Species – Measures to protect and reduce potentially adverse impacts to greater sage-grouse, as discussed under *Game Birds*, benefit special status sagebrush and shrubland species. In general, Alternative D places the second-most restrictions on mineral development in

sagebrush habitat and has the second-most stringent requirements for reclamation, resulting in the second-least adverse impact to migratory birds that depend on sagebrush and shrubland habitats.

Grassland Species – Management actions to limit habitat fragmentation in grasslands under Alternative D would result in impacts similar to those under Alternative B. Livestock grazing management would result in similar impacts to mountain plover as described under Alternative A. Potentially managing grassland and shrubland communities to provide preferred habitat for species such as mountain plover and long-billed curlew would result in similar beneficial impacts to Alternative B. Restrictions on surface-disturbing activities and mineral development in the Chapman Bench Management Area would result in similar beneficial impacts to those under Alternative B, but to a lesser extent.

Riparian/Wetland Species – Biological resource management actions pertaining to water and riparian/wetland habitats would affect special status migratory bird species in these areas. Impacts from riparian/wetland resources management under Alternative D would be similar to those under Alternative C. Under Alternative D, impacts from surface-disturbing activities and livestock grazing would be less than under Alternative C, but similar to Alternative A.

Nongame (Mammals) – Alternative D

Surface-disturbing activities, invasive species control, fire and fuels management, livestock grazing management, and management actions for biological resources would impact special status nongame mammals. Long-term surface disturbance under Alternative D would result in similar adverse impacts as those under Alternative A.

Sagebrush and Shrubland Species – Measures that adversely affect the greater sage-grouse under Alternative C, as discussed under *Game Birds*, would have similar impacts to special status nongame mammals in sagebrush and shrubland communities. Minerals development under Alternative D, based on restrictions applied in sagebrush habitat (Table 4-21) would result in more adverse impacts than under Alternative B, but less than under alternatives A and C. Fire and fuels management under Alternative D would result in impacts similar to those under Alternative A. Conservation measures, terms and conditions, and BMPs would minimize impacts to prairie dogs similarly to Alternative A. Measures to limit habitat fragmentation and NSO restrictions on prairie dog colonies suitable for black-footed ferret reintroduction would limit adverse impacts to these species similarly to Alternative B.

Forest and Woodland Species – Under Alternative D, there are no specific management actions for Canada lynx; however, restrictions on surface-disturbing activities around active raptor nests would result in greater beneficial impacts than under alternatives A and C, due to a year-round CSU stipulation, but less than under Alternative B. Silviculture treatments and fire and fuels management practices under Alternative D would result in similar adverse impacts to those under Alternative A, but to a greater extent by allowing larger clear cuts and precommercial thinning. However, Alternative D does retain old growth forests, which would benefit Canada lynx similarly to alternatives B and C.

Cave Species – Alternative D closes caves during critical bat periods and allows activities in AML areas if the impacts can be avoided or mitigated, limiting adverse impacts to special status bat species similarly to Alternative B, but to a lesser degree. Alternative D manages caves in accordance with the decontamination protocol under BLM IM 2010-181 or the National White Nose Syndrome protocol. This action would limit the potential for adverse impacts to special status bat species from White Nose Syndrome and is unique to Alternative D.

Nongame (Amphibians) – Alternative D

Potential impacts to special status amphibians are correlated with impacts to riparian/wetland habitats. Adverse impacts under Alternative D would be less than those under alternatives A and C, but more

Special Status Species – Wildlife

than those under Alternative B. Impacts to the Great Basin spadefoot toad are proportional to impacts to sagebrush habitat, which would be less than those under alternatives A and C, but more than those under Alternative B. See Section 4.4.6 *Fish and Wildlife Resources – Wildlife* for more information on impacts to amphibians.

Alternative E

Surface Disturbance – Alternative E

Estimated short- and long-term surface disturbance from BLM actions in the Planning Area (Table 4-1) would result in the least loss, degradation, and fragmentation of sagebrush habitat under Alternative E. Surface disturbances under this alternative would be the same as Alternative B, except in the Greater Sage-Grouse Key Habitat Areas ACEC, where fewer acres of surface disturbance would result from mineral development, renewable energy development, and ROW development. Surface disturbance from roads would total 1,229 acres in the short term and 614 acres in the long term under Alternative E (Appendix T), forming fewer barriers to fragment habitat than Alternative A, and slightly less than Alternative B. Similar to Alternative B, reclamation requirements under Alternative E would likely mitigate surface disturbance to a greater degree than the other alternatives.

Resource Uses – Alternative E

Impacts to special status wildlife species from minerals development would generally be the same as Alternative B, except in the Greater Sage-Grouse Key Habitat Areas ACEC, which would be withdrawn from locatable mineral entry and closed to mineral materials disposal under Alternative E. Alternative E would also include management that limits disturbances to one per 640 acres and 3 percent or less of the greater sage-grouse Key Habitat Areas in this ACEC, compared to a larger allowable disturbance of 5 percent under Alternative B. Alternative E would therefore result in the least adverse impacts to wildlife from minerals development relative to the other alternatives. Similar to Alternative B, Alternative E is projected to result in 2,680 new federal oil and gas wells that would result in fewer adverse impacts from less habitat loss and noise disturbance than alternatives A and B.

Alternative E would close the greatest portion of the Planning Area to wind-energy development (1,945,204 acres) and ROW development (1,322,879 acres) of any alternative, resulting in the least potential risk of raptor electrocution and the least adverse impacts to greater sage-grouse nesting, brood-rearing, and winter habitat. Powerline and wind-energy development would therefore impact special status species the least under Alternative E.

Impacts resulting from travel management under Alternative E would be the same as Alternative B and would benefit special status wildlife species by placing the most limitations on and closures to motorized vehicle use of any alternative.

Special Designations – Alternative E

The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative E would result in additional protections to special status species wildlife in comparison to the other alternatives. Specifically, the closure of the proposed Greater Sage-Grouse Key Habitat Areas ACEC to mineral materials disposal, renewable energy development, ROW development, and the withdrawal from locatable mineral entry would result in the greatest beneficial impacts to special status wildlife species compared to the other alternatives. Other impacts to special status wildlife species from special designations outside of the Greater Sage-Grouse Key Habitat Areas ACEC would be same as Alternative B.

Resources – Alternative E

The BLM would use similar wildland fire and other vegetation treatments to restore fire-adapted ecosystems and to reduce hazardous fuels as Alternative B; however, treatments would be designed and implemented with a greater emphasis on protection of sagebrush ecosystems within the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Management of these areas would be beneficial to sage-grouse and other sagebrush obligate species. However, the build-up of fuels from fire management activities under Alternative E also increases the potential for long-term adverse impacts on special status wildlife species resulting from catastrophic fire.

Impacts from invasive species would be the same as Alternative B, except in the proposed Greater Sage-Grouse Key Habitat Areas ACEC, where additional protections against the spread of invasive species would result from reduced surface disturbance and the emphasis on restoring and maintaining native sagebrush ecosystems. Conversely, restrictions on herbicide applications in the Greater Sage-Grouse Key Habitat Areas ACEC could reduce the ability to control infestations, which would have an adverse impact on special status wildlife species.

Surface disturbance limitations under Alternative E would augment protective measures for forest/woodland, grassland/shrubland, and riparian/wetland communities where these areas overlap the proposed Greater Sage-Grouse Key Habitat Areas ACEC, decreasing adverse impacts to special status wildlife species that use these habitats.

Proactive Management – Alternative E

Management for special status wildlife species under Alternative E is generally the same as Alternative B (Map 40), and the beneficial impacts would be the same as Alternative B. However, Alternative E would result in the greatest overall beneficial impacts to greater sage-grouse and other special status wildlife species when compared against the other alternatives due to additional management actions limiting impacts from resource uses within the Greater Sage-Grouse Key Habitat Areas ACEC. Oil and gas leases occur on approximately 26 percent (316,110 acres) of the Greater Sage-Grouse Key Habitat Areas ACEC. Under all alternatives, the BLM would not violate the lease rights, but would apply restrictions, including NSO to protect important habitats. Alternative E expounds upon this by imposing an NSO condition of approval within the Greater Sage-Grouse Key Habitat Areas ACEC.

Indirect beneficial impacts would occur where this ACEC overlaps the ranges of special status wildlife species, as discussed in detail below.

Trophy Game – Alternative E

Impacts to grizzly bears would be similar to Alternative B, but with fewer adverse impacts where forest and woodland areas are subject to protective actions associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Predatory Animals – Alternative E

Impacts to gray wolves would be similar to Alternative B, but with fewer adverse impacts where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Game Birds (Greater Sage-Grouse) – Alternative E

See Table 4-23 for a summary of management actions and impacts under Alternative E specific to greater sage-grouse. A detailed discussion follows in the sections below.

Under Alternative E, estimated short- and long-term surface disturbance from BLM actions in the Planning Area would result in the least amount of loss, degradation, and fragmentation of sagebrush habitat of any alternative due to the relative size and additional surface-disturbance limitations associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Prohibitions on surface-disturbing and disruptive activities (including ROWs) are more restrictive than under Alternative B, and this alternative would generally result in less surface disturbance and habitat loss, degradation, and fragmentation of greater sage-grouse habitat than management under any other alternative. Managing disturbance within greater sage-grouse Key Habitat Areas to not exceed one location per 640 acres and cover less than 3 percent of priority greater sage-grouse habitat would result in the least potential for greater sage-grouse habitat fragmentation of any alternative.

Impacts to greater sage-grouse from mineral leasing would be the same as Alternative B; however, because Alternative C withdraws the Greater Sage-Grouse Key Habitat Areas ACEC to locatable mineral entry and closes it to mineral materials disposal, overall adverse impacts from all mineral development would likely be reduced under this alternative.

Managing greater sage-grouse Key Habitat Areas as ROW and renewable energy exclusion areas (Table 4-22) under Alternative E would reduce the potential for adverse impacts to greater sage-grouse to a greater extent than any other alternative. Outside of Key Habitat Areas, management and impacts would be the same as under Alternative B.

Alternative E management of wildland fire and fuels treatment is similar to management under Alternative B, and focuses on restoring fire-adapted ecosystems and reducing hazardous fuels, which would result in long-term beneficial impacts to greater sage-grouse. However, unlike the other alternatives, treatments would be designed and implemented with a focus on the protection of sagebrush in Key Habitat Areas. As a result of this focus, Alternative E management would prioritize the creation and maintenance of greater sage-grouse cover and forage over meeting other resource objectives, increasing the quality of greater sage-grouse habitat over the long term.

Closing Key Habitat Areas to livestock grazing would result in similar adverse and beneficial impacts as described under Alternative B. Unlike management under Alternative B, Alternative E allows the use of livestock grazing as a management tool to address certain goals (such as the reduction of fine fuels), which could help achieve some of the potential beneficial effects of livestock grazing in the closed Key Habitat Areas.

The management of range improvement and supplements would be similar to management under Alternative B, but would include additional restrictions in Key Habitat Areas to ensure compatibility of the placement and/or design of supplement, fences, and other range improvements with greater sage-grouse conservation objectives. Evaluating existing structural range improvements and supplements to ensure that potential adverse impacts to greater sage-grouse are mitigated and additional monitoring requirements to ensure range improvements do not contribute to the proliferation of invasive species would result in additional beneficial impacts beyond those achieved by Alternative B or the other alternatives.

The effects of wild horse grazing in HMAs would be similar to those under Alternative A.

Alternative E specifically retains all lands in the proposed Greater Sage-Grouse Key Habitat Areas ACEC, providing additional protection for these areas from disposal out of federal management.

Alternative E includes the largest area of special designations of any alternative, and would provide the greatest benefit due to the additional restrictions on activities that could adversely affect greater sage-

grouse in these locations. In addition, this alternative designates the 1,232,583 acre Greater Sage-Grouse Key Habitat Areas ACEC (Table 4-22) specifically to protect greater sage-grouse.

Travel management under Alternative E would result in impacts similar to those under Alternative B. Additional restrictions on the placement of new roads, including the prohibition of new road construction within 4 miles of occupied greater sage-grouse leks, and a requirement that project proponents use existing routes to access valid existing rights to the extent possible, would further limit the potential for adverse impacts from surface disturbance associated with new roads and increased human disruption from their use.

Alternative E requires that Special Recreation Permits in the proposed Greater Sage-Grouse Key Habitat Areas ACEC have neutral or beneficial effects to greater sage-grouse habitat, which would reduce the potential for disruptive activities in these areas.

Impacts from vegetation management would be similar to those described under alternatives A, B, and D, except that Alternative E places greater focus on greater sage-grouse habitat restoration and improvement. Prioritizing treatments that improve greater sage-grouse habitat and managing projects to meet defined sage-grouse habitat parameters would result in greater beneficial impacts than management under the other alternatives. Additional requirements, such as the use of native seeds and management toward the restoration of native (or desirable) plant communities to ESD reference states could result in further habitat enhancements. Alternative E also restricts activities that facilitate the spread of invasive, nonnative plant species in greater sage-grouse habitat through requirements for livestock flushing and vehicle washing.

Alternative E manages conifer encroachment and invasive plant species the same as Alternative B, and impacts would be the same as described under that alternative.

Limitations on new sources of noise would be the same as described under Alternative B.

Alternative E includes the development of a statewide adaptive management plan for greater sage-grouse that identifies monitoring requirements and specific adaptive management triggers. Alternative E would likely result in similar beneficial impacts as the adaptive management strategy articulated under Alternative D by supporting population management objectives for greater sage-grouse set by the State of Wyoming (State of Wyoming Office of the Governor, EO 2011-5).

Nongame (Raptors) – Alternative E

Impacts to special status raptor species would be the same as Alternative B, except where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Nongame (Migratory Birds) – Alternative E

Impacts to special status migratory bird species would be the same as Alternative B, except where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Nongame (Mammals) – Alternative E

Impacts to special status mammals would be the same as Alternative B, except where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Special Status Species – Wildlife

Nongame (Amphibians) – Alternative E

Impacts to special status amphibians would be the same as Alternative B, except where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse Key Habitat Areas ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Alternative F

Surface Disturbance – Alternative F

Alternative F would result in 137,064 acres of short-term and 17,663 acres of long-term surface disturbance. Impacts to wildlife from surface disturbance under Alternative F are projected to be greater than under alternatives A, B, and E, but less than under alternatives C and D. Similar to Alternative D, greater erosion prevention measures and reclamation requirements under Alternative F may mitigate impacts to wildlife habitat to a greater extent than Alternative A.

Resource Uses – Alternative F

Resource uses under Alternative F would result in fewer adverse impacts to wildlife habitat than Alternative D and slightly greater impacts than Alternative A. Like Alternative D, Alternative F applies a NSO stipulation within 0.6 mile of occupied greater sage-grouse leks within PHMAs. However, Alternative F limits surface disturbances to one per 640 acres and 3 percent or less of the Wyoming Density and Disturbance Calculation Tool (DDCT) analysis area, compared to 5 percent under Alternative D, which would afford greater protection for greater sage-grouse and other special status wildlife species that use habitats within the ACEC. Overall, fewer new federal wells are anticipated under Alternative F than alternatives A, C, and D, but more than alternatives B and E, with proportional adverse impacts to special status species.

Powerline development would be similar to alternatives A and D, but with additional restrictions within the proposed Greater Sage-Grouse PHMAs ACEC that would impose seasonal restrictions on powerline development, encourage the use of buried lines, and consider upgrades to enhance sage-grouse habitat security.

Alternative F would also limit motorized vehicle use to designated roads and trails and exclude renewable energy development over a greater area than Alternative D, resulting in fewer adverse impacts than alternatives A, C, and D, but more than alternatives B and E. Impacts from livestock grazing management would be the same as Alternative D across much of the Planning Area, but would incorporate greater sage-grouse habitat objectives within the proposed Greater Sage-Grouse PHMAs ACEC that would result in beneficial impacts to greater sage-grouse and other special status species that use sagebrush habitats.

Special Designations – Alternative F

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land in the Greater Sage-Grouse PHMAs ACEC. The additional restrictions (discussed under Resource Uses and Resources) on surface disturbance, oil and gas leasing, motorized vehicle use, and renewable energy development in the proposed Greater Sage-Grouse PHMAs ACEC would result in fewer adverse impacts to wildlife habitat than Alternative D. Beneficial impacts would be similar to Alternative E, but to a lesser extent due to the designation of less area as ACECs and fewer restrictions on resource uses and activities in special designation areas to protect special status wildlife species habitat and WSR eligible waterway segments.

Resources – Alternative F

Impacts to special status wildlife species from management actions to protect resources would be generally the same as Alternative D, except in the proposed Greater Sage-Grouse PHMAs ACEC, where specific management actions for habitat restoration, invasive species management, fire and fuels management, and livestock grazing that prioritize the protection of greater sage-grouse populations and sagebrush habitat would apply (Map 43). Therefore, management actions within these areas are likely to be more beneficial for sage-grouse and other special status wildlife species that use sagebrush habitats than under Alternative D.

Surface disturbance limitations under Alternative F would lower the potential for disturbance in forest/woodland, grassland/shrubland, and riparian/wetland communities where these areas overlap the proposed Greater Sage-Grouse PHMAs ACEC, decreasing adverse impacts to special status wildlife species that use these habitat areas.

Proactive Management – Alternative F

In general, proactive management actions under Alternative F (Map 43) provide more benefits and mitigate adverse impacts to special status wildlife species to a greater extent than alternatives A and C; slightly more than Alternative D due to the designation of the Greater-Sage Grouse PHMAs ACEC; and less than alternatives B and E. Oil and gas leases occur on approximately 50 percent (554,048 acres) of the Greater Sage-Grouse PHMAs ACEC. Under all alternatives, the BLM would not violate the lease rights, but would apply restrictions, including NSO conditions of approval to protect important habitats. Impacts due to proactive management and other impacts are described in detail under each special status wildlife species category below.

Trophy Game – Alternative F

Impacts to grizzly bears would be similar to Alternative D, but with fewer adverse impacts where forest and woodland areas are subject to protective actions associated with the proposed Greater Sage-Grouse PHMAs ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Predatory Animals – Alternative F

Impacts to gray wolves would be similar to Alternative D, but with fewer adverse impacts where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse PHMAs ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Game Birds (Greater Sage-Grouse) – Alternative F

See Table 4-23 for a summary of management actions and impacts under Alternative F specific to greater sage-grouse. A detailed discussion follows in the sections below.

Estimated short- and long-term surface disturbance from BLM actions under Alternative F are similar to alternatives A and D, but with greater restrictions on oil and gas development in sagebrush habitat (Table 4-21). Overall, Alternative F management would result in greater beneficial and reduced adverse impacts to greater sage-grouse than would management under alternatives A or C, similar impacts to alternatives B and D, and fewer beneficial impacts and greater adverse impacts than management under Alternative E.

Adverse impacts to greater sage-grouse from mineral leasing under Alternative F would be reduced compared to Alternative A and similar to under Alternative D. This alternative closes more than twice the amount of federal mineral estate to oil and gas leasing as Alternative D, but applies similar NSO restrictions, and limits surface disturbances from oil and gas to one location per 640 acres. However,

Alternative F includes additional constraints on oil and gas development, including a lower threshold of allowable cumulative surface disturbance in PHMAs (3 percent here versus 5 percent under Alternative D) and requirements to unitize leases and consider development on a larger scale, such as through the use of Master Development Plans. Unlike the greater sage-grouse focused ACEC under Alternative E, the Greater Sage-Grouse PHMAs ACEC would not preclude mineral development, resulting in greater potential for adverse impacts to greater sage-grouse and their habitats within PHMAs.

Adverse impacts to greater sage-grouse from ROW and renewable energy management would be similar to Alternative E, but to a greater extent because Alternative F includes fewer ROW exclusion areas in greater sage-grouse habitat. Compared to alternatives A, C, and D, management under Alternative F is anticipated to reduce the potential for new ROW development in greater sage-grouse habitat, and thus reduce the potential for adverse impacts compared to those alternatives. Alternative F generally manages PHMAs as avoidance areas for renewable energy and ROW development, which may necessitate the application of project design or mitigation features that would limit adverse impacts to greater sage-grouse. Although surface disturbance from ROW and renewable energy development would still result in adverse impacts from increased habitat fragmentation, habitat degradation, and disruption under this alternative, Alternative F includes a number of additional constraints in PHMAs that would help limit these effects (e.g., requirements to remove, bury, or modify existing powerlines and the application of TLSs to transmission line construction).

Alternative F management of wildland fire and fuels treatment is similar to management under Alternative D, and focuses on restoring fire-adapted ecosystems and reducing hazardous fuels. Overall, lower fuel loads and a return to natural wildland fire return interval would result in long-term beneficial impacts to greater sage-grouse. However, as under Alternative E, Alternative F implements wildland fire and fuels management with a focus on protecting existing sagebrush ecosystems in PHMAs.

Alternative F manages livestock grazing similar to Alternative D, and impacts would be similar to those described under that alternative. In addition, Alternative F includes additional restrictions in PHMAs to ensure that livestock use does not affect greater sage-grouse habitat quality. These measures include temporarily excluding livestock grazing in areas recovering from fire and incorporating greater sage-grouse habitat objectives and management considerations into all BLM grazing allotment management plans. Implementation of these additional restrictions would reduce the potential for livestock grazing in PHMAs to impede greater sage-grouse habitat recovery or adversely affect habitat quality.

The effects of wild horse grazing in HMAs would be similar to those under Alternative A.

Lands and realty management under Alternative F is the same as under Alternative D, and impacts would be the same as under that alternative.

Alternative F includes the second largest area of special designations of any alternative, and would provide the similar benefits to greater sage-grouse as Alternative E from the additional, restrictive management applied in these locations. Like under Alternative E, this alternative includes an ACEC specifically to protect greater sage-grouse, the 1,116,698 acre Greater Sage-Grouse PHMAs ACEC (Table 4-22). However, the Greater Sage-Grouse PHMAs ACEC includes fewer exclusions and closures to resource uses than does the greater sage-grouse focused ACEC under Alternative E, which would limit the potential for adverse impact reduction compared to that alternative.

Travel management under Alternative F is the same as under Alternative D, and impacts would be the same as under that alternative. Similar to Alternative D, this alternative restricts the placement of new roads in and around certain greater sage-grouse habitat (1.9 miles from the perimeter of occupied sage-grouse leks inside core areas). Like Alternative E, this alternative requires that project proponents

use existing routes where possible to access valid existing rights as methods to limit potential adverse impacts from surface disturbance associated with new roads and increased human disruption from their use.

Similar to Alternative E, Alternative F requires that Special Recreation Permits issued in the proposed Greater Sage-Grouse PHMAs ACEC have neutral or beneficial effects to greater sage-grouse habitat, which would reduce the potential for disruptive activities in these areas.

Impacts from vegetation management would be similar to those described under alternatives A, B, and D, except that Alternative F emphasizes habitat restoration and improvements that would specifically benefit greater sage-grouse. Prioritizing projects that improve greater sage-grouse habitat and managing toward defined greater sage-grouse habitat parameters would improve habitat conditions in comparison to those alternatives. Additional requirements, such as the use of native seeds and management toward the restoration of native (or desirable) plant communities, could also enhance habitat for greater sage-grouse.

Alternative F manages conifer encroachment the same as Alternative A, and impacts would be the same as described under that alternative.

Alternative F invasive plant species management is similar to management under Alternative D, but incorporates additional beneficial management actions in the Greater Sage-Grouse PHMAs ACEC, such as requirements to restore habitat to a higher community state or phase and conduct post-treatment monitoring and control requirements for invasive vegetation. Alternative F invasive plant species management in PHMAs is similar to Alternative E's management for Key Habitat Areas, and beneficial impacts from focusing on the maintenance of sagebrush ecosystems would be similar to those described under that alternative.

Limitations on new sources of noise would be the same as described under Alternative D, and impacts would be the same as described under that alternative.

Like Alternative E, proactive management under Alternative F includes the development of a statewide adaptive management plan for greater sage-grouse. The use of adaptive management plans would result in beneficial impacts to greater sage-grouse by aligning and frequently recalibrating BLM management strategies to support population management objectives for greater sage-grouse developed by the State of Wyoming (State of Wyoming Office of the Governor, EO 2011-5).

Nongame (Raptors) – Alternative F

Impacts to special status raptor species would be similar to Alternative D, but with fewer adverse impacts where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse PHMAs ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Nongame (Migratory Birds) – Alternative F

Impacts to special status migratory bird species would be similar to Alternative D, but with fewer adverse impacts where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse PHMAs ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Nongame (Mammals) – Alternative F

Impacts to special status mammals would be similar to Alternative D, but with fewer adverse impacts where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse PHMAs ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

Nongame (Amphibians) – Alternative F

Impacts to special status amphibians would be similar to Alternative D, but with fewer adverse impacts where habitats are subject to protective actions associated with the proposed Greater Sage-Grouse PHMAs ACEC, as discussed in Section 4.4.6 *Fish and Wildlife Resources – Wildlife*.

4.4.10 Wild Horses

Wild horses are managed for self-sustaining populations of healthy, free-roaming animals in balance with other uses and the productive capacity of their habitat. Management of wild horses is performed consistent with the Wild Free Roaming Horses and Burros Act of 1971, multiple use objectives in the FLPMA, and conformance with the *Wyoming Standards for Healthy Rangelands* (Appendix N), and in compliance with relevant court orders and agreements.

Adverse impacts to wild horses include management that reduces vegetation for forage, the availability of water, or other habitat components necessary to maintain the health of horses and the initial appropriate management level in HMAs. Beneficial impacts to wild horses result from management that increases the health, forage, genetic variability, and movement of wild horses in HMAs.

Direct impacts to wild horses result from management that affects their health, forage, and free-roaming nature. Actions that alter wild horse habitat in HMAs, such as surface disturbance that reduces forage in the short term, would result in direct impacts. Indirect impacts to wild horses may result from the construction of fences and activities that increase the competition for resources among wild horses, livestock, and wildlife in the long term, such as increased resource uses and land tenure adjustments or other management actions that subsequently alter the health, forage, and free-roaming character of wild horses.

Because appropriate management levels are typically set at levels that leave forage available for livestock and wildlife, wild horse populations are impacted most directly through gathers and fertility controls rather than reductions in forage availability (National Resource Council 2013). However, decreases in forage availability due to surface-disturbing activities in HMAs without a corresponding increase in reclamation or restoration of forage in another area, could indirectly impact wild horses by necessitating adjustments in the appropriate management level to compensate for the overall decline in forage availability.

4.4.10.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- The number of wild horses would increase by about 15 percent annually and be maintained by periodic removals, based on the estimated population increase for the McCullough Peaks HMA (BLM 2008a).
- Wild horse removals (gathers) would occur about every 3 to 5 years in each HMA.

- Maintenance of wild horse populations at initial appropriate management levels in existing HMAs would be accomplished through removals and selected application of other population control practices.
- Wild horse gathers would use existing trap locations for the most part.
- Conducting wild horse gathers in the fall, when temperatures are lower, would reduce stress on the animals; however, summer gathers scheduled during the cooler morning hours would also limit such stress.

4.4.10.2 Summary of Impacts by Alternative

Adverse impacts to wild horses primarily result from management that reduces the forage, health, and free-roaming nature of wild horses. The expansion of the McCullough Peaks Herd Management Area (HMA) under alternatives B, E, D, and F would result in beneficial impacts to wild horses by adjusting the HMA boundary to more accurately correspond to the range the resident herd uses, rather than continued attempts to recapture and move horses that venture outside of the existing HMA boundary. No changes would be made to the Fifteenmile HMA. Alternatives B and E, and to a lesser extent alternatives D and F, implement proactive management and constrain resource uses and disruptions (e.g., restrictions on organized special recreation permits [SRPs] in HMAs) in ways beneficial to wild horse forage and health. Limitations on surface disturbance and resource uses within proposed greater sage-grouse ACECs under alternatives E and F would augment protective management actions applied within the HMAs and provide additional protection for wild horses where these areas overlap. Alternatives A and C would result in similar impacts to wild horses, with the implementation of Alternative C causing more adverse impacts to wild horses than Alternative A, especially in the short term. Under all alternatives, wild horse populations may be brought into balance with available habitat and resources needed to sustain genetically viable herds.

4.4.10.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

The types of potential impacts to wild horses under the various alternatives are similar. However, the extent and intensity of impacts would vary by alternative. Therefore, discussions for individual alternatives describe impacts to wild horses from surface-disturbing activities, minerals development, ROW development, motorized vehicle use, recreation, livestock grazing, special designations, fire and fuels management, and proactive management actions.

Managing HMAs to be consistent with the *Wyoming Standards for Healthy Rangelands* (Appendix N) results in adverse and beneficial long-term impacts to wild horses. Fencing to improve livestock grazing distribution would affect the movement of wild horses and would affect their overall free-roaming nature. Water developments may improve the distribution of wild horses in each HMA. Conformance with the *Wyoming Standards for Healthy Rangelands* in upland areas would result in improved plant vigor, production, and diversity of species available as forage, which would result in beneficial impacts to wild horses.

Increased incidence of drought and associated increases in wildfire and reductions in the availability of water from climate change may result in long-term adverse impacts to wild horses. See the climate change section at the end of this chapter for more information regarding potential impacts from climate change.

Management that decreases adverse impacts to water quality, watersheds, and soils, such as avoiding or prohibiting surface disturbance near water or on slopes, maintaining watershed improvement projects, and using BMPs to reduce runoff, soil erosion, and sediment yield to retain water on landscapes would result in long-term benefits to wild horses. Management of resources that enhance habitat and forage production would contribute to habitat health and the overall health of horses.

Under all alternatives, the following Herd Areas would not be managed for wild horses: Sand Draw (15,302 acres), Zimmerman Springs (12,277 acres), Alkali Spring Creek (5,183 acres), Foster Gulch (141,300 acres), and North Shoshone (22,626 acres). Analysis for the previous RMPs determined that managing wild horses in these Herd Areas resulted in management issues or conflicts that were most appropriately resolved by the removal of wild horses. These decisions and findings remain valid because the resource conditions have not changed; therefore, the continued exclusion of wild horses from these areas results in beneficial impacts to wild horse management.

Managing the initial appropriate management level of wild horses in the Fifteenmile HMA (70 to 160 breeding adults) and the McCullough Peaks HMA (70 to 140 breeding adults) to be adjusted as necessary based upon monitoring would result in beneficial long-term impacts to wild horses from maintaining genetic viability in the HMAs. Allowing free movement of herds in HMAs would further increase the genetic viability of wild horse populations in HMAs. Employing selective removal criteria in accordance with current national policies during periodic gathers to increase the prevalence of desired genetic characteristics and avoid genetic depression would result in long-term benefits to wild horses by increasing long-term health and genetic viability.

Considering the use of natural and artificial population control measures, as needed, to maintain the populations of wild horses in the initial appropriate management levels may result in long-term beneficial impacts to wild horses by improving health of populations and facilitating effective strategies for managing wild horses and their habitat.

Basing future adjustments to appropriate management levels in the HMAs on monitoring and multiple use considerations through development of and/or revisions to HMA Plans would result in long-term beneficial impacts to wild horses by providing an appropriate review of herd objectives and conditions before forage allocations are made.

The use of certified weed-free forage supplements would result in beneficial impacts to wild horses by decreasing the potential for invasive species establishment and spread that would compete with native vegetation and lead to losses in forage. The use of forage supplements would also reduce competition for food sources in times of drought between wild horses and other wildlife.

Maintaining up-to-date Herd Gathering Plans and emphasizing the gathering of wild horses that move outside HMAs or onto private lands would result in overall beneficial impacts to management of the wild horses program within the context of multiple use. A strategic and reasoned approach to gathering wild horses would result in more effective and efficient gathering activities. Gathering excess wild horses would also result in reduced competition for resources (e.g., forage, water, and habitat) which may increase the health and viability of the horses remaining within the initial appropriate management level.

Special designations may result in beneficial impacts to wild horses by limiting impacts to resources (e.g., soil, water, and vegetation) that would affect wild horses. Under all alternatives, HMAs overlap with WSAs. Managed to be consistent with BLM Manual 6330 (BLM 2012a), activities that would adversely impact resource uses may be limited or prohibited in WSAs. These limitations would result in beneficial impacts to wild horses in the HMAs, except that new water development or other projects to benefit wild horses would likely be precluded from construction in WSAs.

Alternative A

Surface Disturbance

Surface disturbance affects wild horses both directly and indirectly. The severity of impacts to wild horses from surface disturbance depends on the location of the surface disturbance. Disturbance in HMAs would more directly affect wild horses. The location of surface disturbance projected in Appendix T has not been determined. However, land use allocations under each alternative may affect the location of surface disturbance. Land use allocations by alternative in each HMA are summarized in Table 4-24.

Table 4-24. Land Use Allocations (acres) within Herd Management Areas by Alternative

Management		McCullough Peaks HMA						Fifteenmile HMA

HMA Herd Management Area
 ROW rights-of-way

Under Alternative A, 28,392 acres (16 percent) of HMAs are within WSAs, which will limit adverse impacts to HMAs from surface-disturbing activities. Surface disturbance and the removal of vegetation would directly limit the available forage for wild horses and other grazing animals and, without appropriate reclamation or rehabilitation, may also lead to the establishment and spread of invasive species, potentially contributing to forage reduction. Reductions in forage would impact wild horses by increasing competition between livestock and other wildlife.

Resource Uses

Management actions for minerals would result in both short-term and long-term impacts to wild horses. Mining activity would result in both short-term and long-term surface disturbance and loss of vegetation, which would reduce available forage. Construction and operation of mineral facilities and infrastructure would also displace horses and prevent movement in certain circumstances (e.g., linear infrastructure such as aboveground pipelines, transmission lines, and roads). Increased human presence and activity associated with mining may also reduce the wild and free-roaming nature of the horses.

Untreated invasive weeds that outcompete native vegetation and grasses may reduce available forage for wild horses. Treatments and reductions in invasive weeds may displace wild horses and reduce forage in the short term, but would reduce competition with native vegetation and increase available forage for wild horses in the long term. Under Alternative A, there would be beneficial impacts from treatments of invasive species on approximately 2,000 acres.

Management of ROWs would result in short- and long-term adverse impacts to wild horses. Wild horses would be displaced in the short term during construction activities and may be displaced in the long term depending on the size and activity level associated with ongoing operations on the ROW. The development of ROWs would also increase human activity and may result in avoidance behavior of wild horses, affecting access to resources and additional energy expenditure. Construction of ROWs and associated surface disturbance would result in short-term impacts to wild horses by removing forage. Successful reclamation of surface disturbance would reduce the potential for long-term loss of forage associated with ROW development. However, permanent (or long-term) facilities and infrastructure would still result in long-term surface disturbance that would reduce overall forage. Developing new ROWs in or adjacent to disturbed areas associated with existing ROWs or high traffic gravel roads or highways would reduce impacts to wild horses from the development of new ROWs. Alternative A has the most area open to ROW development in the Fifteenmile and McCullough Peaks HMAs (Table 4-24).

Management for travel and transportation would result in both short- and long-term impacts to wild horses. Travel designations that permit motorized vehicle use may disturb wild horses and result in short-term displacement when activity is occurring. In areas of frequent motorized vehicle use, wild horses may adjust behavior to adapt to human activity and noise, which may affect their wild and free-roaming nature and has been observed in the McCullough Peaks HMA. Areas open to cross-country motorized travel may reduce available vegetation and forage for wild horses; however, no areas in HMAs are completely open to cross-country motorized travel under any of the alternatives. Less than half of the area in HMAs is limited to designated roads and trails (Table 4-24). Limiting motorized vehicle use to designated roads and trails would limit adverse impacts to wild horses by restricting motorized access to help maintain their overall free-roaming and wild nature and to minimize disturbance.

Recreation management under Alternative A would result in localized short-term impacts to wild horses. Recreational activities may result in the temporary disturbance of horses from recreational wild horse viewing, hiking, hunting, camping, and other activities.

Livestock grazing management would result in adverse and beneficial impacts to wild horses. Impacts of livestock grazing on wild horses depend on the location, timing, intensity, duration, and frequency of grazing. Livestock grazing management results in the maintenance or improvement of range conditions as directed by the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N). Range improvements associated with livestock such as springs, wells, and reservoirs would also result in beneficial impacts to wild horses by increasing the availability of water. Conversely, fences constructed for range improvements may cause adverse impacts to wild horses by preventing herd movement and access to resources, necessitating additional management actions to open gates to allow horse movement. Livestock grazing may also result in competition for forage, water, and habitat with wild horses resulting in adverse impacts during periods of drought. Drought conditions can exacerbate conflicts between wild horses and livestock management relating to water and forage availability on rangelands and in HMAs. These impacts would occur only in the portions of HMAs managed as open to livestock grazing. Under Alternative A, over 99 percent of HMAs are open to livestock grazing (Table 4-24).

Special Designations

Management for regionally important prehistoric and historic trails (i.e., Other Historic Trails) would result in beneficial impacts to wild horses. The Bridger Trail passes through the eastern portion of the McCullough Peaks HMA. Restrictions on surface-disturbing activities, ROW development, and motorized vehicle use on and in the vicinity of the trail would result in beneficial impacts by reducing the potential for activities that would decrease forage and may disturb or displace wild horses.

Resources

Fire and fuels management would result in both adverse and beneficial impacts to wild horses. Management that increases the occurrence and spread of wildland fires in the short term, such as restrictions on fire suppression activities, would result in temporary displacement of wild horses and short-term reductions in available forage. However, fires of the appropriate intensity would improve forage production in the long term and result in vegetative communities with increased diversity, cover, and age class. Burned areas may also require fencing during stabilization and rehabilitation, which may temporarily decrease the movement of wild horses. Due to the short-term impact of these fences, they are not expected to affect the long-term genetic variability of wild horses.

Fire suppression activities, such as firebreaks and staging areas for suppression, would also result in short-term loss of forage. These impacts are expected to be minor, considering the amount of suppression activities and localized disturbance, compared to the size of the Planning Area and HMAs. However, the firebreaks historically have resulted in increased road use, which may fragment wild horse habitat. Any fire suppression activities in or near HMAs would increase short-term impacts to wild horses.

Mechanical fuels treatments, prescribed fire, and other fuels reduction activities may result in short- and long-term impacts to wild horses. However, most HMAs do not have a history of wildfires, and the likelihood of these areas receiving fuels treatments or being susceptible to wildfires is low. In the short term, any fuels reduction treatment that does occur may temporarily displace wild horses from localized areas. In the long term, any fuels reduction activities that help return fire to locations in the HMAs where it historically facilitated ecosystem health would benefit wild horses through improved forage production and vegetative diversity.

Proactive Management

Under Alternative A, the McCullough Peaks HMA would be maintained at about 103,866 acres and the Fifteenmile HMA at 70,527 acres (Map 45). Providing opportunities for the public to view wild horses in the McCullough Peaks and Fifteenmile HMAs may result in both adverse and beneficial impacts to wild horses. Increased human presence may adversely impact wild horses by acclimating horses to human presence and reducing their wild, free-roaming nature. Increases in foal mortality due to foal abandonments and increased risk of injuries to humans would result as horses continue to be acclimated to humans. However, increasing public interest in wild horses may result in beneficial impacts to wild horses by heightening awareness of the wild horse program and public opportunities to adopt excess horses removed from the range. Adoption activities may result in public participation in and support for the wild horse management program and long-term management activities.

SRPs in the HMAs would result in impacts similar to those described above for providing opportunities for public viewing of wild horses. However, these impacts may be greater due to the closer proximity and larger scale of activities associated with SRPs, camps, events, activities, and an increase in the number of visitor use days. When SRP holders use horses, additional risks can result from wild stallions approaching domesticated mares that are in estrus (in season). In large groups, domesticated horses may also escape and join bands of wild horses; the SRP holder is responsible for any costs associated with the collection of their horses. Additional impacts would result from the introduction of parasites and diseases brought into the HMA by domestic horses.

Evaluating and potentially allowing fences in the McCullough Peaks HMA on a case-by-case basis may result in beneficial and adverse impacts to wild horses. Fences may help achieve healthier rangelands by allowing for rotational livestock grazing. Any fence decision would require site-specific analysis with public participation under NEPA to ensure the consideration of adequate alternatives and mitigations, including gate management and horse movement, before construction.

Mitigating surface-disturbing and disruptive activities in the Fifteenmile HMA would result in beneficial impacts to wild horses by reducing adverse impacts associated with these activities, as previously described.

Alternative B

Surface Disturbance

Impacts of surface disturbance on wild horses would be similar to those described under Alternative A, although to a lesser extent, because the projected overall surface disturbance in the Planning Area is less under Alternative B (Table 4-1). With the expansion of the McCullough Peaks HMA, 38,268 acres (21 percent) of HMAs are contained in WSAs, which would limit adverse impacts to HMAs from surface-disturbing activities. Applying seasonal restrictions from February 1 to July 31 in the McCullough Peaks and Fifteenmile HMAs would further limit the potential for adverse impacts from surface-disturbing and disruptive activities on wild horses during foaling. Implementation of Alternative B would result in 46 percent and 31 percent less short- and long-term surface disturbance than Alternative A, respectively, and would therefore have less adverse impacts to wild horses.

Resource Uses

Management of minerals would result in impacts similar to those under Alternative A, although to a lesser extent. Implementation of Alternative B would close fewer acres in HMAs to mineral activity (Table 4-24).

Management of invasive species would result in impacts similar to those under Alternative A. However, under Alternative B, the BLM would treat less area (5 percent of the area treated under Alternative A) for invasive species, potentially allowing for increased weed establishment in HMAs, with associated forage reductions.

Management of ROWs would result in impacts similar to those under Alternative A, although to a lesser extent because there are more restrictions on ROW development under Alternative B. Alternative B includes more ROW avoidance or exclusion areas in the HMAs compared to Alternative A (Table 4-24). In addition, no areas are open to ROWs in the HMAs under Alternative B. ROW development would occur only in ROW avoidance areas, where the BLM would apply appropriate mitigation measures and BMPs to limit impacts to wild horses and other resources.

Management of travel and transportation would result in impacts similar to those under Alternative A, although to a lesser extent. Under Alternative B, the BLM would close or limit to designated roads and trails motorized vehicle travel in the HMAs in more area than under Alternative A (Table 4-24). Therefore, there would be fewer impacts from motorized vehicle use under Alternative B.

Impacts from recreation management under Alternative B would be similar to those under Alternative A.

Under Alternative B, fewer spring and reservoir developments associated with livestock grazing would be constructed compared to Alternative A, resulting in fewer beneficial impacts to wild horses. Under Alternative B, 94,875 acres (51 percent) of the HMAs are managed as closed to livestock grazing (Table 4-24), reducing competition for forage across most of the area open to wild horses and resulting in a beneficial impact to these animals. Apportioning additional sustained yield forage for wild horses and wildlife would result in beneficial impacts to wild horses by increasing forage and decreasing the potential for competition with livestock and other wildlife. Alternative B would result in greater potential to increase forage availability for wild horses, resulting in the greatest benefit to health and vigor for the constrained number of horses in the HMAs (i.e., 70 to 160 horses for the Fifteenmile HMA and 70 to 140 horses for the McCullough Peaks HMA).

Special Designations

Management of the Bridger Trail, which passes through the McCullough Peaks HMA, would result in similar beneficial impacts under Alternative B as those described under Alternative A, but to a greater extent due to the increased restrictions on resource uses and activities around the trail.

Resources

In general, management under Alternative B emphasizes the conservation and protection of resources (e.g., vegetation, water, and soils) which may improve forage and the health of wild horses. As a result, management of resources under Alternative B would have greater beneficial indirect impacts to wild horses compared to Alternative A.

Impacts to wild horses from fire and fuels management would be similar to those under Alternative A. However, under Alternative B, the likelihood of mechanical treatments for fuels and prescribed fire use in the HMAs would be lower, which may further reduce the potential disturbance and displacement of wild horses. Fewer fuels treatments also may increase the potential for larger, more intense fires in the long term and associated adverse impacts to wild horses. However, as under Alternative A, such fires would likely remain uncommon due to the historical absence of wildfires in the HMAs.

Proactive Management

Under Alternative B, expansion of the McCullough Peaks HMA and maintaining the initial appropriate management level of horses in the HMA would result in beneficial impacts to wild horses (Map 45). Beneficial impacts include accommodating the routine movement of wild horses, which is in conflict with the currently designated HMA, and reducing the need for roundups to remove horses outside of the HMA. Providing opportunities for wild horse viewing in the McCullough Peaks HMA would have the same impacts as those described under Alternative A. However, not promoting wild horse viewing in the Fifteenmile HMA under Alternative B may help retain the remote natural conditions and the wild and free-roaming nature of horses compared to Alternative A. Opportunities for wild horse viewing would be less under Alternative B compared to Alternative A, but only in the Fifteenmile HMA.

Prohibiting horse use-based organized SRPs in the HMAs would result in beneficial impacts to wild horses by retaining the remoteness of the herds and reducing the potential for human and domestic horse interaction that would reduce the wild and free-roaming nature of the horses. The chance of domestic horses joining wild horse herds, which would result in stress and harassment to wild horses from recapturing domestic horses and potential disease and parasite transmission, would be greatly reduced. However, this prohibition would reduce public opportunities to gain an appreciation for wild horses, possibly reduce adoption demand, and restrain public interest in wild horse management in the Planning Area.

Evaluating and removing interior fences in the McCullough Peaks HMA would result in beneficial impacts to wild horses by allowing movement in the HMA, increasing genetic viability, and reducing injuries and deaths.

Under Alternative B, applying seasonal restrictions from February 1 to July 31 to surface-disturbing and disruptive activities and land uses in the McCullough Peaks and Fifteenmile HMAs, as appropriate, and avoiding wild horse gathers from 6 weeks before to 6 weeks after foaling would beneficially impact wild horses by reducing the potential for foal abandonment or jeopardy of wild horse health and welfare.

Relative to Alternative A, Alternative B would result in the most indirect beneficial impacts to wild horses and their habitat because it conserves the most land area for physical, biological, and heritage resources and is the most restrictive to motorized vehicle use and mineral development.

Alternative C

Surface Disturbance

Impacts from surface disturbance on wild horses under Alternative C would be similar to those described under Alternative A, although to a greater extent. Similarly to Alternative A, 28,392 acres (16 percent) of HMAs are contained in WSAs, which will limit adverse impacts to HMAs from surface-disturbing activities under Alternative C. However, Alternative C is projected to result in the greatest amount of short- and long-term surface disturbance in the Planning Area (80 percent and 165 percent more than Alternative A, respectively), increasing the probability that surface disturbance would adversely affect wild horse habitat.

Resource Uses

Management of minerals under Alternative C would result in impacts similar to those under Alternative A, although to a greater extent. Implementation of Alternative C would result in the greatest amount of minerals development compared to other alternatives (Appendix T). There would be less acreage closed to mineral activity in the HMAs under Alternative C than under other alternatives (Table 4-24).

Management of invasive species would result in impacts similar to those under Alternative A.

Management of ROWs would result in impacts similar to those under Alternative A, although to a lesser extent because there are more restrictions on ROW development under Alternative C. Compared to Alternative A, Alternative C includes more ROW avoidance areas and less area open to ROW development within HMAs. Overall, Alternative C would result in the second-greatest adverse impact to wild horses from ROW development.

Management of travel and transportation would result in impacts similar to those under Alternative A, although to a greater extent. Under Alternative C, the BLM would not close areas to motorized vehicle travel in the Fifteenmile HMA and would limit motorized vehicle travel to designated roads and trails in HMAs in more area than under Alternative A, but less than under alternatives B and D (Table 4-24).

Impacts from recreation management would be similar to those described for Alternative A.

Management of livestock grazing, including areas in the HMAs closed to livestock grazing (Table 4-24), under Alternative C is similar to Alternative A, thereby resulting in similar impacts. Under Alternative C, additional sustained yield forage would only be apportioned to satisfy suspended permitted use of permittees and not for the benefit of wild horses or other wildlife as under Alternative B. This management action would result in the fewest beneficial impacts to wild horses from forage apportionment.

Special Designations

Management of the Bridger Trail, which passes through the McCullough Peaks HMA, would result in similar beneficial impacts under Alternative C as those described under Alternative A, but to a greater extent due to greater restrictions around the trail under Alternative C. Management of the Bridger Trail under Alternative C would result in more restrictions on resource uses and activities than Alternative A, but less than alternatives B and D.

Resources

In general, management under Alternative C would emphasize resource use over resource conservation, which would result in more adverse impacts to forage and the health of wild horses, compared to the other alternatives. As a result, management of resources under Alternative C would have the greatest adverse impacts on wild horses compared to other alternatives.

Impacts to wild horses from fire and fuels management would be similar to those under Alternative A, although to a greater extent because the BLM would perform mechanical fuels treatments and prescribed burns on more acreage. Impacts from vegetation management in the Planning Area to wild horses under Alternative C would be similar to those under Alternative A. However, Alternative C does not prohibit surface-disturbing activities in riparian/wetland areas, which may cause short- and long-term adverse impacts.

Proactive Management

Under Alternative C, the McCullough Peaks HMA would be maintained at about 103,866 acres and the Fifteenmile HMA at 70,527 acres (Map 45). Wild horse viewing would be actively promoted in the McCullough Peaks HMA with opportunities for public viewing, education, and interpretation under this alternative. Opportunities for wild horse viewing would also be provided in the Fifteenmile HMA. In general, management under Alternative C would result in the same level of wild horse viewing as under Alternative A, but less than under alternatives B and D.

The beneficial impacts from evaluating and removing interior fences in the McCullough Peaks HMA realized under alternatives B and D would not occur under this alternative.

Alternative C does not include seasonal restrictions on surface-disturbing or disruptive activities in HMAs. This would result in long-term adverse impacts to wild horses by increasing the potential for disturbance to wild horses during sensitive times of the year and by reducing forage and overall health of horses in the HMAs. Allowing SRPs in HMAs would cause impacts similar to those under Alternative A, although to a greater extent because the BLM would issue more SRPs under Alternative C. Evaluating fences on a case-by-case basis in the McCullough Peaks HMA would cause the same impacts as under Alternative A. Overall, proactive management for the protection of wild horses would provide the least beneficial impacts under Alternative C.

Alternative D

Surface Disturbance

Impacts of surface disturbance on wild horses would be similar to those described under Alternative A, although to a slightly greater extent because the projected short- and long-term surface disturbance in the Planning Area is 3 percent and 17 percent more, respectively, under Alternative D. The expansion of the McCullough Peaks HMA would be the same as under Alternative B, resulting in 38,268 acres (21 percent) of HMAs being contained in WSAs, which will limit adverse impacts to HMAs from surface-disturbing activities. Like Alternative B, Alternative D also applies seasonal restrictions from February 1 to July 31 in the McCullough Peaks and Fifteenmile HMAs, which would further limit the potential for adverse impacts from surface-disturbing and disruptive activities on wild horses during foaling.

Resource Uses

Management of minerals would result in impacts similar to those under Alternative A. The amount of disturbance associated with minerals development is projected to be slightly less than under Alternative A. In HMAs, the acreage closed to mineral activity under Alternative D is greater than under alternatives A and C, but less than under Alternative B (Table 4-24).

Management of invasive species would result in impacts similar to those under Alternative A.

Management of ROWs would result in impacts similar to those under Alternative A, although to a lesser extent because there are more restrictions on ROW development under Alternative D. The BLM would manage the majority of the McCullough Peaks and Fifteenmile HMAs as ROW avoidance areas where mitigation measures and the application of BMPs would limit impacts to wild horses (Table 4-24). Overall, Alternative D would result in the second-fewest adverse impacts to wild horses from ROW development.

Under Alternative D, HMAs are closed to motorized vehicle use or it is limited to designated roads and trails on more acreage than under alternatives A and C, but less than under Alternative B. The overall adverse impacts to wild horses from travel management would be similar to those described under Alternative A, although to a lesser extent. Restricting motorized travel would benefit wild horses by minimizing surface disturbance and stress to wild horses associated with motorized vehicle use.

Impacts from recreation management under Alternative D would be similar to those described under Alternative A.

The amount of rangeland improvement projects, such as springs, reservoirs, and fence development, constructed under Alternative D would be similar to that under Alternative A, resulting in similar adverse and beneficial impacts. Under Alternative D, the BLM would manage the same amount of acreage as

open to livestock grazing as under Alternative A (Table 4-24), resulting in impacts similar to those under Alternative A.

Special Designations

Under Alternative D, management of the Bridger Trail, which passes through the McCullough Peaks HMA, would cause beneficial impacts similar to those under Alternative A, but to a greater degree due to increased restrictions on resource uses and activities around the trail. Management of the Bridger Trail under Alternative D would result in more restrictions on resource uses and activities than under alternatives A and C, but less than under Alternative B.

Resources

Management designed to protect resources such as soil, water, and vegetation would benefit wild horses by limiting surface-disturbing activities and minimizing impacts to forage and habitat. Several management actions require avoidance of surface-disturbing activities for the protection of resources under Alternative D. In areas that require avoidance, surface-disturbing activities would be prohibited unless the impacts could be mitigated, thereby limiting long-term adverse impacts to wild horses.

Prescribed fire and mechanical fuels treatments are projected to disturb the same acreage as Alternative A, therefore causing similar impacts.

Proactive Management

Similar to Alternative B, expansion of the McCullough Peaks HMA and maintaining the initial appropriate management level of horses in the HMA would result in beneficial impacts to wild horses (Map 45). Under Alternative D, the BLM would promote opportunities for public viewing, education, and interpretation of wild horses in the McCullough Peaks HMA, but would not actively promote the Fifteenmile HMA to the public. Under Alternative D, fewer opportunities for wild horse viewing would exist in the Fifteenmile HMA than under alternatives A and C, resulting in similar beneficial impacts to those under Alternative B. In general, opportunities for wild horse viewing in the McCullough Peaks HMA would be similar under all alternatives, resulting in impacts similar to those described under Alternative A.

Under Alternative D, the BLM would prohibit and avoid, respectively, organized SRPs using domestic horses in the McCullough Peaks and Fifteenmile HMAs. Restricting SRPs using domestic horses in the HMAs would result in impacts similar to those described under Alternative B. Although SRPs are not prohibited in the Fifteenmile HMA, avoidance would require that impacts are mitigated, reducing the potential for long-term impacts.

Evaluating and removing interior fences in the McCullough Peaks HMA to provide for wild horse movement would result in similar beneficial impacts as those under Alternative B.

Seasonal restrictions to prevent foal abandonment and jeopardy of wild horse health would result in similar beneficial impacts as those under Alternative B, although to a lesser extent because the restrictions would not apply to disruptive activities.

Alternative E

Surface Disturbance

Impacts from surface disturbance on wild horses under this alternative would be the same as Alternative B, except in the Greater Sage-Grouse Key Habitat Areas ACEC. Under Alternative E, greater restrictions on locatable mineral entry, mineral materials disposal, renewable energy development, and ROW

development would apply in the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Implementation of Alternative E would result in the least amount of short- and long-term surface disturbance compared to the other alternatives, and would therefore have the fewest adverse impacts to wild horses.

Resource Uses

Impacts to wild horses from minerals development would be the same as Alternative B, except within the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Alternative E would have additional restrictions on surface-disturbing activities and mineral development within the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Alternative E would therefore result in the least adverse impacts to wild horses from mineral development relative to the other alternatives and would close the most acreage in HMAs to mineral activity (Table 4-24).

Management of ROWs under Alternative E would result in the same impacts to wild horses as Alternative B, although to a greater extent due to the larger area of ROW exclusion in the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Alternative E includes the most area in HMAs managed as ROW exclusion areas (Table 4-24).

Alternative E requires that Special Recreation Permits in the proposed Greater Sage-Grouse Key Habitat Areas ACEC have neutral or beneficial effects to sage-grouse habitat, which would reduce the potential for disruptive activities in areas of the HMAs that overlap the ACEC.

Special Designations

Under Alternative E, restrictions on surface-disturbing activities, including locatable mineral entry, mineral materials disposal, renewable energy development, and ROW development, would be the same as Alternative B, except within the Greater Sage-Grouse Key Habitat Areas ACEC. Alternative E would reduce impacts to wild horses relative to Alternative B in areas of overlap between the proposed ACEC and HMAs. Reduced surface disturbance and associated disruptive activities would augment the protective management actions for wild horses under Alternative E, resulting in the greatest beneficial indirect impacts to wild horses compared to the other alternatives. All other impacts to wild horses from special designations would be consistent with Alternative B.

Resources

Impacts from the management of resources under Alternative E would be the same as Alternative B, except in the proposed Greater Sage-Grouse Key Habitat Areas ACEC. Management actions for habitat restoration/vegetation, invasive species, and fire and fuels within the proposed Greater Sage-Grouse PHMAs ACEC may indirectly improve wild horse forage and health by incorporating objectives for the conservation and restoration of sagebrush habitats. Conversely, additional restrictions on fuels treatments in these areas also may increase the potential for larger, more intense fires in the long term and associated adverse impacts to wild horses. However, as under Alternative A, such fires would likely remain uncommon due to the historical absence of wildfires in the HMAs.

Proactive Management

Under Alternative E, proactive management actions that limit surface disturbance and disruptive activities within the proposed Greater Sage-Grouse Key Habitat Areas ACEC would augment protection provided by seasonal restrictions in HMAs under Alternative B. Proactive management actions outside the proposed Greater Sage Grouse Key Habitat Areas ACEC would be the same as Alternative B.

Alternative F

Surface Disturbance

Impacts from surface disturbance on wild horses under this alternative would be the same as Alternative D, except in the proposed Greater Sage-Grouse PHMAs ACEC. Alternative F would place greater restrictions on oil and gas development and motorized vehicle use in the proposed Greater Sage-Grouse PHMAs ACEC when compared to Alternative D. Impacts of surface disturbance on wild horses would be similar to Alternative A, although to a slightly greater extent because the projected short- and long-term surface disturbance in the Planning Area is greater under Alternative F.

Resource Uses

Resource uses under Alternative F would result in fewer adverse impacts to wild horses than Alternative D and greater adverse impacts than Alternative A. This alternative closes more than twice the amount of federal mineral estate to oil and gas leasing as Alternative D, but like Alternative D, applies a NSO stipulation within 0.6 mile of occupied sage-grouse leks in PHMAs. However, Alternative F limits surface disturbances to one per 640 acres and 3 percent or less of the Wyoming DDCT analysis area, compared to 5 percent under Alternative D, which would afford greater protection for wild horses that use habitats within the Greater Sage-Grouse PHMAs ACEC.

ROW development would be similar to alternatives A and D across much of the Planning Area but would be subject to additional restrictions within the proposed Greater Sage-Grouse PHMAs ACEC. Additional management in these areas may indirectly benefit wild horses where they overlap HMAs by imposing seasonal restrictions on powerline development and encouraging the use of buried lines.

Alternative F would also limit motorized vehicle use to designated roads and trails over a greater area within HMAs than Alternative D, resulting in fewer adverse impacts than alternatives A, C, and D, but more adverse impacts than alternatives B and E. Where these limitations on motorized travel overlap HMAs, they would benefit wild horses by minimizing surface disturbance and stress to wild horses associated with motorized vehicle use.

Impacts from livestock grazing management would be consistent with Alternative D across much of the Planning Area but would incorporate greater sage-grouse habitat objectives within the proposed Greater Sage-Grouse PHMAs ACEC, which may have beneficial indirect impacts on wild horse forage and habitat.

Impacts from all other resources uses would be the same as Alternative D.

Special Designations

Under Alternative F, impacts to wild horses from special designations would be the same as Alternative D, except within the proposed Greater Sage-Grouse PHMAs ACEC. Additional constraints on oil and gas leasing and motorized vehicle use in the proposed Greater Sage-Grouse PHMAs ACEC under Alternative F would result in fewer adverse impacts to wild horses than Alternative D in areas of overlap with HMAs. Similarly, beneficial indirect impacts to wild horses may result from management actions that conserve or restore greater sage-grouse habitat within these areas of overlap.

Resources

Management designed to protect resources such as soil, water, and vegetation would benefit wild horses by limiting surface-disturbing activities and minimizing impacts to forage and habitat. These benefits would be slightly greater under this alternative than under Alternative D due to additional management actions that require avoidance of surface-disturbing activities for the protection of

Wild Horses

resources within the proposed Greater Sage-Grouse PHMAs ACEC. In areas that require avoidance, surface-disturbing activities would be prohibited unless the impacts could be mitigated, thereby limiting long-term adverse impacts to wild horses.

Prescribed fire and mechanical fuels treatments are projected to disturb the same acreage as alternatives A and D, therefore causing similar impacts. Although fuels buildup within the ACEC would be greater than under Alternative D, adverse impacts from wildfires are unlikely given the historical absence of wildfires in the HMAs.

Proactive Management

Proactive management actions that limit specific surface disturbances and disruptive activities within the proposed Greater Sage-Grouse PHMAs ACEC would augment protection provided by seasonal restrictions in HMAs under Alternative D. All other proactive management actions outside of the proposed Greater Sage-Grouse PHMAs ACEC would be consistent with Alternative D.

4.5 Heritage and Visual Resources

4.5.1 Cultural Resources

Because cultural resources are fragile, often unique, nonrenewable resources that occupy relatively small areas, almost any management action has the potential to affect the resource. Actions under each alternative may directly or indirectly affect cultural resources, and impacts may be beneficial or adverse. Except for setting, there is little distinction between short- and long-term impacts. Refer to Section 4.7.3 *National Historic Landmarks* for a discussion of impacts to the Heart Mountain Relocation Center. Section 4.7.4 *National Historic Trails and Other Historic Trails* in this chapter analyzes historic trails in detail. This section and Section 4.8.5 *Tribal Treaty Rights* identify Native American concerns.

Direct adverse impacts to cultural resources from RMP alternatives typically result from actions that disturb the soil or physically alter, damage, or destroy all or part of a resource; alter characteristics of the surrounding environment that contribute to resource significance; introduce visual or audible elements out of character with the property or alter its setting; or result in neglect or physical exposure of the resource to the extent that it deteriorates or is destroyed. Surface-disturbing activities would result in direct adverse impacts because, once a cultural resource has been disturbed, it cannot be replaced and the potential for collecting or preserving meaningful data is compromised. Actions resulting in data collection are considered to be adverse, despite being a common mitigation requirement for disturbance of properties with significant scientific-data potential. Indirect impacts to cultural resources result from project-induced increases or decreases in activity in the Planning Area, such as an interpretive area that increases visitor use. A beneficial impact to cultural resources enhances their value (for example, constructing interpretive signs). Paradoxically, the same actions that can result in direct or indirect adverse impacts also may result in beneficial impacts. The discovery of previously unknown cultural resources, or the facilitation of data collection, preservation, or public education are possible beneficial impacts.

Once a cultural resource is physically altered, the impact is permanent; therefore, there is no difference between short- and long-term direct impacts from surface disturbance. Stabilization can halt deterioration, and restoration may be possible in unique situations; however, the disruption of cultural deposits on archeological sites and the deterioration of rock art, for two examples, are irreversible. For indirect impacts, the duration of a disturbing element or activity can be short or long. As examples, a pipeline construction corridor that results in erosion to or deposition on a cultural resource may be a short-term disturbance, because normal reclamation ultimately stabilizes the soil. For the analysis, surface disturbance lasting more than 5 years is considered long-term and disturbance lasting 1 year is considered long-term for assessing impacts to the setting for cultural resources.

The BLM complies with NHPA Section 106 for all actions with the potential to adversely impact historic properties (cultural resources eligible for listing or listed on the National Register of Historic Places [NRHP]). Section 106 compliance typically includes a cultural resources inventory and evaluation of any resources found. If historic properties are present, the BLM consults with the State Historic Preservation Office (SHPO), interested Native American tribes, and other interested parties to develop measures to mitigate adverse impacts to affected historic properties.

Under all alternatives, the BLM continues its obligation to engage in government-to-government consultations with interested tribes regarding sensitive resources in the Planning Area. Impacts to Native American traditional resources or sacred sites are identified in consultation with the affected tribes. Alterations to the important characteristics of traditional or sacred resources can adversely

impact traditional use of the area. While temporary disturbances, such as construction activities, may not be of major concern, long-term increases in noise, changes in visual setting and smells, and increases in motion and activity, all have the potential to detract from a site's setting. In addition, physical impacts to traditional or sacred sites and limitations on tribal access can impact traditional uses.

The BLM initiated contact with the following tribes, listed alphabetically, to identify potential impacts of the alternatives to sites of cultural concern on BLM lands:

- Blackfeet, living on the Blackfeet Reservation, Browning, Montana
- Crow, living on the Crow Reservation, Crow Agency, Montana
- Nez Perce, living on the Nez Perce Reservation, Lapwai, Idaho
- Northern Arapaho, living on the Wind River Reservation, Fort Washakie, Wyoming
- Northern Cheyenne, living on the Northern Cheyenne Reservation, Lame Deer, Montana
- Salish and Kootenai, living on the Flathead Reservation, Pablo, Montana
- Shoshone, represented by two tribes
 - Eastern Shoshone, living on the Wind River Reservation, Fort Washakie, Wyoming
 - Shoshone Bannock, living on the Fort Hall Reservation, Fort Hall, Idaho
- Sioux, represented by three tribes
 - Cheyenne River Sioux living on the Cheyenne River Reservation, Eagle Butte, South Dakota
 - Oglala Sioux, living on the Pine Ridge Reservation, Pine Ridge, South Dakota
 - Rosebud Sioux, living on the Rosebud Reservation, Rosebud, South Dakota

4.5.1.1 Methods and Assumptions

For all federal undertakings that may affect cultural resources, the BLM complies with NHPA Section 106 before proceeding with the undertaking. Section 106 compliance typically includes inventory and evaluation, and consultation with the SHPO. Existing Planning Area plans considered the maintenance of a ¼-mile-wide buffer zone adequate protection in most site situations, and the occasional application of a 5-mile-wide buffer zone a generous allowance that would protect the viewshed of the resource. However, with the introduction of new technologies, particularly wind turbines that are often grouped into wind farms, these distances do not always protect the significant values of a resource. Because the historic preservation community has begun placing more emphasis on setting as the initial aspect of integrity for a NRHP-eligible cultural resource, management must approach the application of viewshed criteria with flexibility, and account for the distance from the resource and the type of intrusion when determining the impact. On a case-by-case basis, and as appropriate for some projects, project decisions account for the importance of viewshed in a resource's eligibility and the distance necessary to protect its NRHP significance.

Methods and assumptions used in this impact analysis include the following:

- Cultural resources will continue to be found throughout the Planning Area.
- All surface-disturbing activities may damage, destroy, or otherwise impact cultural resources.
- Natural and prescribed fire may damage rock art sites and sites composed of combustible materials.
- Compliance with Section 106 before project initiation is required by law. All cultural resources will be protected in accordance with federal laws and BLM regulations and agreements,

including the national Programmatic Agreement (BLM, ACHP, and National Conference of SHPO 2012) and the Wyoming State Protocol (BLM and Wyoming SHPO 2014), regardless of whether the resources are specifically identified in the RMP.

- Avoidance is the preferred mitigation measure. When avoidance is not a practicable solution, the BLM will develop measures to mitigate impacts in accordance with Section 106 and other applicable laws and guidance.
- Adverse impacts to historic properties from surface-disturbing activities occur primarily at the time of initial surface disturbance. The BLM used the projected numbers for short-term surface disturbance to quantify impacts to cultural resources.
- The intensity of surface disturbance by alternative, as identified in Appendix T, equates to levels of development and, in turn, increased access to public lands.
- Increases in the number and extent of surface-disturbing activities and improved access may all result in increased impacts to cultural resources.
- The BLM has not identified all tribally sensitive sites in the Planning Area.
- Identifying tribally sensitive sites will benefit heritage resources.
- Tribal consultations benefit heritage resources.

4.5.1.2 Summary of Impacts by Alternative

Because cultural resources are fragile, often unique, nonrenewable resources that occupy relatively small areas, almost any management action has the potential to affect them. Principal impacts to cultural resources result directly from surface disturbance or visual intrusions, and indirectly from increased access related to management of other resources. The BLM anticipates impacts to cultural resources from the alternatives to be similar in type, but different in intensity. Proactive cultural resource management actions result in beneficial impacts across all alternatives. Overall, Alternative C allows the most resource use; therefore, it may result in the most direct and indirect impacts, adverse and beneficial, to cultural resources. However, despite the most use and the most potential impact, Alternative C incorporates a contemporary understanding of cultural resources management, in contrast to current management (Alternative A), which reflects the status of cultural resource management from the 1980s. While the BLM instituted current management in good faith and in compliance with Section 106 and BLM regulations, improved approaches and increased knowledge of options allow for more protection, even with more resource use. Potential impacts are likely to be the least adverse under alternatives B and E because of more restrictions on resource uses for the protection of other resources. However, with less use of other resources, there also is likely to be less Section 106 compliance and associated inventory, so that the knowledge base would not grow at the same rate as it would under Alternative C. Alternatives D and F reflect a balanced approach overall, in some cases mirroring the active management recommendations of Alternative A, providing less specific protection than Alternative B, but acknowledging and specifying situations in which more protective measures would be needed than under alternatives A or C.

Under all alternatives, the BLM continues its obligation to engage in government-to-government consultations with interested tribes. Actions required by the National Historic Preservation Act (NHPA) and the Wyoming State Protocol will form the foundation of all project-specific decisions regarding cultural resources. The Wyoming State Protocol and NHPA provisions will resolve conflicts between cultural resources and other resource uses not addressed in the RMP.

4.5.1.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Potential impacts to cultural resources are similar under all alternatives; however, the BLM anticipates that the intensity of impacts will vary. Therefore, impacts to cultural resources from surface-disturbing activities related to management of other resources are described for individual alternatives. Essentially, any activity that disturbs or has the potential to disturb the surface, regardless of the resource program with which the activity is associated, has the potential to affect cultural resources. Other types of disturbance also can affect cultural resources, including the adverse interaction of vibration impact, dust and airborne chemicals on rock art sites.

A number of management actions are common to all alternatives. These fall into several categories. Reactive actions include the investigation of all alleged violations of the Archeological Resources Protection Act; emergency site stabilization and long-term protection projects on important sites as appropriate, including the Hanson Site and several rock art occurrences; and assignment of an archeologist to all fires with heavy equipment employed beyond Minimum Impact Suppression Techniques (see *Glossary*) to assist in determinations of appropriate suppression strategies.

Native American consultation actions, which can affect how the BLM manages cultural resources, include continuing existing relationships and development of new relationships with Native American tribes to identify sites, areas, and resources important to them; documenting and maintaining confidentiality of sites, areas, and resources worthy of protection and the incorporation of information obtained from the tribes into the planning system; identifying resource conflicts in the earliest stages; avoiding these conflicts whenever possible; and managing identified areas of tribal importance to minimize disturbance to them and to ensure continued access. The BLM must ensure that areas important to Native American communities are not transferred from federal ownership, physically modified, or affected by management actions in ways that restrict or deny access and/or use. The BLM also must inventory potentially sensitive cultural places identified during Native American consultations independent of specific land use actions and apply tools (such as site avoidance and **setting** consideration zones [see the *Glossary*]) to protect sensitive cultural sites, as necessary.

Under all alternatives, all cultural properties will be categorized according to the six use allocations defined in BLM Manual 8110 (BLM 2004d) – scientific use, conservation use, public use, traditional use, experimental use, and discharged from public use.

Under all alternatives, compliance with NHPA Section 106 before an action is approved serves to moderate the amount of actual disturbance to cultural resources. In cases in which there can be no accommodation, the BLM and the SHPO consult to develop and implement a treatment plan to mitigate adverse impacts to historic properties. Often, this results in data recovery, which can take the form of planned excavation, detailed recording and mapping, or Historic American Buildings Survey/Historic American Engineering Record documentation. Other options include interpretation, one of many techniques that can be used for impact mitigation, depending on the type of site and the nature of the potential adverse impacts.

Exploration and development of locatable minerals may result in adverse impacts to cultural resources from the discovery and inadvertent destruction or degradation of cultural resources during project activities. Current regulations require operators to notify the BLM if cultural resources are discovered to reduce potential impacts to those resources. Under current policy, the BLM must allow mining operations to proceed within 10 working days after notification to the authorized officer of a discovery of cultural resources that might be altered or destroyed on BLM-administered lands by operations

(43 CFR 3809.420(b)(8)(ii)). This requirement also applies to not only a plan of operations that requires an approval of an action, but also for operations under a 3809 notice, which does not require agency approval before commencing actions.

For all alternatives, the BLM identified proactive management actions that would have a beneficial impact on cultural resources. These actions include preparation of activity plans for important sites, as appropriate (including the Hanson Site and several rock art occurrences), Ten Sleep Raid, Minick Sheep Camp Raid, historic trails (including the Bridger Trail), and the Fort Washakie to Red Lodge stage route; management of the Legend Rock Petroglyph Site for public education in cooperation with the state of Wyoming; and initiation of work to acquire the private land portions of the Legend Rock Petroglyph Site from willing landowners, preferably through a land exchange. The BLM also will develop additional cultural resource interpretive areas employing scenic overlooks, signs, and walking trails. Surface-disturbing activities associated with the construction and use of sites and facilities are subject to appropriate mitigation developed through implementation of the National Programmatic Agreement (BLM, ACHP, and National Conference of SHPO 2012) and the State Protocol (BLM and Wyoming SHPO 2014). Based on analysis and assessment, the BLM may need to apply additional restrictions beyond those specifically described in the alternatives.

Proactive management actions that protect cultural resources include prohibiting the use of bulldozers in areas of important cultural resources or historic trails for fire suppression unless an archeologist and/or resource advisor is present, and restricting or prohibiting the use of fire-retardant chemicals to protect rock art. All alternatives apply an NSO restriction on the Legend Rock Petroglyph Site and pursue withdrawals on a case-by-case basis for the protection of important cultural sites. The BLM also limits the use of motorized vehicles to designated roads and trails in areas with important cultural and paleontological resources to reduce the potential for looting and resource degradation.

Alternative A

Surface Disturbance

Any action that results in surface disturbance or subsurface disturbance (as identified in Appendix T) through culture-bearing strata may impact cultural resources. However, the net potential adverse impact to historic properties is limited because compliance with NHPA Section 106 requires the application of some type of mitigation to historic properties before any disturbance. The relative amount of surface disturbance projected for each alternative defines the level of potential to impact cultural resources. Under Alternative A, the BLM anticipates that impacts to cultural resources from surface-disturbing activities would increase with a greater intensity of surface disturbance, represented by the reasonable foreseeable actions shown in Appendix T. Moreover, the BLM anticipates that impacts to cultural resources from surface disturbance under Alternative A would primarily be adverse.

Restrictions on surface-disturbing activities for the protection of other resources (e.g., soil, water, biological resources, and special designations) under Alternative A provide additional protection for cultural resources.

Resource Uses

Resource exploration, development, and extraction can result in a long-term, direct adverse impact. Associated resources in the Planning Area, including locatable minerals, leasable minerals, mineral materials disposal, and forest products, all can lead to surface disturbance that may affect cultural resources. In addition to the actions required to develop these resources, associated actions, such as the creation and use of roads and other utilities, may impact cultural resources. Dust and vibration from

some methods of resource exploration can result in a direct impact to rock art (Francian 1998). The dust accumulates on the panels and can degrade the paint, and vibrations from blasting can cause spalling and rock fall that also adversely affects rock art. The BLM anticipates that these actions will occur under Alternative A.

Under Alternative A, the BLM pursues leasable mineral and mineral material restrictions to protect cultural resource sites on a case-by-case basis. The allowance for more case-by-case management under Alternative A, while providing discretionary protection, increases the chance of adverse impacts to cultural resources. Development of locatable minerals may result in adverse impacts to cultural resources if activities degrade or destroy resources. Pursuing mineral withdrawals would result in beneficial impacts to cultural resources by prohibiting mineral activities that may degrade or destroy resources. Under Alternative A, the BLM pursues withdrawals on a total of 72,861 acres.

Land exchanges may result in both beneficial and adverse impacts. The survey required for compliance with NHPA Section 106 in the case of either disposal or acquisition could result in a beneficial impact because of data that furthers understanding of cultural resources in the Planning Area. In addition, if the BLM acquires land with sensitive resources for the purpose of managing that resource, that would be beneficial. However, if historic properties are identified during the inventory, it may result in an adverse impact because once in private ownership, there are no protective measures for cultural resources. For that reason, Section 106 classifies land-tenure adjustment as an adverse impact. Alternative A identifies 115,905 acres as available for disposal, resulting in the potential for adverse impacts.

Any resource use that includes road development has the potential to result in direct impacts to cultural resources because the road may pass through or over a site. These resource uses may include any resource use already mentioned, but also invasive species and pest management, CTTM, and recreation. An indirect impact from this type of development occurs when the road provides access to a previously remote and/or inaccessible location. People who gain access may inadvertently damage fragile resources, or may vandalize or loot sensitive sites, particularly rock art and rock shelters. The BLM anticipates that Alternative A could result in 3,199 acres of short-term disturbance from new road construction and motorized vehicle use (Appendix T).

ROWs and corridors, renewable energy, CTTM, and recreation can result in similar impacts. The linear nature of corridors means they can reach far into areas where remoteness previously provided protection for the cultural resources. Balancing the needs of recreation with preservation presents a challenge because increased recreational use of an area exposes the cultural resources there to inadvertent damage and potential vandalism and looting. Under Alternative A, the BLM manages 940,943 acres as ROW avoidance areas and 61,147 acres as ROW exclusion areas. Renewable energy development is considered on a case-by-case basis, consistent with applicable policy and guidance and other resource management objectives, including cultural resource objectives. CTTM designations that place fewer restrictions on access to portions of the Planning Area, such as limiting travel to existing roads and trails (2,137,574 acres under Alternative A), would result in indirect adverse impacts to cultural resources by increasing the possibility of looting and vandalism. In contrast, CTTM that places greater restrictions on the routes available for use (e.g., limiting travel to designated roads and trails; 797,077 acres) or closes these routes altogether (68,115 acres) may reduce such impacts. Prohibiting and avoiding surface-disturbing activities in specified recreation areas would benefit cultural resources.

Livestock trampling and wallowing in areas of concentrated livestock use can directly affect cultural artifacts and features on or just below the surface by breaking or scattering these artifacts. Placing salt blocks increases the local adverse impact because cows lick the soil as the salt block melts into the ground. Alternatively, cattle trails and other heavily trampled and exposed areas can unearth otherwise

undetected cultural resources and allow them to be identified and recorded, resulting in a beneficial impact. However, in most cases concentrated livestock grazing would result in adverse impacts. Properly managing livestock grazing can mitigate these impacts by improving the distribution of livestock and reducing instances of concentrated use by these animals. Restrictions on livestock grazing also can help reduce impacts by limiting the area in which livestock can graze, and closures under Alternative A would generally benefit cultural resources. However, even in areas closed to livestock grazing, the presence of wildlife or wild horses may result in some impacts from trampling and wallowing.

Special Designations

Under Alternative A, the BLM manages three ACECs (Sheep Mountain, Little Mountain, and Upper Owl Creek) for their cultural values (among other values). Managing these areas as ACECs would provide additional protection to cultural resources and reduce the potential for adverse impacts.

Resources

Management actions related to other resources have the potential to impact cultural resources. As discussed above, compliance with BLM regulations and guidance and NHPA Section 106 would prevent some of the impacts and mitigate others. However, impacts are still possible, and most would be adverse. There may be some beneficial impacts. For example, standards for air quality that reduce dust and chemicals in the air would reduce adverse impacts to rock art and improve the viewshed for cultural resources where setting is an integral part of NRHP eligibility. Similarly, protecting cave and karst resources would benefit cultural resources in these areas.

Fire, fuels, and vegetation management may result in adverse or beneficial impacts. Protecting resources from fire reduces adverse impacts from heat, such as spalling at rock art sites. Protecting resources from fire also protects against the loss of vegetative cover, which protects cultural resources from the effects of erosion and provides camouflage for sensitive resources, protecting them from inadvertent and purposeful damage. However, fire management also can result in adverse impacts from loss of cover, firebreak construction, clearing vegetation, and revegetation activities (e.g., reseeding) and deployment of fire retarding chemicals. Prescribed fire is used on approximately 40,000 acres in the Planning Area over the life of the plan.

Wild horse management under Alternative A allows visitor access to HMAs and recreational use of some HMAs, which may result in greater access to remote areas and put cultural resources at risk.

Proactive Management

Under Alternative A, the BLM manages cultural resources proactively in compliance with BLM regulations and guidelines and the NHPA. The BLM strives to meet its Section 110 responsibility through inventory, and Section 106 compliance through identification, evaluation of cultural resources and mitigating impacts to those resources. Proactive management includes further exploration of the Hanson site, with the goal of nominating it as a National Historic Landmark. If designated as such the BLM will pursue nominating the site to the World Heritage List. Alternative A emphasizes the management of rock art and other archeological sites for research and interpretation, and for preservation for future study. As previously noted, this alternative pursues restrictions on leasable minerals to protect sites on a case-by-case basis and takes similar actions for mineral materials disposal and the location of renewable energy development.

Cultural Resources

Alternative A manages portions of the town of Gebo and adjacent coal mining areas for preservation and interpretation of cultural and historic values and emphasizes management of historic oil and gas fields for scientific and public use.

Alternative B

Surface Disturbance

As for all the alternatives, any action that results in surface disturbance or subsurface disturbance through culture-bearing strata may affect cultural resources. Alternative B would involve less surface disturbance than Alternative A; therefore, Alternative B would result in less impacts to cultural resources associated with surface and subsurface disturbances.

Under Alternative B, there are more restrictions on surface-disturbing activities for the protection of other resources (e.g., soil, water, biological resources, and special designations), providing additional protection for cultural resources and reducing adverse impacts, in comparison to Alternative A. Paradoxically, because less surface disturbance would result in less Section 106 compliance and therefore less cultural resources surveying, the beneficial impacts from such surveys would be lower than Alternative A under this alternative.

Resource Uses

Activities associated with resource exploration, development, and extraction that can have a long-term, direct adverse impact on cultural resources will be less under Alternative B than under Alternative A. Not only will these activities be reduced from Alternative A, Alternative B provides more avoidance protection, including larger buffer zones (see the 'Proactive Management' section, below).

Alternative B applies an NSO restriction for leasable minerals within 3 miles of important cultural sites and a CSU stipulation within 5 miles, in contrast to management under Alternative A, which pursues restrictions on a case-by-case basis. Under Alternative B, mineral materials disposal are prohibited within 3 miles or in view within 5 miles of important cultural sites. These mineral restrictions would benefit cultural resources by prohibiting surface disturbance from mineral activities in areas with cultural sites or resources that may degrade or destroy these resources. Impacts to cultural resources from locatable mineral development would be similar to those described for Alternative A, although to a lesser degree because withdrawals are pursued in more area (314,223 acres) than under Alternative A.

The types of impacts from land exchanges under Alternative B are the same as those under Alternative A, although the intensity varies. Under all alternatives, land available for disposal would be surveyed for the presence of cultural resources, but after disposal it would not necessarily be protected from adverse impacts. Alternative B identifies less area for disposal and more area for retention than Alternative A; adverse impacts from land tenure adjustments would be the same as Alternative A, but to a lesser extent due to the reduced area available for exchange or disposal and greater area retained. However, the BLM expects that most adverse impacts associated with land tenure adjustments would be mitigated through Section 106 compliance.

As described for Alternative A, any resource use that includes road development can result in direct impacts to cultural resources. The BLM anticipates that Alternative B would result in the construction of fewer new roads compared to Alternative A, with the result that Alternative B would result in less impact to cultural resources.

The types of impacts associated with ROWs and corridors, renewable energy, CTTM, and recreation are the same as described for Alternative A, although the intensity varies under Alternative B. Alternative B

is anticipated to result in fewer ROW authorizations than Alternative A and a greater degree of ROW consolidation to limit impacts. In contrast, Alternative B has more than twice the trails and recreational development of Alternative A. The BLM manages areas within 5 miles of trails and sites eligible for the NRHP and traditional cultural properties (TCPs) as renewable energy (specifically, wind turbine) exclusion areas, unless the structures are screened from the site by intervening topography. Under Alternative B, this requirement is more specific and more protective of these resources than under Alternative A, which has no specific management for such development and manages it on a case-by-case basis. CTTM under Alternative B includes a greater amount of area limited to designated road and trails or closed (2,416,378 acres and 170,253 acres, respectively), and less area limited to existing roads and trails than under Alternative A. Adverse impacts from looting and trespassing due to increased access may be less under this alternative than Alternative A.

The types of impacts from livestock grazing under Alternative B are similar to those described under Alternative A, although grazing under Alternative B has more restrictions, resulting in less potential for adverse impacts to cultural resources.

Special Designations

Under Alternative B, the BLM manages the three Alternative A ACECs that include cultural resources among their values of concern (Sheep Mountain, Little Mountain, and Upper Owl Creek) and expands the Carter Mountain ACEC to include cultural resources. Expansion of the Carter Mountain ACEC would result in the greatest beneficial impacts to cultural resources in relation to other alternatives, particularly Alternative C, under which the BLM does not manage any of the previously mentioned areas as ACECs.

In contrast to Alternative A, under Alternative B, the BLM manages all lands with wilderness characteristics specifically to preserve their wilderness characteristics, which would benefit cultural resources by limiting access and travel, imposing more restrictive VRM, and limiting minerals leasing. The only action in lands with wilderness characteristics that results in direct impacts to cultural resources is the restriction that excavation of cultural resource sites is allowed only where scientific information would be collected under permit, with minimum site disturbance.

Resources

As described for Alternative A, management actions related to other resources have the potential to result in both adverse and beneficial impacts to cultural resources. Measures that protect other resources and that may, in turn, protect cultural resources are similar between alternatives A and B, with slightly more protection under Alternative B.

Impacts from fire and fuels management under Alternative B would be similar to those under Alternative A. However, under Alternative B, the BLM would initiate the second-to-least prescribed fire than among the alternatives; therefore, Alternative B would present less potential for adverse impacts. The same is true for silvicultural treatments and timber harvesting, both of which would occur less frequently under Alternative B, resulting in less potential for adverse impacts.

Wild horse management under Alternative B includes more restrictions to HMAs than under Alternative A, which would have the added beneficial impact of limiting access to remote areas that may contain important cultural resources.

Proactive Management

In addition to the BLM managing cultural resources in accordance with its regulations and federal laws, Alternative B would augment existing plans and add a number of proactive measures. For further

exploration of the Hanson site with the goal of nominating it as a National Historic Landmark, Alternative B would identify and test other deposits of similar age to determine the full extent of Folsom-age deposits. Compared to the Alternative A emphasis on managing rock art and other archeological sites for research and interpretation, and preservation for future study, Alternative B would explicitly avoid surface-disturbing activities and ROW authorizations in view within 5 miles of important cultural sites where integrity of setting is a contributing element of NRHP significance, except within designated utility corridors. In contrast to the case-by-case management approach under Alternative A, Alternative B applies an NSO restriction for leasable minerals within 3 miles and a CSU stipulation in view within 5 miles of important cultural sites, and follows a similar plan for mineral materials disposal. Alternative B identifies exclusion areas for renewable energy development and also imposes visual restrictions, depending on the topography, for sites eligible for the NRHP (including trails) and TCPs; Alternative A does not. On a case-by-case basis, visual restrictions under Alternative B may exceed the 5-mile buffer to avoid adverse impacts to cultural resources, where structures are not screened from the resource by intervening topography.

Under Alternative B, the BLM manages portions of the town of Gebo and adjacent coal mining areas for preservation and interpretation, emphasizing a pedestrian trail rather than a road, thereby reducing access and associated indirect adverse impacts. This alternative also will provide comprehensive information about the site on the BLM website.

Finally, under Alternative B, the BLM limits motorized vehicle use to designated roads and trails on BLM-administered land along the Bighorn Slope, Bridger, Owl Creek, and Absaroka foothills to manage (minimize issues such as looting) for cultural and paleontological resources. Alternative A, which does not restrict motorized vehicle use in these areas to designated roads and trails, provides less protection than Alternative B.

Alternative C

Surface Disturbance

Alternative C allows the most surface disturbance compared to the other alternatives, with the consequence that there would be the greatest potential for disturbance of cultural resources. As with the other alternatives, however, potential adverse impact to cultural resources would be limited through compliance with NHPA Section 106.

Because Alternative C places more emphasis on resource use, there are fewer restrictions on surface-disturbing activities for the protection of other resources (such as soil, water, biological resources, and special designations), so that although there is some additional protection for cultural resources, it is less than under the other alternatives. However, the potential for more surface-disturbing activities under Alternative C also may result in the identification of more cultural resources and their subsequent protection than under any of the other alternatives.

Resource Uses

Actions associated with resource exploration, development, and extraction are the most extensive and would have the greatest adverse impact on cultural resources under Alternative C. For leasable minerals, Alternative C applies an NSO restriction within ¼ mile and a CSU stipulation within 1 mile of important cultural sites. Similarly, there is a prohibition on mineral materials disposal within ¼ mile, or in view within 1 mile of these sites. Under Alternative C, adverse impacts to cultural resources from management of mineral leasing and mineral materials disposal would be similar to those under the other alternatives, although to a greater degree because of the smaller area of restriction around

important cultural sites. Impacts to cultural resources from locatable mineral development would be similar to those described for Alternative A, although to a greater degree because withdrawals are pursued over a smaller area (48,095 acres) than under the other alternatives.

The types of potential impacts due to land exchanges under Alternative C are the same as those for the other alternatives. The survey required for compliance with NHPA Section 106 in the case of either disposal or acquisition would result in a beneficial impact because of data that furthers understanding of cultural resources in the Planning Area. However, more area is identified for disposal and less area is identified for retention than under any other alternative, resulting in the greatest potential for adverse impacts.

Alternative C results in more road and trail construction, thereby accommodating more recreational and other uses in the Planning Area than under the other alternatives, exposing more cultural resources to impacts. For example, managing the Basin Gardens Play Area as open to cross-country motorized travel would expose cultural resources to potential damage caused by off-trail motorized recreation.

Under Alternative C, the types of impacts associated with ROWs and corridors, renewable energy, and recreation would be the same as described for Alternative A, although the intensity would vary; impacts from CTTM would be the same as described for Alternative B. Alternative C is projected to result in the greatest extent of ROWs development, potentially providing the most survey acreage and the most access to previously remote cultural resources. The location of renewable energy development is subject to similar restrictions, but compliance with NHPA Section 106 may impose greater visual restrictions to reduce the visual impact of developments such as wind farms on all types of sites, including sites of importance to Native Americans, NRHP-listed and/or eligible sites, and trails. CTTM designations under Alternative C are similar to Alternative A except that a greater area is open to cross-country motorized travel (14,830 acres compared to 1,311 acres) and a smaller area is closed to travel, which may increase impacts in certain areas under this alternative.

Livestock grazing under Alternative C has the least restrictions and therefore the greatest potential adverse impact.

Special Designations

Under Alternative C, the BLM would not manage the Sheep Mountain, Little Mountain, and Upper Owl Creek areas as ACECs, removing any beneficial impacts to cultural resources from the application of restrictions on surface-disturbing activities specific to these special designations.

Resources

Under Alternative C, management for resources (e.g., soils and special status species) is less restrictive than under the other alternatives, which may result in the greatest impact on cultural resources by increasing resource use and the potential for degradation of cultural resources.

Impacts from fire and fuels management and vegetative treatments would be similar to those for the other alternatives, although there is greater disturbance from prescribed fire under Alternative C than the other alternatives. The same relation is true for forest, woodlands, and forest products.

Wild horse management under Alternative C is similar to alternatives A and D, and applies fewer recreational restrictions that allow more access to HMAs than under Alternative B. Management under this alternative may result in greater access to remote areas, which may put cultural resources at increased risk than under Alternative B.

Proactive Management

Proactive management under Alternative C is closer to that under Alternative B than under Alternative A, reflecting current understanding of the importance of cultural resources and the potential impacts of other management actions. Proactive measures include further exploration of the Hanson site and nearby deposits, although Alternative C does not seek World Heritage nomination. Alternative C also emphasizes management of rock art and other archeological sites for research and interpretation, but imposes the smallest buffer zone, avoiding ROW authorizations in view within ¼ mile of important cultural sites where integrity of setting is a contributing element of NRHP significance, except within designated utility corridors. As previously mentioned, management of mineral leasing and mineral materials disposal under Alternative C results in smaller buffers than under the other alternatives. Alternative C imposes visual restrictions, depending on the topography, within 5 miles of sites eligible for the NRHP and TCPs, and specifies avoidance areas (in contrast to the exclusion areas under Alternative B), unless structures are screened from the site by intervening topography.

Under Alternative C, the BLM manages portions of the town of Gebo similar to alternatives A and D. Alternative C also emphasizes interpretation of historic oil and gas fields, providing interpretive signs in safe viewing areas, which would increase beneficial impacts to these historic resources compared to alternatives A or B. As with Alternative B, Alternative C would restrict motorized vehicle use to designated roads and trails on BLM-administered land along the Bighorn Slope, Bridger, Owl Creek, and Absaroka foothills to minimize issues such as looting.

Alternative D

Surface Disturbance

Although Alternative D allows more surface disturbance than alternatives A or B, it results in approximately half the disturbance of Alternative C (Appendix T); there is more potential to disturb cultural resources under this alternative than under alternatives A or B, but considerably less than under Alternative C. As with the other alternatives, adverse impacts to historic properties would be limited through BLM compliance with NHPA Section 106.

Restrictions on surface-disturbing activities for the protection of other resources (such as soil, water, biological resources, and special designations) would provide additional protection for cultural resources on a level overall greater than under Alternative C, and similar to that under alternatives A and B.

Resource Uses

Impacts from resource exploration, development, and extraction under Alternative D would be similar to impacts under alternatives A and C. Restrictions on mineral leasing and mineral materials disposal are more stringent than under Alternative C, but less restrictive than Alternative B in relation to determining the importance of setting and the use of BMPs to avoid, minimize and/or compensate adverse impacts. As with the other alternatives, withdrawals would benefit cultural resources by prohibiting mineral activities that may degrade or destroy resources. Under Alternative D, withdrawals would be less than under alternatives A and B, but greater than Alternative C.

Under Alternative D, beneficial and adverse impacts from land exchanges are the same as for other alternatives, with beneficial impacts resulting from information gathered through compliance with Section 106 and adverse impacts resulting from the loss of mandatory compliance with NHPA once the land has left public ownership. Alternative D allows disposal on more land than Alternative B, but less

than alternatives A and C; the adverse impacts from disposal under Alternative D also are less than under alternatives A and C and more than under Alternative B.

Linear projects that include ROWs and corridors, renewable energy, CTTM, and recreation can result in similar adverse impacts. Potential adverse impacts from ROWs for road development are similar to impacts under Alternative A, but less than under Alternative C (Appendix T). Managing more area as ROW avoidance or exclusion areas than under Alternative A may consolidate ROWs and limit adverse impacts to cultural resources to a greater extent. However, the affected area from open cross-country motorized travel under Alternative D is greater than under alternatives A or B, and approximately half that under Alternative C. CTTM designations under Alternative D are similar to Alternative A, but limiting off-road travel (OHV and mountain bike) to within 300 feet of established roads and trails would limit route proliferation and associated impacts to cultural resources. Additionally, management under Alternative D limits motorized vehicle use to existing roads and trails along the Bighorn Slope, Bridger, Owl Creek and Absaroka foothills. As for alternatives B and C, management of these areas is designed to minimize looting and facilitate management of cultural resources; however, management of motorized travel in these areas under Alternative D is less restrictive than under alternatives B and C and would result in fewer beneficial impacts to cultural resources.

Under Alternative D, impacts from livestock grazing would be similar to those under Alternative A, with management focused on maximizing multiple use while requiring buffer zones and managing livestock grazing to support other resource uses. Furthermore, Alternative D would mitigate new resource uses to minimize or avoid conflicts with livestock grazing where appropriate. Alternative D presents more potential for adverse impacts than Alternative B because of the much smaller area closed to livestock grazing and greater reliance on case-by-case evaluations of impacts.

Special Designations

As for Alternative A, under Alternative D, the BLM would manage the Sheep Mountain Anticline, Little Mountain, and Upper Owl Creek areas as ACECs for their cultural values (among other values), and would manage the Little Mountain ACEC expansion area discussed for Alternative B as the Craig Thomas Little Mountain SMA. Unlike Alternative B, Alternative D would not expand the Carter Mountain ACEC. Management of these areas as ACECs or SMAs provides additional protection for cultural resources and reduces the potential for adverse impacts.

Resources

Fire and fuels management under Alternative D is similar to that under Alternative A and provides fewer restrictions than Alternative B. Prescribed fire would be implemented on approximately 40,000 acres in the Planning Area over the life of the plan.

Wild horse management under Alternative D is similar to that proposed under Alternative B. Alternative D promotes public viewing and education, similar to Alternative C. However, compared to Alternative C, Alternative D limits access and SRPs to some areas, providing additional protection to remote areas that may contain important cultural resources.

Proactive Management

As with alternatives B and C, Alternative D proactively recognizes the current understanding of cultural resources management practices. Proactive measures are a mix of alternatives A, B, and C. The BLM would investigate and nominate the Hanson site as a National Historic Landmark, but would not pursue World Heritage nomination. Rock art and other prehistoric and historic sites and districts are managed for scientific, public and sociocultural use, and research and preservation for future study and use.

Known important cultural sites are protected from surface-disturbing activities. For resources where setting is important to the site's integrity, the site's foreground is to be avoided (in contrast to prohibited under Alternative B) with buffers that may be up to 3 miles wide or the visual horizon, whichever is closer (the setting consideration zones). This buffer is smaller than the buffer under Alternative B, but larger than the buffers under alternatives A and C, and applies to mineral leasing and mineral materials disposal actions for all site types (e.g., trails, sites eligible for the NRHP, and TCP). In addition, implementing BMPs would avoid, minimize and/or compensate adverse effects.

Alternative D management of historic resources in oil and gas fields is the same as Alternative C, including the installation of interpretive signs. Under Alternative D, the BLM would manage the town of Gebo and adjacent coal mining areas as it would under Alternative A.

Alternative E

Surface Disturbance

Any action resulting in the disturbance of culture-bearing strata from surface or subsurface disturbances may impact cultural resources. Among all the alternatives, Alternative E would result in a similar, though slightly reduced, amount of surface and subsurface disturbances to Alternative B; the type of impacts would be the same as Alternative A, and the magnitude of adverse impacts would be similar to Alternative B.

Alternative E provides the same restrictions on surface-disturbing activities as Alternative B, except in greater sage-grouse Key Habitat Areas, where Alternative E further restricts allowable disturbances compared to that alternative. Alternative E provides the overall greatest protection for cultural resources. Conversely, because less surface disturbance would occur under Alternative E, fewer cultural resource surveys would occur during Section 106 consultation and the benefits gained from additional surveys in the Planning Area would be lowest under this alternative.

Resource Uses

Management of activities associated with mineral resource exploration, development, and extraction that could result in long-term impacts to cultural resources under Alternative E would be similar to Alternative B. Impacts from mineral resource exploitation under Alternative E would therefore be similar to Alternative B, except within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), where locatable withdrawals and closure to mineral materials disposal would reduce the area available for mineral exploitation to a greater extent than under any other alternative.

The types of impacts associated with ROWs and renewable energy development under Alternative E would be the same as Alternative A, but to a lesser extent. Alternative E includes the largest ROW and renewable energy exclusion areas (1,322,879 acres and 1,945,204 acres, respectively) of any alternative, which limits the potential for impacts on cultural resources from ROW development across a large portion of the Planning Area. However, the BLM anticipates that even with these additional restrictions, ROWs across BLM-administered land would be approved at the same rate as Alternative B, and impacts would be similar to Alternative B.

Areas available for land tenure adjustments, CTTM, recreation, and livestock grazing management outside greater sage-grouse Key Habitat Areas under Alternative E are the same as Alternative B, and therefore, potential impacts to cultural resources would be the same as Alternative B in these areas.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), is the same as Alternative B, and impacts would be similar to Alternative B. Due to the size and additional restrictions on surface-disturbing activities and resource uses (e.g., the mineral development and CTTM management described under Resource Uses above) applied for the Greater Sage-Grouse Key Habitat Areas ACEC, special designation management under Alternative E would result in additional protection for cultural resources compared to the other alternatives.

Resources

As described for Alternative A, management actions for resources have the potential to result in both adverse and beneficial impacts to cultural resources. Measures that protect other resources and that may, in turn, protect cultural resources are similar under all alternatives, with slightly more protection under Alternative E than under the other alternatives. In particular, management actions restricting resource use in the Greater Sage-Grouse Key Habitat Areas ACEC would provide additional protection for cultural resources compared to the other alternatives.

Fire and fuels management under Alternative E would result in similar, though slightly reduced, surface disturbance from prescribed fire as Alternative B. Impacts from fire and fuels management and silvicultural and other vegetation treatments would be similar to Alternative A, and the magnitude of impacts would be similar to Alternative B.

Wild horse management under Alternative E is the same as Alternative B, and impacts to cultural resources would be the same as Alternative B.

Proactive Management

Under Alternative E, cultural resources would be managed in the same manner as Alternative B and would result in the same beneficial impacts as Alternative B.

Alternative F

Surface Disturbance

Any action resulting in the disturbance of culture-bearing strata from surface or subsurface disturbances may impact cultural resources. Alternative F would result in a similar, though slightly reduced, amount of surface and subsurface disturbances as Alternative D. The type of impacts would be the same as Alternative A, and the magnitude of adverse impacts would be similar to Alternative D, less than under Alternative C, and more than under alternatives A, B, and E.

Under Alternative F, restrictions on surface-disturbing activities for the protection of other resources (such as soil, water, biological resources, and special designations) are the same as Alternative D, except for areas within the Greater Sage-Grouse PHMAs ACEC, where additional restrictions to protect greater sage-grouse would apply. Impacts to cultural resources from surface-disturbing activities would be the same as Alternative D, but to a lesser extent due to these additional restrictions on surface disturbance.

Resource Uses

Management for activities associated with mineral resource exploration, development, and extraction that could result in long-term impacts to cultural resources would be similar to Alternative D. Impacts from mineral exploitation would therefore be similar in type and magnitude to Alternative D, except within greater sage-grouse PHMAs (1,232,583 acres), where an NSO restriction around occupied greater sage-grouse leks would provide additional protection from surface disturbance for cultural resources.

Under Alternative F, areas available for land tenure adjustments, recreational management, and livestock grazing management are the same as Alternative D, and the impacts on cultural resources would be the same as Alternative D.

CTTM practices under Alternative F would be the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC, where motorized vehicle use would be limited to designated roads and trails. CTTM and recreation management under Alternative F would provide greater protections for cultural resources than under alternatives A, C, and D, but fewer protections than under alternatives B and E.

Special Designations

Management of special designations under Alternative F, except in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres), is the same as Alternative D, and impacts would be similar to Alternative D. Due to the relative size and additional restrictions on surface-disturbing activities and resource uses (e.g., the mineral development and CTTM management described under Resource Uses above) applied for the Greater Sage-Grouse PHMAs ACEC under Alternative F, special designation management would result in greater protections for cultural resources in comparison to alternatives A, C, and D, but fewer than under alternatives B and E.

Resources

Management actions for managing other resources have the potential to result in both adverse and beneficial impacts to cultural resources. Measures that protect other resources and that may, in turn, protect cultural resources are similar under all alternatives; effects from these protections under Alternative F would be similar to Alternative D.

Disturbance from fire and fuels management, and silvicultural and other vegetation treatments under Alternative F would be similar to Alternative D, and effects on cultural resources would be similar to Alternative D.

Wild horse management under Alternative F is the same as Alternative D, and impacts to cultural resources would be the same as Alternative D.

Proactive Management

Under Alternative F, cultural resources would be managed in the same manner as Alternative D and would result in the same beneficial impacts as described in Alternative D.

4.5.2 Paleontological Resources

The widespread presence of paleontological resources throughout the Planning Area and their close spatial association with extractive resources present a number of management challenges. Adverse impacts to paleontological resources result from management actions that damage or destroy fossils or their context. Any surface-disturbing activities in an area that contain fossils may result in adverse impacts through disturbance of important paleontological resources. Direct impacts to paleontological resources from RMP alternatives may result from actions that physically alter, damage, or destroy fossils or their context. It is important to remember that trace fossils, exemplified by dinosaur tracks such as those at the Red Gulch Tracksite, are as important as body fossils, and can also be affected by surface-disturbing activities. In fact, the rarity of trace fossils underscores the potential adverse impact from surface disturbance. Indirect impacts may arise as a result of ancillary actions, such as when a construction road provides improved access to sensitive areas, possibly resulting in increased vandalism or unauthorized or unintentional collecting. Paradoxically, the same actions that can result in direct or

indirect adverse impacts from increased public access and awareness may also have beneficial impacts. The discovery of previously unknown deposits or the facilitation of data collection, preservation, or public education are possible beneficial impacts.

There is little difference between short-term and long-term impacts to paleontological resources; once the resource is disturbed, it cannot be restored because it is unique and not renewable. However, the situation is more complicated for indirect impacts. Because some paleontological resources are in inaccessible areas, it is possible that a short-term, direct impact would indirectly lead to a long-term beneficial impact. For example, a road that improves access but leads to vandalism in the short term may also, in the long term, make study of the resource more feasible. Similarly, surface disturbance that exposes or destroys part of an important deposit would simultaneously bring new resources to light, thereby enhancing scientific knowledge.

4.5.2.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Vertebrate and other scientifically important paleontological resources will continue to be found in the Planning Area.
- Adverse impacts to paleontological resources occur from physical damage or destruction of fossils, from loss of related scientific data, including context and stratigraphic control, and potentially due to transfer from public ownership.
- Adverse impacts to paleontological resources from surface-disturbing activities occur primarily at the time of initial surface disturbance. Therefore, it is valid to use the projected numbers for short-term surface disturbance to quantify impacts to paleontological resources. Erosion resulting from long-term surface disturbance also can adversely impact paleontological resources, but generally not to the extent of short-term surface disturbance.
- Development activities over the life of the RMP are anticipated to be similar in intensity to the intensity represented by surface-disturbance acres identified in Appendix T.
- Inventories required before surface disturbance in high-probability areas would result in the identification and evaluation of previously undiscovered resources, which the BLM would then manage accordingly. Surface-disturbing and other disruptive activities also may dislocate or damage paleontological resources that were not discovered before surface disturbance (i.e., unanticipated discoveries). In some cases, surface-disturbing activities, along with avoidance or full mitigation, can benefit the resource.
- The number and types of paleontological resources that could be affected by various actions directly correlate to the degree, nature, and quantity of surface-disturbing activities in the Planning Area.
- Paleontological resources at the surface are most typically associated with bedrock exposures. Areas of deep soils, alluvium, or colluvium only rarely contain scientifically significant fossils. Therefore, the main areas of concern for impacts to paleontological resources are where fossil-bearing bedrock is at or near the surface, such as badlands, along structural uplifts, hill slopes, or in areas with thin soils over bedrock.

4.5.2.2 Summary of Impacts by Alternative

The principal direct impacts to paleontological resources would result from surface-disturbing activities, while indirect adverse impacts would result from increased access to important paleontological locations that lead to overuse, increased legal and illegal collecting, and vandalism. Conversely, all of these adverse impacts may also lead to beneficial impacts as new deposits are located, educational opportunities arise, and research programs are instituted. Proactive paleontological resource management actions result in beneficial impacts across all alternatives. Furthermore, compliance with the Paleontological Resources Preservation Act (PRPA) and BLM PRPA guidance would limit adverse impacts and maximize beneficial impacts. The PRPA provides for criminal and civil penalties for theft and vandalism of fossils on public land. Other resource uses are, by law, required to minimize impacts to paleontological resources from vandalism and theft and maintain the confidentiality of resource locations.

Alternative E, by designating eight ACECs (116,720 acres) for paleontological resources as well as the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), and subjecting the least total acreage to surface-disturbing activities, would have the least adverse impacts and most resource protection compared to the other alternatives. Alternative C provides the least protection and the greatest exposure to direct impacts from surface-disturbing activities, but may result in more identification of paleontological localities due to increased resource use. In terms of potential impacts, management under alternatives D and F fall between management under alternatives A and B, in that alternatives D and F employ a less proactive management approach than Alternative B, but a similar approach to casual use and education.

4.5.2.3 Detailed Analysis of Alternatives

Allowable uses and management actions that impact paleontological resources include all surface-disturbing activities, changes in ownership, visitor accessibility, motorized vehicle use, and proactive paleontological resource management actions.

Impacts Common to All Alternatives

Potential impacts to paleontological resources as a result of other resource management actions are similar, although the intensity varies across alternatives. For all alternatives, impacts may stem from any surface-disturbing activity in an area where fossils are known or found to be present.

Similarly, paleontological resources would experience beneficial impacts from proactive management actions common to all alternatives. Although the degree of protection may vary by alternative, the goals of such management are the same for each alternative. For example, positive interaction with the public to prevent illegal activities and project reviews to avoid scientifically important paleontological resource sites are management priorities that result in beneficial impacts. The latter action will allow the avoidance of surface-disturbing activities that could damage or destroy significant paleontological resources on BLM-administered land, including resources listed in National Park Service inventories of possible National Natural Landmarks. Other proactive, beneficial impacts across all alternatives come from balancing restrictions on access to newly discovered paleontological resources with opportunities for the public to collect fossils in a limited, recreational manner. This is accomplished through the management of scientifically significant paleontological resources for scientific and public use.

The recently enacted PRPA provides a new level of protection for paleontological resources (see Section 3.5.2 *Paleontological Resources* in Chapter 3). The interface of this law with BLM guidance is under

development, and it remains to be seen specifically how it will affect the management of paleontological resources under BLM jurisdiction.

Brown/Howe Dinosaur Area ACEC, which the BLM manages for its paleontological resources, appears under all alternatives. The management of and impacts from the management of this and other ACECs that include paleontological resources is mentioned in this section, but discussed in detail in Section 4.7.1 *Areas of Critical Environmental Concern*.

Alternative A

Surface Disturbance

Under Alternative A, surface-disturbing activities may result in impacts to paleontological resources. The BLM anticipates that impacts to paleontological resources from surface disturbance under Alternative A (see Appendix T) would be primarily adverse. However, required resource identification through on-the-ground survey of PFYC 4 and 5 before surface-disturbing activity will identify resources, and may mitigate adverse impacts, possibly resulting in data collection or preservation of paleontological resources, which would result in a beneficial impact. PFYC 3 may or may not require a survey prior to approval of a surface-disturbing activity. Once a paleontological locality is identified, Alternative A requires a 50-foot-wide buffer to preclude any surface-disturbing activities from damaging the locality.

Restrictions on surface-disturbing activities for the protection of other resources (such as soil, water, biological resources, and special designations) under Alternative A may provide additional protection for paleontological resources, because management that limits the potential for disturbance would result in beneficial impacts.

Resource Uses

Exploration for and development of locatable minerals, leasable minerals, and mineral materials would result in adverse impacts. Impacts would be direct, if exploration for or development led to disturbance of the paleontological resource, or indirect, if a road or other associated activity improved access to an otherwise inaccessible locale. However, mineral exploration or development activity also would lead to beneficial impacts, because discovery, improved access, and avoidance would eventually result in the opportunity to study previously unknown fossils and to educate the public.

Management actions associated with lands and realty would result in adverse and beneficial impacts. The BLM anticipates potential beneficial impacts under Alternative A, wherein the acquisition and retention of lands with significant paleontological resources is to be considered, but is not pursued as an active management strategy. However, if lands with important paleontological resources are disposed of and leave federal management, there may be adverse impacts because these areas would no longer be subject to the PRPA and other federal laws and regulations designed to protect these resources.

Impacts from linear resource uses (e.g., ROWs, corridors, and road development) and renewable energy development are similar, and may result in direct adverse impacts from surface disturbance associated with development. Indirect impacts arise from increased accessibility and resulting increased recreation use provided by the corridors and associated development. These activities may result in beneficial impacts if the development results in the discovery of resources or research and educational opportunities.

Off-road motorized vehicle use on public lands has the potential to directly and indirectly affect paleontological resources. Direct impacts occur when vehicles run over exposed fossils on a trail;

Paleontological Resources

indirect impacts result from accelerated erosion and degradation due to exposure. In addition, off-road motorized vehicle use enables access to remote paleontological localities, and would increase opportunities for theft and vandalism. While there may be adverse impacts due to off-road or inappropriate use of motorized vehicles under any circumstances, restricting motorized vehicle use in certain areas would provide some protection for sensitive resources. The BLM anticipates that Alternative A would result in disturbance associated with motorized vehicle use, which would have the potential to adversely affect paleontological resources in areas such as the Bighorn Slope, Bridger, Owl Creek, and Absaroka foothills. Recreation would result in adverse and beneficial impacts to paleontological resources. Increased use of the Planning Area and an increase in the number of recreational collection permits would increase the potential for damage to paleontological resources; an increase in opportunities to improve education and paleontological interpretation would benefit the resources.

Special Designations

Under Alternative A, the BLM manages four ACECs, including the Brown/Howe Dinosaur Area ACEC, for their paleontological resources. For the Little Mountain ACEC, management would emphasize avoidance of sensitive areas, provide some restrictions for mineral development, and pursue withdrawal from appropriation under the mining laws in limited areas within the ACEC. Under Alternative A, the BLM also manages the Red Gulch Dinosaur Tracksite and Big Cedar Ridge areas as ACECs, limiting surface disturbance and providing other protections to paleontological resources in these areas.

Resources

The BLM anticipates surface disturbance associated with prescribed fire and mechanical fuels treatment under Alternative A. Actions related to fire and fuels management may result in adverse impacts to paleontological resources. Construction of fire breaks can cause surface disturbance, which may damage or destroy important fossils. However, there may also be beneficial impacts if the disturbance exposes previously unknown resources or improves access for study. Surface disturbance related to fire and fuels management would result in fewer impacts to paleontological resources than other types of surface disturbance, because it is less likely to penetrate deeply into strata that contain important resources.

Proactive Management

Under Alternative A, management actions that aid in the identification and preservation of scientifically important fossils include attachment of standard Paleontological Resources Protection Stipulations to surface-disturbing activities on PFYC 3, 4, or 5; retention and acquisition of lands for significant paleontological resources (although this is on a case-by-case basis); and development of additional interpretive areas. Under Alternative A, development of interpretive areas at informational locations is on a case-by-case basis. Surface disturbance associated with development of the interpretive area may result in adverse impacts to the paleontological resources. However, the public would benefit from development of this educational exhibit. Potential impacts from this management illustrate the dichotomy between the adverse impacts of direct disturbance and increased access, and the beneficial impacts of education and discovery.

Alternative A also includes several management actions, all of which are applied on a case-by-case basis, designed to protect paleontological resources from actions not related to resource use, such as theft and vandalism. These management actions include closing areas with vertebrate or other scientifically significant paleontological resources at risk for damage from illegal activities and implementing on-the-

ground surveys before surface disturbance or land disposal actions for all PFYC 4 and 5 formations, while PFYC 3 formations may or may not require a survey prior to approval of these actions.

Alternative B

Surface Disturbance

Alternative B includes fewer acres subject to surface-disturbing activities than Alternative A. Therefore, surface disturbance under this alternative would result in the less impact to paleontological resources. Similar to Alternative A, impacts to paleontological resources from surface disturbance projected for Alternative B may be primarily adverse. However, an increase in resource identification due to on-the-ground surveys of PFYC 3 through 5 before surface-disturbing activity would result in a beneficial impact because it would identify more resources, and may mitigate adverse impacts or result in data collection and preservation of paleontological resources. Alternative B also requires a 100-foot-wide buffer around paleontological localities to preclude any surface-disturbing activities, providing greater protection than the other alternatives.

Alternative B includes more restrictions on surface-disturbing activities for the protection of other resources, thereby resulting in more beneficial impacts than Alternative A.

Resource Uses

As with Alternative A, exploration for and development of locatable minerals, leasable minerals, and mineral materials are likely to result in direct and indirect adverse impacts from disturbance and improved access. However, because Alternative B would result in less surface disturbance associated with minerals development, it also would result in fewer impacts to paleontological resources compared to Alternative A. Making greater sage-grouse Key Habitat Areas closed to mineral leasing would result in indirect beneficial impacts by limiting the potential degradation of paleontological resources in these areas.

Management actions associated with lands and realty would result in adverse and beneficial impacts. Actively pursuing the acquisition and retention of lands with significant paleontological resources under Alternative B would result in greater beneficial impacts than Alternative A, under which acquisition and retention of lands with significant paleontological resources is only considered.

Impacts from ROW-related actions and renewable-energy resource development would be less under Alternative B than under Alternative A. Impacts from trails management and recreation under Alternative B would be similar to those under Alternative A, but to a lesser degree. Alternative B is projected to result in more surface disturbance from cross-country motorized travel in small, localized areas than Alternative A (Appendix T), but limits motorized vehicle use to designated roads and trails and closes more area to motorized vehicle use in the Planning Area. Limiting motorized vehicle use to designated roads and trails in the Bighorn Slope, Bridger, Owl Creek, and Absaroka foothills, and the Absaroka Front Management Area (partially closed to motorized vehicle use) would reduce potential disturbance and restrict access, thus decreasing the risk of looting. As with the other alternatives, the potential for beneficial impacts through discovery and subsequent research and educational opportunities would remain.

Special Designations

Alternative B designates eight ACECs for paleontological resources and increases the size of several existing ACECs. For the Little Mountain ACEC, management under Alternative B is similar to Alternative A, with the addition of an expansion area. The Brown/Howe Dinosaur Area ACEC is maintained across

Paleontological Resources

all alternatives, but under Alternative B it would be closed to mineral leasing, managed as ROW avoidance, and the BLM pursues a withdrawal from appropriations under the mining laws. For the Red Gulch Dinosaur Tracksite and Big Cedar Ridge ACECs, management under Alternative B would be the same as under Alternative A. Alternative B also would add four ACECs with paleontological resources – Clarks Fork Basin/Polecat Bench West Paleontological Area, McCullough Peaks South Paleontological Area, Foster Gulch Paleontological Area, and Rainbow Canyon Paleontological Area. Section 4.7.1 *Areas of Critical Environmental Concern* further discusses the management of and impacts from ACECs.

Resources

Actions related to fire and fuels management are anticipated to have an adverse impact on paleontological resources. Projected impacts are less under Alternative B than under Alternative A.

Proactive Management

Proactive management under Alternative B provides greater protection for paleontological resources than Alternative A. This management includes protection for PFYC below 4 and 5, larger buffer zones around important paleontological discoveries and sites, and prohibitions on surface disturbance. Alternative B also provides more protection for vertebrate or other scientifically significant paleontological resources from actions related to non-resource use (e.g., theft and vandalism) compared to Alternative A through the use of measures such as increased law enforcement and resource specialist presence in areas of high resource values and posting additional signs warning against illegal collection. Alternative B also includes management actions requiring the BLM to pursue opportunities to acquire private lands with vertebrate or other scientifically significant paleontological resources, actively solicit paleontological research, and sponsor data sharing and symposia. While management under Alternative B designates areas for casual use and collection of certain fossil types, it also seeks to minimize the development of interpretive areas in the Planning Area.

Alternative C

Surface Disturbance

The BLM anticipates that Alternative C would result in the most short-term and long-term surface disturbance. Therefore, this alternative would result in the most adverse impacts to paleontological resources of any alternative. Projected impacts to paleontological resources from surface disturbance under Alternative C (Appendix T) are anticipated to be similar to those described for Alternative B, although to a greater extent and intensity. The BLM requires on-the-ground surveys before it approves surface-disturbing activities, and monitoring of surface-disturbing activities in PFYC 5 formations, which would provide some mitigation of adverse impacts and may result in beneficial data collection or the preservation of paleontological resources.

As with the other alternatives, restrictions on surface-disturbing activities for the protection of other resources (e.g., soil, water, biological resources, and special designations) would protect paleontological resources, although the more limited nature of these protections under Alternative C would result in the least additional protection of any alternative.

Resource Uses

Impact from the exploration for and development of locatable minerals, leasable minerals and mineral materials would be greater under Alternative C than the other alternatives due to more projected surface disturbance. Monitoring is only provided for actions in PFYC 5, and standard Paleontological Resources Protection Stipulations are only attached to surface-disturbing activities in PFYC 4 or 5. Once

a paleontological locality is identified, Alternative C requires a 50-foot-wide buffer, as does Alternative A. As with the other alternatives, resource use may also have a beneficial impact if discovery, improved access, and avoidance lead to the opportunity to study previously unknown fossils and to educate the public.

Management actions associated with lands and realty would result in adverse and beneficial impacts. The potential beneficial impact is similar to that under Alternative B, under which the BLM retains lands with important paleontological resources. However, under Alternative C, there would be no beneficial impacts from acquisition of lands with significant paleontological resources, as described for Alternative B.

Impacts from linear resource uses such as ROWs, corridors, and roads, and from renewable-energy resource development, would be greatest under Alternative C. Management under Alternative C includes relatively few restrictions on ROW development and associated surface-disturbing activities, increasing the chance of direct and indirect impacts to paleontological resources. However, although the area affected by this management is larger under Alternative C, it is not likely that the corresponding beneficial impact also would be larger, because the magnitude of the increased use would probably not be balanced by a corresponding beneficial gain in knowledge and resource discovery. A similar adverse-to-beneficial impact imbalance would occur in the management of recreation and motorized vehicle use, because the magnitude of the increase in visits and traffic may outweigh the increase in knowledge gained. Restricting motorized vehicle use to designated roads and trails in the Bighorn Slope, Bridger, Owl Creek, and Absaroka foothills and the Absaroka Front Management Area would result in similar impacts to those under Alternative B.

Special Designations

Special designations under Alternative C would result in the least overall beneficial impact to paleontological resources. Alternative C does not designate any ACECs with paleontological resources other than the Brown/Howe Dinosaur ACEC, which is designated under all alternatives. Paleontological resources in the Little Mountain, Red Gulch Dinosaur Tracksite, Big Cedar Ridge and other areas designated as ACECs under the other alternatives would be at a higher risk of degradation under Alternative C.

Resources

The area potentially affected by management of fire and fuels under Alternative C is projected to be twice that of Alternative A, and therefore likely to result in more adverse impacts to paleontological resources. Although beneficial impacts also are possible, the increased potential for adverse impacts would outweigh the benefits.

Proactive Management

Under Alternative C, some current management practices would continue. However, focus would shift to reactive investigations, such as implementation of the PFYC system for permits exceeding 5 acres and survey and monitoring in PFYC 5 formations. The BLM attaches Standard Paleontological Resources Protection Stipulations to authorization of surface-disturbing activities only for PFYC 4 or 5. Protection of significant paleontological resources from theft and vandalism would be the same as for Alternative A, resulting in similar beneficial impacts. As for alternatives B and D, under Alternative C the BLM retains public ownership of lands with important paleontological resources, but does not seek to acquire additional lands with important fossils. Under Alternative C, the BLM actively develops paleontological interpretive areas where scientifically significant paleontological resources are known to occur, resulting in impacts similar to those described for Alternative A, although to a greater degree.

Alternative D

Surface Disturbance

The BLM anticipates that Alternative D would result in slightly more surface disturbance and associated adverse and beneficial impacts to paleontological resources than Alternative A. However, the amount of surface disturbance varies by resource use, and certain resource uses that adversely affect paleontological resources (e.g., mineral development) would be similar to or disturb less area than Alternative A. New roads and trails, primarily associated with user-pioneered routes in areas designated as open to cross-country motorized travel, are anticipated to result in the largest increase in surface disturbance under Alternative D. Before surface-disturbing activity, on-the-ground surveys of all PFYC 4 and 5 will be performed, which would identify resources and may mitigate adverse impacts. PFYC 3 may or may not require a survey prior to approval of a surface-disturbing activity. This management also may result in beneficial impacts to data collection or preservation of paleontological resources, which would result in a beneficial impact. Surface-disturbing activities are allowed within at least 100 feet of the outer edge of a paleontological locality if the impacts can be adequately mitigated, in contrast to the other alternatives, which prohibit surface-disturbing activity within a certain buffer width of a paleontological locality.

Resource Uses

Minerals development under Alternative D would result in impacts similar to but slightly less than Alternative A, resulting in fewer impacts to paleontological resources. Limitations on mineral leasing in Key Habitat Areas for species such as greater sage-grouse would result in indirect beneficial impacts by limiting potential degradation of paleontological resources in those areas.

Under Alternative D, management actions associated with lands and realty are the same as under Alternative B, including the retention of BLM-administered land with significant paleontological resources and the pursuit of acquisition of private lands with such resources. Impacts from ROW-related actions and renewable-energy resource development would be similar to those described for Alternative A, though to a lesser degree.

Impacts from trails management and recreation under Alternative D would be more than under alternatives A and B, but less than under Alternative C. Alternative D is projected to result in more surface disturbance from cross-country motorized travel in small, localized areas than alternatives A and B (Appendix T). CTTM designations under Alternative D are similar to those under Alternative A, but limiting off-road travel (OHV and mountain bike) for big-game retrieval to within 300 feet of roads would limit route proliferation and the associated impacts to paleontological resources. As with Alternative B, limiting motorized vehicle use to designated roads and trails in the Bighorn Slope, Bridger, Owl Creek, and Absaroka foothills, and the Absaroka Front Management Area (partially closed to motorized vehicle use) would limit potential disturbance and restrict access to decrease the risk of looting. As with the other alternatives, there would be a potential under Alternative D for beneficial impacts through discovery and subsequent research and educational opportunities.

Special Designations

Under Alternative D, the BLM would manage four areas as ACECs for paleontological resources. For the Little Mountain ACEC, management is similar to Alternative A, but with portions managed as closed to oil and gas leasing. The BLM would manage the Brown/Howe Dinosaur Area ACEC under all alternatives, but under Alternative D would manage it as VRM Class III, allow minor ROW authorizations and other minor surface-disturbing activities following on-the-ground surveys before approving such activities or land disposal activities, and monitor surface-disturbing activities for PFYC 4 and 5 formations. For the

Red Gulch Dinosaur Tracksite and Big Cedar Ridge ACECs, management under Alternative D is the same as under Alternative A. The Rainbow Canyon Paleontological Area, proposed under Alternative B, is not managed under Alternative D, and the beneficial impacts from BLM management described for Alternative B would not occur. Three areas proposed under Alternative B – Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch Paleontological Area, and McCullough Peaks South Paleontological Area – are not designated as ACECs, but part of all three of these areas lie within the proposed PETM ACEC, which is only designated under alternatives D and F. Section 4.7.1 *Areas of Critical Environmental Concern* further discusses management of and impacts from these special designations.

Resources

Under Alternative D, actions related to fire and fuels management would result in similar adverse impacts to paleontological resources as for Alternative A.

Proactive Management

Proactive management under Alternative D most resembles Alternative A, with fewer proactive actions than Alternative B. Differences from Alternative A include attaching Standard Paleontological Resources Protection Stipulations to authorization of surface-disturbing activities in PFYC 1 through 5; allowing surface-disturbing activities within at least a 100-foot-wide buffer of the outer edge of a paleontological locality as long as impacts can be adequately mitigated; encouraging research (in contrast to providing opportunities for research).

Alternative E

Surface Disturbance

Among all the alternatives, Alternative E would result in a similar, though slightly reduced, amount of surface and subsurface disturbances to Alternative B; the type of impacts would be the same as Alternative A, and the magnitude of adverse impacts would be similar to Alternative B. When compared to the other alternatives, Alternative E provides the most restrictions on surface-disturbing activities and allows for the greatest protection of other resources, which may subsequently provide additional protection from disturbance for paleontological resources. In particular, Alternative E manages greater sage-grouse Key Habitat Areas to minimize anthropogenic disturbances, resulting in the fewest acres of disturbance and fewest impacts to paleontological resources.

Resource Uses

Management of activities associated with mineral resource exploration, development, and extraction that could result in impacts to paleontological resources under Alternative E would be similar to Alternative B. Impacts from mineral resource exploitation under Alternative E would therefore be similar in type and magnitude to Alternative B, except within the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres) where locatable withdrawals and closure to mineral materials disposal would reduce mineral exploitation to a greater extent than under any other alternative.

Under Alternative E, management actions associated with lands and realty would result in the same adverse and beneficial impacts as Alternative B, except in the Greater Sage-Grouse Key Habitat Areas ACEC. Due to the additional lands and realty restrictions of Alternative E (e.g., retain public ownership of Key Habitat Areas), the greatest benefit to paleontological resources would result when compared to the other alternatives. The least benefit would be under Alternative A, under which acquisition and

Paleontological Resources

retention of lands with significant paleontological resources is only considered and, lastly, under Alternative C, under which no acquisition of private lands is planned.

Impacts from ROW-related actions and renewable-energy resource development would be fewer under Alternative E than the other alternatives. Under Alternative E, the Greater Sage-Grouse Key Habitat Areas ACEC would be managed as a ROW and renewable energy exclusion area, resulting in less surface disturbance from potential renewable developments when compared to Alternative B. However, the BLM anticipates that even with these additional restrictions, ROWs across BLM-administered land would be approved at the same rate as Alternative B, and impacts would be similar to Alternative B.

CTTM under Alternative E would be the same as Alternative B, and therefore, potential impacts to paleontological resources would be the same as Alternative B. As with the other alternatives, the potential for beneficial impacts through discovery and subsequent research and educational opportunities would remain.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), would be the same as Alternative B, and impacts would be similar to Alternative B. Due to the relative size and additional restrictions on surface-disturbing activities and resource uses (e.g., the mineral development and CTTM management described under Resource Uses above) applied for the Greater Sage-Grouse Key Habitat Areas ACEC, special designation management under Alternative E would result in additional protection for paleontological resources in comparison to the other alternatives.

Resources

Fire and fuels management under Alternative E is projected to result in similar, though slightly reduced, surface disturbance from fuels treatment and prescribed fire as Alternative B; impacts would be similar to Alternative A, and the magnitude of impacts would be similar to Alternative B.

Proactive Management

The management of paleontological resources under Alternative E is the same as Alternative B, and the type and magnitude of impacts to paleontological resources would be the same as Alternative B.

Alternative F

Surface Disturbance

Surface disturbances and associated adverse impacts to paleontological resources under Alternative F would be similar, though slightly reduced, to Alternative D. Under Alternative F, restrictions on surface-disturbing activities for the protection of other resources (such as soil, water, biological resources, and special designations) are the same as Alternative D, except for areas within the Greater Sage-Grouse PHMAs ACEC, where additional restrictions to protect greater sage-grouse would apply. Impacts to paleontological resources from surface-disturbing activities would be the same as Alternative A, but to a lesser extent due to these additional restrictions on surface disturbance.

Resource Uses

Management for activities associated with mineral resource exploration, development, and extraction that could result in long-term impacts to cultural resources is similar to Alternative D. Impacts from mineral exploitation would be the same as Alternative D, except within the Greater Sage-Grouse PHMAs

ACEC (1,116,698 acres), where an NSO restriction around occupied greater sage-grouse leks would provide additional protection from surface disturbance for paleontological resources.

Under Alternative F, areas available for land tenure adjustments, recreational management, and livestock grazing management are the same as Alternative D, and the impacts on paleontological resources would be the same as Alternative D.

CTTM practices under Alternative F would be the same as Alternative D, except within the Greater Sage-Grouse PHMAs ACEC, where motorized vehicle use would be limited to designated roads within priority sage-grouse habitat. CTTM and recreation management under Alternative F would provide greater protections for paleontological resources than under alternatives A, C, and D, but fewer protections than under alternatives B and E.

Special Designations

Management of special designations under Alternative F, except in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres), is the same as Alternative D, and impacts would be similar to Alternative D. Due to the relative size and additional restrictions on surface-disturbing activities and resource uses (e.g., the mineral development and CTTM management described under Resource Uses above) applied for the Greater Sage-Grouse PHMAs ACEC under Alternative F, special designation management would result in greater protections for paleontological resources in comparison to alternatives A, C, and D, but fewer than under alternatives B and E.

Resources

Disturbance from fire and fuels management and prescribed fire under Alternative F would be similar to Alternative D, and effects on paleontological resources would be similar to Alternative D.

Proactive Management

The management of paleontological resources under Alternative F is the same as Alternative D, and the type and magnitude of impacts to paleontological resources would be the same as Alternative D.

4.5.3 Visual Resources

Adverse impacts result from projects that create visual contrast with the natural form, line, color, or texture of the landscape to the extent that it degrades the visual values of an area, which are documented in the visual resource inventory (see Chapter 3 and Appendix X, *Visual Resource Inventory*). The visual values recorded in the visual inventory form the baseline assessment of the quality of the visual landscape against which impacts from changes in management proposed under the management alternatives are measured. Adverse impacts can occur regardless of whether a resource development project meets an established visual objective. Adverse impacts are not limited to human-caused activity, as wildland fire or other natural phenomenon also can adversely affect visual values. If resource development creates little or no contrast with the natural form, line, color, and texture of the landscape in the area of development, little or no impact would result. Human activity may, in certain cases, create beneficial impacts to visual resources if the activity adds visual variety that is in harmony with the natural landscape.

Direct impacts to visual resources occur if the visual values of the landscape are diminished or enhanced through the creation of natural or human-caused contrast. Indirect impacts on VRM include actions on lands the BLM does not administer, or lands managed under a different VRM objective, that can change the characteristic of the landscape. For example, a BLM-authorized surface-disturbing project or use

allocation located on public lands under VRM Class IV objectives would influence the characteristic of the immediate landscape, and could also influence neighboring areas managed under VRM Class I, II, or III objectives.

For purposes of this analysis, short-term impacts are those that last up to 5 years before the visual impact is mitigated or removed. Long-term impacts are any impacts that affect visual resources for longer than 5 years, such as visual intrusions associated with the construction of wind turbines.

4.5.3.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- The BLM will manage public lands in a manner that conforms to visual objectives established in this RMP. Resource development proposals in areas with VRM Class I, II, or III visual objectives will be held to those standards. The VRM Class objectives are defined in Section 3.5.3.
- The Class I objective is to preserve the existing character of the landscape. Projects in Class I areas must not attract attention.
- The Class II objective is to maintain the existing character of the landscape. Projects may be seen, but may not attract the attention of the casual observer.
- The Class III objective is to partially maintain the existing character of the landscape. Projects may be seen and attract attention, but must not dominate the attention of the casual observer.
- The Class IV objective provides for major changes to the landscape. Projects may be seen and be the major focus of attention for the casual observer. Class IV allows for substantial changes to the form, line, color, and texture of the landscape.
- The visual inventory classes (I, II, III, IV) are used to represent the relative value of visual resources in the Planning Area; these classes are based on an areas scenic quality, sensitivity level, and distance zone (see Chapter 3 for a list of the criteria used to rate these three factors). Visual inventory Classes I and II are applied to the most visually valuable areas, Class III represents somewhat lesser value areas, and Class IV represents the least valued areas (due to low scenic quality or substantial development). In the Planning Area, visual inventory Class I is generally assigned to WSAs.
- Adverse impacts would occur where an area's visual management is less protective than warranted by its inventory class. For example, adverse impacts would occur if an inventory Class II area (i.e., a highly visually valuable area) was managed as VRM Class IV (i.e., managed to allow for a major modifications of the existing landscape). Conversely, beneficial impacts would occur in areas where the management applied is consistent with or more restrictive than warranted by the inventory class. For example, a beneficial impact would occur where a visual inventory Class III area (i.e., an area of moderate visual value) is managed as VRM Class II (i.e., managed to allow for minimal visual contrast). Generally, any activity that creates new visual contrast is considered adverse; however, contrast that is commensurate with the area's visual inventory class is generally considered to have a smaller adverse impact.
- Inconsistency between an areas visual values and its management, particularly where management is less restrictive, can degrade or improve an areas visual values to the point that it shifts visual inventory classes. For example, a visual inventory Class II area managed as VRM Class IV may become altered by human actions to the point that it takes on the lower visual values of a visual inventory Class IV area.

4.5.3.2 Summary of Impacts by Alternative

VRM Classes establish a measurable standard for the amount of change allowed to visual resources in a specific area. Visual Resource Inventory (VRI) Classes establish the general value of the landscape in terms of its scenic resources. VRM Classes range from I-IV with Class I allowing the least amount of change and IV allowing the most amount of change to the characteristic landscape. VRI Classes also range from I-IV with Class I being the highest value scenic resource and Class IV being the lowest value scenic resource. Comparing and contrasting VRM Classes to VRI Classes in the Bighorn Basin provides an indicator of the level of impact to visual resources across the Planning Area.

Alternatives A and C would be the least protective of visual values because both alternatives manage substantial portions of the Planning Area below their visual inventory class, including substantial areas of visual inventory Class II managed as VRM Classes III and IV (see Table 4-25). However, compared to Alternative C, Alternative A manages a larger portion of lower visual value visual inventory Class IV areas as a more restrictive VRM Class III, which would result in greater beneficial impacts in those areas. Alternatives B and E are the most protective of visual values, as they would manage almost the entire Planning Area consistent with or more restrictive than the classification determined from the visual inventory (see Table 4-26). Alternatives B and E would therefore be the most effective at maintaining the existing, primarily undeveloped, character of the landscape; managing areas of lower visual value under more restrictive management may also lead to an enhancement of these areas, primarily over the long term. Under alternatives D and F, VRM closely matches the updated Visual Resource Inventory Classes and manageability (i.e., most visual inventory Class II areas are managed as VRM Class II); this management would thereby be aimed at retaining the visual values identified during the visual inventory.

Table 4-25. Acres of Visual Resource Inventory Classes in Visual Resource Management Classes by Alternative

VRM Class and Acreage	Visual Resource Inventory Class Acreage ^{1,2}			
	Class I	Class II	Class III	Class IV
Alternative A				
Class I (141,127)	140,949	178	0	0
Class II (340,784)	21	288,571	32,726	19,102
Class III (890,482)	0	314,379	170,858	405,234

¹The inventory classes provide the baseline for visual resources in the Planning Area and are the indicator of visual values against which the impacts from VRM under the various management alternatives are measured. Inventory and visual resource management class acreages shown are for BLM-administered surface.

²The BLM does not assign surface lands managed by another federal agency, such as the National Park Service, to a visual resource management class, and these areas are therefore not included in the by-alternative comparison in this table.

VRM Visual Resource Management

4.5.3.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

There would be adverse impacts to visual resources under each alternative. However, the intensity and extent of impacts would vary. Impacts to visual resources may occur where VRM is not commensurate with an area's visual inventory class rating, or where major visually impairing projects, such as wind farms or mining areas, located in areas with low VRM objectives (Class IV) negatively influence the scenic quality of areas managed to maintain scenic quality, such as Class I or II areas. To a lesser extent, any project that creates new visual contrast, regardless of whether that contrast is commensurate with the area's visual values as identified in the visual inventory, would result in impacts. Under any of the alternatives analyzed here, the major sources of visual contrast in the Planning Area would be from ongoing oil and gas development; renewable energy (wind) development; mining; fire, fuels, and vegetation management; and off-road motorized vehicle activities. Depending on the visual values of an area, varying degrees of visual contrast may be compatible with the landscape and can occur without being considered an adverse impact.

Energy development would cause surface disturbance and introduce facilities that create contrasts with the form, line, color, and texture in the landscape. The forms of tanks, wind turbines, and similar facilities, and earthwork would contrast with the natural form of the landscape. The lines created by roads, powerlines, and facilities would contrast with the natural lines in the landscape. Energy facilities would typically be a lighter color and have smoother surfaces than the surrounding landforms and vegetation, thus creating contrasts of color and texture. Implementing BMPs to reduce visual contrast with surroundings may mitigate potential adverse impacts to visual resources resulting from the development of energy and associated facilities. Through the design and placement of facilities in consideration of the surrounding environment, visual contrast can be reduced, although not completely eliminated.

Mining activity, particularly for locatable minerals, would result in new visual contrast on the landscape due to road construction and excavation. As mining proceeds, artificial forms such as spoil piles and excavation pits are created that contrast with the surrounding natural landscape. For example, locatable bentonite mining usually involves establishing temporary stockpiles of mined bentonite, which would be a much lighter color than the surrounding undisturbed landscape. Locatable mineral development would be evaluated for conformance to the VRM Class objectives. However, since development of these minerals is not a discretionary activity, the BLM may not be able to deny a permit based on non-conformance to the VRM objective. If site-specific NEPA analysis discloses that a locatable mineral development project would not be in conformance with the VRM objectives after all opportunities of mitigation have been integrated into the proposed plan, then the VRM Class may need to be amended to be consistent with the level of visual change associated with the non-discretionary proposed action. Adverse impacts from locatable mineral development are most likely to occur on the 346,206 acres with known bentonite potential and the 114,095 acres with known gypsum potential.

The development of wind energy would result in substantial visual contrast over relatively large areas. Wind turbines can reach up to 500 feet in height and also add an element of movement that can attract the attention of viewers. In addition, changes to the characteristic landscape from wind farms are often greater than other types of development because they generally require multiple wind turbines in a concentrated area. Wind potential is typically greater at higher elevations and, consequently, in more visible and sensitive locales that experience greater and more constant wind speed. These characteristic of wind development mean that mitigating its visual contrast can be difficult. Highly visible areas

(mountaintops and ridges) and areas with high visual value (generally visual inventory Class I and II areas) with high potential for wind-energy development, such as Rattlesnake Mountain, may be the most adversely affected by this type of development if the values commensurate with their visual classification are not protected or mitigated. Mineral and renewable energy development would produce both short- and long-term visual contrast on the landscape. Construction and staging activities are generally short-term, whereas the life of a mineral development or renewable energy project is either long-term (30 to 50 years, plus final reclamation) or permanent. Interim reclamation measures can reduce the degree of contrasting elements of long-term surface disturbance.

Motorized vehicle activity would further exhibit or create contrasting elements of line and color from roads and trails against the natural elements in the surrounding landscape. The exposed lighter-colored soil would contrast with the surrounding vegetation, which is usually a darker gray-green color. Unreclaimed surface disturbance from unauthorized motorized vehicle activity would be either short-term or long-term. There would likely be unauthorized use (e.g., cross-country motorized travel in areas with limited travel designations) under all alternatives, though restrictions and the use of travel management designations may limit the creation of additional roads and trails that would cause new visual contrast.

Fire, fuels, and vegetation management can remove or alter the structure and density of vegetation and affect visual resources. Wildland fires can create substantial visual contrast in the form of large burned areas that, depending on the visual value of an area, may result in short-term adverse impacts. However, reducing hazardous fuels to decrease the chance of stand-replacing fires and diversifying stand age and improving forest health would reduce the chance of more severe fires and their associated large burn areas. Fire suppression activities and vegetation management can change the natural line, color, form, and texture of vegetative communities and the introduction of new visual intrusions, such as access roads or fire lines and breaks. The new contrasts from most of these activities would be short-term in nature. Over the long term, visual contrast would diminish as vegetative communities regenerate.

Under all alternatives, the BLM would manage visual resources in accordance with VRM Class objectives (see the 'Methods and Assumptions' section above). Before authorizing land uses that may affect the visual values of the landscape, the BLM would require the land use to align with the VRM Class objective. For example, the BLM would allow surface-disturbing activities within VRM Class II areas only if the level of change to the landscape from the activities are low, and will not attract attention of the casual observer, or the if project can be mitigated to meet these objectives. The BLM manages all WSA areas under VRM Class I objectives, resulting a minimal potential for adverse impacts to visual values in these areas. The size of the VRM Class areas vary by alternative, as discussed below.

Alternative A

Under Alternative A, the BLM manages 141,127 acres of BLM-administered surface as VRM Class I, 340,784 acres as VRM Class II, 890,482 acres as VRM Class III, and 1,815,043 acres as VRM Class IV. The objective of VRM Classes I and II (9 percent of BLM-administered surface) is to preserve or retain the existing character of the landscape. VRM Classes III and IV (85 percent of BLM-administered surface) would generally allow changes to the characteristic landscape, subject to some level of mitigation.

VRM under Alternative A is generally not commensurate with the visual values (represented by the visual inventory classes) identified in the visual resource inventory for the Planning Area, resulting in the potential for both adverse and beneficial impacts. As shown in Table 4-25, Alternative A manages substantial portions of the Planning Area at or above (i.e., less protective of visual values) their visual

inventory Class, which would result in adverse impacts to visual values by potentially allowing the construction of contrasting elements (described below and under *Impacts Common to All Alternatives*) incompatible with these areas. The potential for adverse impacts would be greatest where visual inventory Class II and III areas are managed as VRM Class IV (381,403 acres and 180,959 acres, respectively), but would also occur in the 314,379 acres of visual inventory Class II managed as VRM Class III. As shown in Table 4-26, this alternative would also manage large portions of the Planning Area with High Sensitivity as either VRM Class III (353,686 acres) or VRM Class IV (388,893 acres), providing a lower degree of protection to these areas of high viewer sensitivity; similarly, large areas inventoried as Scenic Quality A are to be managed as VRM Class III (368,435 acres) and VRM Class IV (702,384 acres). Such management would allow easily seen projects and/or strongly contrasting elements to be added to these high scenic quality and/or sensitivity areas, resulting in adverse impacts to these visual values. Without other restrictions, VRM Class III or IV objectives on lands identified as Inventory Class II could eventually alter these areas toward a lower rated inventory class.

¹Total acreage of each BLM class for each alternative. Scenic quality, sensitivity, and Visual Resource Management Class acreages shown are for BLM-administered surface.

²Wilderness Study Areas. For the visual resource inventory, “Special Areas” include Wilderness Study Areas and surface lands managed by other federal agencies, such as the National Park Service. However, the BLM does not assign surface lands managed by other federal agencies to a Visual Resource Management Class, and are therefore not included in this table.

VRM Visual Resource Management

Surface Disturbance

Under Alternative A, all surface-disturbing activities anticipated to occur in the Planning Area (Appendix T) may affect visual resources, although the intensity of the impact will vary by resource use and the visual values of the location. Alternative A would result in 136,253 acres of short-term surface disturbance. Adverse impact from surface-disturbing activities would be greater in areas where VRM allows disturbance that are inconsistent with the areas visual values identified in the visual resource inventory. Small-scale, dispersed development (e.g., range improvements) will result in less contrast due to the ability to blend these developments into the natural landscape. Large-scale, concentrated development, such as oil and gas development, is likely to result in more contrast, because these developments are more difficult to blend into the surrounding landscape.

Management actions that restrict surface disturbance for the protection of other resources (e.g., soil, water, biological resources, cultural resources, and special designations) would help to protect visual values by reducing visual contrast.

Resource Uses

Under Alternative A, mineral development would result in surface disturbance that would degrade visual values, particularly in areas where VRM is inconsistent with the area’s visual inventory class. Activities associated with leasable mineral and other mining, such as well pad development and road and pipeline construction, would result in adverse impacts to visual values through disturbances to the natural form, line, color, and texture in the landscape, subject to VRM restrictions. Except on the 72,861 acres of BLM mineral estate withdrawn under Alternative A, locatable mineral development would be evaluated for conformance to the VRM Class objectives. However, since development of these minerals is not a discretionary activity, the BLM may not be able deny a permit based on non-conformance to the VRM objective. If site-specific NEPA analysis discloses that a locatable mineral development project

would not be in conformance with the VRM objectives after all opportunities of mitigation have been integrated into the proposed plan, then the VRM Class may need to be amended to be consistent with the level of visual change associated with the non-discretionary proposed action.

Visual impacts from ROW projects, such as powerlines, pipelines, and wind-energy projects, are required to conform to VRM objectives, but would still result in adverse impacts to some high visual value areas under Alternative A. In the case of renewable energy, a long-term visual contrast and, depending on location, an adverse impact to visual values could occur. Alternative A does not include specific management for renewable energy, but is instead managed consistent with other ROWs.

CTTM under Alternative A limits potential damage to resources from motorized vehicles by restricting their use to existing roads and trails in most of the Planning Area (2,137,574 acres). Allowing off-road motorized vehicle use for big game retrieval and dispersed campsite access in areas with limited travel designations may increase road and trail proliferation, introducing more contrast in the form of unnatural lines and vegetation removal. Alternative A also includes a small area (1,311 acres) managed as open to cross-country motorized travel where substantial visual contrast from vegetation and user-pioneered routes could occur. However, because these areas have been open to cross-country motorized travel for a number of years, substantial visual contrast is already evident, resulting in visual inventory Class IV ratings.

Special Designations

Under Alternative A, management for special designations (e.g., ACECs and WSR eligible waterways) generally includes restrictions or limitations on surface-disturbing activities (such as ROW development, mining, and renewable energy) intended to protect the values for which the area is managed. Restrictions, limitations, or specific mitigation requirements for surface-disturbing activities, mining, ROW development, and renewable energy development would reduce activities that may cause visual contrast. Such restrictions may result in beneficial impacts to visual values where they limit development that results in new contrast, but is consistent with VRM objectives.

Proactive Management

Proactive management actions for visual resources under Alternative A would provide some protection for visual resources in the Planning Area by identifying or reducing the potential for adverse impacts. Alternative A requires VRM contrast rating worksheets and visual simulations for highly visible projects and those proposed in VRM Class I areas. Contrast rating worksheets may also be used for other projects where it would appear to be the most effective design or assessment tool. Under Alternative A, simulations would also be used when they may serve as a means to evaluate design opportunities for reducing visual contrast, even in areas already conforming to the VRM class objective. However, because VRM classes under this alternative are not commensurate with the visual inventory classes across a large portion of the Planning Area, VRM Class-specific proactive management would not benefit all areas with high visual values.

Alternative B

Alternative B emphasizes conservation of resources over resource use and would result in less adverse impacts compared to Alternative A by reducing development that may affect visual values, and by increasing proactive management. Under Alternative B, the BLM manages 154,359 acres of BLM-administered surface as VRM Class I, 1,784,854 acres as VRM Class II, 394,106 acres as VRM Class III, and 858,263 acres as VRM Class IV. The area managed as VRM Class IV, where major modifications to existing landscape are allowable, is less than under Alternative A. This alternative includes more

Visual Resources

acreage of VRM Classes I and II than Alternative A, (61 percent of BLM-administered surface acreage in the Planning Area) with the goal of maintaining the existing landscape character. As shown in Table 4-25, Alternative B manages more acreage than Alternative A consistent with or more protective than its visual values (i.e., at a lower visual inventory class). Alternative B manages the smallest acres of visual inventory Classes II and III areas as VRM Class IV (3 acres and 18,965 acres, respectively), and would generally restrict activities where major modifications to the landscape can occur to visual inventory Class IV areas, where adverse impacts would be concentrated in areas of lower visual value and where existing disturbances are already present. Many of the areas inventoried as Class III or IV that Alternative B manages as VRM Class II or III contain sensitive resources, such as proposed ACECs, ACEC expansions, lands with wilderness characteristics, and Special Recreation Management Areas.

As shown in Table 4-26, this alternative also places the majority of areas inventoried as High Sensitivity and Scenic Quality A into more protective VRM Classes I and II. More than Alternative A, VRM under Alternative B would prevent easily seen projects and/or strongly contrasting elements from being added to these high scenic quality and/or sensitivity areas.

Surface Disturbance

Alternative B places more restrictions on surface-disturbing activities for the protection of other resources (e.g., soil, water, biological resources, cultural resources, and special designations) and would result in less surface disturbance than Alternative A. These restrictions would decrease the potential for the creation of new visual contrast from such disturbance. For example, Alternative B applies an NSO restriction to avoid surface disturbance in big game crucial winter range year-round, compared to Alternative A, which applies a TLS for part of the year. In relation to Alternative A, large-scale disturbances, high-profile intrusions, and concentrated development are more limited under this alternative. Because the BLM would manage more acres as VRM Classes I and II under Alternative B, fewer and less-intrusive activities would be permitted and visual resources would be more protected, including in high visual value visual inventory Class I and II areas. However, in locations where visual contrast from intensive development in VRM Class IV occurred, adverse impacts to visual values may still result, particularly where areas of such development abut areas of substantially higher visual value (i.e., visual inventory Class I and II) (see Map 48).

Resource Uses

Mineral resource development under Alternative B would result in fewer acres of surface disturbance than Alternative A. Relatively fewer disturbances from well pad development, road, and pipeline construction would limit new visual contrast that would disrupt the natural form, line, color, and texture of the landscape.

Under Alternative B, ROW projects such as powerlines and pipelines are anticipated to result in fewer disturbances and, therefore, fewest instances of new contrast compared to Alternative A.

Renewable energy projects are more restricted under Alternative B than Alternative A. Alternative B classifies more acres as renewable energy exclusion areas and less acres as open to renewable energy development. Because wind-energy development is often visible from far away, even when it is placed in areas where such development is consistent with the underlying VRM Class objective, the visual values of the surrounding scenic quality rating units will be compromised and altered to a lower visual resource inventory class. Excluding and avoiding renewable energy development across large portions of the Planning Area would reduce potential adverse impacts to visual values.

CTTM under Alternative B places more restrictions on motorized vehicle use than Alternative A, limiting the potential for new visual contrast from route creation. In particular, prohibiting off-road motorized

vehicle (OHV and mountain bike) use for big game retrieval in areas with limited travel designations would reduce the potential for road and trail proliferation that may adversely affect visual values. Alternative B is anticipated to result in more contrasting elements due to the creation of more new roads, hiking trails, and trailheads than Alternative A.

Special Designations

Under Alternative B, impacts from management in special designations would be similar to those described for Alternative A, but would occur over a larger area. Alternative B includes more ACECs than Alternative A and manages all the WSR-eligible waterways segments discussed under Alternative A as suitable for inclusion in the NWSRS. Although most of these areas are managed under VRM Class II objectives, additional restrictions on development in the portions managed under less restrictive VRM (primarily VRM Class III) would further reduce contrast and resulting adverse impacts to visual values.

Additionally, managing all lands with wilderness characteristics specifically to preserve their wilderness characteristics (476,349 acres of BLM-administered land) and managing them as VRM Class II would result in beneficial impacts to visual values in these areas.

Proactive Management

In addition to managing to meet the more restrictive VRM Class objectives under Alternative B, specific proactive management under this alternative imposes additional visual resource protections compared to Alternative A. Alternative B requires the project proponent to submit VRM contrast rating worksheets for all proposed actions in areas managed as VRM Class I, II, or III, and to submit visual simulations and mitigation design in VRM Class I and II areas. This alternative also limits motorized vehicle use to designated roads and trails in VRM Class II areas and closes VRM Class I areas to motorized vehicle use to preserve areas of high visual resource value by reducing the potential for road and trail proliferation. Because VRM classes under this alternative are generally commensurate with or more protective than the visual inventory classes for the same areas, VRM Class-specific proactive management would be more effective under this alternative than under Alternative A.

Alternative C

Management of visual resources under Alternative C places a greater emphasis on resource use and development compared to the other alternatives, and more impacts to visual values from surface-disturbing and other activities would result than under the other alternatives. Under Alternative C, the BLM would manage 140,976 acres of BLM-administered surface as VRM Class I, 333,027 acres as VRM Class II, 510,535 acres as VRM Class III, and 2,202,825 acres as VRM Class IV. Compared to the other alternatives, Alternative C manages the most area as VRM Class IV (69 percent of BLM-administered surface in the Planning Area), which may result in more visual contrast due to surface disturbance in support of resource development activities.

Alternative C manages substantial portions of the Planning Area at or above their visual inventory class (see Table 4-25) and would have the greatest adverse impacts to visual values of any alternative because it allows the construction of contrasting elements (described below and under *Impacts Common to All Alternatives*) incompatible with visual inventory classes. The potential for adverse impacts would be greatest where visual inventory Class II and III areas are managed as VRM Class IV (424,930 acres and 272,219 acres, respectively), but also in the 238,062 acres of visual inventory Class II managed as VRM Class III. Similar to Alternative A, this alternative would manage large areas with High Sensitivity as VRM Class III (225,922 acres) or VRM Class IV (468,013 acres) (Table 4-26). Similarly, large areas inventoried as Scenic Quality A are managed as VRM Class III (244,656 acres) or VRM Class IV (776,564 acres). Such

Visual Resources

management would allow new strongly contrasting elements to be added to these high scenic quality and sensitivity areas and, without other restrictions, would eventually alter these areas toward a higher visual inventory class.

Surface Disturbance

Alternative C would result in the most surface disturbance of any alternative and, therefore, the greatest potential for new visual contrast. Adverse impacts from surface-disturbing activities would be greater in areas where VRM allows disturbance that is not commensurate with the area's visual values identified in the visual resource inventory. Compared to the other alternatives, Alternative C allows for more large-scale disturbances, high-profile intrusions, and concentrated developments. The larger area managed as VRM Class IV under Alternative C would allow more visually intrusive activities in the Planning Area and with less mitigation.

Alternative C places the least restriction on surface-disturbing activities for the protection of other resources, providing the least protection against new visual contrast compared to the other alternatives.

Resource Uses

Under Alternative C, mineral resource development would result in impacts similar to Alternative A, except that withdrawals under this alternative would be smaller (48,095 acres). ROW development under Alternative C would result in impacts similar to those described under Alternative A, though to a greater degree. Due to the increased acreage being designated as VRM Class III and IV across the spectrum of inventoried visual values, the ROW projects under Alternative C are anticipated to result in the most disturbances and, therefore, the greatest adverse impacts to high visual value areas under this alternative. Except for Alternative A, which does not include specific management for renewable energy authorizations, Alternative C includes the most area open to renewable energy development, which would increase the potential for wind-energy development and resulting impacts to visual values.

CTTM under Alternative C places the fewest restrictions on motorized vehicle use, including managing the largest acreage as open to cross-country motorized travel, and would provide the least protection from travel-related visual contrast. Areas open to cross-country motorized travel, such as OHV "play" areas, would display substantial visual contrast due to user-pioneered routes and damage to vegetation. However, areas open to cross-country motorized travel under Alternative C, are all located in visual inventory Class IV areas of the least visual value. These areas may help to concentrate this type of motorized vehicle use in these relatively small, lower visual value areas, and potentially focus use that might otherwise occur in higher visual value areas not designated for cross-country motorized travel. Allowing off-road motorized vehicle (OHV and mountain bike) use for big game retrieval and dispersed campsite access would result in impacts similar to those under Alternative A. Alternative C is anticipated to result in the greatest surface disturbance associated with the creation of new roads and trails compared to the other alternatives and would have the greatest potential to introduce new contrasting lines to the landscape.

Special Designations

Impacts to visual resources from management of special designations would be similar to those described for Alternative A, though to a lesser degree. Under Alternative C, the BLM would designate the fewest ACECs of any alternative and would not manage eligible waterways as suitable for inclusion in the NWSRS, resulting in the least protection from adverse impacts of any alternative.

Proactive Management

Proactive management actions for visual resources under Alternative C provide the fewest protections for visual resources of any alternative. Like Alternative A, Alternative C requires the project proponent to submit VRM contrast rating worksheets for highly visible projects and those proposed in VRM Class I areas, but this alternative also exempts the project proponent from submitting contrast rating worksheets and visual simulations for all mineral actions and activities in designated ROW corridors. As under Alternative A, VRM inconsistent with visual inventory classes under this alternative may reduce the benefits of this management. This alternative also does not require visual simulations and does not limit motorized vehicle use by VRM class, which will not minimize the degree of contrasting elements and may not adequately mitigate the impact surface-disturbing activities to visual values.

Alternative D

Compared to the other alternatives, management of visual resources under Alternative D would balance the protection of visual values with resource uses and development. Under Alternative D, the BLM would manage 141,127 acres of BLM-administered surface as VRM Class I, 731,812 acres as VRM Class II, 738,531 acres as VRM Class III, and 1,580,470 acres as VRM Class IV. Alternative D manages less area as VRM Class IV than alternatives A and C, but more than Alternative B.

As shown in Table 4-25, Alternative D matches VRM classes to their corresponding visual inventory class more than alternatives A and C, but less than Alternative B. For example, most visual inventory Class II areas are managed as VRM Class II, resulting in fewer adverse impacts from managing areas with higher visual values under less stringent visual objectives. Adverse impacts to the visual resource inventory would therefore be lower under this alternative than under alternatives A and C. Alternative D manages the second smallest number of acres of visual inventory Classes II and III areas as VRM Class IV (97,922 acres and 45,548 acres, respectively), which would restrict locations where major changes to the landscape could occur to primarily less visually valuable areas. Areas such as portions of the Absaroka Mountain Foothills and the Clarks Fork River inventoried as Class III have SRMA management prescriptions specific to protect the visual values. Other areas that do not have specific VRM management prescriptions, such as the Absaroka Mountain Foothills ERMA and areas north of Thermopolis contain other resources, which would benefit from VRM Class II or III, or management to maintain the viewshed for travelers visiting the Bighorn Basin. Alternative D manages 313,912 acres of visual inventory classes III and IV with more protective VRM, resulting in the potential for beneficial impacts in these areas as described under Alternative B.

As shown in Table 4-26, this alternative also places nearly the same area inventoried as High Sensitivity and Scenic Quality A into more protective VRM Classes I and II as Alternative A, less area than Alternative B, and more area than Alternative C. Such VRM would increase the management protection for these areas compared to Alternative C, and would result in similar beneficial impacts in these areas to management under Alternative A, and would result in somewhat less beneficial impacts in these areas to management under Alternative B.

Surface Disturbance

The amount of projected surface disturbance under Alternative D is more than under alternatives A and B, but less than under Alternative C. The impacts to visual values from surface disturbance would be similar to the impacts described for Alternative A, although to a lesser degree because VRM commensurate with the Planning Area's visual values, as identified in the visual resource inventory, focuses disturbances likely to result in the greatest visual contrast in areas of lower visual value. As

Visual Resources

noted for Alternative A, visual contrast from surface disturbance will vary based on the type of resource use, location, and other factors. For example, compared to Alternative A, Alternative D is projected to result in more disturbance associated with the creation of new roads and trails for recreational purposes, introducing more linear features to the visual landscape, but less disturbance from mineral development.

As described under Alternative A, management actions that restrict surface disturbance for the protection of other resources, especially where they overlap areas less restrictive VRM, would further reduce visual contrast from mineral leasing, ROW development, and other activities.

Resource Uses

While mining under Alternative D would result in a similar amount of surface disturbance than Alternative A, applying VRM that is more commensurate with visual inventory classes would reduce the potential for impacts to visual values, compared to that alternative. Effects from Oil and Gas Management Areas would be similar to those described for Alternative C, although to a lesser extent due to the smaller size of these areas under Alternative D (348,617 BLM-administered surface acres). Alternative D would result in more withdrawals (83,321 acres) than Alternative A and therefore may have more beneficial impacts to visual values. However, Alternative D would result in fewer beneficial impacts to visual values than management under Alternative B, due to fewer withdrawals.

Under Alternative D, ROW projects and renewable energy development are projected to result in the same amount of surface disturbance as under Alternative A. Nevertheless, impacts to visual resources are anticipated to be lower under Alternative D due to the compatibility of VRM with visual inventory classes. Compared to alternatives A and C, Alternative D would result in additional restrictions on the placement of ROWs and additional mitigation to protect visual values where ROW permits are granted. Alternative D also places more restrictions on motorized vehicle use, through closures and limiting motorized vehicle use to designated roads and trails, than alternatives A and C, but also designates the second largest area as open to cross-country motorized travel. Closing areas, limiting motorized vehicle use to designated roads and trails, and limiting off-road motorized use to access primitive campsites and to retrieve big game to within 300 feet from existing routes would reduce adverse impacts from user-pioneered routes. As with Alternative C, areas open to cross-country motorized travel under Alternative D are all located in areas of the least visual value, visual inventory Class IV areas. These areas may help to concentrate this type of motorized vehicle use in these relatively small, lower visual value areas, and potentially focus use that might otherwise occur in higher visual value areas not designated for cross-country motorized travel.

Special Designations

Under Alternative D, the BLM would manage special designations and other management areas that would minimize surface disturbance, which would reduce visual contrast beyond that required by VRM in the areas, benefitting visual values. Alternative D designates a larger portion of the Planning Area as ACECs compared to Alternative A, but less than Alternative B. Impacts from ACECs would be similar to those described under Alternative B. Alternative D does not manage any of the eligible waterways as suitable for inclusion in the NWSRS; even without special management, impacts to visual values under Alternative D would be similar as Alternative B because these waterways would be primarily managed as VRM Class I or II under both alternatives. Alternative D does not manage lands with wilderness characteristics specifically to preserve their wilderness characteristics, which would result in fewer beneficial impacts in these areas than under than Alternative B.

Proactive Management

Under Alternative D, VRM contrast rating worksheets would be required for all proposed actions in areas managed as VRM Classes I and II and for all projects with a high degree of impact, resulting in enhanced identification of potential adverse visual impacts in VRM Class II areas compared to Alternative A. Visual simulations use under Alternative D would be the same as described for Alternative A, and would allow the identification of potential adverse impacts as described under that alternative. Similar to, though to a lesser degree than, Alternative B, VRM classes under this alternative are consistent with visual inventory classes for the same areas, which may make VRM Class-specific proactive management more effective under this alternative than under alternatives A and C. Alternative D, like Alternative C, does not limit motorized vehicle use by VRM Class, which will not minimize the potential for the creation of contrasting elements from user-pioneered routes to the same degree as Alternative B.

Alternative E

Under Alternative E, the BLM manages the same acreages of VRM Class I, II, III, and IV areas as Alternative B (Map 48), and the resulting benefits to visual values would be the same as Alternative B. The same beneficial impacts to visual resources described under Alternative B would result under Alternative E, except to a greater extent. Under Alternative E, greater sage-grouse Key Habitat Areas are managed so that anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) do not exceed one disturbance per 640 acres and cover less than 3 percent of the total sage-grouse habitat, compared to a larger allowable disturbance of 5 percent in these areas under Alternative B. Therefore, Alternative E would reduce development affecting visual values to the greatest extent of any alternative.

Surface Disturbance

Alternative E places the most restrictions on surface-disturbing activities for the protection of resources, and would therefore result in the fewest visual impacts from surface disturbance. In comparison to the other alternatives, large-scale disturbances, high-profile intrusions, and concentrated development are the most limited under Alternative E. In particular, Alternative E includes management in greater sage-grouse Key Habitat Areas (1,232,583 acres) that would exclude or limit new aboveground ROWs and renewable energy developments and prohibit most mineral development activities.

Resource Uses

Mineral resource development under Alternative E would result in the least surface disturbance of any alternative. Relatively fewer disturbances from well pad development, road, and pipeline construction would limit new visual contrast that would disrupt the natural form, line, color, and texture of the landscape.

Renewable energy and ROW development are more restricted under Alternative E than the other alternatives, reducing the potential adverse impacts to visual values from such developments. Despite this larger area of exclusion that results from the management of the Greater Sage-Grouse Key Habitat Areas ACEC, the BLM projects that under Alternative E, renewable energy and ROW projects (e.g., roads, powerlines and pipelines) would result in similar surface disturbances and impacts to visual values as Alternative B (Appendix T).

Restrictions on motorized vehicle use under Alternative E are the same as Alternative B, such as designating and implementing the seasonal closures to motorized use within greater sage-grouse Key Habitat Areas. However, impacts from the CTTM under Alternative E would be slightly less adverse than

Visual Resources

those described under Alternative B due to limitations on the construction of new roads and a focus on closing roads not serving a public function in the Greater Sage-Grouse Key Habitat Areas ACEC.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), is the same as Alternative B, and impacts would be similar to Alternative B. Due to the size and additional restrictions on surface-disturbing activities and resource uses (e.g., the mineral development and CTTM management described under Resource Uses above) applied for the Greater Sage-Grouse Key Habitat Areas ACEC, special designation management under Alternative E would reduce contrast and resulting adverse impacts to visual values compared to the other alternatives.

Proactive Management

Alternative E manages the Planning Area under the same VRM Classes as Alternative B; beneficial impacts from this management under Alternative E would be the same as Alternative B.

Alternative F

Under Alternative F, the BLM manages the same acreage of VRM Class I, II, III, and IV areas as Alternative D, and the impacts to visual values would be the same as Alternative D, but to a greater extent. The Greater Sage-Grouse PHMAs ACEC (1,116,698 acres) would be managed so that anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) do not exceed one disturbance per 640 acres and cover less than 3 percent of the total sage-grouse habitat.

Surface Disturbance

Under Alternative F, adverse impacts to visual values from surface disturbance would be the same as Alternative D (Map 50), but to a lesser extent. Compared to Alternative D, additional restrictions on surface-disturbing activities for the protection of resources would provide greater protection from new visual contrast, especially where they overlap areas of less-restrictive VRM. In particular, Alternative F is projected to result in less surface disturbance associated with mineral development due to restrictive management for lands in the Greater Sage-Grouse PHMAs ACEC. These restrictions would provide a beneficial impact to visual values by reducing the amount of visual contrast on the landscape resulting from mineral development.

Resource Uses

Management of mineral exploration and development under Alternative F would result in similar adverse impacts on visual resources as Alternative D, but to a lesser extent due to additional restrictions on leasable mineral development in greater sage-grouse PHMAs under Alternative F.

Alternative F applies additional constraints on ROW grants and renewable energy development compared to Alternative D, but is still anticipated to result in a similar amount of surface disturbance to that projected under alternatives A and D. Management for ROW and renewable energy development in the Greater Sage-Grouse PHMAs ACEC that requires the use of existing roads to the extent practicable and limits the potential to develop wind developments for the protection of greater sage-grouse would reduce adverse impacts compared to Alternative D.

Alternative F CTTM is the same as Alternative D, except that travel in greater sage-grouse PHMAs is limited to designated roads and trails, which would reduce adverse impacts to visual resources in these areas.

Special designations under Alternative F are the same as Alternative D, with the exception of an additional 1,116,698 acres of BLM-administered land within greater sage-grouse PHMAs that would be designated as an ACEC under Alternative F. The relative size and additional restrictions on surface-disturbing activities and resource uses in special designation areas under Alternative F would further reduce contrast and resulting adverse impacts to visual values in comparison to alternatives A, C, and D. Alternative F manages 49,396 acres of lands with wilderness characteristics specifically to preserve their wilderness characteristics, which would result in beneficial impacts in these areas, but less than under than Alternative B.

Proactive Management

Under Alternative F, the use of VRM contrast rating worksheets and visual simulations are the same as described for Alternative D and would allow the identification of potential adverse impacts as described under that alternative. VRM Class would be managed in the same manner as Alternative D, and the beneficial impacts would be the same as Alternative D. However, Alternative F would result in greater overall beneficial impacts to visual resources when compared to alternatives A and D due to the additional management actions in the Greater Sage-Grouse PHMAs ACEC.

4.6 Land Resources

4.6.1 Lands and Realty

This section describes potential impacts to the lands and realty program from implementing the alternatives. The lands and realty program includes land tenure adjustments (e.g., sales, exchanges, acquisitions), land use authorizations (i.e., leases, permits, grants), and withdrawals, classifications, and segregations. The BLM authorizes ROWs and renewable energy through lands and realty actions (land use authorizations). Refer to Sections 4.6.2 *Renewable Energy* and 4.6.3 *Rights-of-Way and Corridors* for impacts to these resource uses. This section focuses on how management actions could impact the lands and realty program by increasing, limiting, or preventing the potential for realty actions.

The purpose of the lands and realty program is to facilitate management of BLM-administered lands and resources in the Planning Area. The program adapts according to changing land management, resource needs, demand for public land to meet expanding communities and other public purposes, and other issues. Therefore, lands and realty program actions generally result in beneficial impacts to multiple-use objectives in the Planning Area.

Adverse impacts to the lands and realty program result from management actions that make land tenure adjustments or land use authorizations more difficult to complete. Beneficial impacts to lands and realty result from land tenure adjustments that increase land management efficiency or enhance the management of resources through consolidation of public lands into more easily managed blocks. Direct impacts to lands and realty occur when other resources are present, preventing or making it more difficult to complete a transaction. Mitigating resource values required for a land disposal transaction can require additional lands and realty actions and increase processing costs and timeframes required to complete the transaction, which would temporarily delay the transaction. Indirect impacts to the lands and realty program result from management that subsequently affects realty actions, such as the development of parcels disposed out of BLM ownership, which can increase, limit, or prevent the potential for future realty actions. Most impacts to the lands and realty program are long-term and result from management that allocates land for land tenure adjustments or land use authorizations over the life of the plan.

4.6.1.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- The demand for land tenure adjustments and land use authorizations will increase over the life of the plan based on reasonably foreseeable actions listed in Appendix T.
- The BLM's ability to respond to or to satisfy increased demands for land tenure adjustments will be limited by budget and personnel constraints into the foreseeable future.
- Land acquisition is a support function for resources programs (e.g., cultural resources, fish and wildlife, recreation). The priority or the urgency associated with any acquisition is established by the resource program benefiting from the acquisition.
- Public lands are managed under BLM guidance and policy. The lands and realty program follows guidance when disposing of public lands or when acquiring lands to support BLM management programs.
- The number of land use authorizations will increase over the life of the plan.
- Disposal of lands would be consistent with disposal criteria.

- All proposed land tenure adjustments would require site-specific NEPA review and determination of mineral development potential in accordance with FLPMA sections 206 and 209.
- Before any potential land disposal, mineral development potential would be evaluated according to FLPMA sections 206 and 209.
- The BLM will retain existing withdrawals not otherwise specified in the alternatives.
- The BLM would use voluntary approaches to increase access to lands.
- Except where specified, BLM-administered lands will be retained in federal ownership.
- During the life of this RMP, the BLM will continue to address known trespass issues; however, additional trespasses may continue during the life of the plan. Continued resolution of trespass issues will depend on staff and funding availability.
- Consolidation of public lands would decrease the cost of public land administration in the Planning Area and enhance efficiency in management of the remaining public lands.

4.6.1.2 Summary of Impacts by Alternative

Impacts to the lands and realty program from implementing the alternatives include land disposal, acquisition, and withdrawal, and management that makes realty actions more difficult to complete. Alternative C includes the largest area available for disposal (117,845 acres), followed by Alternative A (115,905 acres), alternatives D and F (66,363 acres), and alternatives B and E (24,042 acres). In the past, there has been an overall net decrease of BLM-administered land in the Planning Area, and this trend is expected to continue under all the alternatives. Land would continue to be available for community expansion under all alternatives, with Alternative C providing more opportunities for small-scale property boundary adjustments and agricultural expansion for private land owners. Long-term impacts associated with the withdrawal and segregation of lands would be the greatest under Alternative E, because the BLM would recommend withdrawal of the largest area, followed by Alternative B, Alternative A, alternatives D and F, and Alternative C, respectively.

4.6.1.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

This section describes impacts to the lands and realty program from management common to all alternatives.

Land Tenure Adjustments

Under all alternatives, acquiring state and private lands from willing sellers to consolidate the land ownership pattern would result in long-term beneficial impacts to the lands and realty program by increasing the land base and enhancing the BLM's ability to effectively manage resources and resource uses (e.g., wildlife habitats, riparian/wetland areas, special designations). Consolidating public lands also results in long-term beneficial impacts by improving access to public lands, reducing the number of easements needed, and helping reduce conflicts from encroachment and subdivision of private land by adjacent property owners.

Considering opportunities to acquire access easements across private lands for access to BLM-administered land under all alternatives would result in long-term benefits to the lands and realty

Lands and Realty

program by eliminating the need for future land acquisitions to meet resource use needs and reducing potential trespass conflicts with other landowners. Identifying areas of interest for acquiring easements, which are based on criteria listed in Appendix M, also would benefit the lands and realty program.

Conveyance of 16,122 acres of land to the Westside Irrigation District would create long-term impacts to the lands and realty program by removing these lands from the land base available for land tenure adjustments and land use authorizations.

Special designations (WSAs, ACECs, WSRs) and the designation of SRMAs could encourage the acquisition of adjacent private and state lands and inholdings, and affect the lands and realty program for as long as these areas are designated. Acquiring adjacent lands or inholdings in or surrounding designated areas would improve the manageability of these areas.

Similar to land use authorizations, requiring on-the-ground surveys (for paleontological, cultural, and other resources) before any land disposal action could create long-term adverse impacts to the lands and realty program. Requiring resource inventories, surveys, and analyses before land tenure adjustments and land use authorizations could make it more difficult to complete lands and realty actions. Site-specific NEPA analyses for land tenure adjustments and land use authorizations could further decrease the efficiency of processing land tenure adjustments and land use authorizations.

Ensuring that important Native American TCPs and historic properties are not transferred from BLM ownership or affected by management in ways that restrict or deny access could affect the lands and realty program over the long term. Preventing land tenure adjustments or land use authorizations that may affect these sites reduces the land base available for lands and realty actions.

Considering opportunities for the acquisition of small parcels of land from private landowners for cultural and other resource values (such as acquiring the private land portions of the Legend Rock Petroglyph Site) would result in long-term beneficial impacts to the lands and realty program. However, because of the small size of these acquisitions, benefits would be minimal.

Land Use Authorizations

Under all alternatives, the BLM considers land use authorizations (permits, grants, etc.) on a case-by-case basis consistent with other resource objectives. During processing of a land use authorization, the BLM would perform site-specific inventories and NEPA analyses for cultural, paleontological, biological, and other appropriate resources as part of the case-by-case assessment. Identifying these resources in areas considered for a land use authorization may require mitigation, implementation of BMPs, and other stipulations, or the BLM may deny the application. If the BLM denies the application, there may be indirect impacts to lands and realty from an applicant pursuing land use authorizations in other areas.

Responding to R&PP applications and approving leases and conveyances to qualified applicants would benefit the lands and realty program by providing locations for certain uses (e.g., shooting ranges, landfills) that may reduce illegal use, trespass, or other issues on other BLM-administered land.

Retaining classification of BLM-administered land for the future expansion of Park County landfill south of Cody and of lands to the north, south, and west of the Worland landfill would have long-term impacts to the lands and realty program by classifying these areas in preparation of an R&PP lease or conveyance. These lands would not be available for other land tenure adjustments and land use authorizations.

Impacts specific to ROW and renewable energy development are discussed in their respective sections of this chapter.

Withdrawals, Classifications, and Segregations

Table 4-27 summarizes withdrawals and segregations by alternative. Withdrawals that close areas to operation of the public land laws cause long-term impacts to the lands and realty program by limiting or restricting lands and realty actions in these areas. Reviewing other agency withdrawals and BLM-administered power withdrawals would help the BLM determine whether the withdrawals are serving or are needed for their intended purposes. Revoked or modified withdrawals could open these public lands to allocation and management under the public land laws and mining laws. The BLM would open restored U.S. Bureau of Reclamation (BOR) lands to mineral location on a case-by-case basis, except where said lands should remain closed to mineral entry to meet other resource objectives. Opening public lands to management and allocation would result in long-term impacts to the lands and realty program by increasing the available land base for land tenure adjustments and land use authorizations.

Alternative A

Land Tenure Adjustments

Alternative A identifies a total of 115,905 acres in the Planning Area for disposal by sale, exchange, or other means (Map 51) (Appendix M). Disposal can include none, some, or all of the mineral estate. A mineral potential report would determine if a surface estate disposal includes none, some, or all of the mineral estate. Alternative A identifies the remaining land base of 3,071,909 acres of BLM-administered land for retention. Table 4-28 lists acreages associated with retention and disposal under each alternative. Disposal of lands out of federal ownership could result in indirect impacts if the new landowner develops the land. Development of disposed land could increase management difficulties and diminish resource values on adjacent BLM-administered lands (due to visual impacts, noise, barriers to migration, etc.). Reducing the resource values of BLM-administered land could increase the potential for disposal of additional BLM-administered land and result in long-term impacts to the lands and realty program. Lands identified for retention identify the BLM-administered land base to be kept in federal ownership; however, these lands could still be disposed of on a case-by-case basis. Lands kept in retention result in long-term impacts to the lands and realty program because land tenure adjustments and land use authorizations could occur on these lands, consistent with other resource objectives.

Under Alternative A, the BLM would consider the acquisition of private or state land to enhance resource objectives, consolidate management, and enhance public access in:

- Important wildlife areas;
- Public lands on the Bighorn, Shoshone, Clarks Fork of the Yellowstone, and Greybull rivers; Gooseberry Creek; the upper portions of Cottonwood and Grass creeks; and on lands where other riparian areas occur to enhance recreational opportunities and wildlife management;
- Lands with significant paleontological resources (case by case);
- Areas in the Bighorn River SRMA for hunting, fishing, boating, and camping;
- The Tatman Mountain Area for recreational opportunities;
- Areas in Horse Mountain, Trapper Creek, and White Creek for hunting, fishing, and camping;

Lands and Realty

- The Brokenback Logging Area, including North and South Brokenback creeks for hunting, fishing, boating, and camping;
- Areas in the South Bighorns including Otter Creek, Deep Creek, Little Canyon Creek, and along the Nowood River;
- The Canyon Creek area for hunting, fishing, and camping;
- Area in the Carter Mountain ACEC; and
- Bobcat Draw WSA.

Acquiring these areas could result in long-term beneficial impacts to the lands and realty program by enhancing management efficiency and consolidating land ownership in these areas. For example, riparian restoration projects have a higher chance for success when implemented along a continuous corridor of BLM-administered land than when applied to discontinuous tracts managed by multiple entities.

Under Alternative A, considering Desert Land Entry (DLE) applications for unclassified lands on a case-by-case basis, subject DLE criteria (43 CFR §2520), would cause long-term impacts to the lands and realty program by removing these lands from the land base for potential land use authorizations and land tenure adjustments. However, because most of the lands suitable for agricultural development in the Planning Area have already been transferred into private ownership, impacts would be minimal.

Land Use Authorizations

Under Alternative A, the BLM considers land use authorizations on a case-by-case basis consistent with other resource objectives. BLM would not classify, open, or make available any BLM-administered lands for agricultural entry under the Desert Land Act that meet one or more of the following criteria: unsuitable topography, presence of sensitive resources or resource conflicts, lack of water or access, small parcel size, or unsuitable soils. Impacts to lands and realty from land use authorizations result primarily from management actions associated with ROWs, communications sites, and renewable energy, which are discussed in their respective sections.

Withdrawals, Classifications, and Segregations

Under Alternative A, the BLM withdraws 72,861 acres from locatable mineral entry (Map 9) and pursues another 115,942 acres of land disposals. Table 4-27 summarizes withdrawals by area and type. Withdrawals that close areas to operation of the public land laws cause long-term impacts to the lands and realty program by limiting or restricting lands and realty actions in these areas.

Table 4-28. Land Retention and Disposal by Alternative

Disposal	115,905	24,042	117,845	66,363	24,042	66,363

Source: BLM 2013a

Alternative B

Land Tenure Adjustments

Alternative B identifies a total of 24,042 acres in the Planning Area for disposal by sale, exchange, or other means (Map 52) (Appendix M). Disposal can include none, some, or all of the mineral estate. All land actions to acquire or dispose of lands would require a site-specific analysis under NEPA. Alternative B identifies the remaining land base of 3,164,297 acres of BLM-administered land for retention. Table 4-28 lists acreages associated with retention and disposal under each alternative.

The impacts of retention and disposal would be less than those for Alternative A, because Alternative B identifies more areas for retention and a fewer areas for disposal.

Under Alternative B, the BLM would consider the acquisition of all areas identified under Alternative A. Under Alternative B, the BLM would also consider acquisition of the following:

- Private lands with vertebrate or other scientifically significant paleontological resources and values adjacent to public lands for protection via exchange, purchase, or donation from a willing seller;
- Lands and interests in lands for public access for motorized and/or mechanized access in the Trapper Creek RMZ;
- Lands and interests in lands in the Brokenback/Logging Road RMZ including Luman Creek Road, Military Creek Road, Dorn Draw Road, and other sites determined on a case-by-case basis;
- Lands and interests in lands in the South Bighorns RMZ including Cherry Creek Road to Hazelton Road Back Country Byway and Lysite Mountain, access to lands within Spring Creek, Spring Creek Road to Rome Hill Road, and other sites determined on a case-by-case basis; and
- Inholdings and lands or interests in lands within all WSA boundaries.

Impacts from acquisitions would be similar to Alternative A, although to a slightly greater extent because Alternative B considers more areas for acquisition.

Under Alternative B, the BLM would terminate existing DLE classifications and would not classify new lands for this purpose. This would result in long-term impacts to the lands and realty program by opening these lands to allocation under the public land laws. Because these areas are small (1,409 acres), impacts from opening these lands would be minimal.

Under Alternative B, disposing of the federal mineral estate under the Cody Industrial Park to entities who wish to purchase the surface estate would result in long-term impacts to lands and realty. Disposing of the mineral (sub-surface) estate along with the surface area would eliminate potential issues associated with split-estate management. However, disposing of federal mineral estate would reduce the total available land base of federal minerals in the Planning Area. A mineral potential report would determine if a surface estate disposal includes none, some, or all of the mineral estate.

Under Alternative B, pursuing conservation easements on lands adjacent to areas managed as VRM Class I and II would result in long-term benefits to the lands and realty program by increasing the land base available for realty actions and increasing management effectiveness in these areas.

Land Use Authorizations

Under Alternative B, the BLM would consider land use authorizations on a case-by-case basis consistent with other resource objectives. Impacts to lands and realty from land use authorizations result primarily

from management actions associated with ROWs, communications sites, and renewable energy, which are discussed in their respective sections.

Withdrawals, Classifications, and Segregations

Under Alternative B, the BLM would pursue withdrawals from locatable mineral entry on a total of 314,223 acres in the Planning Area (Map 10). Alternative B would also pursue 2,724 acres of land disposals. Table 4-27 summarizes withdrawals by area and type of segregation. Alternative B identifies more areas for withdrawal than Alternative A, including select ACECs, WSR suitable waterway segments (27,317 acres), and the Cody Industrial Park (208 acres). Withdrawals that close areas to operation of the public land laws would result in impacts similar to Alternative A, although to a greater extent because Alternative B would withdraw more acreage.

Alternative C

Land Tenure Adjustments

Alternative C identifies a total of 117,845 acres in the Planning Area for disposal by sale, exchange, or other means (Map 53) (Appendix M). Disposal can include none, some, or all of the mineral estate. All land actions to acquire or dispose of lands would require a site-specific analysis under NEPA. Alternative C identifies the remaining land base of 3,069,967 acres of BLM-administered land for retention. Table 4-28 lists acreages associated with retention and disposal under each alternative.

Impacts from retention and disposal of lands would be similar to those for Alternative A; however, Alternative C identifies slightly less acres for retention and slightly more acres for disposal. As a result, Alternative C identifies more area for disposal and less area for retention than all other alternatives. The larger acreages of BLM-administered lands identified for disposal under Alternative C may benefit private landowners and community development more than the other alternatives.

Under Alternative C, the emphasis for acquisition of lands and interests in lands in recreation areas and special designations is to address use and user conflicts, public health and safety, or resource protection. Long-term impacts to the lands and realty program could result from not identifying lands that could increase management efficiency and help meet management objectives in these areas. Future acquisitions of lands or interests in lands to accomplish these goals may be more difficult.

Under Alternative C, considering DLE applications for unclassified lands on a case-by-case basis would result in the same impacts as for Alternative A.

Under Alternative C, maintaining the mineral estate under the Cody Industrial Park would result in long-term adverse impacts to lands and realty by creating a split-surface estate where the BLM administers sub-surface minerals and a private landowner manages the surface area. However, maintaining the federal mineral estate would retain the minerals in federal ownership and contribute to the overall federal mineral land base in the Planning Area. A mineral potential report would determine if a surface estate disposal includes none, some, or all of the mineral estate.

Land Use Authorizations

Under Alternative C, the BLM would consider land use authorizations on a case-by-case basis consistent with other resource objectives. Impacts to lands and realty from land use authorizations result primarily from management actions associated with ROWs, communications sites, and renewable energy, which are discussed in their respective sections in this chapter.

Withdrawals, Classifications, and Segregations

Under Alternative C, the BLM would pursue locatable mineral withdrawals on a total of 48,095 acres of federal mineral estate in the Planning Area (Map 11). Existing withdrawals and segregations that are not carried forward will be allowed to expire. Table 4-27 summarizes withdrawals by area and type. Withdrawals that close areas to operation of the public land laws would result in impacts similar to Alternative A, although to a lesser extent because the BLM would withdraw fewer acres under Alternative C. Under Alternative C, the BLM would pursue the least area for withdrawals compared to the other alternatives.

Alternative D

Land Tenure Adjustments

Alternative D identifies a total of 66,363 acres in the Planning Area for disposal by sale, exchange, or other means (Map 54) (Appendix M). Disposal can include none, some, or all of the mineral estate, which would be determined through a mineral potential report. All land actions to acquire or dispose of lands would require a site-specific analysis under NEPA. Alternative D identifies the remaining land base of 3,121,558 acres of BLM-administered land for retention (Map 54). Table 4-28 lists acreages associated with retention and disposal under each alternative.

Impacts from retention and disposal of lands would be less than Alternative A. Alternative D has more area identified for disposal than Alternative B, but less than alternatives A and C. Alternative D identifies more area for retention than alternatives A and C, but less than Alternative B.

Under Alternative D, management and acquisition of lands along the Bighorn River would be similar to Alternative C, with the addition of other river tracts acquired over the life of the plan. Under Alternative D, areas considered for acquisition in the Bighorn River SRMA would be the same as for Alternative A, with similar long-term beneficial impacts. Similar to Alternative B, Alternative D emphasizes the acquisition of lands for legal and physical access in recreational areas to maximize recreational opportunities. Acquiring lands in recreational areas would result in long-term benefits in these areas by increasing management efficiency, consolidating ownership, and reducing the potential for trespass and illegal access.

Under Alternative D, considering DLE applications for unclassified lands on a case-by-case basis would result in the same impacts as Alternative A. Similar to Alternative B, disposing of the federal mineral estate under the Cody Industrial Park to entities who wish to purchase the surface estate would result in long-term impacts to lands and realty. However, disposing of the mineral (sub-surface) estate along with the surface area would eliminate potential issues associated with split-estate management described for Alternative C. A mineral potential report would determine if a surface estate disposal includes none, some, or all of the mineral estate. Pursuing conservation easements on lands adjacent to areas managed as VRM Class I and II would result in long-term benefits, but pursuing these easements on a case-by-case basis may decrease the potential (and quantity) of easements compared to Alternative B.

Land Use Authorizations

Similar to the other alternatives, under Alternative D, the BLM considers land use authorizations on a case-by-case basis, consistent with other resource objectives. Impacts to lands and realty from land use authorizations result primarily from management actions associated with ROWs, communications sites, and renewable energy, which are discussed in their respective sections in this chapter.

Withdrawals, Classifications, and Segregations

Under Alternative D, the BLM would pursue withdrawals from locatable mineral entry on a total of 83,321 acres in the Planning Area (Map 12). Alternative D also pursues 625 acres of land disposals. Table 4-27 summarizes withdrawals by area and type of segregation. Withdrawals that close areas to operation of the public land laws would have similar impacts to Alternative A, although to a greater extent because the BLM would withdraw more acres under Alternative D. Under Alternative D, the BLM would pursue withdrawals for more acres than alternatives A and C but fewer than alternatives B and E.

Alternative E

Land Tenure Adjustments

Alternative E identifies the same acreage (24,042) as Alternative B in the Planning Area for disposal by sale, exchange, or other means (Map 55) for community expansion, exchanges, and other purposes, subject to the disposal criteria (Appendix M). Also as in Alternative B, Alternative E identifies the remaining land base of 3,164,297 acres of BLM-administered surface ownership for retention (Map 55). Table 4-28 lists acreages associated with retention and disposal under each alternative.

Impacts of retention and disposal would be less than Alternative A, as Alternative E identifies the same area for disposal as Alternative B. Along with Alternative B, Alternative E identifies the least amount of acreage for standard disposal compared to alternatives A, C, D and F.

The areas considered for acquisition under Alternative E are the same as Alternative B, but also include lands and interests to conserve, enhance, or restore greater sage-grouse habitat in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres).

Under Alternative E, the effects of terminating the existing DLE classifications and disposing of the federal mineral estate under the Cody Industrial Park would be the same as Alternative B.

In addition to the conservation easements pursued under Alternative B, Alternative E also pursues conservation easements on lands for the benefit of greater sage-grouse habitat. This would result in long-term benefits to the lands and realty program by increasing the land base available for realty actions and increasing management effectiveness in these areas.

Land Use Authorizations

Under Alternative E, the BLM considers land use authorizations on a case-by-case basis consistent with other resource objectives. Impacts to lands and realty from land use authorizations would result primarily from management actions associated with ROWs, communications sites, and renewable energy, which are discussed in their respective sections.

Withdrawals, Classifications, and Segregations

Under Alternative E, the BLM pursues withdrawals from locatable mineral entry on a total of 1,764,321 acres in the Planning Area (Map 13), including withdrawals in priority greater sage-grouse habitat from mineral entry. As with Alternative B, Alternative E would pursue 2,764 acres of land disposals. Table 4-27 summarizes withdrawals by area and type of segregation. Impacts from withdrawals that close areas to operation of the public land laws would be similar to Alternative A, but to a greater extent because Alternative E pursues withdrawals on the largest area of any alternative.

Alternative F

Land Tenure Adjustments

Alternative F identifies the same total as Alternative D in the Planning Area for locatable mineral withdrawals (Map 12) and disposals by sale, exchange, or other means (Map 54) for community expansion, exchanges, and other purposes, subject to the disposal criteria (Appendix M). Also as in Alternative D, Alternative F identifies the remaining land base of 3,121,558 acres of BLM-administered surface ownership for retention (Map 54). Table 4-28 lists acreages associated with retention and disposal under each alternative.

Like Alternative D, Alternative F has more area identified for disposal than Alternative B, but less than alternatives A and C, and identifies more area for retention than alternatives A and C, but less than Alternative B.

Impacts from retention and disposal of lands would be less than Alternative A.

Under Alternative F, considering DLE applications for unclassified lands on a case-by-case basis would result in the same impacts as Alternative A. Management of land tenure adjustments for the Cody Industrial Park, under Alternative F would be the same as Alternative B, and impacts to the lands and realty program would be the same as Alternative B.

Alternative F pursues the same conservation easements associated with areas managed as VRM Class I and II as Alternative D, and impacts to the lands and realty program would be the same as Alternative D. Similar to Alternative E, Alternative F pursues conservation easements to benefit greater sage-grouse habitat, and effects would be similar to those described under Alternative E.

Land Use Authorizations

Under Alternative F, the BLM would consider land use authorizations on a case-by-case basis, consistent with other resource objectives. Impacts to lands and realty from land use authorizations would result primarily from management actions associated with ROWs, communications sites, and renewable energy, which are discussed in their respective sections in this chapter.

Withdrawals, Classifications, and Segregations

Withdrawals, classifications, and segregations under Alternative F are the same as Alternative D, and impacts would be the same as Alternative D (see Table 4-27).

4.6.2 Renewable Energy

This section describes potential impacts to renewable energy development from implementing the alternatives. The BLM approves renewable energy facilities for wind, solar, and biomass through ROW authorizations. Therefore, the descriptions of impacts to ROWs and corridors in this chapter (including restrictions and avoidance and exclusion areas) apply to renewable energy development. This section focuses on management specific to renewable energy development in the alternatives that would increase, limit, or prohibit renewable energy development (in addition to that discussed in Section 4.6.3 *Rights-of-Way and Corridors*). Wind energy is the only type of anticipated renewable energy development in the Planning Area. Therefore, this section primarily describes impacts to wind-energy development. Map 56 shows wind-energy development potential in the Planning Area based on wind power class ratings. Impacts to geothermal resources are discussed in Section 4.2.4 *Leasable Minerals – Geothermal*.

Adverse impacts to renewable energy include management that limits or prohibits the development of renewable energy resources. Beneficial impacts to renewable energy result from management actions and resource uses that increase the potential for renewable energy development. Conversely, adverse impacts to renewable energy development result from actions or uses that decrease such development potential.

Direct impacts to renewable energy include management actions that designate renewable or ROW energy avoidance and exclusion areas. Other examples of direct impacts include resource uses that conflict with or prohibit the development of renewable energy, such as development of a surface mine in an area with a high wind-power-class rating. Indirect impacts to renewable energy include management actions that result in subsequent restrictions, such as management for resource values that require mitigation, relocation, or denial of authorizations for renewable energy. Impacts to renewable energy would be long-term.

4.6.2.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Wind energy is the most likely type of renewable energy to be developed in the Planning Area; however, due to emerging research and technology, other types of renewable energy development may increase during the life of the plan.
- With advances in technology, lands with moderate (Class 2 to 3) potential may become more attractive for renewable energy development.
- Wind-energy demand and development is expected to increase during the life of the plan related directly to energy prices, national and state policy involving renewable energy, and other factors that encourage demand for and development of renewable energy resources.
- Wind-energy development will be in accordance with the BLM Final Programmatic EIS on Wind Energy Development on BLM-Administered Lands in the Western United States, IM 2009-043 (Wind Energy Development Policy) and any future BLM policy or guidance for wind-energy development.
- Increased development of wind-energy turbines (or other renewable energy) also would increase the demand for ROW authorizations for transmission lines to distribute produced energy to the grid.
- The potential for wind-energy development in the Planning Area will be in direct relation to wind power classification ratings (Map 56), proximity to transmission lines, and impacts to other resources or resource uses (such as visual resources).
- For analysis purposes, the percentage of electrical energy generated from wind would increase from 0.8 percent of total generation in 2007 to 2.5 percent by 2030 (EIA 2009).
- Because the BLM authorizes facilities and infrastructure associated with wind, solar, and biomass development through ROW grants, the location and development of renewable energy facilities relates directly to the ability of the lands and realty staff to process ROW authorizations.
- Management objectives for other resources and resource uses may limit the location and development of wind-energy infrastructure in the Planning area.
- Mapping of renewable energy potential (wind power classifications) is based on a large-scale nationwide mapping (BLM 2005a). Site-specific monitoring and testing may indicate areas with higher (or lower) wind-energy potential than previously identified.

- Wind-energy development would likely occur in areas open to wind-energy development more than in areas avoided to wind-energy development.
- Any wind-energy development would require site-specific NEPA review.

4.6.2.2 Summary of Impacts by Alternative

Impacts to renewable energy development would result from restrictions that limit or prohibit renewable energy development, including the designation of renewable energy avoidance and exclusion areas. Each alternative proposes restrictions on renewable energy development to a varying degree of intensity.

Under Alternative A, no specific renewable energy avoidance or exclusion areas are identified. Alternative E includes the most restrictions and constraints to renewable energy development, with 1,945,204 acres managed as exclusion areas and 988,459 acres managed as avoidance areas. Alternative E also includes the most constraints to renewable energy development in ACEC areas, followed by alternatives B, F, D, and C, respectively. Alternative B is the second most constraining alternative, with 1,244,948 acres managed as renewable energy exclusion areas and 1,691,663 acres managed as avoidance areas. Alternative C is the least constraining to renewable energy development, with 148,416 acres managed as renewable energy exclusion areas and 1,611,040 acres managed as avoidance areas. Management under all alternatives would seek to minimize impacts to other resources from renewable energy development, which may result in adverse impacts through siting and design requirements and mitigation that could limit development (such as limits on allowable surface disturbance in priority greater sage-grouse habitat under alternatives D, E, and F).

4.6.2.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Under all alternatives, the development of renewable energy would consider the management and objectives of other resources. Considering the management of other resource objectives could restrict the development of renewable energy in certain areas or impose siting and design requirements or other mitigation that could limit the potential for development.

Government-to-government consultation with potentially affected Tribes could further limit or restrict the development of renewable energy in the Planning Area. However, consultation with Tribes could also increase the potential for successful renewable energy development by establishing communication with Tribes to allow for more effective and collaborative planning of projects.

Under all alternatives, WSAs are closed to renewable energy development, which would result in long-term adverse impacts by prohibiting the development of renewable energy in these areas.

Alternative A

Under Alternative A, no specific renewable energy avoidance or exclusion areas are identified. Renewable energy projects are considered on a case-by-case basis. However, exclusion and avoidance areas for ROWs would apply to the development of wind-energy (and solar and biomass) facilities. Wind-energy development also is constrained by existing management policies and prohibitions involving lands with high resource values. Case-by-case permitting of renewable energy projects increases the processing timeframe and costs associated with these facilities. Case-by-case permitting

of renewable energy could also result in a distributed pattern of renewable energy development and require additional ROW authorizations to support required infrastructure such as transmission lines to distribute the energy.

Management actions for ROW authorizations would have long-term impacts to renewable energy development. Management actions that restrict ROW authorizations in areas of high potential for wind energy (Map 56) would limit the potential for development in these areas. Additionally, management for ROWs that limits or restricts the development of ROWs (including transmission lines) in areas needed to connect renewable energy facilities to the electrical grid would also adversely impact renewable energy development.

Under Alternative A, all management for ROW exclusion and avoidance applies to renewable energy, except that renewable energy is open in the following areas, all of which are ROW avoidance areas:

- Brokenback/Logging Road RMZ
- South Bighorns area
- Canyon Creek area
- Basin Gardens Play Area
- Basin Gardens

Alternative A manages only the fossil concentration area in the Big Cedar Ridge ACEC and the Heart Mountain Relocation Center National Historic Landmark as ROW exclusion areas.

Requiring a visual contrast rating worksheet in VRM Class I areas for projects would affect renewable energy development in these areas; wind turbines cause a high degree of visual impact because of their size. A visual contrast rating worksheet may reveal visual impacts of renewable development and result in mitigation to meet VRM objectives in VRM Class I areas, or the BLM may prohibit development if visual impacts cannot be adequately mitigated.

Alternative B

Under Alternative B, a total of 251,203 acres is open to renewable energy development (area not included in renewable energy avoidance or exclusion areas). Identifying areas open to renewable energy development would reduce the potential for adverse impacts associated with case-by-case permitting described under Alternative A.

Under Alternative B, a total of 1,691,663 acres are managed as renewable energy avoidance areas. Managing renewable energy avoidance areas would create long-term adverse impacts by limiting the development of renewable energy in these areas and potentially placing additional constraints, mitigation, monitoring, or other stipulations on development approved in avoidance areas. Under Alternative B, the Chapman Bench, Foster Gulch Paleontological Area, McCullough Peaks South Paleontological Area, Rainbow Canyon, and Sheep Mountain ACECs are managed as renewable energy avoidance areas.

Under Alternative B, a total of 1,244,948 acres are managed as renewable energy exclusion areas. Allocation of renewable energy exclusion areas would result in long-term adverse impacts by prohibiting the development of renewable energy in these areas. Under Alternative B, the Clarks Fork Basin/Polecat Bench, Clarks Fork Canyon, and Rattlesnake Mountain ACECs are managed as renewable energy exclusion areas.

Under Alternative B, all management for ROW exclusion and avoidance applies to renewable energy except that renewable energy is excluded in the Brokenback/Logging Road RMZ, which is a ROW avoidance area.

Designation of ACECs under Alternative B would create adverse impacts to renewable energy as these areas are all managed as renewable energy avoidance or exclusion areas. Renewable energy development would be limited or prohibited in these areas.

Avoiding wind-energy development in big game winter ranges, raptor concentration areas, and mitigating wind-energy development for the protection of greater sage-grouse nesting, brood-rearing, and winter concentration areas would result in long-term adverse impacts to renewable energy by limiting development in these areas.

Managing areas within 5 miles of trails and eligible NRHP and TCP sites as exclusion areas for wind-energy development (unless screened from the site by intervening topography) would result in long-term adverse impacts to renewable energy by prohibiting facilities in these areas.

Requiring a visual contrast rating worksheet in VRM Class I, II, or III areas and requiring a visual simulation and design mitigation for all areas viewable from VRM Class I and II areas would create adverse impacts to renewable energy development. Wind turbines are large structures and these VRM requirements prior to project approval may limit wind-energy development in these areas or necessitate certain design requirements that make projects infeasible.

Alternative C

Under Alternative C, a total of 1,428,360 acres are open to renewable energy development (area not included in renewable energy avoidance or exclusion areas). Identifying areas open to renewable energy development would reduce the potential for adverse impacts associated with case-by-case permitting described under Alternative A. Implementation of Alternative C would result in an approximate 469 percent increase in area open for renewable energy development compared to Alternative B.

Under Alternative C, a total of 1,611,040 acres are managed as renewable energy avoidance areas. Long-term impacts would be similar to those described for Alternative B, although to a lesser extent because Alternative C allocates less acreage.

Under Alternative C, a total of 148,416 acres are managed as renewable energy exclusion areas. Impacts would be the same as for Alternative B, although to a lesser extent because Alternative C allocates less acreage.

Managing areas within 5 miles of trails and eligible NRHP and TCP sites as avoidance areas for wind-energy development (unless screened from the site by intervening topography) would create adverse long-term impacts to renewable energy by limiting facilities in these areas. If renewable energy is allowed in these areas, it may require substantial siting and design requirements and other BMPs to ensure the protection of cultural resources.

Requiring a visual contrast rating worksheet in VRM Class I areas would result in the same impacts to renewable energy development as those described under Alternative A, although to a lesser extent because of exemptions in allocated ROW corridors.

Alternative D

Under Alternative D, a total of 1,315,309 acres are open to renewable energy development (area not included in renewable energy avoidance or exclusion areas). Identifying areas open to renewable energy development would reduce the potential for adverse impacts associated with case-by-case permitting described under Alternative A. Alternative D would result in approximately 424 percent more area open for renewable energy development than Alternative B and approximately 8 percent less than Alternative C.

Alternative D manages a total of 1,500,395 acres as renewable energy avoidance areas. Long-term impacts would be similar to Alternative B, although to a lesser extent because Alternative D allocates less acreage as avoidance areas. Similar to Alternative B, Alternative D designates the Chapman Bench area and the Sheep Mountain ACEC as a renewable energy avoidance area.

Alternative D manages a total of 372,110 acres as renewable energy exclusion areas. Impacts would be the same for Alternative B, although to a greater extent because Alternative D allocates more acreage as exclusion areas.

Collocating renewable energy ROWs where possible in the Southern Bighorns ERMA may result in long-term impacts to renewable energy development by limiting the location of renewable energy facilities and related infrastructure (e.g., roads and transmission lines) in this area.

Avoiding wind-energy projects in big game winter range, raptor concentration areas, and greater sage-grouse PHMAs would result in long-term impacts to renewable energy similar to Alternative B. Avoidance in these areas would constrain the development of wind resources.

Avoiding surface-disturbing activities (including renewable energy development) up to 3 miles from important cultural sites and requiring the use of BMPs to avoid, minimize and/or compensate adverse impacts would result in lesser long-term adverse impacts to renewable energy than those described under alternatives B and C. If renewable energy development is allowed in these areas, authorization may require substantial siting and design requirements and other BMPs to protect important cultural sites.

Requiring a visual contrast rating worksheet in VRM Class I areas would result in the same impacts to renewable energy development as those described under Alternative A.

Alternative E

Under Alternative E, a total of 254,151 acres are open to renewable energy development (areas not included in renewable energy avoidance or exclusion areas), which is slightly more than Alternative B (251,203 acres), and impacts to renewable energy development would be similar to those described under Alternative B.

Under Alternative E, a total of 988,459 acres are managed as renewable energy avoidance areas and 1,945,204 acres are managed as renewable energy exclusion areas (Map 60). Alternative E allocates additional acreage (700,256 acres) as renewable energy exclusion areas in comparison to Alternative B. The single largest contributing factor to the increase in renewable energy exclusion areas under Alternative E, compared to Alternative B, is the management of the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres). The amount of renewable energy exclusion areas (61 percent of the BLM-administered surface in the Planning Area) may affect the ability of project proponents to site renewable energy on BLM-administered surface lands. In addition, Alternative E manages 24 percent of BLM-administered surface lands as a ROW avoidance area, potentially adversely affecting the ability of

proponents to develop on inholdings and other non BLM-administered lands that would require a BLM ROW for access or new electrical transmission to move generated power off-site. However, wind-energy potential is generally low across the Planning Area (66 percent is classified as “poor” and 25 percent “marginal”), and the BLM anticipates that even with these additional restrictions, renewable energy development on BLM-administered land would be approved at the same rate as Alternative B, and impacts would be similar to Alternative B.

Management for cultural sites, VRM, and other considerations that could affect the development of renewable energy under Alternative E is the same as Alternative B, and impacts to renewable energy would be the same as Alternative B.

Alternative F

Under Alternative F, a total of 607,429 acres are open to renewable energy development (areas not included in renewable energy avoidance or exclusion areas). Identifying areas open to renewable energy development would reduce the potential for adverse impacts associated with case-by-case permitting described under Alternative A. Alternative F would manage more area open for renewable energy development than alternatives B and E, but less than alternatives C and D.

Under Alternative F, a total of 2,507,581 acres are managed as renewable energy avoidance areas, the most of any alternative. Alternative F allocates 292,949 acres as renewable energy exclusion areas, which is more than Alternative C, but less than alternatives E, B, and D, respectively (Map 61). Alternative F manages habitat (including big game winter ranges and raptor concentration areas) consistent with Alternative D, except that Alternative F manages the Greater Sage-Grouse PHMAs ACEC as a renewable energy avoidance area. Within the Greater Sage-Grouse PHMAs ACEC, the BLM only authorizes new applications for wind power development where a proponent could demonstrate that no declines in greater sage-grouse PHMA populations would occur. In addition, proponents are not permitted to exceed one disturbance per 640 acres or disturb more than 3 percent of sagebrush habitat in PHMAs. Long-term impacts under Alternative F would be similar to Alternative D, except that additional “no decline” requirements and stricter surface disturbance restrictions in priority greater sage-grouse habitat would place additional limitations on the ability to develop renewable energy resources. Unlike Alternative E, Alternative F allows new ROWs, subject to applicable surface disturbance restrictions, to access private and state inholdings, reducing potential adverse effect on renewable energy development in these non BLM-administered lands. However, as noted under Alternative E, because wind-energy potential is generally low across the Planning Area, the effects of additional restrictions on renewable energy may be limited.

Management for cultural sites, VRM, and other considerations that could affect the development of renewable energy under Alternative F are the same as Alternative D, and impacts to renewable energy would be the same as Alternative D.

4.6.3 Rights-of-Way and Corridors

This section describes the potential impacts to ROWs and corridors from implementation of the alternatives. ROWs are for infrastructure and facilities that are in the public interest and require authorization for location over, under, on, or through BLM-administered land. A ROW grant is a land use authorization for a specific area of public land for certain types of projects, such as developing roads, pipelines, transmission lines, and communication sites. Renewable energy facilities (wind, solar, biomass) are also authorized through a ROW, and impacts discussed in this section apply to ROW

authorizations for renewable energy. However, specific impacts to renewable energy from management under the alternatives are discussed in Section 4.6.2 *Renewable Energy*. This section focuses on how management actions could impact ROWs and corridors by increasing, limiting, or preventing the potential for these authorizations.

The most common type of adverse impact to ROWs results from restrictions that limit or prohibit the location of ROWs or corridors because of other resource values and objectives. Adverse impacts result from implementing management actions that influence or modify the location, size, or design of a ROW authorization, require substantial mitigation, or, in some cases, preclude approval of the application. Beneficial impacts to ROWs and corridors result from management actions that increase the area available for ROWs and reduce restrictions on ROW authorizations. Direct impacts to ROWs and corridors can result from management actions that allocate an area for ROW avoidance or exclusion, or management actions that designate specific ROW corridors or concentration areas. Indirect impacts to ROWs and corridors can result from management that results in subsequent restrictions on ROW authorizations, such as management for resource values or uses that require mitigation, relocation, or denial of ROW authorizations. All impacts to ROWs would be long-term.

4.6.3.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- ROW grants will be directly proportional to the development of other resources and resource uses in the Planning Area.
- In terms of major utility lines, companies would focus first on the maintenance and upgrading of existing lines before undertaking new construction of major utility lines in the Planning Area.
- New construction of major infrastructure and utility facilities will be based on public need and demand.
- ROWs will be granted to qualified individual, business, or government entities in a manner which protects natural resources associated with public lands and adjacent lands, whether administered by the government or a private entity (43 CFR 2801).
- At ROW renewal, existing ROWs would be allowed to continue without cost prohibitive restrictions, where appropriate. In general grants would be allowed to continue under existing constraints.
- Existing ROWs and communication sites would be managed to protect valid existing rights.
- If the current rate of ROW development continues, designated corridors should adequately meet future needs over the life of the plan. Under this rate of development, corridors may eventually be more intensely used, but unsafe or unreliable conditions are not anticipated.
- ROW corridors and communication site concentration areas are designated as the preferred future locations for ROWs.
- ROW authorizations would require the appropriate level of site-specific environmental analysis.

4.6.3.2 Summary of Impacts by Alternative

Impacts to ROWs and corridors would result from management actions that limit, prohibit, or increase the potential for ROWs and include the management of ROW avoidance and exclusion areas, ROW corridors, and resource specific restrictions and stipulations on surface-disturbing activities and ROW authorizations. ROW avoidance and exclusion areas would both result in adverse impacts by prohibiting

or limiting the development of ROWs and potentially resulting in additional constraints, mitigation, and other stipulations. ROW avoidance and exclusion areas are the greatest under alternatives E (2,933,608 acres) and B (2,936,142 acres) followed by alternatives D and F (2,449,464 acres), Alternative C (1,180,748 acres), and Alternative A (1,002,090 acres). Alternative A includes the most area allocated for ROW corridors (787,618 acres) which would reduce the potential for resource conflict and additional mitigation or modification of ROW facilities, followed by alternatives D and F (131,852 acres), and alternatives B, C, and E allocating the least (133,184 acres). Overall, Alternative C has the lowest level of constraints that would prohibit ROW authorizations and may result in the greatest number of new ROWs and communication sites. Alternative E includes the most constraints that would limit or prohibit ROW authorizations and would result in the fewest new ROWs and communication sites.

4.6.3.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Withdrawing areas from locatable mineral entry or closing areas to oil and gas development may reduce requests for ROWs and other land use authorizations. However, closure of these areas may concentrate ROWs in other parts of the Planning Area that are open to mineral exploration and development.

All alternatives include limitations and restrictions on surface-disturbing activities, including ROWs. Restrictions on surface-disturbing activities result in long-term adverse impacts to ROWs by limiting or prohibiting the authorization of ROWs or corridors to meet other resource objectives. Limitations and restrictions on ROWs may also require modification of the location, size, or design of facilities associated with a ROW grant. Management of ROWs in areas with limitations on surface-disturbing activities may require additional mitigation and monitoring to ensure ROW development and operation is in accordance with established resource management objectives.

Managing ROW exclusion areas would result in long-term impacts to ROWs and corridors by prohibiting or limiting ROWs in these areas. Management of ROW exclusion areas may prohibit the location of ROWs along the most direct route for the intended purpose (for linear infrastructure such as transmission lines). This may result in increased potential for additional ROW authorizations in other locations.

Allocating ROW avoidance areas would increase mitigation costs to ensure that development is consistent with management objectives for other resources. Managing ROW avoidance areas would result in long-term adverse impacts to ROWs by limiting the development of ROWs in these areas and potentially placing additional constraints, mitigation, monitoring, and other stipulations on any ROWs that are approved in avoidance areas. All alternatives manage the following areas as ROW avoidance areas:

- Areas having a 25 percent slope or greater
- Cave and karst areas
- The Spanish Point Karst ACEC
- WSAs

Under all alternatives, providing reasonable access through ROW authorizations on BLM-administered land for access to private land would result in long-term beneficial impacts by allowing ROW authorizations to private landowners and preventing potential trespass and illegal access issues.

Requiring on-the-ground surveys, resource inventories, and site-specific NEPA analysis prior to any surface-disturbing activity (including ROW authorizations) could require modification to the location, size, or design of facilities and infrastructure or, in some cases, preclude approval of the proposal. These adverse impacts would primarily occur from the implementation of management actions designed to protect resources and limit impacts to those resources from surface-disturbing activities. Management that results in the relocation or redesign of proposed ROWs would increase processing timeframes related to ROW authorizations. This impact would be further increased if relocation resulted in longer linear routes or placement of ROWs in areas that are difficult to develop. If avoidance of sensitive resources is not possible, other mitigation measures would be required, such as application of height and color specifications that serve to redesign ROWs to meet the goals and objectives for other resources.

Management of recreation management areas (SRMAs and ERMAs) and special designations including ACECs and WSRs would affect ROW authorizations in these areas by applying restrictions and stipulations on surface-disturbing activities and ROW development consistent with management objectives. Management prescriptions in these areas generally limit the location of ROWs or prescribe mitigation, BMPs, or monitoring to minimize adverse impacts from development and operation.

Mitigation measures, surface use restrictions, and timing limitations on surface disturbance in wildlife, threatened and endangered species, and riparian habitat would have long-term impacts to ROWs by prohibiting or limiting the potential for ROW authorizations in these areas. Limiting or prohibiting ROW authorizations in these areas may induce ROW authorizations in other areas to meet public use and demand. Seasonal timing limitations for surface-disturbing activities (including ROWs) in wildlife habitat could cause additional adverse impacts to ROWs by requiring construction activities to start and stop at certain times of the year; which could increase costs associated with ROW development.

Management to meet VRM objectives could affect the location, route, height, and color of proposed ROWs and associated facilities. Additional effort would be required to design projects to meet the objectives of the specific VRM class designation of an area in which a ROW is proposed. Because ROWs would generally be compatible with VRM Class IV objectives, this classification would allow increased opportunities for ROW authorizations. This is also true for VRM Class III objectives; however, some additional project planning may be necessary in VRM Class III areas to ensure that the landscape is partially retained. Surface-disturbing activities in areas managed as VRM Class II and VRM Class I would be limited or would require mitigation to minimize visual contrasting elements of projects. Under all alternatives, VRM objectives would be considered before authorizing land uses that may affect the visual character of the landscape. VRM class allocations by alternative would potentially limit or prevent ROW authorizations and are discussed below under each alternative.

Designating ROW corridors could benefit ROW authorizations associated with minerals development and major utility projects. ROW development would benefit from placement in a corridor where land use conflicts have been eliminated or reduced. Designated corridors are intended to reduce resource and land use conflicts as much as possible; which could reduce the potential for modification, or mitigation needed to approve a ROW and develop infrastructure and facilities. Designating and preferring the location of ROW authorizations in corridors could also create adverse impacts to ROWs by preventing the location of ROWs along the most direct route for the intended purpose, or preventing additional ROW authorizations in a corridor that may compromise system safety and reliability. This may result in increased potential for additional ROW authorizations and additional resource surveys and site-specific environmental analysis; which could increase costs and timeframes for ROW authorization and development.

Alternative A

Resource Uses

Under Alternative A, a total of 787,618 acres of BLM-administered surface are designated for ROW corridors (Map 63). Designating ROW corridors would result in impacts similar to those described under *Impacts Common to All Alternatives*.

Under Alternative A, a total of 940,943 acres are managed as ROW avoidance areas (Map 63). Allocation of ROW avoidance areas would result in long-term adverse impacts by limiting ROW authorizations in these areas. Under Alternative A, the BLM designates a total of 61,147 acres as ROW exclusion areas (Map 63). Managing ROW exclusion areas can result in long-term adverse impacts by prohibiting ROW authorizations in these areas.

Under Alternative A, authorization of communication site facilities would occur on a case-by-case basis, and encourage development within designated areas, while co-locating new communication sites where possible. Avoiding the placement of aboveground facilities such as powerlines along major transportation routes would result in long-term impacts to ROWs by limiting the location of aboveground facilities along already disturbed areas. Therefore, ROW authorizations may be more likely to be developed in previously undisturbed areas, which may require additional resource inventories and surveys before ROW authorization, and depending on the presence of resources, additional mitigation and monitoring.

Under Alternative A, a case-by-case development of renewable energy could result in a distributed pattern of renewable energy development and require additional ROW authorizations to support required infrastructure, such as transmission lines, to distribute the energy.

Special Designations

Management of ROW avoidance and exclusion areas in ACECs and other special management areas would result in adverse impacts to ROWs by limiting or prohibiting ROW authorizations in these areas. Under Alternative A, the BLM manages the fossil concentration area of the Big Cedar Ridge ACEC as a ROW exclusion area and management in ACECs would result in 67,727 acres of ROW avoidance areas. Prohibiting surface-disturbing activities (including construction and development of ROWs) above cave and cave passages in the Sheep Mountain Anticline ACEC would result in adverse impacts to ROWs by prohibiting authorizations in these areas.

Avoiding surface-disturbing activities within ¼ mile of the Nez Perce NHT would result in adverse impacts to ROWs by limiting ROW authorizations in these areas. Avoiding surface-disturbing activities in the immediate vicinity of important cultural resources and canals and in view within ¼ mile of significant segments of the Bridger Trail and the Fort Washakie to Meeteetse to Red Lodge Trail would also result in adverse impacts to ROWs by limiting ROW authorizations in these areas.

Resources

Prescribing specific timing limitations under Alternative A could eliminate the potential for discretionary seasonal limitations when reviewing and approving ROW authorizations. Additionally, avoiding or excluding surface-disturbing activities (including ROWs) during portions of the year may limit the development of ROWs in these areas by creating start/stop cycles in construction and operation that may make projects infeasible. Under Alternative A, the following areas include timing limitations for ROW avoidance or exclusion:

- Big game crucial winter range (1,324,371 acres) from November 15 through April 30
- Greater sage-grouse nesting and early brood-rearing habitats within 2 miles of occupied greater sage-grouse leks (834,543 acres) or in identified greater sage-grouse nesting and brood-rearing habitat outside the 2-mile buffer from March 15 to July 15 (February 1 to July 31 in CYFO)
- Greater sage-grouse winter concentration areas from November 15 to March 14
- Within $\frac{3}{4}$ -mile radius of any active raptor nest sites (337,662 acres) from February 1 through July 31

Managing VRM Class I (141,127 acres) and VRM Class II (340,784 acres) areas may result in adverse impacts to ROWs by limiting development that would not meet associated VRM objectives or may require specific design or mitigation guidelines for ROW authorization.

Alternative B

Resource Uses

Under Alternative B, a total of 133,184 acres of BLM-administered surface are designated for ROW corridors (Map 64). Management of ROW corridors would result in similar impacts as under Alternative A, although to a lesser extent because Alternative B would designate 654,434 fewer acres as ROW corridors compared to Alternative A.

Alternative B manages a total of 2,710,695 acres as ROW avoidance areas (Map 64). Managing ROW avoidance areas would result in adverse impacts similar to Alternative A, although to a greater extent because Alternative B manages 1,769,752 more acres as ROW avoidance areas than Alternative A. Alternative B manages a total of 225,447 acres as ROW exclusion areas (Map 64). Managing ROW exclusion areas would result in adverse impacts similar to Alternative A, although to a greater extent because Alternative B manages 164,300 more acres as ROW exclusion than Alternative A.

Under Alternative B, prohibiting communication sites in all avoidance and exclusion areas and requiring the co-location of sites would create long-term impacts to ROWs. ROW avoidance and exclusion areas comprise a large portion (2,936,142 acres) of the Planning Area under Alternative B, and prohibiting communications sites in these areas could prevent the location of these sites in operator-preferred locations. As a result, additional ROWs and associated facilities may be required in less than optimal locations, from an operator's perspective, to meet the goals and objectives of a project and meet community expansion and telecommunications needs. Additionally, a closure of Tatman Mountain for emergency communications would adversely impact the dispatch abilities of Big Horn County emergency services (i.e., ambulance, fire, search and rescue, and law enforcement).

Concentrating aboveground facilities along major transportation routes would have long-term impacts on the lands and realty program by encouraging ROW development in already disturbed areas, which may decrease potential mitigation and monitoring and reduce processing time. Conversely, preferring concentration of aboveground facilities in these areas, along with prohibiting construction in ROW

exclusion areas and limiting these facilities in ROW avoidance areas, may prevent the location of aboveground facilities along the most direct route for the intended purpose. This may result in increased potential for additional ROW authorizations, and associated resource surveys and site-specific environmental analysis, which could increase costs and time for ROW authorization and development.

Considering night skies in the evaluation of ROW applications and applying BMPs as appropriate could increase the processing time and costs for ROWs and potentially limit the approval of ROW authorizations when impacts cannot be adequately mitigated.

Special Designations

Managing ROW avoidance and exclusion areas in ACECs and other Management Areas would result in adverse impacts similar to Alternative A, although to a greater extent because Alternative B would designate more ACECs. Under Alternative B, management in ACECs would result in 56,942 acres of ROW exclusion areas and 245,480 acres of ROW avoidance areas. Alternative B includes more ROW avoidance and exclusion areas in ACECs compared to Alternative A. Prohibiting surface-disturbing activities (including construction and development of ROWs) above cave and cave passages in the Sheep Mountain Anticline ACEC would result in the same adverse impacts as those described under Alternative A. Managing all lands with wilderness characteristics specifically to preserve their wilderness characteristics under Alternative B would result in long-term impacts to ROWs by avoiding or prohibiting surface-disturbing activities in these areas.

Management for NHTs and Other Historic Trails would result in adverse impacts to ROWs similar to Alternative A, although to a greater extent because Alternative B avoids surface-disturbing activities in a larger area (within 5 miles of the Nez Perce NHT and Other Historic Trails). Exempting existing utility corridors from this restriction within 5 miles of other trails may reduce adverse impacts to ROW corridors compared to Alternative A.

Under Alternative B, avoiding surface-disturbing activities in view within 5 miles of Heart Mountain Relocation Center National Historic Landmark would result in adverse impacts by limiting ROW authorizations in these areas or requiring mitigation or other stipulations to minimize impacts to Heart Mountain.

Prohibiting surface-disturbing activities in all WSR suitable waterway segments would result in adverse impacts to ROWs by preventing ROW authorizations in these areas.

Resources

Mitigation measures, surface-use restrictions, and timing limitations on surface disturbance in wildlife, threatened and endangered species and riparian habitat would result in impacts similar to Alternative A, although to a greater extent because Alternative B places more restrictions on surface-disturbing activities in these areas and has more areas with restrictions.

Alternative B manages big game crucial winter range (1,324,371 acres) as ROW avoidance areas. There would be more adverse impacts to ROWs in these areas than under Alternative A because Alternative B avoids areas year-round.

Under Alternative B, impacts to ROWs from management of greater sage-grouse would be similar to Alternative A, although to a greater extent because Alternative B has more year-round restrictions. Alternative B manages the following areas as ROW mitigation or exclusion areas:

- Within 0.6 mile of occupied greater sage-grouse leks (117,398 acres)
- Within 3 miles of occupied greater sage-grouse leks (1,526,277 acres) or in identified nesting and early brood-rearing habitat outside the 3-mile buffer from February 1 through July 31
- Greater sage-grouse winter concentration areas
- Greater sage-grouse Key Habitat Areas (1,232,583 acres)

Timing limitations for the protection of nesting raptors would result in impacts similar to Alternative A, although to a greater extent because Alternative B includes larger buffer areas associated with timing limitations.

Managing the Absaroka front as a ROW avoidance area (130,872 acres) would result in adverse impacts to ROWs by limiting authorizations in this area or requiring mitigation and monitoring to reduce adverse impacts to resource values.

Avoiding surface-disturbing activities (including ROW authorizations) in view within 5 miles of important cultural sites where the integrity of setting is a contributing element of NRHP significance may result in adverse impacts to ROWs, especially major ROWs that have larger surface disturbance and higher potential to affect the integrity of setting. Exempting designated utility corridors from this restriction would reduce impacts to linear ROWs in designated corridors. Under Alternative B, management of cultural resources would have greater adverse impacts to ROWs than Alternative A.

Impacts from VRM would be similar to those under Alternative A, except more area is managed as VRM Class I (154,359 total acres) and VRM Class II (1,784,854 total acres); which would increase the restrictions designed to protect visual resources and would subsequently decrease opportunities for ROW authorizations in these areas.

Alternative C

Resource Uses

Alternative C designates a total of 133,184 acres of BLM-administered surface for ROW corridors (Map 65). Impacts to ROWs from the designation of ROW corridors would be similar to those described under Alternative B, because Alternative C designates a similar acreage of ROW corridors.

Alternative C manages a total of 1,173,162 acres as ROW avoidance areas and 7,586 acres as ROW exclusion areas (Map 65). Managing ROW avoidance would result in impacts similar to Alternative A, although to a greater extent because Alternative C manages 232,219 more acres as ROW avoidance areas. Conversely, Alternative C manages 53,561 less acres as ROW exclusion areas compared to Alternative A, reducing impacts to ROWs from this management compared to that alternative.

Alternative C manages more area as ROW avoidance areas and less area as ROW exclusion areas than Alternative A, and fewer avoidance and exclusion areas than alternatives B and D.

Avoiding the placement of aboveground facilities such as powerlines along major transportation routes under Alternative C would result in the same long-term impacts as Alternative A. Under Alternative C, the authorization of communication site facilities would be the same as Alternative A, and would result in the same impacts as Alternative A.

Special Designations

Management of ACECs would result in adverse impacts similar to Alternative A by limiting authorizations in these areas, although to a lesser extent because Alternative C manages only two ACECs.

Management in the Spanish Point Karst ACEC would create 6,298 acres of ROW avoidance area, the least ROW avoidance and exclusion areas in ACECs compared to the other alternatives.

Avoiding surface-disturbing activities within ¼ mile of the Nez Perce NHT would result in impacts similar to Alternative A. Avoiding surface-disturbing activities in view within ¼ mile of other trails would result in impacts similar to Alternative A, although to a greater extent. Alternative C includes all regionally important prehistoric and historic trails (i.e., Other Historic Trails); Alternative A includes only significant segments of the Bridger Trail and the Fort Washakie to Meeteetse to Red Lodge Trail. Exempting existing utility corridors from this restriction would further reduce adverse impacts compared to Alternative A. Management of NHTs and other trails would result in fewer adverse impacts to ROWs than alternatives A and B.

Resources

Exempting Oil and Gas Management Areas (Map 24) and ROW corridors (Map 65) from seasonal stipulations would have long-term beneficial impacts to ROWs and corridors by increasing the potential for authorizations in these areas, allowing year-round construction, and eliminating the potential for discretionary seasonal limitations applied to ROW authorizations in these areas. Mitigation measures, surface use restrictions, and timing limitations on surface disturbance in wildlife, threatened and endangered species, and riparian habitat would result in fewer impacts than Alternative A because Alternative C includes fewer restrictions in these areas.

Adverse impacts to ROWs from management of greater sage-grouse under Alternative C would be similar to under Alternative A, except that shorter periods associated with certain seasonal limitations could reduce impacts from project delay and disruption to a greater extent under this alternative.

Under Alternative C, there would be fewer adverse impacts to ROWs from management of raptor nests than under the other alternatives because Alternative C includes a smaller buffer area (¼ mile) associated with seasonal restrictions.

Managing cultural resources would result in adverse impacts to ROWs similar to Alternative B, although to a lesser extent because Alternative C reduces the avoidance area to a ¼-mile buffer. Under Alternative C, there would be fewer adverse impacts to ROWs from managing cultural resources than under any other alternative.

Under Alternative C, impacts from VRM would be similar to Alternative A, except Alternative C manages slightly less area as VRM Class I (140,976 acres) and VRM Class II (333,027 acres). This could decrease the level of restrictions designed to protect visual resources and may increase opportunities for ROW authorizations in the Planning Area.

Alternative D

Resource Uses

Alternative D manages a total of 131,852 acres of BLM-administered surface for ROW corridors (Map 66). Alternative D would result in impacts to ROWs from the designation of ROW corridors similar to those described under Alternative B, because the alternatives designate similar amounts of area for ROW corridors. Alternative D has more area designated for ROW corridors than alternatives B and C, but less than Alternative A.

Rights-of-Way and Corridors

Alternative D manages a total of 2,408,662 acres as ROW avoidance areas (Map 66). Designating these avoidance areas would cause adverse impacts similar to Alternative A, although to a greater extent because Alternative D designates 1,467,719 more acres than Alternative A.

Alternative D manages a total of 40,802 acres as ROW exclusion areas. Managing these exclusion areas would result in impacts similar to Alternative A, although to a lesser extent because Alternative D designates 20,345 fewer acres than Alternative A.

Avoiding the placement of aboveground powerlines in the areas identified under Alternative D would result in adverse impacts to linear ROWs by limiting these authorizations in the identified areas. If the BLM authorizes aboveground powerlines in these areas, specific design guidelines and mitigation may be required to reduce adverse impacts to resource values. Under Alternative D, the authorization of communication site facilities would be the same as Alternative A, and would result in the same impacts as Alternative A.

Considering night skies in the evaluation of ROW applications would result in the same impacts as Alternative B.

Special Designations

Managing ROW avoidance and exclusion areas in ACECs and other management areas would result in adverse impacts similar to Alternative A, although to a greater extent because Alternative D includes more ACECs and other management areas and more acreage of these areas. Under Alternative D, management in ACECs would result in 13,619 acres of ROW exclusion areas and 81,765 acres of ROW avoidance areas. ACEC designations under Alternative D would result in more ROW avoidance and exclusion areas compared to alternatives A and C, but less than Alternative B. Allowing minor ROW authorizations and other minor surface-disturbing activities in the Clarks Fork Basin/Polecat Bench West Paleontological ACEC and the Foster Gulch Paleontological ACEC only if preceded by a paleontological survey may result in adverse impacts by limiting ROW authorizations in these areas. Designating the Chapman Bench Management Area would result in 3,425 acres of ROW avoidance area. Prohibiting surface-disturbing activities (including ROW construction and development) above caves and cave passages in the Sheep Mountain Anticline ACEC would result in adverse impacts similar to Alternative A.

Prohibiting development with a moderate or strong contrast in the viewshed of the Heart Mountain Relocation Camp would result in adverse impacts similar to Alternative B, although to a greater extent because Alternative B only avoids surface-disturbing activities in view within 5 miles of the Heart Mountain National Historic Landmark. However, under Alternative D, the BLM may authorize more ROWs that could result in less than moderate contrast in this area compared to Alternative B.

Avoiding surface-disturbing activities up to 3 miles from the NHT (and 2 miles from Other Historic Trails) where the setting is an important aspect of the trail would cause impacts to ROWs similar to Alternative B, although to a lesser extent because Alternative D includes less acreage (distance from NHT and Other Historic Trails). Similar to alternatives B and C, exempting these restrictions in existing utility corridors would reduce these impacts in ROW corridors. Under Alternative D, management of NHTs and historic trails would result in greater adverse impacts to ROWs than alternatives A and C, but less than Alternative B.

Resources

Impacts to ROWs from management of big game crucial winter range would be similar to Alternative A, although to a lesser extent because of the exemption of Oil and Gas Management Areas from discretionary big game seasonal limitations.

Impacts to ROWs from management of greater sage-grouse would be greater than under Alternative A, because Alternative D includes more restrictions and timing limitations inside and outside greater sage-grouse PHMAs. Alternative D only authorizes major overhead powerlines in greater sage-grouse PHMAs if they are constructed within 0.5 miles of existing 115 kV or greater powerlines or within a designated corridor, which could increase the costs and complexity of utility projects by limiting development to specific corridors where construction, maintenance, and repairs must be coordinated with other utility owners.

Management of raptor nests would result in similar adverse impacts to ROWs as under Alternative A, although to a lesser extent because Alternative D includes less acreage associated with restrictions and seasonal limitations. Under Alternative D, there would be more impacts from management of raptor nests than under Alternative C, but less than under alternatives A and B.

Managing the Absaroka Front Management Area with measures to protect wildlife habitat would cause adverse impacts similar to Alternative B.

Management of cultural resources would result in adverse impacts to ROWs similar to Alternative B, although to a lesser extent because Alternative D includes less avoidance area (3 miles). Under Alternative D, adverse impacts to ROWs from management of cultural resources would be less than Alternative B, but greater than Alternative C.

Impacts from VRM would be similar to those under Alternative A, except that Alternative D manages more area as VRM Class II (731,812 total acres), which may increase the restrictions designed to protect visual resources and would subsequently decrease opportunities for ROW authorizations in these areas. Compared to the other alternatives, Alternative D includes more area designated as VRM Class I and VRM Class II than alternatives A and C, but less than Alternative B.

Alternative E

Resource Uses

Alternative E includes the same ROW corridors Alternative B (a total of 133,184 acres of BLM-administered surface), and impacts would be similar to Alternative B. However, under Alternative E, in greater sage-grouse Key Habitat Areas the BLM only allows below ground ROWs in designated ROW corridors and only allows new ROWs in corridors containing existing authorizations if the entire footprint of the new ROW is within the existing ROW footprint. These additional requirements may require modification of the location, size, or design of facilities associated with ROW corridors, which could affect the ability of proponents to use these areas for new ROW placement compared to alternatives A or B. In addition, the BLM relocates existing designated ROW corridors crossing greater sage-grouse Key Habitat Areas without authorized ROWs or undesignates the entire corridor. Undesignating corridors would limit future potential routes for ROWs and could limit the ability to access renewable energy or other resources to a greater extent than under other alternatives.

Alternative E manages a total of 2,933,608 acres as ROW avoidance and exclusion areas, which is 1,931,518 acres more than Alternative A. Impacts from managing ROW avoidance and exclusion areas would be similar to Alternative B. However, Alternative E would allow new ROWs where needed to access valid existing rights, with a preference toward the re-use of existing access routes, thus decreasing adverse effects on valid existing rights. Any new access routes would be subject to the 3 percent cap on disturbance, and reclamation to remediate other existing disturbance would be implemented before new ROW-related disturbances would be permitted in areas that exceed that cap.

Rights-of-Way and Corridors

Communication site management under Alternative E is similar to Alternative B, and impacts would be similar to Alternative B, but to a greater extent because more area is managed as ROW avoidance and exclusion areas.

Management for aboveground facilities, night skies evaluations, and other resource use considerations that could affect ROW development under Alternative E would be the same as Alternative B.

Special Designations

Management of ROWs in special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC, would be the same as Alternative B, and impacts would be similar to those described under Alternative B. In the Greater Sage-Grouse Key Habitat Areas ACEC, the BLM would pursue opportunities to remove, bury, or modify existing powerlines and would amend existing ROW grants during the ROW renewal process to require features that enhance sage-grouse habitat security. This ACEC-specific management would place additional constraints and mitigation stipulations on existing ROW grants, which would produce adverse impacts.

Resources

Alternative E would manage wildlife habitat, cultural sites, and other resource considerations consistent with Alternative B, except that Alternative E would manage the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres) as a ROW energy exclusion area and allows only below ground ROWs in designated ROW corridors within this ACEC.

Alternative F

Resource Uses

Alternative F includes the same ROW corridors as Alternative D (a total of 131,852 acres of BLM-administered surface), and impacts would be similar to Alternative D. However, in PHMAs, the BLM places timing restrictions on the construction or new transmission line ROWs in ROW corridors. These additional requirements may require modification of facility construction timing that could affect ROW development in those corridors. In addition, the BLM relocates existing designated ROW corridors crossing greater sage-grouse PHMAs without authorized ROWs or undesignates the entire corridor. Undesignating corridors would limit future potential routes for ROWs and could limit the ability to access renewable energy or other resources. Under Alternative F, the BLM manages 2,315,730 acres as ROW avoidance and 133,734 acres as ROW exclusion areas; 1,374,787 and 72,587 acres more than Alternative A, respectively. Impacts from managing ROW avoidance and exclusion areas would be similar to Alternative D; however, Alternative F would manage 92,932 acres of stock driveways as ROW exclusion areas whereas Alternative D would manage the same areas as ROW avoidance areas.

However, Alternative E would allow new ROWs where needed to access valid existing rights, with a preference toward the re-use of existing access routes, thus decreasing adverse effects on valid existing rights. Any new access routes would be subject to the 3 percent cap on disturbance.

Under Alternative F, the authorization of communication site facilities would be similar to Alternative A, and would result in similar impacts, but to a greater extent because more area is managed as ROW avoidance and exclusion areas than under Alternative A.

Management for aboveground facilities and other resource use considerations that could affect ROW development under Alternative F are the same as Alternative D, and impacts would be the same as described under Alternative D. Management for night skies evaluations under Alternative F are the same as Alternative B, and impacts would be the same as described under Alternative B.

Special Designations

Management of ROWs in special designations under Alternative F, except in the Greater Sage-Grouse PHMAs ACEC, is the same as Alternative D, and impacts would be similar to Alternative D. In the Greater Sage-Grouse PHMAs ACEC, the BLM allows the maintenance and continued operation of existing communications towers and other structures but could stipulate additional upgrades (e.g., installing anti-perching devices, minimizing wires and other collision hazards, and retrofitting existing towers to discourage use by raptors) where needed to protect greater sage-grouse. Such requirements could increase costs for ROW grantees but would not preclude continued use of the ROW. Like Alternative E, Alternative F allows only below ground ROWs in designated ROW corridors within the Greater Sage-Grouse PHMAs ACEC.

Resources

Alternative F manages wildlife habitat, cultural sites, and other resource considerations consistent with Alternative D within greater sage-grouse priority habitat managed as part of the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). In the Greater Sage-Grouse PHMAs ACEC, proponents are not permitted to exceed one disturbance per 640 acres or disturb more than 3 percent of sagebrush habitat in PHMAs; reclamation to remediate existing disturbance would need to be implemented before new ROW-related disturbances would be permitted in areas that exceed the disturbance cap. Long-term impacts under Alternative F would be similar to Alternative D, except that these stricter surface disturbance restrictions in greater sage-grouse PHMAs (35 percent of BLM-administered surface lands) would limit the ability to develop, or increase the cost and difficulty of siting new ROWs compared to alternatives A and D through a large portion of the Planning Area.

4.6.4 Comprehensive Travel and Transportation Management

This section describes potential impacts to access and travel management from managing other resources or resource uses. The CTTM program operates as a support program, rather than a resource in and of itself, because it supports other management activities in the Planning Area. The CTTM program addresses planning for OHV activities and other motorized vehicle use, and the travel needs for all BLM-administered resource management programs for such activities as mineral extraction, livestock grazing, habitat enhancement projects, and recreation. The program responds to a need to maintain an adequate transportation system to provide access to and use of public land resources. Travel designations for motorized travel (open, limited, closed) include off-road vehicles.

For the purposes of this analysis, adverse impacts to travel and transportation management are those that restrict travel (e.g., managing areas as closed or limited to motorized travel, or road closures). In general, adverse impacts to CTTM are greater when areas are closed to motorized travel than when travel is limited. Management limiting motorized travel to designated roads and trails is more restrictive than limiting travel to existing roads and trails and would therefore result in greater adverse impacts to CTTM. Limiting travel to designated roads and trails only allows motorized vehicle use in areas defined with specific signage or areas identified in travel management plans. Beneficial impacts result from management that increases the number or quality of roads and trails, or that provides opportunities for access on- or off-road using motorized, mechanized, equestrian, or foot travel. Beneficial impacts also include improvements to travel that reduce potential health and safety concerns associated with travel and transportation use in the Planning Area.

This section does not address the adverse or beneficial impacts of travel and transportation management on other resources and resource uses. While impacts from travel and transportation

management to other program areas do occur and are considered as part of travel management planning, in this RMP, these types of impacts are described under the resource or resource use affected by this management. For example, Section 4.4.6 *Wildlife* addresses the impacts to elk from seasonal closures in elk crucial winter range, while this section addresses the impacts of this restriction to access and travel across BLM-administered lands.

Direct impacts to CTTM include actions that restrict or enhance road or trail use in the Planning Area. Direct impacts include closures or rerouting of trails and roads due to safety concerns such as shooting ranges and H₂S-related health concerns. Indirect impacts result from management that limits, restricts, or enhances development or activities that require travel and transportation use and access (e.g., ROW development, recreation, withdrawals).

4.6.4.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- The analysis assumes OHV designations are to be fully implemented 5 years after approval of this RMP.
- The greater the area of authorized roads open to motorized vehicles, the greater the benefit to travel management. Reductions to road density result in beneficial impacts to some resources (e.g., big game, soils), but may require additional effort for users (e.g., longer travel routes).
- Demand for new ROWs or access is expected to decrease because there is existing infrastructure. ROW applications for energy related transportation facilities (e.g., roads, pipelines) are expected to increase with the number of RFDs.
- Existing ROWs granted to other parties for access across the public lands are not affected by this RMP.
- The average road width is 12 feet.

4.6.4.2 Summary of Impacts by Alternative

Impacts to CTTM would result from travel designations that open, limit, or close areas to travel. Additional impacts would result from management that affects the number or quality of roads and trails, or management that affects opportunities for access on- or off-road using motorized, mechanized, equestrian, or foot travel.

Alternative C would result in the most new road and trail development, primarily due to the larger acreage open to cross-country motorized travel, followed by alternatives D and F, B, A, and E. Under alternatives D and F, the BLM specifically establishes the most new trails and roads for motorized, mechanized, and primitive recreational uses, but it does not manage as many acres as open to cross-country motorized travel as under Alternative C.

ROW exclusion areas would prohibit all ROW actions including the construction of new roads that could be used for motorized vehicle use under Alternative E, unless they can be co-located with existing ROWs only to access valid existing rights. ROW exclusion areas would restrict the development of new travel routes most under alternatives E and B, followed by alternatives F, A, D, and C.

Alternatives B and E include the most limitations on and closures to motorized and mechanized vehicle use for resource protection. Therefore, these alternatives would cause the greatest adverse impacts to access opportunities for motorized vehicle use, followed by alternatives F, D, A, and C.

Alternatives B and E limit the most acreage to designated roads and trails in the Planning Area (2,416,378 acres), followed by alternatives F (1,820,427 acres), D (1,159,557 acres), C (1,020,748 acres), and A (797,077 acres). The area limited to existing roads and trails is greatest under Alternative A (2,137,574 acres) followed by alternatives C (2,137,574 acres), D (1,955,943 acres), F (1,295,072 acres), E (592,742 acres), and B (592,563 acres). Alternatives E and B close the largest area to motorized vehicle use (170,253 acres), followed by Alternative A (68,115 acres), alternatives D and F (61,010 acres), and C (9,274 acres). Due to the size of the Planning Area and the limited number of new projected roads, restrictions on motorized and/or mechanized travel on existing routes may have a greater effect on travel and transportation management than the miles or location of new road development.

Overall, Alternative C would cause the fewest adverse impacts (and the most benefits) to CTTM, followed by alternatives D, A, F, B, and E.

4.6.4.3 Detailed Analysis of Alternatives

Each of the alternatives includes an increase in the level of travel management planning to improve travel management in the Planning Area. Certain resource management actions would result in adverse impacts to CTTM by placing limitations on the development of new routes or limiting access to portions of the Planning Area in ways that affect the ability to meet multiple-use objectives.

Impacts Common to All Alternatives

Management of resources and resource uses that affect travel and transportation management include mineral resources, recreation, special designations, soil, water, cave and karst resources, fish and wildlife resources, special status species, cultural resources, and paleontological resources. Appendix R includes a travel designation matrix that describes specific travel management designations by area. Unless otherwise specified, motorized vehicle use on BLM-administered land is limited to existing roads and trails on an interim basis until completion of travel management planning. Terms “interim existing roads and trails” or “existing roads and trails” are used throughout the document to identify areas of low travel management planning priority. Interim existing roads and trails may be maintained for continued access until completion of a travel management plan.

Increased development for oil and gas and other minerals would modify the road network by creating new travel routes, which would provide new travel and access opportunities throughout the Planning Area. Under Alternative A, approximately 50 percent of anticipated new road development would be oil and gas related (Appendix T), and this development would increase access and provide opportunities for recreational travel, particularly for OHVs. Routine and emergency maintenance of these roads would be required to maintain access and to ensure that the roads are maintained and used in accordance with other resource objectives. After mineral activities conclude and a road is no longer needed for the authorized purpose, a review would determine if the road meets BLM travel management objectives. If the road does not meet the needs and objectives of the BLM transportation system in the Planning Area or does not provide access for multiple use or administrative use, the operator would be required to reclaim the road. The development of mineral resources may adversely impact CTTM by creating hazardous conditions, noxious odors, and dangerous gas (such as H₂S).

Management for other resources including vegetation, cultural resources, special status species, and paleontological resources may result in adverse impacts to CTTM by restricting trails or limiting use for the protection of resource values. Some special designations (such as ACECs) and areas with important resource values (such as some educational trails or special status species habitat) restrict motorized

vehicle use and other forms of travel under all the alternatives. Such restrictions would generally result in adverse impacts to CTTM by limiting or restricting travel in these areas.

Limiting motorized travel to designated roads and trails would limit travel to areas specifically designated for travel through appropriate signage or other methods. Although limiting motorized travel to designated roads and trails would result in greater adverse impacts to CTTM than limiting travel to existing roads and trails, travel would still be allowed in these designated areas. Under all alternatives, motorized vehicle use is limited to designated roads and trails in the following areas:

- Over important caves or cave passages
- Medicine Lodge and Upper Renner Wildlife Habitat Areas (with a seasonal closure)
- Essential and recovery habitat for threatened or endangered species
- Areas containing important cultural and paleontological resources
- Bald Ridge Area (with a seasonal closure)
- Twin Creek Trail (with a seasonal closure)
- Carter Mountain area (with a seasonal closure)
- Little Mountain area (with a seasonal closure on a portion of the area)
- The Brown/Howe Dinosaur Area ACEC
- Upper Nowood and South Brokenback areas
- LU Sheep Company cooperative area
- Rattlesnake Mountain
- McCullough Peaks Area

Closing areas to motorized vehicle use would cause the greatest adverse impacts to travel and transportation use compared to other travel limitations (limited to existing, limited to designated, seasonal restrictions) by prohibiting use in certain areas. Under all alternatives, the following areas are closed to motorized vehicle use:

- Spanish Point Karst ACEC
- Duck Swamp-Bridger Trail Environmental Education Area
- Salt Lick Trail
- Gooseberry Badlands Interpretive Trail
- Paint Rock Trail
- Lone Tree Trail
- Canyon Creek Access Trail
- Bald Ridge Area (seasonal)
- Cottonwood Creek Trail
- Pete's Canyon Trail
- Five Springs Road (beyond the locked gate in the CYFO)

Under all alternatives, travel designations, closures, or routing of roads and trails in areas that pose health and safety risks would result in long-term impacts to CTTM. Areas closed year-round to motorized and mechanized vehicle use to protect visitor safety include the Lovell shooting range, the rifle range west of Worland, and the Cody Archery Range.

Under all alternatives, implementing existing travel management plans in the following areas would benefit CTTM by providing site-specific travel designations that accommodate appropriate access while considering resource protection and user safety:

- Carter Mountain ACEC
- Little Mountain
- Upper Nowood
- South Brokenback
- Renner (Upper and Lower) Wildlife Habitat Management Units
- Medicine Lodge Wildlife Habitat Management Units
- Paint Rock Area
- Cooperative Management Agreement between Bureau of Land Management, Worland District, LU Sheep Company, the Wyoming Game and Fish Department, and the Wyoming State Board of Land Commissioners (LU Management Agreement)
- Rattlesnake Mountain

Under all alternatives, LAUs are closed to over-snow travel, which would result in adverse impacts to CTTM by restricting travel in these areas.

Implementing the site-specific management documented in travel management plans would benefit the specific goals described in these documents, such as minimizing impacts to resources (e.g., soils) or protecting the characteristics of specially designated areas (e.g., WSAs). Travel management plans developed subsequent to this RMP would benefit CTTM by addressing the maintenance and use of roads and trails considering site-specific conditions.

Allowing pedestrian and equestrian travel on or off roads and trails, except for limited seasonal restrictions for the protection of resources in the Bald Ridge Area, would benefit CTTM by allowing these types of travel throughout the Planning Area.

Restrictions and limitations on surface-disturbing activities associated with water quality, watershed, and soils management, would result in adverse impacts to CTTM by restricting or limiting the development of new roads for the protection of these resources.

Alternative A

Resource Uses

Alternative A would result in approximately 847 miles (1,233 acres) of new road and trail creation due to user-pioneered routes in areas open to cross-country motorized travel and new BLM-created routes. Additionally, the BLM anticipates 1,351 miles (1,966 acres) of short-term road creation, of which 675 miles (983 acres) is anticipated to remain in the long term following reclamation (Appendix T). These roads would primarily result from ROW authorizations related to mineral and other facility developments under this alternative.

New recreational roads and trail development and improvements to the existing travel network would result in beneficial impacts by increasing opportunities for motorized recreational use and maintaining or improving the quality of existing routes. Specific new road and trail management actions that would result in beneficial impacts include developing scenic driving loops in the Badlands SRMA, and access improvements in the Trapper Creek, Paint Rock, South Bighorns, and Canyon Creek areas, which

Comprehensive Travel and Transportation Management

includes road and trail maintenance, and possible new trail and route construction to enhance access. Alternative A opens 1,311 acres to off-road motorized vehicle use.

Management of ROW avoidance and exclusion areas would result in long-term impacts to travel and transportation management by limiting or restricting the development of roads authorized through a ROW permit, and by restricting the routing of new roads. Alternative A manages 940,943 acres as ROW avoidance areas and 61,147 acres as ROW exclusion areas.

Recreation management areas would result in long-term impacts to travel and transportation by prescribing travel designations in these areas. Under Alternative A, motorized vehicle use in SRMAs and ERMAs is generally limited to existing or designated roads and trails (see Appendix R). The WSAs in the Badlands SRMA are the only recreation-related management areas closed to motorized vehicle use managed for their wilderness characteristics (e.g., outstanding opportunities for solitude, and primitive and unconfined recreation) that may not be compatible with motorized vehicle use.

Special Designations

Alternative A restricts motorized travel to protect resources and values in special designations (ACECs, WSAs, WSRs, NHTs). These restrictions limit motorized vehicle use in these areas or close all or certain portions of an area, which would affect CTTM.

Of the nine ACECs designated under this alternative, seven limit motorized vehicle use to designated roads and trails (with a seasonal closure in the Carter Mountain ACEC); Alternative A limits motorized travel in the Big Cedar Ridge ACEC to existing roads and trails, and the Spanish Point ACEC is closed to motorized use. Four WSAs are closed to motorized vehicle use, with use limited to existing primitive routes in the Cedar Mountain and Honeycombs WSAs, and limited to designated primitive routes in the Alkali Creek, McCullough Peaks, Medicine Lodge, and Trapper Creek WSAs. Most of the WSR eligible waterway segments are managed to limit motorized vehicle use to designated roads and trails or close the areas to motorized vehicle use. Management under Alternative A includes avoidance of surface-disturbing activities in view within ¼ mile of the Nez Perce (Neeme-poo) NHT and Other Historic Trails, which would restrict the construction of new roads, but does not specifically close motorized use (managed as limited to existing roads and trails).

Resources

Travel designations (e.g., seasonal restrictions) and mitigation measures to protect wildlife resources and threatened and endangered species and important habitats would restrict the timing of surface-disturbing and other disruptive activities, which would limit or restrict the development of new roads.

Under Alternative A, requiring the closure of spur roads after completion of timber management practices and limiting motorized vehicle use to designated roads and trails in areas with fragile soil, which may require the closure of some existing, undesignated routes in these areas, would result in adverse impacts to CTTM. The closure of spur roads may limit opportunities for new access if they occur in areas where routes did not previously exist.

Proactive Management

Beneficial impacts to CTTM under Alternative A would result from allowing open cross-country motorized vehicle use on 1,311 acres and over-snow travel on a case-by-case basis, and managing most of the Planning Area as limited to existing roads and trails (2,137,574 acres). The BLM manages for or tolerates cross-country motorized travel in several locations across the Planning Area, including the Worland OHV area, the Bentonite Hills area, the Lovell Lakes “Motocross” area, hill climbing areas near Cowley, the Rattlesnake Ridge area, and the Basin Gardens area. Allowing cross-country travel in these

areas and the continued management of most of the Planning Areas as limited to existing roads and trails would provide motorized and other non-motorized travel opportunities across most of the Planning Area. In addition, travel restrictions and limitations in the Paint Rock area, Dry Farm Road area, and LU Sheep Company cooperative area, and implementation of the travel management plans in the South Brokenback, Renner Units, Medicine Lodge, Upper Nowood, McCullough Peaks, and Little Mountain areas would clarify routes available for travel and help to target management to meet the desired outcomes for these areas.

Allowing off-road motorized (OHV) and/or mechanized (mountain bike) vehicle use outside of the open areas to provide access for big game retrieval and campsite access would be beneficial impacts because it would increase access.

Alternative B

Resource Uses

Compared to Alternative A, Alternative B would result in fewer new roads from ROW authorizations and fewer new roads in locales open to cross-country motorized travel or from BLM road and trail creation. Alternative B would result in 1,908 miles (2,776 acres) of new road and trail creation due to user-pioneered routes in areas open to cross-country motorized travel and new BLM-created routes (Appendix T). Primarily the result of ROW authorizations, Alternative B would result in an additional 845 miles (1,229 acres) of short-term road creation, of which 422 miles (615 acres) is anticipated to remain in the long term following reclamation (Appendix T).

Alternative B would benefit CTTM through new recreational road and trail development similar to Alternative A, but to a greater extent. Alternative B includes motorized touring loops in the Trapper Creek RMZ (connecting with the Paint Rock RMZ and Bighorn National Forest), the Paint Rock RMZ (connecting with the Bighorn National Forest and the Brokenback/Logging Road RMZ), and the Brokenback/Logging Road RMZ (connecting with the aforementioned areas). Alternative B also includes more new trailheads and trails development for recreational use, such as new trails in the Canyon Creek and Horse Pasture SRMAs, to enhance mechanized and primitive forms of travel. Alternative B would result in greater beneficial impacts to CTTM from the establishment of new motorized, mechanized, and primitive travel routes than Alternative A.

Impacts to CTTM from ROW management would result in impacts similar to Alternative A, although to a greater extent because Alternative B manages more area as ROW avoidance and exclusion areas. As a result, Alternative B would result in greater adverse impacts to CTTM from restrictions and limitations on new roads and routes authorized through ROWs, compared to Alternative A.

Alternative B limits most motorized vehicle use in SRMAs and ERMAs to designated roads and trails (see Appendix R). Alternative B would close the Wild Badlands RMZ (in the Badlands SRMA), and the Horse Pasture, Beck Lake, and Newton Lake Ridge SRMAs to motorized vehicle use. Closing the Rattlesnake Ridge area, which contains high levels of H₂S gas from oil and gas development that poses a substantial health risk to trail users, would cause long-term impacts to CTTM. Although the BLM would construct more trailheads and access routes under this alternative compared to Alternative A, management of recreation areas under Alternative B would limit or close more areas to motorized travel, which would cause greater adverse impacts to CTTM.

Special Designations

Managing special designations under Alternative B would result in the greatest adverse impacts to CTTM compared to Alternative A. Although the types of impacts would be similar to those under

Alternative A, Alternative B places more restrictions on motorized travel to protect resources in areas with special designations. Overall, motorized travel restrictions in special designations under Alternative B would result in greater adverse impacts to access opportunities. Adverse impacts would include new constraints on access to areas that were previously accessible to motorized vehicles.

Of the 17 ACECs designated under this alternative, 14 limit motorized vehicle use to designated roads and trails (with a seasonal closure in the Carter Mountain and Rattlesnake Mountain ACECs and partial closures in the Clarks Fork Canyon and Sheep Mountain ACECs). Alternative B closes most WSR suitable waterway segments to motorized and mechanized vehicle use. The alternative closes all ACECs and WSR suitable waterway segments to over-snow motorized travel, which may adversely affect other resource programs. For example, closing the Dry Medicine Lodge WSR suitable waterway segment to motorized vehicle use would adversely affect the ability of the WGFD and others to access the Medicine Lodge Wildlife Habitat Management Area. Alternative B manages all lands with wilderness characteristics specifically to preserve their wilderness characteristics and limits motorized vehicle use to designated roads and trails in these areas, which have no specific travel designations under Alternative A.

Motorized vehicle use in areas in view within 5 miles of the Nez Perce (Neeme-poo) NHT and Other Historic Trails is limited to designated roads and trails, which would restrict the use of non-designated routes near the NHT more than Alternative A.

Resources

Under Alternative B, the emphasis of resource protection over resource use would result in more restrictions on motorized vehicle use compared to Alternative A. Increased restrictions that limit or close motorized travel would result in adverse impacts to CTTM.

Travel designations (e.g., seasonal restrictions) and mitigation measures to protect wildlife resources, special status species, and important habitats would result in impacts to CTTM similar to Alternative A, although to a greater extent because Alternative B includes more restrictions in these areas. Limiting motorized vehicle use to designated roads and trails (with seasonal closures) in big game crucial winter range would restrict access to and opportunities for travel in these areas. Seasonally closing greater sage-grouse Key Habitat Areas from March 15 to June 31 would adversely affect travel in these areas by restricting the use of some routes or eliminating opportunities for travel through some areas during a portion of the year to a considerably higher degree than under Alternative A. Under Alternative B, partially closing the Absaroka Front Management Area (130,872 acres) to motorized vehicle use and limiting use to designated roads and trails in the remainder of the area would result in adverse impacts to CTTM in the area by limiting travel opportunities.

Under Alternative B, closing roads used for timber access and hauling that are not required for existing uses would result in adverse impacts to CTTM by reducing available routes and access for travel.

Limiting motorized vehicle use to designated roads and trails for the protection of cultural resources in the Gebo/Crosby Area would result in adverse impacts to CTTM in this area by limiting travel opportunities.

Prohibiting off-road motorized (OHV) (and/or mechanized [mountain bike]) vehicle use for big game retrieval or dispersed campsites in areas with limited travel designations would substantially restrict access in these areas, adversely affecting CTTM more than Alternative A.

Proactive Management

Beneficial impacts to CTTM under Alternative B would result from allowing open cross-country motorized vehicle use on 3,132 acres and limiting motorized vehicle use to existing roads and trails (592,563 acres). Overall, Alternative B includes more restrictions and fewer beneficial proactive management actions for motorized vehicle use than Alternative A. Under Alternative B, over-snow vehicle use would be subject to more restrictive requirements (e.g., an average of 12 inches of snow) before it would be allowed, with the special designations and wildlife habitat areas discussed previously closed entirely to this type of travel. The beneficial impacts to winter, over-snow motorized vehicle use under Alternative A would not be realized under Alternative B.

Alternative B would implement and maintain the current travel management plans identified under *Impacts Common to All Alternatives* and implement new travel management plans that will cover the remaining areas managed as Designated Roads and Trails. Alternative B closes 150 percent more area to motorized vehicle use on BLM-administered public lands than Alternative A. Therefore, Alternative B would cause greater adverse impacts to CTTM by limiting or closing more areas to motorized travel than under Alternative A.

Alternative C

Resource Uses

Compared to the other alternatives, Alternative C would result in the greatest area of new roads from ROW authorizations and new roads in locales open to cross-country motorized travel or from BLM road and trail creation. Based on projected long-term surface disturbance, Alternative C would result in 8,873 miles (12,907 acres) of new road and trail creation due to user-pioneered routes in areas open to cross-country motorized travel and new BLM-created routes (Appendix T). Primarily the result of ROW authorizations, Alternative C is projected to result in 3,188 miles (4,638 acres) of short-term road creation, of which 1,594 miles (2,319 acres) would remain in the long term following reclamation (Appendix T).

Alternative C would result in similar types of beneficial impacts to motorized travel and opportunities for access from new recreational road and trail development as the other alternatives, but to a lesser extent. Alternative C establishes hiking trails in developed recreation areas and an access road at Rainbow Canyon; however, overall management under this alternative would result in the establishment of fewer new recreational travel routes compared to the other alternatives. Alternative C may result in the greatest amount of new user-pioneered roads and trails because it contains the greatest area open to cross-country motorized travel.

Impacts to CTTM from ROW management would be similar to those described under Alternative A. Alternative C includes more area designated as ROW avoidance and exclusion compared to Alternative A, but less than alternatives B and D. As a result, adverse impacts to CTTM from ROW management would be less than alternatives B and D, but greater than Alternative A.

Most motorized vehicle use in the Planning Area is limited to existing roads and trails under Alternative C, whereas the alternative manages the Rattlesnake Ridge SRMA and the Basin Gardens Play Area ERMA as open for cross-country travel.

Special Designations

Overall, motorized travel restrictions in special designations under Alternative C would result in the fewest adverse impacts to CTTM. Though the types of impacts would be similar to those described

Comprehensive Travel and Transportation Management

under Alternative A, Alternative C places the fewest restrictions on motorized travel to protect resources in areas with special designations. Alternative C designates only two ACECs, the Brown/Howe Dinosaur Area and Spanish Point Karst ACECs, and travel management in these areas does not vary across alternatives. Motorized vehicle use is limited to designated primitive routes in all WSAs in Alternative C, with impacts similar to those described under Alternative A.

Motorized vehicle use in areas in view within ¼ mile of the Nez Perce NHT and Other Historic Trails is limited to designated roads and trails, which would limit motorized vehicle use in areas proximate to these trails more than Alternative A, but less than Alternative B.

Resources

Under Alternative C, the emphasis of resource use over resource protection would result in decreased restrictions on motorized vehicle use compared to the other alternatives. As a result, Alternative C includes the most area open and limited to existing or designated roads and trails; which would benefit CTTM in the Planning Area by maximizing travel opportunities.

Stabilizing heavily eroded or washed out roads and trails, and allowing timber management spur roads to remain open to meet travel and other resource goals, would benefit CTTM by increasing the accessibility of BLM-administered land.

Management and restrictions in wildlife, special status species, and crucial habitat would result in less adverse impacts to CTTM compared to Alternative B. Travel management in the Absaroka Front Management Area would be less restrictive than Alternative B resulting in increased travel and access opportunities in this area.

Under Alternative C, as in Alternative A, allowing off-road motorized (OHV) and/or mechanized (mountain bike) vehicle use off of existing roads and trails to provide access for big game retrieval and campsite access would be beneficial because it would increase access.

Proactive Management

Beneficial impacts to CTTM under Alternative C would result from allowing the most open cross-country motorized vehicle use on 14,830 acres and allowing over-snow travel, unless precluded by other resource needs, and managing most of the Planning Area as limited to existing roads and trails (2,137,574 acres).

Overall, Alternative C includes the fewest restrictions and the greatest amount of beneficial proactive management actions that allow opportunities for motorized and mechanized vehicle access to BLM-administered lands. Under Alternative C, the BLM would maintain any previously implemented site-specific travel management plans; impacts would be similar to those described under Alternative A. Allowing off-road motorized (OHV) and/or mechanized (mountain bike) vehicle use for big game retrieval and accessing dispersed campsites would result in impacts similar to those described under Alternative A. Overall, the motorized travel restrictions for the Planning Area under Alternative C would result in the least adverse impacts to CTTM compared to the other alternatives.

Alternative D

Resource Uses

Alternative D would result in the same amount of new roads from ROW authorizations as Alternative A and the second-most new roads in locales open to cross-country motorized travel or from BLM road and trail creation. Based on projected surface disturbance, Alternative D would result in 4,001 miles (5,820

acres) of new road and trail creation due to user-pioneered routes in areas open to cross-country motorized travel and new BLM-created routes (Appendix T).

Alternative D would benefit CTTM from new recreational road and trail development similar to Alternative B, but to a greater extent. Under Alternative D, the BLM would develop the same motorized touring loops, trails, and trailheads in SRMAs and RMZs as Alternative B. Alternative D opens 5,885 acres to off-road motorized vehicle use, the second most among the alternatives.

Impacts to CTTM from ROW management would be similar in type but greater in extent than those under alternatives A and C and less than under Alternative B. Under Alternative D, the BLM would manage the third-largest acreage as ROW avoidance areas and exclusion areas among the alternatives.

Adverse impacts from restricting motorized vehicle use in recreation areas would be similar to those under Alternative B, but to a lesser extent. Under Alternative D, the BLM would place fewer restrictions on motorized vehicle use in the Basin Gardens area and the McCullough Peaks, Beck Lake, Newton Lake Ridge, and Horse Pasture SRMAs than under Alternative B, but more than under alternatives A and C. Alternative D opens 4,421 acres to cross-country motorized vehicle use in the Basin Gardens Play Area SRMA, which would benefit CTTM.

Special Designations

The types of impacts to CTTM from the management of special designations would be similar to those described under Alternative A; however, special management criteria for routes within sage-grouse PHMAs would be implemented in subsequent travel management planning efforts under Alternative D. Due to more motorized vehicle use restrictions to limit access, management of special designations under Alternative D would result in a greater adverse impact to CTTM than alternatives A and C, but less than Alternative B. Alternative D designates all nine ACECs designated under Alternative A with similar restrictions on motorized and mechanized vehicle use. Additionally, Alternative D designates the PETM, Clarks Fork Canyon, and Sheep Mountain ACECs, but there would be fewer restrictions on motorized and mechanized vehicle use in these areas than under Alternative B.

Restrictions on motorized vehicle use in WSAs would result in impacts to CTTM similar to Alternative A. Impacts to CTTM may be to a lesser extent because designated primitive routes in WSAs may include the primitive routes inventoried during the initial WSA assessment, generally expanding access. However, impacts to CTTM may be to a greater degree because CTTM planning may designate only those routes inventoried during the initial WSA assessment, or even close those routes. Limiting motorized vehicle use to existing roads and trails in view within 5 miles of the Nez Perce (Neeme-poo) NHT would cause fewer adverse impacts to CTTM than would restrictions imposed around the NHT under alternatives B and C, but greater than those imposed under Alternative A.

Resources

In general, Alternative D emphasizes resource protection more than alternatives A and C, but less than Alternative B, resulting in proportional access restrictions and adverse impacts to CTTM. Adverse impacts from travel designations (e.g., seasonal restrictions) and mitigation measures to protect wildlife resources, special status species, and important habitats would be similar in type to Alternative A, although to a greater extent than under alternatives A and C and a lesser extent than under Alternative B. Restrictions on motorized vehicle use in the Absaroka Front Management Area would result in impacts similar to Alternative B. Allowing temporary closures of designated roads, trails, or geographic areas within big game crucial winter range would result in impacts similar to Alternative B, although to a lesser extent. Limiting motorized vehicle use to designated roads and trails to protect resource values in

essential and recovery habitat for threatened and endangered species and areas over important caves or cave passages would adversely affect CTTM by limiting access to these areas.

Closing timber haul roads after completion of timber management would result in impacts similar to Alternative A. Restricting off-road motorized (OHV) and mechanized (mountain bike) vehicle use to within 300 feet of established roads in areas with a limited designation (existing or designated roads and trails) would result in impacts similar to Alternative B, although to a lesser extent.

Proactive Management

Beneficial impacts to CTTM under Alternative D would result from allowing the second most open cross-country motorized vehicle use on 5,885 acres and allowing over-snow travel on a case-by-case basis, and managing motorized vehicle use in most of the Planning Area (1,955,943 acres) as limited to existing roads and trails. Alternative D limits motorized vehicle use to designated roads and trails on 61 percent of BLM-administered land, 14 percent more than Alternative C, 46 more than Alternative A, and 52 percent less than Alternative B. Alternative D closes motorized vehicle use on a similar amount of acreage as Alternative A, but would result in greater adverse impacts to CTTM than alternatives A and C by limiting motorized vehicle use to designated roads and trails on more acreage than those alternatives.

Alternative E

Resource Uses

Alternative E would result in a similar number of new roads from ROW authorizations and new roads in locales open to cross-country motorized travel or from BLM road and trail creation as anticipated under Alternative B (839 miles [1,221 acres] of new road and trail creation due to user-pioneered routes and 422 miles [615 acres] from ROW authorizations in the long term) (Appendix T). However, unlike Alternative B, Alternative E contains a Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres) that applies additional restrictions on new road and trail development. Management in that ACEC that limits the allowable surface disturbance, prohibits construction within 4 miles of leks, and restricts the types of routes that can be constructed could limit the BLM's ability maintain a transportation system that meets certain user needs where those needs conflict with the predominant management objective (i.e., the protection of greater sage-grouse habitat).

Management of new recreational road and trail development under Alternative E is the same as Alternative B, and impacts to CTTM would be the same as Alternative B.

Impacts to CTTM from ROW management would be similar to Alternative A, although to a greater extent because Alternative E manages more area as ROW avoidance and exclusion areas. Alternative E includes the largest ROW exclusion area (1,322,879 acres) compared to the other alternatives. As a result, Alternative E would result in the greatest adverse impacts to CTTM from restrictions and limitations on new roads and routes authorized through ROWs. Alternative E prohibits new roads and routes authorized through a ROW permit unless they can be co-located with existing ROWs only to access valid existing rights.

Alternative E limits motorized vehicle use to designated roads and trails in the same areas and imposes the same seasonal closures (March 15 through June 30) as Alternative B (Map 73), and impacts to CTTM would be the same as Alternative B.

Special Designations

Special designations under Alternative E are the same as Alternative B, with the exception of the additional Greater Sage-Grouse Key Habitat Areas ACEC. Managing special designations under Alternative E would result in the greatest adverse impacts to CTTM compared to the other alternatives. Although the types of impacts would be similar to those under Alternative B, Alternative E places more restrictions on motorized travel to protect resources in areas with special designations than any other alternative. Overall, motorized travel restrictions in special designations under Alternative E would result in the greatest adverse impacts to access opportunities.

Resources

Management of wildlife habitat, forest products, harvest and vegetation treatments, cultural sites, and other resource considerations under Alternative E is the same as Alternative B, and impacts to CTTM from restrictions to protect resources would be the same as Alternative B. Like Alternative B, the emphasis of resource protection over resource use would result in more restrictions on motorized (OHV) and mechanized (mountain bike) vehicle use under Alternative E, compared to the other alternatives. Restrictions of Alternative E that limit or close motorized travel would result in proportional adverse impacts to CTTM.

Proactive Management

Alternative E allows open cross-country motorized vehicle use on the same amount of acreage as Alternative B, and the resulting beneficial impacts to CTTM would be the same as Alternative B. Alternative E also closes the same amount of acreage to motorized vehicle use as Alternative B, and adverse impacts to CTTM would be the same as Alternative B.

Similar to Alternative B, Alternative E would implement and maintain the current travel management plans identified under *Impacts Common to All Alternatives* and would implement new travel management plans that cover the remaining areas managed as Designated Roads and Trails. Under all alternatives, the BLM would designate routes on all BLM-administered land within the Planning Area. Alternative E limits motorized vehicle use to designated roads and trails on 2,416,378 acres. Notably, Alternative E prioritizes the conservation of greater-sage grouse Key Habitat Areas (1,232,583 acres) above other uses, potentially leading to greater route limitations in this area than under other alternatives. However, authorized or permitted uses that specify allowable access would not be affected by travel management designations.

Alternative F

Resource Uses

Alternative F would result in a greater amount of new roads from ROW authorizations (461 miles [672 acres]) than alternatives B and E, but fewer than alternatives A, C, and D. Alternative F also allows the third-most new roads in locales open to cross-country motorized travel or from BLM road and trail creation. Based on projected surface disturbance, Alternative F would result in 2,693 miles (3,917 acres) of new road and trail creation due to user-pioneered routes in areas open to cross-country motorized travel and new BLM-created routes (Appendix T).

Management of new recreational road and trail development, areas open to off-road motorized vehicle use (OHV play areas), and motorized vehicle use in recreation management areas (Special Recreation Management Areas [SRMAs], Resource Management Zones [RMZs], and Extensive Recreation

Recreation

Management Areas [ERMAs]) under Alternative F is the same as under Alternative D, and impacts to CTTM would be the same as Alternative D.

ROW management under Alternative F is similar to Alternative D, and impacts to CTTM would be the same as Alternative D.

Special Designations

Special designations under Alternative F are the same as Alternative D, with the exception of the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres). The types of impacts to CTTM from special designations management under Alternative F would be similar to Alternative D. However, due to additional limitations on motorized vehicle use in the Greater Sage-Grouse PHMAs ACEC from limiting travel to designated roads and trails, Alternative F would result in a greater adverse impact to CTTM than alternatives A, C, and D, but less than alternatives B and E.

Resources

Management of wildlife habitat, forest products, vegetation treatments, cultural sites, and other resource considerations under Alternative F are the same as Alternative D, and impacts to CTTM from restrictions to protect resources would be the same as Alternative D. Like Alternative D, Alternative F emphasizes resource protection more than alternatives A and C, but less than alternatives B and E, resulting in proportional access restrictions and adverse impacts to CTTM.

Proactive Management

Alternative F allows open cross-country motorized vehicle use on the same amount of acreage as Alternative D, and the resulting beneficial impacts to CTTM would be the same as Alternative D. Alternative F also closes the same amount of acreage to motorized vehicle use as Alternative D, and adverse impacts to CTTM would be the same as Alternative D.

Under all alternatives, the BLM would designate routes on all BLM-administered land within the Planning Area. Alternative F would limit motorized vehicle use to designated roads and trails on more acreage (1,820,427 acres) of the Planning Area than alternatives A, C, and D (Map 74), and subsequently would result in greater overall adverse impacts to CTTM than alternatives A, C, and D. Alternative F would limit motorized vehicle use to existing roads and trails on less acreage (1,295,072 acres) of the Planning Area than Alternative D (1,955,943 acres). However, authorized or permitted uses that specify allowable access would not be affected by travel management designations.

4.6.5 Recreation

This section describes potential impacts to recreational uses of public lands under the alternatives in terms of direct, indirect, short-term, and long-term impacts.

Direct impacts to recreation affect the recreational resources, settings, experiences, and ultimately the desired beneficial outcomes from uses on public lands, including hunting, motorized travel (including OHV use), target shooting, wildlife viewing, camping, and other activities. Direct impacts also include impacts to recreational facilities such as campsites. Certain resource development or management actions (e.g., oil and gas development, fire and fuels management) will interfere with realizing desired beneficial outcomes, which will displace recreational users from their desired setting-specific areas, resulting in direct adverse impacts to recreation. Indirect impacts occur when competing uses of the land adversely affect natural recreational resources or recreational setting character conditions (RSCC) that no longer support desired experiences and beneficial outcomes. For example, impacts to wildlife

habitats from competing land uses that result in a decrease in big game populations will therefore decrease the hunting (recreational) opportunities, and impact the experiences and beneficial outcomes.

Beneficial impacts to recreational resources include actions that improve the desired RSCC, increase recreational opportunities, contribute to better recreational experiences, and ultimately contribute to increase realized beneficial outcomes from recreational use of the public lands. Managing areas as SRMAs and ERMAs benefit recreation by managing for the desired RSCC, and marketing (niche matching) based on identified desired settings, activities, experiences, and benefits. Adverse impacts are those that degrade the desired RSCC, reduce the amount of recreation opportunity, and detract from the recreation experience, resulting in unrealized desired beneficial outcomes for recreational users.

4.6.5.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- The impact of RAMPs will be assessed following completion of the RMP revision.
- The SRMAs will be managed for the Niche, Management Objective, desired RSCC, experiences, and benefits, and Activity Planning Framework specified in the alternatives.
- Traditional recreational uses of Planning Area lands will continue, despite new recreational activities based on new technologies occurring in the area.
- The demand for fishing, floating, camping, OHV use, mountain biking, and new technology-based recreation is expected to increase. The number of hunters will fluctuate with the size of herds and other indirect factors, but because of less interest by younger generations, the number of hunters will decrease ([Outdoor Foundation 2009](#)).
- The incidence of resource damage and conflicts between OHV users and nonmotorized recreationists will increase as OHV use increases.
- Visitation throughout the Planning Area will continue to increase as resource availability and conditions allow. As the population of both neighboring states and the local area continues to grow, the need or search for less crowded or more remote recreational opportunities will continue to bring more people to the public lands in Wyoming.

4.6.5.2 Summary of Impacts by Alternative

Management for surface disturbance, land tenure adjustments, areas closed to mineral development, special designations, proactive recreation management actions, and other resource management actions form the basis for comparing impacts to recreation among the alternatives. Proactive management under alternatives B and E would most enhance facilities and amenities to meet niche demands for recreation while minimizing potential user conflict, followed by alternatives F, D, A, and C. Alternatives B and E would enhance the recreational experience of users expecting a more primitive recreational experience and opportunities for solitude the most, followed by alternatives F, D, A, and C. Dispersed motorized recreation opportunities would be limited to designated areas the most under alternatives B and E, which may result in the greatest adverse impacts to motorized recreation use compared to the other alternatives, followed by alternatives F, D, C, and A. Alternative C would result in the most opportunities for dispersed motorized recreation, but primitive forms of recreation and opportunities for solitude would not be a priority and may diminish as OHV use increases over the planning cycle. Alternative F manages the second-most area for off-road motorized vehicle use, but also

restricts motorized vehicle use to designated roads and trails in the second-most acreage that would limit recreation opportunities for motorized travel.

Special designations and management for resource protection in ACECs and WSRs that maintain their recreation settings for scenery and wildlife viewing would result in the greatest benefit to recreationists under Alternative E, followed by alternatives B, F, A, D, and C.

Alternatives E and B would result in the least amount of surface disturbance, minerals development, ROW authorizations, and other conflicting resource uses that would displace recreation and potentially degrade the recreation setting, followed by alternatives F, D, A, and C. Alternatives B and E would benefit recreational settings the most because these alternatives manage the most areas as SRMAs for desired recreation settings to benefit outcome objectives, activities, experiences, and benefits, followed by alternatives F, D, A, and C. However, alternatives B and E would also result in the greatest impacts to desired experiences and beneficial outcomes through seasonal closures on the greatest acreage among the alternatives; seasonal restrictions on travel could limit the ability of certain recreational users to access some desired recreation areas and sites (e.g., recreation sites in greater sage-grouse Key Habitat Areas) during certain times of the year.

Alternative C manages the fewest areas as SRMAs and would result in the greatest adverse impacts to the desired settings, opportunities, activities, experiences, and beneficial outcomes in areas with substantial recreation values. Alternatives F and D manage more acreage in SRMAs than Alternative A, and while managing these areas for the realization of benefits by maintaining the desired recreational setting character condition (RSCC), SRMAs would result in more beneficial impacts to recreation experiences than under Alternative A.

4.6.5.3 Detailed Analysis of Alternatives

The NHTs and Other Historic Trails, National Back Country Byways, and CTTM sections describe impacts to these resource areas that are often used for recreation. This analysis focuses on impacts to recreational opportunities, experiences, and benefits for users, which often are associated with the recreation setting. Recreation management matrices in Appendix O identify the primary market strategy, niche, recreation management objective, desired RSCC, experiences, and beneficial outcomes, and implementation strategy/actions for each SRMA.

Impacts Common to All Alternatives

Surface Disturbance

Under all alternatives, activities that result in surface disturbance (e.g., facilities construction, clearing land, prescribed fires, and drilling activities related to minerals exploration and development) would result in adverse impacts by displacing recreationists from degrading the desired RSCC, opportunities, experiences, and desired beneficial outcomes for the life of the disturbance, or until the area is reclaimed or recovers. Surface disturbance would more intensively affect areas where the desired RSCC necessitates a high degree of naturalness (i.e., back country). Adverse impacts from surface disturbance would be less intensive in areas where the desired RSCC allows for moderately dominant alterations to the natural setting (i.e., middle country and front country). Development activities that improve legal access to public lands, establish new and improve existing roads, and increase opportunities for motorized travel may benefit recreational experiences. Refer to Appendix O for descriptions of the desired RSCCs throughout the Planning Area. Management actions limiting surface-disturbing activities

in identified SRMAs would benefit recreational experiences by ensuring the maintenance of the recreational setting.

Resource Uses

Under all alternatives, minerals leasing and development would further alter supplemental values important for recreation such as scenic quality and natural, social, and administrative settings, and open previously limited areas to recreational use. The industrialized character associated with oil and gas activity would introduce new contrasting elements affecting the scenic quality of the recreation setting, interfering with recreationists' experiences and beneficial outcomes, which will displace recreationists from their desired settings to alternative areas. Travel off existing roads for "necessary tasks" associated with minerals management and other programs may generate new primitive routes for recreation opportunities, but the proliferation of roads and trails may threaten the recreation setting of certain areas and adversely affect such values as scenic quality, solitude, and wildlife. Hazards associated with road use would be proportional to the amount of mineral activity plus the historical recreational use. Minerals development would cause mostly adverse impacts to recreation under all of the alternatives.

Locatable mineral exploration and mineral materials disposal may result in adverse impacts to recreation. Mining activities may displace recreational activities and have an adverse impact on the desired recreation settings by altering the viewshed of some areas, and associated supplemental values such as wildlife and habitat, resulting in indirect impacts to recreation. Mining activities can also disrupt wildlife and alter habitat resulting in indirect impacts to recreation. Mitigation measures would minimize impacts to recreation resources from surface disturbance, but no mitigation would be applied to locatable mining activities to minimize adverse impacts to scenic qualities. The development of mineral resources may adversely affect recreation management due to hazardous conditions, noxious odors, and dangerous gas (such as H₂S) (see Section 4.8.3 *Health and Safety*). Post-mining reclamation is planned and implemented on a case-by-case basis. Regardless of the measure of success of post-mining reclamation, the landscape, viewshed, habitat, topography, and potentially other desired recreation settings would not be restored to original conditions at a reasonable expense.

Land tenure adjustments, including acquisition and disposal of land, generally benefit recreation if the adjustment considers recreational values. Acquisitions can result in beneficial impacts by improving public access in areas with intermingled land ownership and facilitating increased or improved access to recreation areas and resources such as WSAs and river access points. Private land that fragments BLM-administered land may interfere with recreationists' access, goals, activities, experiences, and benefits, and affect local and regional tourism. Acquiring and consolidating BLM-administered land and disposing of inholdings of private or state land would result in beneficial impacts to recreation, especially in SRMAs, WSAs, and other areas managed for specific recreation experiences. The acquisition of access easements can also increase recreational use across the Planning Area and would generally result in beneficial impacts to recreation.

Development activities associated with ROW authorizations would include renewable energy development, utility/transportation systems development, and communication site development. These developments, especially wind-energy facilities, may have a substantial impact on the recreation setting and recreationists' goals, experiences, and benefits by altering the scenic quality of open space and displacing users.

Under all alternatives, motorized and mechanized travel may enhance some recreationists' goals, experiences, and realize desired beneficial outcomes by allowing greater access to BLM-administered land while impairing those recreation users seeking a nonmotorized recreation experience. Therefore,

impacts from motorized and mechanized travel are likely to be site-specific. The BLM would address these impacts in more detail in assessing RAMPs.

The presence of livestock in a landscape setting is probably not detrimental to the experience of most recreationists; however, on a site-specific level, high levels of livestock use and facilities associated with grazing (e.g., water developments) may degrade recreationists' experiences due to noise, odor, and damage to vegetation. Such impacts would be more likely to occur around campgrounds, picnic areas, and trailheads. Off-road motorized vehicle use to support livestock management activities (e.g., round-ups) may affect the desired recreation settings by introducing new trails that may be used by other motorized travelers introducing new conflicting uses, as well as further augmenting the contrasting elements to the scenic characteristics, all of which would further interfere with recreationists' goals, experiences, and benefits.

Special Designations

Management actions in special designations under all alternatives would maintain legal public access and natural qualities that will maintain the recreational setting characteristics and continue to provide for recreation opportunities and experiences. These actions include continuing the Red Gulch/Alkali Road National Back Country Byway designation and developing educational materials and facilities to enhance the knowledge of the Red Gulch/Alkali Road National Back Country Byway; closing WSAs to renewable energy development and mineral leasing; and various resource protection measures in the Spanish Point Karst ACEC. Resource protection measures also would preclude other forms of recreation, such as motorized travel. Impacts to special designations and the values for which they are designated are discussed in their respective sections of this chapter.

Resources

Management to protect soils and water quality and watershed management actions such as avoidance, mitigation, or application of BMPs (Appendix L) would protect water sources for campground facilities and would enhance recreation opportunities by providing potable water. Water and watershed management activities indirectly protect existing flow conditions and water quality that benefit activities and opportunities such as fishing and other river-related recreational activities, and maintains and enhances other related recreational resources.

Caves provide recreational opportunities but must also be protected for their unique and fragile biological and paleontological resources. Actions that restrict or limit access to caves for resource protection would result in adverse impacts to recreational use in these areas.

Short-term impacts to recreation from fire and fuels management would result in temporary closure of areas during and after fire events (including prescribed burns) and mechanized fuel treatments, which would displace recreationists. Long-term impacts from wildland fire may degrade the recreation setting and displace recreationists.

Temporary recreation displacement would occur during commercial timber harvest activities because of a change in recreation settings, such as increased traffic, dust, noise, and loss of solitude. Logging operations that degrade the physical setting of naturalness may displace visitors. The intensity of the displacement would vary with the change in setting. Allowing harvests of minor wood products would provide recreation opportunities such as fuel wood gathering for campfires and may improve the recreation setting by improving forest health.

Vegetation management actions in riparian, wetland, and upland areas may displace recreationists from closed areas undergoing vegetation treatments (e.g., noxious weed control). In the long term, managing vegetation to meet the *Wyoming Standards for Healthy Rangelands* would, overall, maintain or improve

the desired natural recreational resources and recreation setting conditions, thus improving desired opportunities, activities, experiences, and a realization of desired beneficial outcomes.

Fish and wildlife management decisions affect the habitat and health of fish and wildlife populations. Many recreation activities, such as hunting, wildlife viewing, bird watching, and fishing, would benefit from the presence of healthy and abundant wildlife habitats and populations. Spatial and temporal restrictions (e.g., CSU, TSL), and BMPs and mitigation to protect and improve habitat would benefit recreation under all alternatives, although the extent of these impacts varies by alternative.

Management actions to protect or improve wildlife habitat that restrict certain activities, such as OHV use, may adversely affect some recreationists. Under all alternatives, the construction of new recreation facilities is prohibited in greater sage-grouse PHMAs unless the development would result in a net conservation gain or is required for visitor or resource protection. Combined with other restrictions on recreation and OHV use in PHMAs, management of these areas would generally favor nonmotorized forms of recreation.

Wild horse management actions would protect, maintain, and control viable, healthy herds while retaining their free-roaming nature and providing opportunities for public viewing of wild horses. These actions would maintain a quality recreation setting and provide for unique supplemental values, opportunities, and experiences.

Management actions for cultural resources may require the relocation of potential recreation facilities in areas where the integrity of the setting contributes to NRHP eligibility. Areas containing important cultural and paleontological resources may restrict certain recreational access or activities such as OHV use. However, developing cultural resource interpretive sites and making use of scenic overlooks, signs, and walking trails would increase recreation opportunities in these areas. Such actions may minimally impact recreation opportunities by moving facilities or rerouting access, displacing recreationists to other potentially less desirable areas.

Management of visual resources would maintain the overall integrity of the Planning Area's scenic qualities while allowing for development of existing and future uses. Limiting the visual impacts of management actions in VRM Class I and II areas would retain the recreation setting, whereas VRM Class III and IV areas would allow more modification of the natural environment that may detract from the recreation setting. Altering the recreation setting would influence recreational activities and may displace some recreationists seeking a back country recreation setting. Managing WSAs as VRM Class I areas under all alternatives would benefit recreationists seeking back country settings.

Proactive Management

Recreation management provides opportunities for outdoor recreation activities at both developed sites and dispersed areas. Under all alternatives, the BLM would manage recreation to provide for visitor health and safety, coordinate with other programs to minimize conflicts and adverse impacts to recreation opportunities, protect resources, maintain the desired RSCC, and enhance recreation by managing for realization of desired beneficial outcomes. Proactive management actions that would benefit recreation under all alternatives include continuing a withdrawal from appropriation under the mining laws in the Castle Gardens Scenic Area; maintaining an easement across private land for public access to Rainbow Canyon; retaining recreational access in the Bighorn River HMP/RAMP area; and mitigating surface-disturbing and disruptive activities associated with constructing, maintaining, and using roads, campgrounds, interpretive sites, and other recreation facilities, as described in Appendix H. Short-term benefits from proactive recreation management actions would preserve or increase visitor satisfaction by maintaining recreational settings, opportunities, and experiences. Long-term benefits would result from sustained recreation activity and realization of beneficial outcomes.

Recreation

Managing areas as SRMAs would result in beneficial impacts to recreation in the Planning Area. The BLM manages the respective areas to provide specific “structured” recreation systems (i.e., identified settings, activities, experiences, and beneficial outcomes) based on identified desirable outcomes in areas containing unique recreational resources. SRMA management focuses on meeting outcome objectives developed in response to identified desired activities, experiences, and benefits. Recreation settings are prescribed to achieve the outcome objectives and guide allowable use decisions and management actions. In areas managed as ERMAs, recreation is not the predominant resource use, but recreation is recognized as one of the many uses on public lands. ERMA management actions are custodial in nature to address visitor health and safety, user conflicts, resource protection, and local planning issues. Management actions in ERMAs would result in a lower amount of recreational related focus such as niche-matching, marketing, and desired RSCC than the SRMAs. Table 4-29 summarizes ERMAs and SRMAs by alternative.

Table 4-29. Recreation Management Areas by Alternative

Area	Recreation Management Designation (acres)			
	Alternative A	Alternatives B and E	Alternative C	Alternatives D and F

RMA Recreation Management Area
RMZ Recreation Management Zone
SRMA Special Recreation Management Area

Alternative A

Surface Disturbance

Under Alternative A, a total of 136,253 acres of short-term and 15,646 acres of long-term surface disturbance is projected (Appendix T), most of which would result in adverse impacts to recreation. A portion of this disturbance would result from new facilities development (campsites, interpretive areas) and roads that may benefit recreation, but most would result in short- and long-term adverse impacts by displacing recreation and impairing the recreation setting for those seeking undisturbed landscapes. The intensity of impacts to recreation would depend on the location of surface disturbance in relation to the desired RSCC in the area being disturbed (see *Impacts Common to All Alternatives*). Alternative A manages the third most acreage in SRMAs, and it does not manage for the realization of desired outcomes and benefits to the same degree in these areas as alternatives B and D. Therefore, under Alternative A surface disturbance may limit the realization of benefits to recreationists more than alternatives B and D.

Resource Uses

Oil and gas development in areas of moderate potential (where most development is anticipated) is expected to add 1,184 new federal wells (Appendix T) resulting in 3,552 acres of short-term surface disturbance during the planning cycle (Appendix T). The additional oil and gas facilities, equipment, noise, dust, vehicles, night lighting, pipelines, and human activity would alter the recreation setting to an industrial setting in certain areas, which would interfere with recreationists' goals, and influence their opportunities, activities, experiences, and benefits. Under Alternative A, 3,122,944 acres of BLM-administered surface are available for locatable mineral entry and 10,000 acres of long-term surface disturbance are projected from locatable mining activities. Minerals development would result in adverse impacts by displacing recreation opportunities in areas with degraded scenic qualities. The potential increase in the visitor concentration in alternate recreation settings may detract from the quality of recreational experiences in those areas, especially for those seeking solitude.

Acquisitions and land tenure adjustments under Alternative A may increase recreation opportunities and enhance recreationists' experiences as described under *Impacts Common to All Alternatives*. Considering acquisitions for public access in areas such as the Bighorn and Greybull rivers and in SRMAs could result in beneficial impacts to recreation by increasing recreation opportunities in these areas.

Pursuing withdrawals results in beneficial impacts to recreation by reducing surface-disturbing activities associated with mining, protecting the scenic quality, and maintaining the recreation setting. Alternative A withdrawals of 174,228 acres, including the Beck Lake Scenic Area, result in a direct beneficial impact by preserving the recreation setting of this area.

The BLM considers renewable energy development, including wind-energy development, on a case-by-case basis throughout the Planning Area under Alternative A. Due to the lack of management actions to facilitate its consolidation, wind-energy development may result in adverse impacts to recreation opportunities and scenic values important to the desired RSCC and associated opportunities, experiences, and benefits under Alternative A. The designation of ROW corridors would concentrate ROW authorizations and result in adverse impacts in and around these areas. However, concentrating ROWs in designated areas and avoiding or excluding ROW development in areas may result in beneficial impacts to recreation by prohibiting or limiting ROW infrastructure that can detract from the desired RSCC, opportunities, experiences, and benefits. Alternative A manages 940,943 acres as ROW avoidance and 61,147 acres as ROW exclusion areas.

Alternative A places few restrictions on motorized vehicle use and most of the Planning Area is limited to existing roads and trails, which would result in beneficial impacts by facilitating access for recreation opportunities. Allowing OHV use for big game retrieval would result in beneficial impacts to hunting and recreation. Alternative A, however, opens the smallest area to off-road use, limiting recreation opportunities in this regard. In the 15-mile and Rattlesnake Ridge areas, where cross-country motorized travel is allowed or tolerated, recreationists would have off-road opportunities, though the use of these areas may result in adverse impacts to the cultural and recreational opportunities along some Other Historic Trails (see Chapter 3, Section 3.6.4 *Comprehensive Travel and Transportation Management* for additional information). Allowing OHV use for big game retrieval, dispersed campsite access, and other "necessary tasks" may result in route proliferation and alterations to the scenic qualities of the landscape, which would affect the recreation setting and experience of those desiring solitude or primitive forms of recreation.

Closing Bighorn River tracts and campgrounds to livestock grazing, and managing livestock grazing for the protection and enhancement of other resource values, would maintain the recreation setting and

minimize the potential for the displacement or impairment of recreation opportunities or experiences in these areas.

Special Designations

Special designations under Alternative A would affect the desired RSCC, opportunities, experiences, and realization of beneficial outcomes to recreationists in the Planning Area. Alternative A designates nine ACECs, seven of which have recreation values that include scenery, spelunking, hunting, and camping. Placing various restrictions on activities (e.g., mineral development, motorized vehicle use) that threaten the scenic values and natural setting in these areas would benefit these recreation values. Avoiding surface-disturbing activities and applying an NSO restriction within ¼ mile of the Nez Perce (Neeme-poo) NHT and Other Trails would preserve the recreation setting of these areas.

Managing WSR eligible waterway segments to protect their free-flowing conditions and ORVs, including prohibiting water impoundments, limiting various mineral development activities, preventing an increase in grazing, and managing segments as VRM Class I or II would preserve the recreation setting and would maintain or enhance the primitive and recreational experiences and opportunities these segments provide. Under Alternative A, there are 12 WSR eligible waterways in the West Slope SRMA, and the Clarks Fork of the Yellowstone segment is in The Rivers SRMA. Prohibiting water impoundments, major diversions, or hydroelectric power facilities; pursuing a withdrawal from appropriation under the mining laws; applying NSO restrictions, and limiting geophysical exploration to foot access on various WSR eligible segments would provide beneficial impacts by helping to maintain the desired setting and experiences in these areas. However, closing segments to recreational dredging would adversely affect recreation management by eliminating recreational opportunities in these areas and opening the Middle Fork of the Powder River, Dry Medicine Lodge Creek, and Paint Rock Creek Unit segments to various mineral activity (e.g., leasing, geophysical exploration).

Allowing motorized vehicle use in WSAs may adversely affect recreationists seeking a natural setting and solitude, although recreationists seeking opportunities for motorized travel in remote areas would benefit. The lack of management prescriptions in lands with wilderness characteristics under Alternative A also would threaten the natural setting and opportunities for recreationists seeking solitude in lands with wilderness characteristics. Prior to impacting or impairing wilderness characteristics in lands with wilderness characteristics, however, Alternative A requires project specific reviews that could help reduce the potential for adverse impacts to wilderness characteristics and associated recreational values.

Resources

Impacts from water quality, watershed, and soils management would be similar to those discussed in the *Impacts Common to All Alternatives* section, except for the action authorizing surface discharge of produced water from oil and gas development. The surface discharge of produced waters would change the physical hydrology of receiving waters and may affect water quality and create additional temporary water sources or evaporation/infiltration reservoirs that would require reclamation upon project completion. Changes in water quality in recreational fisheries may alter aquatic habitats, as described under Section 4.4.5 *Fish and Wildlife Resources – Fish*, and cause adverse impacts to fishing and other recreation opportunities provided by functioning and healthy aquatic habitat. Under Alternative A, the BLM allows recreational use of Spirit Mountain cave and manages cave and karst resources under the Worland Caves SRMA to provide for recreation opportunities. Although not requiring a minimum group size in caves may increase safety risks for recreationists, management actions under this alternative would primarily benefit users of caves for recreation.

Wildland fire management actions would allow wildland fire to play its natural role and would be used for resource benefit when appropriate. Short-term localized impacts to recreation from fire and fuels management, including prescribed fire and mechanical fuels treatments, would result in temporary closure of areas during and after fire events and activities, which would displace recreationists to other areas. Prescribed fires may result in long-term impacts from the displacement of some recreationists because of the altered recreation setting, but would prevent larger catastrophic fires that would displace recreation for a longer time and create long-term safety hazards (e.g., tree fall) for recreationists. Stabilization and rehabilitation activities after a wildfire may prohibit recreational use in the short term while the area recovers, but would reduce the potential for future fires and result in long-term benefits to recreation.

Forest management would use a full range of methods in a manner that protects and benefits watershed, wildlife, and riparian/wetland habitat values to improve forest health. Timber harvesting activities (projected to affect 30,000 acres under Alternative A [Appendix T]) would temporarily displace recreationists because of a change of recreation settings, such as increased traffic, dust, noise, and loss of solitude; these activities would also cause a loss of recreation opportunities during logging operations. Timber harvesting, when completed, would alter recreation settings, which would influence recreational opportunities and experiences. In the long term, closing timber access and haul roads, although eliminating potential motorized recreational use, would provide non-motorized access into areas for other recreational opportunities, activities, and experiences.

Short-term impacts from vegetation treatments would temporarily displace recreationists from treated areas to other areas. The long-term impacts would be to enhance the recreation setting and recreational experiences by improving vegetation health and wildlife habitat.

Management actions under Alternative A that benefit fish and wildlife would benefit recreational activities such as fishing, hunting, bird watching, and general wildlife viewing. However, management actions that restrict public access to protect wildlife or its habitat from disturbance (e.g., restricting OHV use in areas with fragile soils) would limit access for motorized recreation opportunities. These management actions would interfere with some recreationists' goals and experiences, but would enhance the experiences and benefits for those pursuing non-motorized related activities and experiences.

Impacts from management of cultural resources would be similar to those described under the *Impacts Common to All Alternatives* section.

VRM Class allocations for the Planning Area under Alternative A would result in beneficial impacts by preserving or retaining scenic qualities vital to the recreation setting in VRM Classes I and II (see Chapter 2). Requiring a VRM contrast rating worksheet in VRM Class I areas would help preserve the scenic characteristics of the landscape in these areas to be enjoyed by recreationists. However, limiting motorized vehicle use to designated roads and trails in VRM Class I and II areas would reduce access for those seeking recreational motorized travel in these areas. The BLM manages many areas popular for recreational activities and opportunities as Classes III and IV, which allows for noticeable and observable changes in the landscape. These changes, or unnatural contrasts introduced to the landscape, would impact the desired settings, which would interfere with recreationists' goals, experiences, and realized beneficial outcomes.

Proactive Management

Recreation Sites

Recreation management of developed sites would enhance recreation experiences and opportunities by prohibiting surface-disturbing activities (except those related to development of recreation facilities or wildlife habitat) and applying an NSO restriction in fishing and hunting access areas, the Five Springs Falls Campground, the Cody Archery Range, and the R&PP lease area for the Lovell Rod and Gun Club shooting range.

Recreation Management Areas (SRMAs, ERMAs)

Under Alternative A, the BLM manages seven areas as SRMAs (Table 4-29). The remainder of the Planning Area is in the Cody ERMA or Worland ERMA (identified as ERMAs in prior Recreation Planning guidance; the new recreation guidance does not recognize the remainder of the Planning Area as a recreation management area). The *Impacts Common to All Alternatives* section describes the benefits of designating SRMAs. The Recreation Management Area Matrix (Appendix O) provides a summary of management actions under each alternative in areas with specific recreation management designations. This section focuses on recreation management areas and proactive management actions under Alternative A that limit or prohibit resource uses and activities and result in beneficial impacts to recreation by maintaining or enhancing recreation settings, opportunities, experiences, and realization of beneficial outcomes.

Applying NSO restrictions on all or part of the Absaroka Foothills, Bighorn River, The Rivers, and Historic Trails SRMAs and the Canyon Creek area would help maintain the recreational setting and experience in these areas by limiting surface access to oil and gas and other leasable minerals. Additionally, mitigation through activity-level planning on mineral leases in the following areas would minimize potential impacts to the recreation setting: the Badlands, Bighorn River, Absaroka Mountain Foothills, and West Slope SRMAs, and the Red Canyon Creek and Horse Pasture areas.

Closing the Bighorn River SRMA to surface-disturbing activities, such as geophysical exploration and salable mineral exploration, would maintain the recreation settings important for river related activities such as fishing, hunting, and boating.

Managing the Bighorn River, West Slope, and The Rivers SRMAs as ROW avoidance areas would help prevent recreation displacement by preserving the desired RSCC, opportunities, experiences, and beneficial outcomes. All SRMAs are open to renewable energy development under Alternative A; however, limitations on ROW authorizations would apply to the development of renewable energy and may restrict development or require mitigation to minimize adverse impacts to recreation. Wind-energy development would result in adverse impacts to recreation by diminishing the recreation setting.

Although limiting motorized vehicle use to designated roads and trails would restrict opportunities for motorized recreational travel, recreationists seeking naturalness and more primitive forms of recreation would benefit in the following areas: the Bighorn River (CYFO only), Absaroka Mountain Foothills, and West Slope SRMAs, and Red Canyon Creek areas; the North and South Forks of the Shoshone and the Clarks Fork of the Yellowstone rivers; and portions of the McCullough Peaks and Newton Lake Ridge areas. Motorized vehicle use is limited to existing roads and trails in other recreation areas, with off-road use tolerated in the Basin Gardens Play Area and Rattlesnake Ridge area to maximize recreation opportunities for activities such as motocross and hill climbing. Allowing unrestricted, motorized access to the Rattlesnake Ridge area poses a health and safety risk by exposing recreationists to high levels of H₂S gas in the area.

Recreation

SRMAs are generally managed as VRM Classes IV, III, and II under Alternative A, retaining the existing character of the landscape to preserve the recreation setting, but allowing management activities and facilities development to respond to recreational needs. Managing areas such as the Red Canyon Creek area, areas in the West Slope, Absaroka Mountain Foothills, and Badlands SRMAs as VRM Class II would retain the scenic characteristics of this area, benefitting recreationists seeking a natural setting.

Alternative B

Surface Disturbance

Under Alternative B, a total of 73,940 acres of short-term and 10,893 acres of long-term surface disturbance is projected (Appendix T), most of which would result in adverse impacts to recreation. A portion of this disturbance would result from new facilities development and roads that may benefit recreation, but most would result in short- and long-term adverse impacts by displacing recreation and impairing the recreation setting for those seeking undisturbed landscapes. Alternative B would result in less adverse impacts to recreation from surface disturbance compared to Alternative A. The intensity of impacts to recreation would depend on the location of surface disturbance in relation to the desired RSCC in the area being disturbed (see *Impacts Common to All Alternatives*). Under Alternative B, the BLM would manage more acres in SRMAs (Table 4-29) to maintain the desired RSCC than Alternative A, which would minimize the impacts of surface-disturbing activities where they would most adversely affect recreational experiences.

Resource Uses

Oil and gas development in areas of moderate potential (where most development is anticipated) is expected to add 502 new federal wells resulting in 1,506 acres of short-term surface disturbance during the planning cycle (Appendix T). Adverse impacts from oil and gas development under Alternative B would be similar to Alternative A, although to a lesser extent because Alternative B includes more restrictions on development. Under Alternative B, 2,919,360 acres of BLM-administered surface are available for locatable mineral entry (see Chapter 2) and the BLM projects 5,000 acres of long-term surface disturbance from mining activities. Adverse impacts from locatable mineral development would be similar to Alternative A, although to a lesser extent because Alternative B includes more mineral withdrawals (and less area open to mineral entry).

Acquisitions and land tenure adjustments under Alternative B would benefit recreation similar to Alternative A, although to a greater extent. Emphasizing acquisitions for public access in the Bighorn and Greybull rivers and recreation management areas would result in beneficial impacts similar to Alternative A, although to a greater extent because Alternative B considers more areas for acquisition for public access. Working collaboratively with landowners to identify opportunities for acquisitions under Alternative B also may increase the potential for adjustments that would increase recreational access and opportunities. Under Alternative B, as in Alternative A, pursuing a withdrawal in the Beck Lake Scenic Area would benefit recreation by maintaining the recreation setting and public access in the area.

Alternative B manages a total of 2,710,695 acres as ROW avoidance and 225,447 acres as ROW exclusion areas, resulting in similar impacts to those under Alternative A, but to a greater extent due to the consolidation of ROWs that would preserve the RSCC more than Alternative A. Reducing and consolidating potential renewable energy development under Alternative B, especially wind-energy facilities, would decrease the potential for recreation displacement and visual impacts to recreation settings relative to Alternative A.

Alternative B places more restrictions on motorized vehicle use than Alternative A and limits most of the Planning Area to designated roads and trails. Restricting motorized vehicle use under this alternative would benefit recreation opportunities for solitude, natural settings, and primitive forms of travel more than under Alternative A. Impacts to motorized forms of recreation would be more adverse under Alternative B than Alternative A due to the seasonal closure (March 15 through June 30) of greater sage-grouse Key Habitat Areas to motorized access. The seasonal closure would impact desired recreational opportunities, experiences, and beneficial outcomes by repudiating motorized access within Key Habitat Areas as well as limiting access to other areas that require travel through Key Habitat Areas. Many areas of the Bighorn Basin are remote and difficult to access without the use of a motorized vehicle. Activities that may be adversely impacted by this seasonal closure include antler shed hunting, hiking, motorized touring and OHV use, caving, camping, sightseeing and wildlife viewing, rock hounding, environmental education, and general touring throughout the Bighorn Basin. Certain activities, such as cougar and bear hunting, would be available during fall, but not spring hunts within Key Habitat Areas. Desirable recreational areas that would be affected by the seasonal closure include, but are not limited to, portions of the McCullough Peaks, public lands south of Cody, Wyoming, portions of the West Slope of the Bighorns, the Red Gulch/Alkali Road National Back Country Byway, Castle Gardens Scenic Area, and portions of the Absaroka Front and the foothills. Alternative B, however, opens a larger area to off-road use than Alternative A, providing more recreation opportunities in this regard. Prohibiting OHV use for big game retrieval, dispersed campsite access, and other “necessary tasks” would benefit recreationists seeking solitude and primitive forms of recreation, but would adversely affect recreationists seeking more accessibility for certain activities (e.g., big game retrieval or dispersed campsites). Restricting over-snow vehicle use to areas with a minimum average of 12 inches of snow or groomed trails would limit recreation opportunities for snowmobilers and public access for other recreational uses, such as hunting.

Under Alternative B, the BLM would close crucial winter range for elk and bighorn sheep and greater sage-grouse Key Habitat Areas to livestock grazing. This action may indirectly benefit hunters and wildlife viewers, but would also adversely impact livestock grazing permittees. Livestock grazing may impact wildlife habitat due to competition for forage. Improper grazing management can lead to a lack of residual forage for big game winter use. However, proper management of livestock grazing can be beneficial to certain wildlife species.

Special Designations

Under Alternative B, the BLM would manage special designations for the desired RSCC, opportunities, experiences, and realized beneficial outcomes for recreationists in the Planning Area. Alternative B designates 17 ACECs, 11 of which have recreation values that include scenery, nature viewing, spelunking, hunting, and camping. The benefits of these designations would be similar to Alternative A, but to a greater extent because Alternative B includes more special designations that cover a greater area. Managing all lands with wilderness characteristics specifically to preserve their wilderness characteristics, including where they overlap the Absaroka Mountain Foothills (11,193 acres), West Slope (CYFO and WFO, not including RMZs) (17,230 acres), Bighorn River (3,052 acres), McCullough Peaks (42,371 acres), and The Rivers (4,030 acres) SRMAs and the Tatman Mountain RMZ (24,008 acres), may result in beneficial impacts to recreation experiences in areas managed for back country desired RSCCs.

Designating the Hyattville Logging Road and the Hazelton Road as Back Country Byways and managing these areas for responsible recreation would increase opportunities for recreation in the Planning Area; however, designation may increase the use of these routes enough to diminish solitude and recreation setting and experiences. Avoiding surface-disturbing activities in view within 5 miles and applying an

Recreation

NSO restriction within 3 miles of the Nez Perce (Neeme-poo) NHT and Other Historic Trails would preserve the recreation setting of these areas to a greater extent than management under Alternative A.

Under Alternative B, the West Slope (CYFO and WFO) SRMA contains six WSR suitable segments and The Rivers SRMA contains one. Desired outcomes in the West Slope (CYFO and WFO) SRMA include experiencing the landscape and developing a greater awareness of outdoor aesthetics in back country and middle country natural settings. Desired outcomes in The Rivers SRMA include developing a closer relationship with the natural world in areas with a rural natural setting, and enjoying risk-taking adventure and increasing local tourism revenue. In addition to the actions restricting minerals development under Alternative A, Alternative B closes WSR suitable segments to mineral leasing and geophysical exploration. This would provide additional benefits by protecting the desired RSCC in these areas. However, prohibiting surface-disturbing activities in all WSR suitable segments may adversely affect recreational experiences, especially in The Rivers SRMA, where facilities may need to be upgraded or expanded to accommodate more visitors.

Benefits from management actions in WSR suitable segments would be similar to Alternative A, although to a greater extent. Under Alternative B, all WSR eligible segments are recommended as suitable for inclusion in the NWSRS, closing these areas to activities (e.g., surface-disturbing activities, ROW authorizations) that would degrade their free-flowing conditions and ORVs. Prohibiting surface-disturbing activities in WSR suitable segments would preclude recreation facilities development that may enhance the recreational experience in some areas. Under Alternative B, 14 of the 20 WSR suitable waterways would be closed to motorized vehicle use, preserving the natural setting and enhancing the experience for nonmotorized, primitive recreation in these areas.

Allowing maintenance on pre-FLPMA (grandfathered) range improvement projects may affect recreationists seeking a natural setting and solitude in WSAs. Closing all WSAs to motorized vehicle use under Alternative B, though eliminating motorized recreation opportunities, would enhance opportunities for solitude and unconfined, primitive recreation. Acquiring inholdings and/or lands or interest in lands in WSAs would also enhance the recreation setting for solitude and unconfined, primitive recreation in these areas and increase access. Under Alternative B, the BLM manages all lands with wilderness characteristics specifically to preserve their wilderness characteristics. Because many lands with wilderness characteristics are adjacent to WSAs, this management action would buffer the WSAs from activities that threaten the wilderness setting sought by recreationists in these areas.

Resources

Beneficial impacts from soils, water quality, and watershed management under Alternative B would be similar to those under Alternative A, although to a greater extent. Cooperating with local governments to develop watershed improvement practices that would reduce sediment in streams, rivers, lakes, and reservoirs and address impaired waterbodies on the state of Wyoming 303d list would preserve water quality for recreational uses of these resources. Prohibiting the discharge of produced water would eliminate the associated impacts described under Alternative A. Stabilizing or relocating heavily eroded or washed out roads would also benefit water quality for recreational uses and motorized recreation opportunities.

Under Alternative B, the BLM allows commercial recreational use of Spirit Mountain cave and manages cave and karst resources under a separate cave and karst ERMA that would emphasize resource protection, address user conflicts, public health and safety, and maintain the desired RSCC. Requiring a minimum group size in caves may decrease safety risks for recreationists, but would also limit recreation opportunities in caves. Recreation opportunities also would be restricted during critical times for bats

and when the safety of users is at risk. Management actions under this alternative would provide less structured recreation prescriptions for caves than under Alternative A.

Fire and fuels management actions under Alternative B would result in impacts similar to Alternative A, although to a lesser extent because Alternative B includes less fuels treatments. Short-term impacts to recreation from disturbance associated with prescribed fire and treatments would be less than under Alternative A. Because Alternative B includes less fuels treatments, the risk of fuels buildup and larger catastrophic fires may be greater under this alternative. Fuels buildup and larger catastrophic fires may cause more long-term adverse impacts to recreation compared to Alternative A.

Impacts to recreation from forest management would be similar to Alternative A, although to a lesser extent. The BLM uses a full range of methods in a manner that protects and benefits watershed, wildlife, and riparian/wetland habitat values, but only harvests timber on approximately 20,000 acres (Appendix T) during the planning cycle where natural processes are unable to accomplish forest health goals. Improved forest health would benefit the recreation settings and supplemental values, which in turn would influence overall recreation opportunities. As the forest declines in health, there may be adverse impacts to wildlife (e.g., big game) populations, resulting in adverse impacts to recreational experiences. Closing timber access and haul roads would result in the same impacts as Alternative A.

Impacts from vegetation treatments would be similar to Alternative A, although to a lesser extent because the BLM treats less acreage under Alternative B. In treated areas, managing toward achieving the reference state plant community (based on the ESD for the site) in grassland and shrubland communities and DPC in riparian/wetland areas may result in additional indirect benefits to recreationists by improving wildlife habitat to a greater extent than Alternative A.

Management actions under Alternative B that would benefit fish and wildlife would enhance recreational activities such as fishing, hunting, bird watching, and general wildlife viewing more than the other alternatives. However, these management actions also would restrict public access and limit opportunities for motorized recreational travel more than under Alternative A.

Impacts to recreation from management of cultural resources would be similar to those noted under the *Impacts Common to All Alternatives*, although to a greater extent. For example, to minimize issues such as looting, limiting motorized vehicle use to designated roads and trails in the Bighorn Slope, Bridger, Owl Creek, and Absaroka Foothills areas would adversely affect opportunities for motorized recreation.

VRM Class allocations for the Planning Area under Alternative B would result in impacts similar to Alternative A, although to a greater extent. Pursuing conservation easements on lands adjacent to areas managed as VRM Classes I and II and requiring a contrast rating worksheet for proposed actions in areas managed as VRM Classes I, II, and III would result in additional benefits to recreation experiences by maintaining the recreation setting in these areas. Closing VRM Class I areas to motorized vehicle use would eliminate motorized recreation opportunities over a large area (154,359 acres) and cause adverse impacts to motorized recreational use.

Proactive Management

Recreation Sites

Recreation management of developed sites would result in impacts similar to Alternative A, although to a greater extent. More acreage would receive high priority recreation management under Alternative B than Alternative A, which may result in greater realized beneficial outcomes from specifically targeting the desired RSCC to enhance activities and experiences. In addition, management of popular recreation sites in the Planning Area (e.g., Castle Gardens, Duck Swamp, and Nowater OHV Trail System) would result in beneficial outcomes, without the additional prescriptions from management as an SRMA, as

Recreation

ERMAs would receive the recreation management needed to address conflicts, health and safety, and resource protection.

Recreation Management Areas (SRMAs, ERMAs)

This section focuses on recreation management areas and proactive management actions under Alternative B that limit or prohibit resource uses and activities and result in beneficial impacts to recreation by maintaining or enhancing recreation settings, experiences, and opportunities. The Recreation Management Area Matrix (Appendix O) summarizes management actions under each alternative in areas with specific recreation management designations.

Under Alternative B, the BLM would manage 13 areas as SRMAs, including expansions of the Badlands and West Slope (CYFO and WFO) SRMAs (Table 4-29). The *Impacts Common to All Alternatives* section describes the benefits of managing SRMAs. Within the 13 SRMAs, the BLM will manage nine RMZs for distinct recreational products strategically targeted to meet market demand and to manage for realized beneficial outcomes. RMZs may result in more benefits than solely SRMA designations by meeting specific niche demands, activities, opportunities, experiences, and benefits.

The BLM manages the Tour de Badlands RMZ in the Badlands SRMA, the Trapper Creek, Paint Rock, Brokenback/Logging Road, and South Bighorns RMZs in the West Slope (WFO) SRMA, and the Red Canyon Creek and The Rivers SRMAs for motorized and non-motorized recreation opportunities such as hiking, wildlife viewing, and fishing. The BLM emphasizes primitive, non-motorized recreation opportunities in the Wild Badlands and Tatman Mountain RMZs in the Badlands SRMA, and the Canyon Creek, McCullough Peaks, Horse Pasture, Beck Lake, and Newton Lake Ridge SRMAs. Limiting motorized vehicle use to designated roads and trails in most of these areas would result in beneficial impacts to recreation experiences by reducing the potential for user conflicts. Closing the Beck Lake and Newton Lake Ridge SRMAs to motorized vehicle use would adversely affect opportunities for motorized recreation, but would benefit less intensive recreation opportunities such as mountain biking, hiking, and wildlife viewing. Unrestricted, off-road motorized recreation is consolidated in the Basin Gardens Play Area RMZ to maintain an undisturbed recreation setting and benefit recreation opportunities for primitive uses and solitude in other areas of the Planning Area. The Rattlesnake Ridge area is closed due to health and safety hazards associated with H₂S emissions from oil and gas development. This would interfere with motorized recreation and displace these users to other areas, potentially creating new conflicts.

Alternative B includes more proactive management actions to retain the landscape characteristics of areas with recreational value to maintain the desired RSCC than Alternative A. These actions include applying an NSO restriction in all SRMAs, closing all SRMAs to surface-disturbing activities, and managing all SRMAs as ROW avoidance or exclusion areas.

In addition to placing greater restrictions on incompatible uses to preserve the recreation setting in SRMAs, the BLM also expands recreation facilities and amenities in SRMAs and RMZs to a greater extent than under Alternative A to enhance the experience of primary recreation users. For example, adding designated trailheads and hiking trails in areas managed for non-motorized uses (e.g., Canyon Creek SRMA), and vehicle touring loops in areas managed for motorized recreation opportunities as well (e.g., the Trapper Creek, Paint Rock, and Brokenback/Logging Road RMZs), would beneficially impact the recreational experiences in these areas while minimizing the potential for user conflict.

The BLM manages VRM Classes in SRMAs and RMZs consistent with their identified desired RSCC under Alternative B. All SRMAs and RMZs with substantial scenic values that are important to the recreational experience are managed as VRM Class II to retain the existing character of the landscape, while the

Basin Gardens Play Area, where the recreational experience requires opportunities for off-road motorized recreation that partially alter the existing landscape, is managed as VRM Class III.

Although managing recreation more proactively under Alternative B to strategically targeted demands would enhance recreation opportunities and experiences in most areas, restricting recreation opportunities (especially dispersed motorized recreation) in some areas may result in localized adverse impacts to recreationists.

Alternative C

Surface Disturbance

Under Alternative C, a total of 245,642 acres of short-term and 41,485 acres of long-term surface disturbance is projected (Appendix T), most of which would result in adverse impacts to recreation. A portion of this disturbance would result from new facilities development and roads that may benefit recreation, but most would result in short- and long-term adverse impacts by impairing the recreation setting, which would displace those seeking undisturbed landscapes to more suitable areas. Alternative C would result in the greatest adverse impact to recreation from surface disturbance compared to the other alternatives. The intensity of impacts to recreation would depend on the location of surface disturbance in relation to the desired RSCC in the area being disturbed (see *Impacts Common to All Alternatives*). Although the custodial management actions in ERMA would result in limited benefits to recreational experiences, Alternative C manages the least acreage as SRMAs and pursues the least marketing and maintenance of the desired RSCC. Therefore, surface disturbance may affect benefits to recreationists the most under this alternative.

Resource Uses

Oil and gas development in areas of moderate potential (where most development is anticipated) is expected to add 1,304 new federal wells resulting in 3,912 acres of short-term surface disturbance during the planning cycle (Appendix T). Adverse impacts to recreation from oil and gas development under Alternative C would be similar to Alternative A, although to a greater extent because Alternative C includes more projected development. Under Alternative C, 4,155,119 acres of BLM-administered surface are available for locatable mineral entry (see Chapter 2) and 10,000 acres of long-term surface disturbance are projected from mining activities. Adverse impacts from locatable mineral development would be similar to Alternative A, although to a greater extent because Alternative C makes available more area to locatable mineral entry and pursues withdrawals in the least amount of area. Overall, minerals development under Alternative C would result in the greatest adverse impacts to recreation compared to the other alternatives.

Acquisitions and land tenure adjustments under Alternative C would result in impacts similar to Alternative A, although to a lesser extent. Alternative C identifies more area for disposal than Alternative A. In addition, under Alternative C, the BLM would consider acquisition in recreation areas primarily to address use and user conflicts and not to meet management objectives and desired recreation settings and opportunities in these areas. Under Alternative C, the BLM would not actively pursue acquisitions for public access to enhance recreational opportunities in the Bighorn River. This would place recreational access to the river as a low priority, which would affect both recreational opportunities and experiences, and the benefits of recreation to local tourism.

Under Alternative C, the BLM would not pursue a withdrawal from appropriation under the mining laws in the Beck Lake Scenic Area, which may cause adverse impacts to recreation by allowing mining activities that potentially displace recreationists or diminish their experiences in this area.

Recreation

Under Alternative C, the BLM would manage a total of 1,173,162 acres as ROW avoidance areas and 7,586 acres as ROW exclusion areas, resulting in similar impacts to those under Alternative A, but to a lesser extent due the smaller area of ROW exclusion (the most restrictive ROW designation). Alternative C opens a total of 1,428,360 acres to renewable energy development. Alternative C may consolidate renewable energy development, such as wind-energy facilities, more than Alternative A, but not as much as Alternative B, resulting in correlated impacts from displacing recreationists and from visual impacts that may impair recreationists' experiences. A complete list of recreation areas and their respective acreages is located in Table 4-27 and Appendix O, *Recreation Management*.

Alternative C places similar restrictions on motorized vehicle use as Alternative A, but more area is limited to designated roads and trails and open to off-road use. Limiting motorized recreation to designated roads and trails in more area would result in a lower potential for user conflict between motorized and primitive recreationists. However, allowing motorized vehicle use across the largest area and closing the least area under this alternative would cause greater adverse impacts to recreation opportunities for solitude, natural settings, and primitive forms of travel than the other alternatives. The greater accessibility for motorized vehicle use under Alternative C may adversely affect adjacent private lands by increasing the potential for recreationists to trespass. New route development from off-road use also would cause the greatest potential for altering the recreation setting for users seeking undisturbed landscapes. As under Alternative A, allowing cross-country motorized use in the 15-mile and Rattlesnake Ridge areas would provide opportunities for recreationists interested in riding off-road, but may result in adverse impacts to the cultural and recreational opportunities along some Other Historic Trails (see Chapter 3 *Comprehensive Travel and Transportation Management* for additional information). Allowing OHV use for big game retrieval, dispersed campsite access, and other "necessary tasks" would result in impacts similar to Alternative A.

Livestock grazing management under Alternative C would result in impacts similar to Alternative A. However, under Alternative C, the BLM does not manage livestock grazing to protect and enhance other resource values, which may result in greater potential adverse impacts to recreational experiences where grazing practices conflict with recreational values, such as opportunities for solitude or back country settings.

Special Designations

Special designations under Alternative C would affect the opportunities, experiences, and settings available to recreationists less than the other alternatives. Alternative C designates no additional ACECs to those designated under all alternatives. Therefore, only the Spanish Point Karst and Brown/Howe Dinosaur Area ACECs would result in beneficial impacts by providing recreation opportunities for rock climbing, caving, and hiking and maintaining the scenic qualities of the area. No additional back country byways would be designated under this alternative to benefit recreation. Surface disturbance and NSO restrictions around the Nez Perce (Neeme-poo) NHT and Other Historic Trails would result in similar beneficial impacts to those described under Alternative A. However, more utility corridors may affect the recreational setting of the trails under this Alternative.

Under Alternative C, the BLM would not apply any special management actions to WSR eligible waterway segments. Allowing other uses in these areas (e.g., oil and gas leasing, geophysical exploration) would result in the greatest potential adverse impact to recreational opportunities, settings, and experiences in these areas compared to the other alternatives. Back country and more primitive forms of recreational opportunities available in these waterway segments, such as hunting, fishing, camping, hiking, and sightseeing, would be adversely impacted, which would result in non-

realization of beneficial outcomes. Such impacts may also result in adverse impacts to local tourism and its associated benefits.

Impacts from WSAs would be similar to those under Alternative A. However, the BLM limits motorized vehicle use to designated roads and trails in the Honeycombs and Cedar Mountain WSAs under Alternative C, which may result in fewer opportunities for motorized recreationists but would enhance the experience for those seeking solitude and primitive recreation. The converse would be true in the remainder of the WSAs, where Alternative C allows motorized vehicle use to a greater extent than Alternative A. Potential impacts to recreationists from the lack of management prescriptions in lands with wilderness characteristics would be similar to those under Alternative A.

Resources

Beneficial impacts from soils, water quality, and watershed management under Alternative C would be similar to those under Alternative A, although to a lesser extent because Alternative C includes fewer restrictions. Addressing impaired waterbodies on the state of Wyoming 303d list may enhance water quality for both recreational resources and recreational uses of these resources, but a lack of watershed improvement practices would result in the greatest potential for sedimentation in waterbodies that have recreational values. Allowing the discharge of produced water would result in impacts similar to Alternative A. Stabilizing heavily eroded or washed out roads would benefit water quality for recreational uses.

Under Alternative C, the BLM would not manage cave and karst resources under a specific cave and karst ERMA, but instead would manage cave and karst areas consistent with resource objectives. As a result, beneficial impacts could be reduced for recreational users of cave and karst resources under Alternative C compared to alternatives A and B, which both manage cave and karst resources as a separate recreation management area. This management may also result in a greater potential for recreational user conflicts under Alternative C in the absence of specific management determining access to and use of cave and karst areas. Under Alternative C, the BLM encourages commercial caving tours of Spirit Mountain cave, which would enhance opportunities for tourists but may diminish experiences or reduce opportunities for local recreationists. Encouraging tourism may also affect cave and karst resources by exceeding the Limits of Acceptable Change and Carry Capacity. These impacts can degrade physical characteristics, which may result in adverse impacts to recreational experiences and benefits.

Fire and fuels management under Alternative C would result in impacts similar to Alternative A, although to a greater extent because Alternative C includes more prescribed fire and mechanical fuels treatments. Short-term localized impacts to recreation from prescribed fire and fuels treatments would be greatest under Alternative C. Due to increased fuels treatments under Alternative C, the risk of fuels buildup and larger catastrophic fires may decrease under this alternative. Decreased fuels buildup and larger catastrophic fires may result in greater long-term benefits to recreation compared to the other alternatives.

Impacts to recreation from forest management would be similar to Alternative A, although to a greater extent. The BLM uses a full range of timber harvesting methods to maximize forest products. Timber harvesting on approximately 40,000 acres during the planning cycle would have the greatest potential to displace recreation or adversely affect the recreation setting in the long term (Appendix T). However, using a full range of silviculture techniques to manage insect and disease may help prevent the spread of infestations and preserve the recreation setting. Allowing timber access and haul roads to remain open for new recreational purposes would result in increased accessibility and new recreation opportunities,

Recreation

but also may impact the recreation setting in remote areas by altering scenic characteristics or the recreation experience for those seeking solitude.

Impacts from vegetation treatments under Alternative C would be similar to those under Alternative A, although to a greater extent because the BLM treats more acreage under Alternative C. Not managing habitat such as crucial winter range to meet DPC objectives most beneficial for the identified species may result in fewer indirect benefits to recreationists through improving vegetative health for wildlife habitat.

Management actions under Alternative C that would benefit fish and wildlife would enhance recreational activities such as fishing, hunting, bird watching, and general wildlife viewing; however, benefits impacts would be the least under Alternative C compared to the other alternatives. These management actions would permit public access and create opportunities for motorized recreational travel the most compared to the other alternatives. Semi-primitive settings would be affected by this management, and recreationists desiring those settings would not achieve a realization of beneficial outcomes and may seek those benefits in other areas.

Impacts from cultural resources management under Alternative C would be similar to Alternative B.

VRM Class allocations for the Planning Area under Alternative C would result in impacts similar to those under Alternative A, although to a lesser extent. Exempting all mineral actions and activities in designated ROW corridors from contrast rating worksheets would make these developments more visible from surrounding areas, increasing adverse impacts to the setting for recreationists seeking natural landscapes. Under Alternative C, the BLM does not limit motorized vehicle use by VRM Class, increasing opportunities for motorized recreation in scenic areas, but also increasing the potential for new trail and route development to alter the recreation setting for more primitive forms of recreation.

Proactive Management

Recreation Sites

Alternative C would involve the least proactive management to maintain or enhance the desired RSCC, enhance recreationists' opportunities and experiences, and to realize beneficial outcomes. Allowing surface-disturbing activities (e.g., geophysical exploration and salable minerals development) in fishing and hunting access areas; the Five Springs Falls Campground; the Cody Archery Range; and the R&PP lease area for the Lovell Rod and Gun Club shooting range may displace recreation and adversely affect the recreation setting. This would be most notable in the Five Springs Falls Campground and other areas where recreationists may seek a generally undisturbed setting.

Recreation Management Areas (SRMAs, ERMAs)

Under Alternative C, the BLM manages only the Rattlesnake Ridge SRMA (Table 4-29). Management actions in ERMAs are less proactive to enhance recreation opportunities or experiences, and are primarily custodial in nature. By designating only one SRMA, Alternative C would result in the fewest proactive measures to manage for desired RSCC, opportunities, activities, experiences, and desired beneficial outcomes.

Alternative C also places the fewest restrictions on resource uses and surface-disturbing activities to maintain the recreation settings in areas managed as SRMAs under Alternative B (Appendix O). In most areas with recreational use, scenic values are important to recreationists' experiences. Allowing activities such as mineral development and ROW authorizations (i.e., wind-energy development) in these areas would result in the highest potential for degradation of generally undisturbed areas that

benefit recreationists' experiences in popular areas such as the Absaroka Foothills, Badlands, West Slope, Red Canyon Creek, and the Bighorn River.

Allowing more development and motorized vehicle use (permitted on existing roads and trails in all recreation areas except the Trapper Creek area in the Spanish Point Karst ACEC under Alternative C) would diminish the desired settings and those setting-dependent resources and opportunities for solitude in several places. Areas such as the Tour de Badlands (as delineated in Alternative B) produce recreation opportunities for motorized travel and sight-seeing, and for solitude in natural landscapes, which would be threatened by unrestricted motorized vehicle use in remote areas. Other areas where expanded motorized vehicle use would threaten opportunities for solitude include the Absaroka Foothills, West Slope, Canyon Creek, and McCullough Peaks areas. Because the BLM expects OHV use to increase throughout the Planning Area, opportunities for primitive forms of recreation and solitude would decrease unless the BLM limited or closed motorized vehicle use in certain areas.

Under Alternative C, the BLM manages most recreation areas as VRM Classes III and IV, allowing for the greatest alteration of the natural landscape in these areas. For example, this alternative manages the Red Canyon Creek area as VRM Class IV, which would result in the fewest measures to protect the scenic qualities that contribute to the recreation setting of this area.

Designating and expanding the Rattlesnake Ridge SRMA for the allowance of off-road motorized vehicle use, despite potential health and safety risks, would enhance opportunities for motorized recreation and meet the niche demand for activities such as all-terrain vehicle and motorbike use.

Alternative D

Surface Disturbance

Under Alternative D, a total of 140,175 acres of short-term and 18,306 acres of long-term surface disturbance is projected (Appendix T), most of which would result in adverse impacts to recreation. Impacts would be similar in type and extent to those under Alternative A. The intensity of impacts to recreation would depend on the location of surface disturbance in relation to the desired RSCC in the area being disturbed (see *Impacts Common to All Alternatives*). Alternative D manages more acreage in SRMAs than Alternative A, and specifically identifies desired outcomes and RSCCs in SRMAs—and applies certain restrictions to better maintain them, which may limit adverse impacts from surface disturbance to recreation management more than Alternative A.

Resource Uses

Oil and gas development in areas of moderate potential (where the most development is anticipated) is expected to add 1,143 new federal wells resulting in 3,429 acres of short-term surface disturbance during the planning cycle (Appendix T). Adverse impacts from oil and gas development under Alternative D would be similar to Alternative A, although to a lesser extent. For example, Alternative D applies a MLP in the Fifteenmile (230,699 acres), Big Horn Front (379,308 acres), and Absaroka Front (253,112 acres) MLP analysis areas which would reduce impacts to the recreational setting from oil and gas-related development activities through CSU, TLS, and motorized use stipulations. Adverse impacts from locatable mineral development would be similar to Alternative A, although may affect a larger area because Alternative D makes more acreage available for locatable mineral entry.

Acquisition and land tenure adjustments under Alternative D would result in impacts similar to Alternative C, although to a greater extent. Alternative D identifies less land for disposal than alternatives A and C. Under Alternative D, the BLM considers acquisitions for public access to enhance recreational opportunities in the Bighorn River more actively than under Alternative C, but less so than

Recreation

under alternatives A and B. Pursuing a withdrawal from appropriation under the mining laws in the Beck Lake Scenic Area and not issuing an order that opens the land to mineral entry would result in the same, if not slightly improved, benefits as Alternative A.

Renewable energy development and ROW development would result in impacts similar to, but to a greater extent than alternatives A and C (and a lesser extent than Alternative B). Under Alternative D, the total area managed as ROW exclusion or avoidance is larger than under alternatives A and C, which is likely to result in a greater consolidation of ROWs with proportional benefits to the RSCC and recreational opportunities and experiences.

Travel and transportation management under Alternative D would result in impacts similar to those under Alternative A; however, Alternative D places more restrictions on motorized vehicle use, which would result in greater benefits to recreation opportunities for solitude, natural settings, and primitive forms of travel. Alternative D manages the second most acreage as open to cross-country motorized travel, augmenting recreation opportunities in this regard more than alternatives A and B, but less than Alternative C. Restricting off-road motorized vehicle use in areas with limited travel designations to within 300 feet of roads and trails would result in impacts similar to Alternative B, although to a lesser extent.

Livestock grazing management under Alternative D would result in impacts similar to Alternative A.

Special Designations

The ACECs designated under Alternative D would result in impacts similar to Alternative A, although to a greater extent because Alternative D designates three additional ACECs with recreational values. Alternative D also restricts certain resource uses and activities (e.g., minerals development) in the Chapman Bench Management Area to protect sensitive wildlife habitat that may benefit recreational wildlife viewing opportunities, especially bird watching.

Back country byway designations under Alternative D would result in the same benefits as Alternative A. The BLM applies measures to protect the scenic qualities of the Nez Perce (Neeme-poo) NHT and Other Historic Trails in a more discretionary manner under Alternative D than under the other alternatives. The BLM may protect the viewshed in a larger area around the trails than under alternatives A and C, but with the use of mitigation measures and BMPs, may allow more activities that may affect the scenic quality of the trails (e.g., a CSU restriction versus an NSO restriction).

The BLM does not apply any special management actions to WSR eligible segments under Alternative D, and impacts would be similar to Alternative C.

Resources

Beneficial impacts from soils, water quality, and watershed management under Alternative D would be similar to Alternative A, although to a greater extent than alternatives A and C and a lesser extent than Alternative B. Developing watershed improvement practices; cooperating with adjacent landowners, managers, and the Wyoming DEQ to address waterbodies that do not meet state water quality standards; and giving priority to stabilizing or relocating heavily eroded or washed out roads would result in benefits similar to Alternative B.

As under Alternative C, Alternative D would not manage cave and karst resources under a specific cave and karst ERMA, but would instead manage cave and karst areas consistent with resource objectives, resulting in the same as described under Alternative C. Allowing for commercial tours of Spirit Mountain cave would result in impacts similar to Alternative C. Impacts to recreation opportunities in caves from

requiring minimum group sizes and closing caves for critical bat periods and to protect user safety would be similar to Alternative B.

Based on the extent of treatment estimated from the acreage of projected surface disturbance from prescribed fire and mechanical fuels treatments (Appendix T), fire and fuels management under Alternative D would result in impacts similar to Alternative A.

Forest, woodlands, and forest products management under Alternative D would result in 30,000 acres of timber harvest, and similar impacts as Alternative A, except that using the full range of silviculture techniques to manage endemic insect and disease would result in the same benefits as Alternative C.

Based on the acreage of projected surface disturbance (Appendix T), vegetation treatments would result in similar impacts as Alternative A. Managing some grassland and shrubland communities for a higher plant community state or phase (based on state and transition models in ESDs) where site-specific management objectives determine that a higher plant community state or phase is desirable would result in indirect benefits similar to Alternative B.

Management actions under Alternative D would benefit fish and wildlife, and therefore enhance recreational activities such as fishing, hunting, bird watching, and general wildlife viewing, more than alternatives A and C but less than Alternative B. Correspondingly, management actions to protect wildlife habitat would restrict public access and limit opportunities for motorized travel more than alternatives A and C, but less than Alternative B.

Impacts from management of cultural resources would be similar to those described under *Impacts Common to All Alternatives*.

VRM Class allocations under Alternative D would result in impacts to recreation similar to Alternative A, although to a greater extent because Alternative D allocates more acreage in VRM Classes I and II. Not limiting motorized vehicle use by VRM Class would result in similar impacts as Alternative C.

Proactive Management

Recreation Sites

Under Alternative D, the BLM would pursue a greater degree of proactive management to maintain or enhance the desired RSCC in recreation sites than alternatives A and C, but less than Alternative B. Alternative D applies the same NSO restrictions in recreation sites as Alternative B, but allows surface-disturbing activities, similarly to Alternative C, in recreational sites and trails on a case-by-case basis.

Recreation Management Areas (SRMAs, ERMAs)

This section focuses on recreation management areas and proactive management actions under Alternative D that limit or prohibit resource uses and activities and would result in benefits to recreation by maintaining or enhancing recreation settings, experiences, and opportunities. The Recreation Management Area Matrix (Appendix O) summarizes management actions under each alternative in areas with specific recreation management designations.

Under Alternative D, the BLM would manage 13 areas as SRMAs, as compared to the seven SRMAs under Alternative A; however, because the SRMAs vary in size, Alternative D manages the largest total acreage as SRMAs. Under Alternative D, the Absaroka Foothills, Bighorn River, West Slope, and The Rivers SRMAs are smaller than under Alternative A; the Absaroka Foothills SRMA decreases to 42,615 acres because 28,998 acres are managed as an ERMA, the Bighorn River in the WFO is managed as an ERMA (1,522 acres), the West Slope decreases as the South Bighorns is managed as an ERMA (69,325 acres), and Historic Trails and Worland Caves are not managed as SRMAs. On the other hand, under

Alternative D, Canyon Creek (3,675 acres), Middle Fork of the Powder River (14,644 acres), McCullough Peaks (160,838 acres), Basin Garden Play Area (4,421 acres), Horse Pasture (144 acres), Beck Lake (6,473 acres), and Newton Lake Ridge (1,949 acres) are added as SRMAs. The *Impacts Common to All Alternatives* section describes the benefits of managing SRMAs. Alternative D identifies five ERMAs. The *Impacts Common to All Alternatives* section describes impacts from managing ERMAs. Within the 13 SRMAs, the BLM manages five RMZs; see Alternative B for a description of the beneficial impacts of RMZs.

The BLM manages Tour de Badlands RMZ in the Badlands SRMA, the Canyons and Brokenback/Logging Road RMZs in the West Slope (WFO) SRMA, and the Middle Fork of the Powder River, The Rivers, Beck Lake, and Newton Lake Ridge SRMAs for motorized and nonmotorized recreation opportunities such as hiking, wildlife viewing, and fishing. The BLM emphasizes primitive, nonmotorized recreation opportunities in the Wild Badlands and Tatman Mountain RMZs in the Badlands SRMA, and the Absaroka Foothills, Canyon Creek, McCullough Peaks and Horse Pasture SRMAs. Limiting motorized vehicle use to designated roads and trails in these areas, except for the Horse Pasture SRMA and the Wild Badlands RMZ, would result in beneficial impacts to recreation experiences by reducing the potential for user conflicts. Limiting motorized vehicle use to designated roads and trails in the Horse Pasture SRMA would increase the potential for user conflicts and may adversely affect recreation experiences in the area. This impact would be minimal due to the low amount of roads within the area. Designating roads and trails will aid in maintaining the desired settings, activities, and experiences by enhancing the naturalness of the area. Limiting motorized vehicle use in the Beck Lake and Newton Lake Ridge SRMAs would result in impacts similar to Alternative B, although to a lesser extent. Managing the Basin Gardens Play Area SRMA for motorized recreation opportunities would result in impacts similar to Alternative B, but increasing its size under Alternative D would benefit recreation to a greater extent by responding more appropriately to the increasing demand for motorized recreation opportunities. Managing the Rattlesnake Ridge area as a separate ERMA would maintain the current recreational opportunities resulting in benefits similar to Alternative C, although to a lesser extent because the area is not managed as open to cross-country motorized travel, nor will the area be marketed as an OHV area. Management prescriptions specific to this separate ERMA will address the safety concerns (primarily the H₂S hazard) and conflicts due to the oil and gas activities and the motorized recreational activities. Actively addressing these issues will maintain and enhance the desired experiences and beneficial outcomes.

Alternative D includes the second most proactive management actions to retain the scenic landscape characteristics of areas with recreational value to maintain the desired RSCC. Within SRMAs, these actions include applying a CSU stipulation, allowing surface-disturbing activities only if the effects can be avoided or mitigated based on site-specific analysis, and managing most SRMAs as ROW avoidance areas.

However, maintaining the desired RSCC in Alternative D will not be as effective as Alternative B. Managing the SRMAs without an NSO stipulation will allow surface-disturbing activities that may not effectively be mitigated, which will compromise the desired settings. Impacts to the settings within the SRMAs will adversely impact the goals and experiences desired by those visiting the area. These areas are managed for community, destination, and undeveloped strategies, which commits the BLM to effectively manage these areas to address or maintain the outputs (settings, experiences, and benefits), as identified by those who visit and enjoy the SRMAs. Settings compromised by surface-disturbing activities will interfere with visitors' goals and experiences, which will displace visitors to alternative areas. This goal interference and displacement will adversely impact local tourism and will not meet the objectives of the SRMAs.

The beneficial impacts from expanding SRMAs and separate ERMA s would be similar to those under Alternative B, although to a lesser extent because Alternative D manages less acreage of BLM-administered public lands as SRMAs.

VRM Class allocations under Alternative D would result in benefits to the recreation setting similar to Alternative B in the Absaroka Mountain Foothills, Bighorn River, Canyon Creek, and Newton Lake Ridge SRMAs and the Canyons and Brokenback/Logging Road RMZs. Managing the West Slope and Middle Fork of the Powder River SRMAs as VRM Class II and The Rivers SRMA as VRM Class III would result in a greater beneficial impact by preserving the desired RSCC in these areas than under alternatives A and C, but less than under Alternative B. Allocating VRM classes consistent with other resource objectives in the Tour de Badlands and Tatman Mountain RMZs, the Horse Pasture and Beck Lake SRMAs, the South Bighorns and Red Canyon Creek ERMA s, and McCullough Peaks area may cause adverse impacts to the recreation setting. This would be especially true in areas where the desired RSCC depends more on a back country setting, such as the Tatman Mountain RMZ and the Red Canyon Creek and South Bighorns ERMA s.

Alternative E

Under Alternative E, the BLM would designate the same recreation management areas (SRMAs, ERMA s, and RMZs) as Alternative B (see Map 76 and Table 4-29). Management actions to maintain or enhance recreation settings, experiences, and opportunities in these areas and impacts on other resources and resource uses under Alternative E would be the same as Alternative B.

Surface Disturbance

Under Alternative E, a total of 71,829 acres of short-term and 10,802 acres of long-term surface disturbance is projected (Appendix T), most of which would result in adverse impacts to recreation. The intensity of impacts to recreation would depend on the location of the surface disturbance in relation to the desired RSCC in the area being disturbed (see *Impacts Common to All Alternatives*). Surface-disturbing activities and total surface disturbance acreage under Alternative E would be similar to Alternative B, and impacts to recreational experiences would be the similar to Alternative B. However, in greater sage-grouse Key Habitat Areas under Alternative E, disturbances would not be permitted to exceed one disturbance per 640 acres or disturb more than 3 percent of sagebrush habitat, compared to 5 percent under Alternative B. This additional restriction would reduce potential adverse impacts from surface disturbance to recreational experiences, particularly in areas managed for back country desired RSCC, compared to Alternative B.

Resource Uses

Overall, the management of minerals development under Alternative E would result in the least impacts to recreation compared to the other alternatives. Adverse impacts on recreation from locatable mineral development would be similar to Alternative A, but to a lesser extent because Alternative E would withdraw a larger area from locatable mineral entry (1,799,961 acres, the largest area of any alternative). Alternative E would manage leasable minerals development similar to Alternative B, and impacts to recreation would be similar to Alternative B.

Alternative E manages acquisitions and land tenure adjustments for public access similar to Alternative B, and impacts to recreation and public access would be the same as Alternative B. Pursuing a withdrawal from appropriation under the mining laws in the Beck Lake Scenic Area would result in the same benefits as Alternative A.

Recreation

Alternative E manages a total of 1,610,729 acres as ROW avoidance and 1,322,879 acres as ROW exclusion areas (the most of any alternative), resulting in impacts similar to alternatives A and B, but to a greater extent due to the consolidation of ROWs that would preserve the RSCC more than under those alternatives. Alternative E would also restrict renewable energy development the most of any alternative, resulting in reduced recreation displacement and visual impacts to recreation settings compared to the other alternatives.

Alternative E limits motorized vehicle travel to designated roads and trails in the same areas as Alternative B, and impacts to recreation would be the same as Alternative B. Seasonal travel closures within greater sage-grouse Key Habitat Areas under alternatives B and E may impact recreation from the restriction of motorized access to areas either within Key Habitat Areas, or reached by access through Key Habitat Areas. These seasonal closures may impact desired recreational opportunities, experiences, and beneficial outcomes by repudiating motorized access within Key Habitat Areas, which provide access to many areas within the Bighorn Basin and recreational experiences that require motorized access. Such activities that may be delayed include antler shed hunting, hiking, motorized touring and OHV use, caving, camping, sightseeing and wildlife viewing, rock hounding, environmental education, and general touring throughout the Bighorn Basin. Certain activities, such as cougar and bear hunting in areas within greater sage-grouse Key Habitat Areas would only be available during fall hunting periods, and unavailable during the spring. Desirable recreational areas affected by certain seasonal closures include, but are not limited to, portions of the McCullough Peaks, public lands south of Cody, Wyoming, portions of the West Slope of the Big Horn Mountains, the Red Gulch/Alkali Road National Back Country Byway, Castle Gardens Scenic Area, and portions of the Absaroka Front and the foothills.

Under Alternative E, management of and effects from areas open to cross-country motorized travel, OHV use for big game retrieval and dispersed campsite access, and other “necessary tasks” would be similar to Alternative B.

Effects of closing areas to livestock grazing for the benefit of wildlife, including the Greater Sage-Grouse Key Habitat Areas ACEC, would be the same as Alternative B.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), is the same as Alternative B. The impacts of these designations would be similar to alternatives A and B, but to a greater extent because Alternative E includes more special designations that cover a greater area. In the Greater Sage-Grouse Key Habitat Areas ACEC, the BLM would only issue SRPs with neutral or beneficial effects to priority sage-grouse habitat. That ACEC also restricts surface-disturbing activities and certain resource uses and activities (e.g., minerals development) to protect greater sage-grouse habitat that may benefit recreational wildlife viewing opportunities, especially bird watching. Beneficial impacts would accrue to recreation experiences in areas managed for back country desired RSCCs. Restrictions on motorized travel and new road and trail development under Alternative E would result in similar adverse impacts to motorized recreation use from special designations management as described for Alternative B.

Resources

Beneficial impacts from soils, water quality, and watershed management under Alternative E would be similar to alternatives A and B, although to a greater extent due to the smaller area of surface disturbance allowed, which is the least of any alternative. Reclamation of closed routes in the Greater Sage-Grouse Key Habitat Areas ACEC would provide additional benefits to water quality for recreational

uses and primitive recreation opportunities. Management of the discharge of produced water under Alternative E would result in similar effects as Alternative B.

Alternative E manages cave and karst, cultural, and visual resources the same as Alternative B, and impacts would be the same as Alternative B.

Fire and fuels management and vegetation and silvicultural treatments under Alternative E are similar to Alternative B, and impacts to recreation would be similar to Alternative B. Within the Greater Sage-Grouse Key Habitat Areas ACEC, additional vegetation management designed to enhance greater sage-grouse habitat could result in indirect benefits to recreationists by improving wildlife habitat to a greater extent than under alternatives A and B.

Under Alternative E, management actions that would benefit fish and wildlife while also enhancing recreational activities such as fishing, hunting, bird watching, and general wildlife viewing would be the same as Alternative B. However, additional restrictions within the Greater Sage-Grouse Key Habitat Areas ACEC would restrict public access and limit opportunities for motorized recreational travel more than management under Alternative B or the other alternatives.

Cultural resources management and VRM under Alternative E are the same as Alternative B, and impacts would be the same as Alternative B.

Proactive Management

Under Alternative E, recreation management areas and recreation sites are the same as Alternative B, and impacts would be the same as Alternative B.

Alternative F

Under Alternative F, the BLM designates the same recreation management areas (SRMAs, ERMAs, and RMZs) as Alternative D (see Map 78 and Table 4-29). Management actions to maintain or enhance recreation settings, experiences, and opportunities in these areas and impacts on other resources and resource uses under Alternative F would be the same as Alternative D.

Surface Disturbance

Under Alternative F, a total of 137,064 acres of short-term and 17,663 acres of long-term surface disturbance is projected (Appendix T), most of which would result in adverse impacts to recreation. The intensity of impacts to recreation would depend on the location of the surface disturbance in relation to the desired RSCC in the area being disturbed (see *Impacts Common to All Alternatives*). Surface-disturbing activities and total surface disturbance acreage under Alternative F would be similar to Alternative D, and impacts to recreational experiences would be similar to Alternative D. However, in greater sage-grouse PHMAs under Alternative F, disturbances would not be permitted to exceed one disturbance per 640 acres or disturb more than 3 percent of sagebrush habitat. This additional restriction would reduce potential adverse impacts from surface disturbance to recreational experiences, particularly in areas managed for back country desired RSCC, compared to Alternative D.

Resource Uses

The management of minerals development under Alternative F is similar to Alternative D, and impacts to recreational experiences and settings would be similar to Alternative D. Unlike Alternative D, Alternative F includes an NSO stipulation within 0.6 mile of occupied sage-grouse leks in the proposed Greater Sage-Grouse PHMAs ACEC; however, this additional stipulation would not change the projected

Recreation

oil and gas development (see Appendix T) to an extent that would alter the projected impacts from Alternative F compared to those under Alternative D.

Management of acquisitions and land tenure adjustments for public access under Alternative F is the same as Alternative D, and impacts to recreation and public access would be the same as Alternative D. Pursuing a withdrawal from appropriation under the mining laws in the Beck Lake Scenic Area and not issuing an order that opens the land to mineral entry would result in the same, if not slightly greater, benefits as Alternative A.

Renewable energy development and ROW development under Alternative F are similar to, but more restrictive than (i.e., larger areas of renewable energy and ROW avoidance/exclusion) management under Alternative D, and impacts would be similar to Alternative D, though to a lesser extent.

Travel and transportation management restrictions under Alternative F would result in impacts similar to Alternative A, but to a greater extent. Alternative F restricts motorized vehicle use in the Greater Sage-Grouse PHMAs ACEC to designated roads and trails but does not impose seasonal closures like those under Alternative E. Travel and transportation management under Alternative F would result in impacts similar to Alternative A; however, Alternative F restrictions on motorized vehicle use would have greater benefits to recreation opportunities for solitude, natural settings, and primitive forms of travel than under alternatives D, C, and A, but less than alternatives B and E. Alternative F manages the same acreage as open to cross-country motorized travel as Alternative D, and impacts would be the same as Alternative D.

Livestock grazing management under Alternative F is the same as Alternative D, and impacts to recreational experiences would be the same as Alternative D.

Special Designations

Management of special designations in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres) under Alternative F is the same as Alternative D. Special designations under Alternative F would result in impacts similar to alternatives A and D, but to a larger extent because Alternative F includes more special designations that cover a greater area. In the Greater Sage-Grouse PHMAs ACEC, the BLM would only issue SRPs with neutral or beneficial effects to priority sage-grouse habitat. This management action may preclude or defer some commercial recreational activities (e.g., OHV race events) currently taking place within the Greater Sage-Grouse PHMAs ACEC. This ACEC also places restrictions on surface-disturbing and resource use activities for the protection of greater sage-grouse that could in turn have beneficial impacts on recreational wildlife viewing opportunities, especially bird watching.

Resources

Beneficial impacts from soils, water quality, and watershed management under Alternative F would be similar to alternatives A and D, although to a greater extent due to the smaller area of surface disturbance allowed under Alternative F in greater sage-grouse PHMAs. Watershed management practices under Alternative F would be the same as Alternative D, and the associated beneficial impacts on recreation would be the same as Alternative D.

Alternative F manages cave and karst the same way as Alternative C, and impacts would be the same as Alternative C.

Fire and fuels management and vegetation and silvicultural treatments under Alternative F are similar to Alternative D, and impacts to recreation would be similar to Alternative D. Within the Greater Sage-Grouse PHMAs ACEC, additional vegetation management designed to enhance greater sage-grouse

habitat could result in indirect benefits to recreationists by improving wildlife habitat to a greater extent than under alternatives A and D.

Under Alternative F, management actions that would benefit fish and wildlife while also enhancing recreational activities such as fishing, hunting, bird watching, and general wildlife viewing are the same as Alternative D. However, greater sage-grouse protective management applied to the Greater Sage-Grouse PHMAs ACEC would restrict public access and limit opportunities for motorized recreational travel to a greater extent than under alternatives A, C, and D, but less so than under alternatives B and E.

Cultural resources management and VRM under Alternative F are the same as Alternative D, and impacts would be the same as Alternative D.

Proactive Management

Under Alternative F, recreation management areas and recreation sites would be the same as Alternative D, and impacts would be the same as Alternative D.

4.6.6 Lands with Wilderness Characteristics

The BLM inventory identified approximately 476,349 acres (in 43 lands with wilderness characteristics) of BLM-administered land with wilderness characteristics in the Planning Area, or approximately 15 percent of total BLM-administered land in the Planning Area. Chapter 3 describes the process used to inventory lands with wilderness characteristics and lists the current key management for each of these areas.

This section presents an analysis of proposed management actions for lands with wilderness characteristics that are likely to result in impacts to other resources, resource uses, and special designations. This section also analyzes the effects of management actions on the wilderness characteristics identified in these areas.

Adverse impacts from management in lands with wilderness characteristics result from actions that restrict resource uses or the management of resources, while beneficial impacts are those that enhance other resource uses or the management of resources. Adverse impacts to lands with wilderness characteristics occur when apparent naturalness, opportunities for solitude, or opportunities for primitive, unconfined recreation (collectively known as wilderness characteristics) are compromised. Beneficial impacts occur when the above conditions are preserved or improved. Direct impacts would result from management actions that affect other resource uses or activities in lands with wilderness characteristics. Indirect impacts to other resources (e.g., soils and vegetation) may result if management actions in lands with wilderness characteristics displace resource uses or activities (e.g., minerals development) to areas outside of these lands, thereby augmenting impacts in other areas.

For a discussion of wilderness characteristics in WSAs, please refer to Section 4.7.6 *Wilderness Study Areas*.

4.6.6.1 Methods and Assumptions

This analysis considers potential effects on wilderness characteristics under each alternative for all inventoried lands with wilderness characteristics (476,349 acres) in the Planning Area, regardless of whether the alternative manages these areas to maintain their wilderness characteristics. All instances of the phrase “lands with wilderness characteristics” in the sections that follow refer to inventoried lands with wilderness in the Planning Area (476,349 acres), except where immediately followed by

Lands with Wilderness Characteristics

“managed for their wilderness characteristics”, “managed to maintain their wilderness characteristics”, or a similar qualifying phrase. Inventoried lands with wilderness characteristics are the same under all alternatives, but management of these areas differs by alternative. For alternatives B and E, all inventoried lands with wilderness characteristics are managed for their wilderness characteristics.

The analysis considers only present conditions, not the potential for other areas to become lands with wilderness characteristics through restoration or other changes in existing conditions. This analysis includes the following assumptions:

- Lands with wilderness characteristics in the Planning Area are not subject to BLM Manual 6330, *Management of Wilderness Study Areas* (BLM 2012a) or other policies or guidance applicable to WSAs or Wilderness Areas.
- All alternatives recognize valid existing rights on lands with wilderness characteristics. In some cases, the exercise of valid existing rights may be incompatible with protection of wilderness characteristics and may result in impact to wilderness characteristics.
- Management actions that enhance biological or other environmental characteristics would improve the quality of the wilderness characteristics of lands with wilderness characteristics over the long term.
- Management actions that reduce surface disturbance or decrease evidence of human presence in these areas would improve the quality of wilderness characteristics in lands with wilderness characteristics.
- Managing lands with wilderness characteristics to maintain their wilderness characteristics would benefit naturalness, and opportunities for solitude, and primitive and unconfined recreation.

Under Alternative A, decisions on projects in lands with wilderness characteristics would be consistent with current management.

4.6.6.2 Summary of Impacts by Alternative

Under alternatives A, C, and D, no lands with wilderness characteristics are managed to maintain their wilderness characteristics. Therefore, the preservation of wilderness characteristics (e.g., sufficient size, a high degree of naturalness, outstanding opportunities for solitude, or outstanding opportunities for primitive and unconfined recreation) in lands with wilderness characteristics would be least effective under these alternatives. In contrast, lands with wilderness characteristics under alternatives B and E (476,349 acres) are managed to maintain naturalness, outstanding opportunities for solitude or a primitive and unconfined recreation. Although many lands with wilderness characteristics in the Planning Area contain potential resource conflicts that may be inconsistent with retention of wilderness characteristics (see Table 3-51), under alternatives B and E the BLM would apply management to maintain these characteristics to the extent practicable. Such management would be a beneficial impact for wilderness characteristics. Under Alternative F, 49,396 acres (in nine lands with wilderness characteristics) are managed to maintain wilderness characteristics; the remaining lands with wilderness characteristics under Alternative F are not managed to maintain their wilderness characteristics.

Alternatives A and C include the least restrictive management of resource uses that involve surface disturbance or degrade the natural character of the landscape in lands with wilderness characteristics. Alternative C would result in the greatest adverse impacts to these lands due to the greater intensity of resource uses and the amount of surface disturbance under this alternative. Overlapping special designations under alternatives A, D, and F provide some maintenance for wilderness characteristics in

lands with wilderness characteristics. No special designations under Alternative C overlap lands with wilderness characteristics. Under Alternative A, 9,008 acres of WSR eligible waterway segments and 27,231 acres of ACEC designations overlap lands with wilderness characteristics. Under Alternative F, 48,770 acres of lands with wilderness characteristics are overlapped by ACECs.

Alternatives E, B, and F, respectively, would reduce the potential for adverse impacts to wilderness characteristics in lands with wilderness characteristics to the greatest degree by restricting or limiting resource uses and activities that could degrade wilderness characteristics. Management actions under alternatives that maintain wilderness characteristics would restrict, and thereby adversely affect, resource uses and certain activities (e.g., motorized vehicle use) to maintain the naturalness and opportunities for solitude and primitive, unconfined recreation in these areas. However, the comparatively more restrictive management of mineral resources and ROW development under alternatives B, E, and F could benefit other resources and resource uses in areas with wilderness characteristics, such as soils, primitive and back country recreation, and visual resources.

4.6.6.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Under all alternatives, any surface-disturbing activity, including fire and fuels management, paleontological and cultural excavations, ROWs and renewable energy development, and the maintenance of existing facilities may result in adverse impacts to wilderness characteristics in lands with wilderness characteristics. Hazardous fuels treatment and activities to control wildland fire, such as the construction of fire breaks, create surface disturbance that may result in adverse impacts to wilderness characteristics in lands with wilderness characteristics. Motorized vehicle use can disturb vegetation and contribute to the spread of invasive species that degrade native vegetation communities and diminish wilderness characteristics. Livestock, wild horse, and wildlife grazing could contribute to the spread of invasive species, and concentrated grazing by any species can compact soils and degrade riparian/wetland areas. Facilities maintenance can require the use of mechanized equipment and vehicles and can alter the natural state of vegetation and affect wilderness characteristics.

Alternative A

Surface Disturbance

Management actions under Alternative A are projected to result in approximately 136,253 acres of short-term and 15,646 acres of long-term surface disturbance on BLM-administered land over the life of the plan (Table 4-1). Most surface-disturbing activities are not specifically prohibited in lands with wilderness characteristics under Alternative A, and could therefore result in adverse impacts to these lands by compromising wilderness characteristics.

Resource Uses

Alternative A does not manage lands with wilderness characteristics to maintain their wilderness characteristics; however, management for other resource uses that overlap lands with wilderness characteristics under Alternative A may cause impacts to wilderness characteristics. Table 4-30 provides a summary of acreages and allocations associated with resources and resource uses in those lands that have the potential to affect wilderness characteristics. Management under Alternative A includes the second largest amount of area open to mineral materials disposal and available for mineral leasing, the second largest amount of area open to ROW authorizations, and the greatest amount of area where

Lands with Wilderness Characteristics

motorized vehicle use is limited to existing roads and trails. Opening lands with wilderness characteristics to mineral development, managing areas as open to ROWs and renewable energy authorizations, and allowing motorized vehicle use on existing roads and trails may result in adverse impacts to wilderness characteristics in these areas. In general, because of the intensity and extent of allowable resource uses under Alternative A, management under this alternative would result in adverse impacts to wilderness characteristics. Although the wilderness characteristics of these areas have been maintained since the last wilderness review 30 years ago, they do not guarantee continued maintenance of these wilderness characteristics in response to potential changes in land use and development interest that may occur during the planning period.

Special Designations

Special designations that overlap lands with wilderness characteristics may result in beneficial impacts to these lands by restricting resource uses and surface-disturbing activities that can degrade wilderness characteristics, or by requiring additional mitigation for allowable activities. ACECs, WSRs, and NHTs and Other Historic Trails overlap some lands with wilderness characteristics under Alternative A, and some of these specially designated areas include management that would reduce adverse impacts to wilderness characteristics (e.g., VRM, management of surface-disturbing activities, travel designations, etc.). Resource protections provided by the management of these areas would be beneficial to wilderness characteristics in certain lands, though these impacts would vary by location and designations. Under Alternative A, 9,088 acres of WSR eligible waterway segments and 27,231 acres of ACEC designations overlap lands with wilderness characteristics.

Table 4-30. Acres of Management in Inventoried Lands with Wilderness Characteristics by Alternative

Alternative	Mineral Closures (acres)		Rights-of-Way (acres)			Visual Resource Management Class (acres)				Travel Management (acres)				Lands with Wilderness Characteristics Managed to Maintain their Wilderness Characteristics	
	Minerals Material Closure	Closed to Mineral Leasing	Exclusion	Avoidance	Open	Class I	Class II	Class III	Class IV	Closed	Limited to Designated	Limited to Existing	Open		Seasonal Restrictions
Alternative A ¹	14,355	33,603	12,902	116,045	347,402	6	106,900	106,899	278,969	5,714	145,392	325,236	0	17,725	0
Alternative B ²	471,584	471,727	26,459	449,873	17	4,884	470,975	164	20	9,049	467,282	3	0	182,983	476,349
Alternative C ¹	7,201	3,422	659	103,017	372,674	<6	90,760	113,932	271,345	3,184	179,892	293,258	0	17,717	0
Alternative D ¹	96,174	46,712	5,428	336,636	134,285	6	166,405	141,856	168,049	3,186	302,899	170,251	0	17,748	0
Alternative E ²	471,707	471,727	169,554	306,778	17	4,884	470,975	164	20	9,137	467,194	3	0	182,983	476,349
Alternative F ²	33,313	48,996	4,860	44,537	0	6	49,372	2	0	3,149	46,069	180	0	11,042	49,396

Sources: BLM 2009a; BLM 2013a

¹Alternatives A, C, and D do not contain specific management for any identified lands with wilderness characteristics; however, the areas identified as lands with wilderness characteristics was a finding in the inventory conducted for this Resource Management Plan Revision Project and do not reflect a land use classification.

²Acreages are based on BLM-administered lands managed for wilderness characteristics.

Note: Due to variations in data coverage, acreages within each management category may not add to the total acreage for lands with wilderness characteristics in the Planning Area.

< Less than

Lands with Wilderness Characteristics

Resources

Fire and fuels management may result in adverse impacts if mechanical fuels treatments and prescribed fire result in surface disturbance or changes in the structure of vegetation that degrades wilderness characteristics. However, fuels treatments and prescribed fire may reduce the potential for future larger-scale wildfires that would result in adverse impacts to primitive and unconfined recreation in lands with wilderness characteristics before an area recovers. The adverse impacts to wilderness characteristics in these lands would increase with the amount of treatment.

Under Alternative A, the BLM manages visual resources in lands with wilderness characteristics primarily as VRM Class IV (Table 4-30). In areas managed as VRM Class IV, modification of the natural environment would be allowed (via increased tolerance for surface disturbance and fewer requirements related to facility location and other types of mitigating design modifications) and there could be adverse impacts to the identified wilderness characteristics of the areas.

Proactive Management

Under Alternative A, the BLM does not manage lands with wilderness characteristics to maintain their wilderness characteristics; these areas would be managed consistent with management for other resources and resource uses.

Alternative B

Surface Disturbance

Under Alternative B, the acreage of surface disturbance in lands with wilderness characteristics is likely to be substantially less than under Alternative A. Management actions under Alternative B are projected to result in approximately 30 percent less long-term surface disturbance on BLM-administered land than Alternative A (Table 4-1). Restrictions on minerals, ROWs, vegetative treatments, and other resource uses in lands with wilderness characteristics under Alternative B would further reduce the potential for adverse impacts from surface disturbance in these areas relative to Alternative A by leaving these areas in a more natural, unmodified state.

Resource Uses

Management for lands with wilderness characteristics under Alternative B designed to protect naturalness and outstanding opportunities for solitude and primitive and unconfined recreation could result in adverse impacts to other resource uses as described below, but would be beneficial to the protection of wilderness characteristics. Restrictions on mineral development, timber harvest practices, mechanical vegetation treatments, motorized vehicle use, ROWs, and rangeland improvements under Alternative B would help to maintain wilderness characteristics in these lands. These restrictions may displace some resource uses and activities, such as minerals development or motorized vehicle use, which could potentially adversely affect resources (e.g., wildlife and vegetation) in areas outside of lands with wilderness characteristics.

Under Alternative B, lands with wilderness characteristics are closed to oil and gas and solid mineral leasing and mineral materials disposal. This management would result in greater adverse impacts to these resources than Alternative A (see Table 4-30), particularly in areas with development potential, because new leasing or disposal would be prohibited. The BLM would consider measures to minimize impacts to wilderness characteristics in project level analysis. Lands with wilderness characteristics encumbered with valid existing rights may be impacted where development of those rights is incompatible with protection of wilderness characteristics.

Under Alternative B, lands with wilderness characteristics also are closed to commercial and personal-use wood cutting, which may adversely affect forest products by reducing the area open to timber harvest compared to Alternative A.

Under Alternative B, the BLM limits motorized vehicle use to designated roads and trails in all lands with wilderness characteristics and closes them to over-snow travel. Increased restrictions on motorized vehicle use under Alternative B would adversely affect travel opportunities to a greater extent than Alternative A (see Table 4-30). These lands also are closed to new road construction under Alternative B, which may adversely affect CTTM by restricting the development of new routes if access issues are discovered.

Under Alternative B, the BLM manages lands with wilderness characteristics as ROW avoidance areas, which would result in greater adverse impacts to the ability to grant ROW authorizations on these lands compared to Alternative A (see Table 4-30).

Special Designations

Special designations cover a larger percentage of the Planning Area under Alternative B compared to Alternative A, restricting resource uses that could adversely affect naturalness and outstanding opportunities for solitude and primitive and unconfined recreation. Under Alternative B, the area of WSR suitable waterway segment overlap is the same as under Alternative A, while acres of ACEC and lands with wilderness characteristics overlap would be greater than under Alternative A (79,225 acres). However, because the characteristics of these areas are already protected under Alternative B, the magnitude of the impact would be smaller than under Alternative A.

Resources

Under Alternative B, resources adversely affected by surface-disturbing activities or motorized vehicle use would benefit from the restriction on these activities in lands with wilderness characteristics. Resources that would benefit from management under this alternative include recreation and related opportunities and experiences derived from primitive-based settings, soil, water, wildlife and special status species, and cultural and visual resources. Under Alternative B, the BLM would manage all lands with wilderness characteristics as VRM Class I or II. Alternative B manages for more VRM Class I and II in these lands than Alternative A. A larger area of more restrictive VRM Class I and II areas would affect the design and occurrence of actions that result in surface disturbance, and would provide increased protection for wilderness characteristics compared to Alternative A.

Fire and fuels management would be more restricted in lands with wilderness characteristics under Alternative B than under Alternative A. Although the BLM allows prescribed fire in these lands, it allows mechanical vegetation treatments only to restore natural resource systems. Because fuels reduction through thinning is more restricted than under Alternative A, there may be more risk of catastrophic wildfires in these areas.

Proactive Management

Under Alternative B, the BLM manages all lands with wilderness characteristics to maintain their wilderness characteristics (476,349 acres), which include naturalness, outstanding opportunities for solitude, and primitive and unconfined recreation. As described in the sections above, Alternative B applies specific management actions for lands with wilderness characteristics that, in addition management for other resources that overlaps lands with wilderness characteristics, prohibits or limits resource uses that that could degrade wilderness characteristics.

Alternative C

Surface Disturbance

Surface disturbance would result in impacts to wilderness characteristics in lands with wilderness characteristics similar to Alternative A, although to a greater extent because Alternative C involves more projected surface disturbance. Management actions under Alternative C are projected to result in approximately 80 percent more short-term (245,642 acres) and 165 percent more long-term (41,485 acres) surface disturbance on BLM-administered land than Alternative A. Adverse impacts are likely to increase with the amount of total Planning Area surface disturbance, because lands with wilderness characteristics are not managed to maintain their wilderness characteristics under Alternative C. Adverse impacts to wilderness characteristics from surface disturbance in these lands would be the greatest under Alternative C.

Resource Uses

The impacts from resource uses to wilderness characteristics in lands with wilderness characteristics under Alternative C would generally be similar in extent to Alternative A and would result from the same types of resource use. Table 4-30 summarizes acreages and allocations associated with resources and resource uses in those lands that have the potential to affect wilderness characteristics. Management under Alternative C includes the largest areas open to mineral materials disposal and available for mineral leasing, the largest area open to ROW authorizations, and the second largest area where motorized vehicle use is limited to existing roads and trails. Alternative C is generally the least restrictive alternative in terms of allowable resource uses and resource protection, and although the extent of impacts would be similar to Alternative A, the intensity of these impacts under this alternative may result in the greatest adverse impacts to wilderness characteristics in inventoried lands.

Special Designations

Special designations that overlap lands with wilderness characteristics may result in beneficial impacts to wilderness characteristics by restricting resource uses and surface-disturbing activities or requiring additional mitigation. Due to the limited extent of lands with special designations under Alternative C, the potential beneficial impacts to wilderness characteristics in these lands would be lowest under this alternative. Under Alternative C, 3,181 acres of ACEC designations overlap lands with wilderness characteristics.

Resources

Impacts to wilderness characteristics in lands with wilderness characteristics from fire and fuels management would result in impacts similar to those under Alternative A, although to a greater extent. In general, the extent and intensity of fuels treatment under Alternative C are greater than under the other alternatives. Adverse impacts to wilderness characteristics in these lands would be proportional to the amount of treatment.

Under Alternative C, lands with wilderness characteristics include more VRM Class III and IV areas and less VRM Class I and II areas than any other alternative. Visual management in these lands under Alternative C would have the greatest potential to result in adverse impacts to wilderness characteristics compared to the other alternatives.

Proactive Management

Under Alternative C, the BLM does not manage lands with wilderness characteristics to maintain their wilderness characteristics; these areas would be managed consistent with management for other resources and resource uses.

Alternative D

Surface Disturbance

Under Alternative D, the BLM would not manage lands to protect wilderness characteristics outside of existing WSAs. Some wilderness characteristics may be afforded indirect protections through the application of management actions (i.e., ACECs, travel designations, VRM classifications) and allowable use decisions for other resources and resource uses (e.g., application of NSO, CSU, and TL stipulations). However, no land use planning decisions would be made specifically to protect wilderness characteristics in Alternative D. Surface disturbance would result in impacts to wilderness characteristics in lands with wilderness characteristics similar to Alternative A, although to a greater extent because Alternative D involves more projected surface disturbance. It is estimated that 1,143 new well pads could be constructed on BLM-administered land, resulting in 3,429 acres of surface disturbance in the Planning Area under this alternative (Appendix T). Some of this development could likely occur in identified lands with wilderness characteristics. Management actions under Alternative D are projected to result in approximately 3 percent more short-term (140,175 acres) and 17 percent more long-term (18,306 acres) surface disturbance on BLM-administered land than Alternative A. The noise and presence of these developments in conjunction with access road construction, vehicle traffic associated with the construction, drill rig transport, and production of the wells are likely to change or degrade the natural character and opportunities for solitude and primitive and unconfined types of recreation throughout the life of the plan. Adverse impacts to wilderness characteristics from surface disturbance in lands with wilderness characteristics would be similar to Alternative C, but to a lesser extent.

Encouraging the use of native plant species to re-seed areas could reduce opportunities for the establishment of noxious weeds and invasive species, which could improve the overall naturalness of an area, creating conditions favorable to maintaining wilderness characteristics or even creating new areas through remediation which could be found to have wilderness characteristics in the future.

Resource Uses

Under Alternative D, the BLM does not manage lands with wilderness characteristics to maintain their wilderness characteristics; these areas would be managed consistent with management for other resources and resource uses. Table 4-30 shows acres of management in lands with wilderness characteristics under this alternative. The impacts from resource uses to wilderness characteristics in inventoried lands with wilderness characteristics under Alternative D would generally be similar in extent to Alternative A and would result from the same types of resource use. Table 4-30 summarizes acreages and allocations associated with resources and resource uses in those lands that have the potential to affect wilderness characteristics. Management under Alternative D includes the third smallest amount of area open to mineral materials disposal and the third smallest amount of area available for mineral leasing. Recreation management areas where they contain lands with wilderness characteristics, especially the Absaroka Mountain Foothills SRMA, Tatman Mountains RMZ, and McCullough Peaks SRMA containing 3,044 acres, 27,035 acres, and 42,425 acres, respectively, would

Lands with Wilderness Characteristics

beneficially affect wilderness characteristics by preserving the desired back country naturalness sub-component of the RSCCs in these areas.

In general, management of resource uses in lands with wilderness characteristics under Alternative D is similar to that under Alternative A, although more mitigation and reclamation requirements under Alternative D may limit impacts to wilderness characteristics.

Special Designations

Several special designations overlap lands with wilderness characteristics under Alternative D. Restrictions on surface disturbance and constraints on resource uses from overlapping special designations would limit adverse impacts to wilderness characteristics. These beneficial impacts to lands with wilderness characteristics would be similar to those described under Alternative A, although to a greater extent due to the larger area of overlapping ACECs (51,681 acres).

Resources

Impacts to wilderness characteristics in lands with wilderness characteristics from fire and fuels management would result in impacts similar to those under Alternative A.

Under Alternative D, the BLM would manage 166,405 acres of lands with wilderness characteristics under VRM Class II objectives, which is 304,570 acres less than alternatives B and E, and 59,506 acres more than Alternative A. Benefits to wilderness characteristics from this alternative would be the same as under Alternative B, though to a lesser extent due to the smaller area of lands with wilderness characteristics managed under VRM Class II objectives.

Proactive Management

No management actions exist specific to protecting lands with wilderness characteristics under Alternative D. Consequently no impacts as a result of management actions specific to lands with wilderness characteristics are expected. However, management actions associated with other resources in which NSO stipulations, CSU stipulations or other COAs are applied that would create conditions favorable to maintaining wilderness characteristics (such as helping to retain naturalness or opportunities for primitive or unconfined types of recreation) could have a beneficial impact if these COAs apply to lands with wilderness characteristics. See Table 4-31 below for a summary of Resource Allocations that could create conditions favorable for maintaining wilderness characteristics.

Additionally under all alternatives, implementing existing and travel management plans developed subsequent to this RMP would benefit lands with wilderness characteristics by providing site-specific travel designations that accommodate appropriate access while considering resource protection and user safety.

Table 4-31. Overlap between Resource Allocations whose Management could Create Conditions Favorable to Maintaining Wilderness Characteristics and Inventoried Areas Found to Have Wilderness Characteristics

Resource Allocation Protection	Acres within inventoried units that may receive indirect protections from overlapping mitigation for other resource protections	Naturalness may be indirectly protected from overlapping mitigation for other resource protection	Outstanding opportunity for solitude may be indirectly protected from overlapping mitigation for other resource protection	Opportunities for primitive recreation may be indirectly protected from overlapping mitigation for other resource protection
ACECs	11,343	Yes	Yes	Yes

 NSO No Surface Occupancy
 RMA Recreation Management Area

Alternative E

Under Alternative E, the BLM manages all lands with wilderness characteristics to maintain their wilderness characteristics (476,349 acres), the same as Alternative B. Management actions to maintain wilderness characteristics in lands with wilderness characteristics and impacts on other resources and resource uses under Alternative E would be the same as Alternative B. Table 4-30 shows acres of management in lands with wilderness characteristics under this alternative.

Surface Disturbance

Under Alternative E, surface disturbance in lands with wilderness characteristics would be less than under any alternative. Management actions under this alternative are projected to result in approximately 47 percent less short-term and 31 percent less long-term surface disturbance on BLM-administered land than Alternative A. Restrictions on minerals, ROWs, vegetative treatments, and other resource uses in lands with wilderness characteristics for the protection of other resource values under Alternative E would further reduce the potential for surface disturbance in these areas more than any other alternative. As a result, there would be greater benefits to the wilderness characteristics in these lands because these areas would be left in a more natural, unmodified state.

Lands with Wilderness Characteristics

Resource Uses

Management of mineral development, timber harvest practices, mechanical vegetation treatments, motorized vehicle use, ROWs, and rangeland improvements for the maintenance of wilderness characteristics under Alternative E are the same as Alternative B; impacts to wilderness characteristics, as well as impacts on other resources use from the management of these areas, would be the same as Alternative B.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), is the same as Alternative B. Special designations could benefit wilderness characteristics by restricting resource uses that adversely affect naturalness and outstanding opportunities for solitude and primitive and unconfined recreation. Special designations cover a larger percentage of the Planning Area under Alternative E compared to the other alternatives. Under Alternative E, the area of ACEC overlapping lands with wilderness characteristics managed to maintain their wilderness characteristics would be substantially greater than under alternatives A or B (225,306 acres). However, because the characteristics of these areas are already protected, the impacts from these overlapping special designations would be the same as Alternative B.

Resources

Alternative E management to maintain wilderness characteristics in lands with wilderness characteristics is the same as Alternative B; beneficial impacts to soil, water, wildlife and special status species, and cultural and visual resources would be the same as Alternative B.

Under Alternative E, the management of fire and fuels in lands with wilderness characteristics managed to maintain wilderness characteristics is similar to Alternative B, and impacts to fire and fuels management from managing lands with wilderness characteristics would be the similar to Alternative B.

Proactive Management

Impacts to lands with wilderness characteristics under Alternative E would be the same as those described under Alternative B.

Alternative F

Surface Disturbance

Surface disturbance under Alternative F would be similar to Alternative A and would result in adverse impacts to wilderness characteristics in lands with wilderness characteristics, although to a slightly greater extent because Alternative F involves additional projected surface disturbance. Under this alternative, management actions are projected to result in an approximately 1 percent increase in short-term and a 13 percent increase in long-term surface disturbance on BLM-administered land than Alternative A. Adverse impacts under Alternative F would be similar to Alternative D and would be likely to increase with the amount of total surface disturbance.

Resource Uses

Management of minerals, ROWs, vegetative treatments, and other resource uses in lands with wilderness characteristics under Alternative F would be similar to Alternative B from constraints on mineral leasing and ROW avoidance and exclusion areas, but to a lesser extent because Alternative F manages 426,952 acres less than Alternative B. Table 4-30 summarizes acreages and allocations

associated with resources and resource uses in lands with wilderness characteristics that have the potential to affect these characteristics. Generally, impacts under Alternative F would be similar to Alternative D.

Special Designations

Management of special designations under Alternative F, except in the Greater Sage-Grouse PHMAs ACEC (1,116,698 acres), would be the same as Alternative D. Beneficial impacts to lands with wilderness characteristics from restrictions on surface disturbance and constraints on resource uses from overlapping special designations would limit adverse impacts to wilderness characteristics, similar to Alternative A, but to greater extent because of the larger area of overlapping ACECs (48,770 acres) under Alternative F.

Resources

Impacts to wilderness characteristics in lands with wilderness characteristics from fire and fuels management would result in impacts similar to those under Alternative A.

Proactive Management

Under Alternative F, 49,396 acres (in nine lands with wilderness characteristics) are managed to maintain wilderness characteristics. Impacts to wilderness characteristics in these areas would be similar to Alternative B. The remaining lands with wilderness characteristics under Alternative F are not managed to maintain their wilderness characteristics.

4.6.7 Livestock Grazing Management

Adverse impacts to livestock grazing management result from management actions that limit, reduce, or prohibit livestock grazing or AUMs in the Planning Area. Additionally, management actions that degrade rangeland health (e.g., the condition of soils, watersheds, and vegetation communities) and livestock forage or that restrict the placement, construction, or maintenance of range improvement projects would result in adverse impacts. Management actions that are beneficial to livestock grazing include those that increase AUMs, decrease restrictions on the grazing of livestock, improve rangeland health or livestock forage, distribute or disperse livestock in ways that increase access to forage, or reduce the cost associated with livestock grazing management.

Direct impacts to livestock grazing result from management actions that change AUM allocations or restrict livestock grazing. Indirect impacts to livestock grazing result from management actions that affect rangeland health and productivity or that change livestock grazing management on BLM-administered lands with the Planning Area.

4.6.7.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Surface disturbances reduce the amount of forage available to herbivory use and can be short- and long-term (Appendix T).
- Surface disturbances increase the likelihood for the introduction and spread of invasive species, which degrade rangeland health and impact forage quality and quantity.

- To varying degrees, areas of concentrated herbivory use exist in most allotments (i.e., riparian/wetland areas, salting areas, fence corridors, etc.). Range improvements and managed livestock grazing methods disperse livestock and minimize livestock concentrations.
- Grazing management practices such as season of use and kind of livestock and stocking level modification, rotational grazing, and temporary closures can maintain or improve rangeland health and ensure the achievement of Wyoming Standards for Healthy Rangelands (Appendix N).
- Range improvements would include the following types of projects: spring/seep development and protection, reservoirs and pits, wells, new or modified fencing, vegetation treatments, and pipelines.
- Any changes in grazing management, including changes in permitted use, would be based on rangeland monitoring and documented field observations, in accordance with grazing regulations (43 CFR 4110.3).
- Management actions for other resource uses (e.g., oil and gas leasing) can affect livestock grazing allocations and management.
- Managing wildlife and special status plants and wildlife can affect livestock grazing allocations.
- As described in the Footnote 1 in Table W-1, *Utilization Levels in the Planning Area* (Appendix W), the BLM may adjust utilization levels downward to ensure that total utilization of the current year's growth following the use period of wildlife does not exceed the prescribed level for dormant season use in areas where extensive wildlife use occurs (i.e., crucial winter ranges for elk, bighorn sheep, pronghorn, and greater sage-grouse, and winter sage-grouse concentration areas or sage-grouse nesting habitat). Potential changes would be analyzed through AMPs or permit renewals.
- If a portion of an allotment is closed to livestock grazing, a proportional loss of AUMs in that allotment would result. Issues related to compensation of permittees or lessees for the loss of use of range improvements in allotments closed to livestock grazing would be addressed at the time an allotment is closed, and in accordance with regulations at 43 CFR 4120.3-6.

4.6.7.2 Summary of Impacts by Alternative

Principal impacts to livestock grazing would result from actions that limit the area available to livestock grazing and reduce the number of AUMs in the Planning Area. Overall, AUM reductions under Alternative B would result in the greatest adverse impacts to livestock grazing, followed by alternatives E, C, D, F, and A. Alternative C, under which the BLM would manage resources in the Planning Area to increase commodity production, would result in the greatest beneficial impacts to livestock grazing. Alternatives B and E would place the most restrictions on the utilization of forage by livestock and the placement and construction of range improvements. In addition, alternatives B and E would close large portions of the Planning Area to livestock grazing, including elk and bighorn sheep winter range areas and within Greater Sage-Grouse Key Habitat Areas ACEC.

Alternative C places the fewest restrictions on livestock grazing management and livestock forage and utilization. Livestock grazing management under alternatives A, D, and F—the alternatives most likely to apply management actions on a case-by-case basis—would generally result in a continuance of current grazing practices. Impacts to livestock grazing from the protection of other resources, such as wildlife and cultural resources, are generally less adverse under Alternative C than under the other alternatives. Proactive management under Alternative C would benefit livestock grazing the most because it focuses on maximizing livestock forage use. Because there are fewer restrictions on other resource uses such as

mineral development, Alternative C would result in the greatest loss in AUMs from surface-disturbing activities, with a short-term loss of 1,170 AUMs per year, followed by alternatives D, F, A, B, and E with short-term losses of 668, 653, 649, 352, and 342 AUMs per year, respectively. Over the long term, closing areas to livestock grazing and long-term surface disturbance would result in the greatest loss of active (use) AUMs per year under alternatives B and E (163,609 AUMs and 163,609 AUMs, respectively), followed by Alternative C (4,120 AUMs), Alternative D (1,912 AUMs), Alternative F (1,851 AUMs), and Alternative A (1,663 AUMs).

4.6.7.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Resource Uses

Impacts on livestock grazing would generally be the result of activities affecting forage quantity/production or quality in grazing allotments, such as vegetation treatments, and management that constrains or enhances livestock grazing management. Surface-disturbing activities, fire and fuels management and vegetation treatments, invasive species, grazing and surface-disturbance restrictions intended to protect resources, and proactive management actions have the greatest impact on livestock grazing in the Planning Area.

Mining of locatable, leasable, and salable minerals would affect soils and vegetation communities and would result in a loss of forage in developed areas. Surface-disturbing and disruptive activities associated with all types of mineral and geophysical exploration and development are subject to the *Wyoming BLM Standard Mitigation Guidelines for Surface-Disturbing and Disruptive Activities* (Appendix H), which would help to reduce impacts to livestock forage through the application of standard mitigation. Compared to the other minerals, locatable minerals development would result in the largest acreage of surface disturbance and would have the greatest short-term and long-term impacts to available livestock forage.

The revegetation of disturbed areas, resulting from reclamation of oil and gas drilling and other operations, would occur under all the alternatives and would reduce the long-term adverse impacts to forage. Even with successful reclamation, there may be a permanent loss of available livestock forage in the form of limited or lost access to grazing areas from road and industrial facility development. This development may result in temporary or long-term closure of affected allotments or in reductions in permitted use in developing or producing gas fields. The construction and improvement of roads associated with minerals development may provide livestock operators with better access to livestock and would enhance their ability to maintain improvements. Disturbed areas associated with nonproducing wells would result in short-term impacts, as they would be reclaimed quickly and most forage production would be restored. Typically, livestock concentrate on newly reclaimed areas and forage utilization decreases on the native rangeland. Although utilization levels may vary from year to year, utilization levels that remain consistently high would not be expected to meet watershed and vegetation management objectives. Adjustments in livestock management to meet these objectives may result in temporary adverse impacts. Appendix W describes the appropriate utilization levels for key species in the Planning Area.

The presence and extent of invasive plant species in an area affects rangeland health and forage productivity. Invasive plant species displace native vegetation and, because they typically are unpalatable to livestock and wildlife, often remain ungrazed. Invasive plant species may spread or become established as a result of surface-disturbing activities, motorized vehicle use, or dispersal by

livestock or wildlife. Surface-disturbing activities include mechanical disturbance, such as construction of well pads, roads, pits, reservoirs, pipelines, and powerlines; mining; and vegetation treatments. Even when reclamation occurs, allotments where surface-disturbing activities have occurred may experience increased invasive plant species infestations over both the short and long term. The prevention and treatment of areas infested with invasive species are required under all alternatives. Management of invasive species would temporarily displace livestock and reduce the available forage, but would also maintain or improve rangeland health and forage quality over the long term.

Land disposals would result in adverse impacts if they reduced the available AUMs in active grazing allotments. Typically, land disposals occur on small, isolated parcels of BLM-administered land, with the goal being the consolidation of land ownership to enhance management of resource values. Exchange is the preferred method for all land tenure adjustments, and changes in AUMs resulting from any exchange would be site-specific and depend on the qualities of the both the disposal and acquisition parcels. However, because the land acquired is often located some distance from the disposal parcels, impacts to individual allotments due to AUM loss may occur.

The development of ROWs would result in both short-term and long-term reductions in forage. ROW authorizations for permanent facilities or roads would result in long-term reductions in forage. ROW authorizations that include only initial disturbance would be reclaimed to reduce long-term impacts to livestock grazing resulting from reductions in forage.

Allowing motorized vehicle use and recreational use and development would result in adverse impacts to livestock grazing through damage to soils and livestock forage, but would also benefit livestock grazing management activities. Adverse impacts from allowing motorized vehicles may include gates being left open by recreationists, the displacement of livestock from heavily used areas, or a reduction in forage palatability from the spread of invasive plants along motorized travel corridors and an increase in dust on forage near areas of heavy motorized vehicle use. Beneficial impacts from less restrictive motorized vehicle use would be minor to negligible. Adverse impacts due to closures could result from increased restricted access to permittees.

Provided resource damage does not occur and new roadways are not created, the BLM authorizes necessary tasks requiring off-road use of motorized vehicles under all the alternatives in areas not designated as closed to motorized vehicle use.

The BLM allows the development of range improvement projects (e.g., fences and spring developments) in portions of the Planning Area under all the alternatives, which would generally result in long-term beneficial impacts to rangeland health and livestock grazing management. Range improvement projects allow livestock managers and permittees to better implement grazing management practices and manage the distribution and movement of livestock in allotments. Adverse impacts associated with the construction of fencing, water pipelines, and other range improvements would include short-term impacts to forage; revegetation would usually occur within several growing seasons. Long-term adverse impacts associated with the construction of range improvements may include undesirable changes to livestock grazing patterns and distribution in an allotment, congregation of livestock and wildlife around new water sources, and changes in livestock trailing patterns that alter vegetation or affect rangeland health. Any long-term adverse impacts from range improvements would be site-specific in nature.

Special Designations

Prohibition of surface-disturbing activities associated with some special designations would result in adverse impacts to livestock grazing because they would limit the ability to construct range improvements (e.g., along the Nez Perce [Neeme-poo] NHT) or require additional mitigation for their

construction (e.g., the Brown/Howe Dinosaur Area ACEC) that may increase the cost of such improvements.

Resources

Management actions to prevent or mitigate soil loss would generally result in beneficial impacts to vegetation, which would increase livestock forage production and quality. All alternatives maintain existing watershed improvement projects; use BMPs to reduce runoff, soil erosion, and sediment yield; and subject all surface-disturbing activities associated with mineral and geophysical exploration and development to application of the *Wyoming BLM Standard Mitigation Guidelines for Surface-Disturbing and Disruptive Activities* (Appendix H). Projects designed to enhance watershed health would enhance vegetation resources by reducing erosion and improving water quality, thereby increasing forage and water for livestock over the long term. However, adjustments in livestock management that may be needed to meet or maintain riparian habitat requirements, PFC, and water quality objectives may result in temporary adverse impacts. Surface disturbance associated with the implementation of such watershed enhancement projects would also result in short-term site-specific adverse impacts to livestock forage.

Water can be a limiting factor for livestock grazing management, especially during drought, affecting livestock survival and distribution. Water developments designed to provide new water sources for wildlife or livestock would result in beneficial impacts to livestock through increased water availability. New water sources may also promote improved distribution of livestock by opening areas to grazing where a lack of water was previously the limiting factor.

The continued closure of 4,805 acres along the Bighorn River to most livestock grazing occurs under all alternatives and would restrict livestock grazing in the area and reduce the available forage base.

Wildland fire and fuels management would have varying impacts to livestock grazing, depending on fire size, intensity, and climatic factors. Wildland fire may result in adverse impacts such as the spread of invasive plant species, the destruction of range improvements, the displacement of livestock, and short-term impacts to livestock forage. With proper stabilization and rehabilitation, long-term impacts of wildland fire would generally be beneficial due to improvements in forage quality, quantity, and availability following the fire. For a period after a fire in shrubland communities, there would be enhanced forage production as herbaceous vegetation becomes temporarily dominant.

Vegetation treatments designed to reduce fuel hazards, improve wildlife habitat, enhance vegetation production or plant community health, or regenerate plant communities would result in long-term beneficial impacts to livestock grazing by increasing forage availability. Vegetation treatments would also result in short-term reductions in forage even though they are designed and conducted in accordance with the rangeland health requirements in the *Wyoming Standards for Healthy Rangelands* (Appendix N).

Wildlife and special status species habitat management would affect livestock grazing by restricting the placement of range improvement projects and potentially affecting the ability to implement grazing management practices. Management of greater sage-grouse habitat, white-tailed prairie dog towns, and the Bighorn River HMP/RAMP and Yellowtail Wildlife Habitat Management Area would affect the location, cost, required mitigation, and design standards and BMPs of range improvements. In addition, the maintenance of sagebrush and understory diversity in crucial seasonal greater sage-grouse habitat, particularly in PHMAs, may result in an adverse impact by reducing the time livestock could graze in an area, changes in seasons of use, and, in some cases, result in temporary removal of livestock until vegetation treatments are in place. In areas where DPC is being met, current grazing practices would continue and there would be no adverse impacts. The inclusion of specific management thresholds for

sage-grouse in NEPA analysis for renewals and modifications of livestock grazing permits/leases in PHMAs could result in adverse impacts to permittees by requiring modifications of existing grazing practices to meet greater sage-grouse habitat objectives and the potential for livestock grazing adjustments if thresholds are exceeded. Wild horses and livestock generally rely on the same resources, so the appropriate management level (i.e., herd size) of wild horses in the Planning Area may affect forage availability for livestock. The initial appropriate management levels in the two HMAs do not vary across alternatives.

Cultural and paleontological resource management may have adverse impacts to livestock grazing through the removal of forage during site excavations, or through restrictions on the design and placement of range improvements. For example, the BLM requires avoidance of surface-disturbing activities in areas near scientifically significant paleontological resource sites, which may affect the placement of range improvements. VRM may also affect the location or design of range improvements in visually sensitive areas.

Proactive Management

The application of the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* (Appendix N), BMPs, requirements that forage supplements be weed free, the use of rangeland health assessments, and the development of range improvement projects would result in beneficial impacts to livestock grazing from increased forage quality and quantity and improved rangeland health. The intent of any grazing management practices and range improvement projects is to improve the quality or quantity of forage, thereby enhancing grazing management flexibility. These practices may increase costs to the livestock permittees associated with increased livestock herding and maintenance of range improvements. Under all alternatives, AMPs remain in effect or are revised as necessary, and the *Standards for Healthy Rangelands and Guidelines for Livestock Grazing Management for the Public Lands Administered by the BLM in the State of Wyoming* are applied across the Planning Area. Livestock grazing management actions are designed to enhance rangeland health, improve forage for livestock, and meet other multiple-use objectives through the application of these standards, other appropriate BMPs (see Appendices L and W), and the use of appropriate range improvements.

Alternative A

Surface Disturbance

Management actions under Alternative A are projected to result in approximately 136,253 acres of surface disturbance on BLM-administered land over the life of the plan (Appendix T); this disturbance would result in the short-term loss of approximately 12,977 AUMs, or roughly 649 AUMs per year. Most of this acreage, 120,607 acres, would be reclaimed in the short term, reducing the long-term loss of AUMs. Table 4-32 lists the total long-term loss of AUMs under Alternative A due to surface disturbance and the loss of active (use) AUMs due to livestock grazing closures (Map 81). The baseline active (use) AUMs for the Planning Area were 305,264 in 2012 and, therefore, the loss of AUMs under this alternative would represent less than a 1 percent reduction.

Table 4-32. Change in Active Animal Unit Months (AUMs) per Year by Alternative

	Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Acres Closed to Livestock Grazing	5,009	1,984,211	5,009	5,009	1,984,211	5,009
AUMs Lost ¹	169	162,572	169	169	162,572	169
Acres of Long-Term Disturbance	15,646	10,893	41,485	18,306	10,802	17,663
AUMs Lost ²	1,490	1,037	3,951	1,743	1,029	1,682
Total Loss of AUMs (long-term)	1,659	163,609	4,120	1,912	163,601	1,851

Sources: BLM 2009a; BLM 2013a

¹AUMs lost due livestock grazing closure were calculated by subtracting active (use) AUMS in areas closed to livestock grazing from active (use) AUMs in open grazing allotments.

²Because it is not possible to determine the exact allotments where there would be surface disturbance, AUMs lost to long-term surface disturbance were calculated using the Planning Area average of 10.5 acres per AUM.

Resource Uses

Silviculture treatments may benefit livestock grazing management where they reduce canopy cover and increase understory forage. Under Alternative A, precommercial thinning in overstocked and regenerated timber sale areas for trees in the 20- to 30-year age class, timber harvesting in commercial forestland to protect and benefit ecosystem functions, and clear cuts subject to certain stipulations may benefit livestock grazing management. The use of silvicultural treatments may also result in beneficial impacts by moving forests and woodlands towards DPC, though the degree to which these treatments would move areas towards DPC would depend on the location, timing, and other factors of treatments. Silvicultural treatments that move areas toward DPC would make more forage available for herbivory by stimulating herbaceous plant growth in the forest and woodland understory.

Alternative A may result in additional expense or delay to grazing permittees as it allows livestock flushing on a case-by-case basis to avoid the dispersal of invasive species.

Under Alternative A, the BLM closes approximately 68,115 acres to motorized vehicle use. These closures may have an adverse impact on permittee access to livestock and range improvements but would result in a beneficial impact to rangeland health and forage palatability, as described under *Impacts Common to All Alternatives*.

Special Designations

Special designations under Alternative A would result in adverse impacts to the development of range improvements due to management that prohibits, or requires avoidance of, surface-disturbing activities. ACECs under Alternative A with such management include Red Gulch Dinosaur Tracksite, Sheep Mountain Anticline (above caves and cave passages), Carter Mountain, Five Springs Falls, and Upper Owl Creek. Alternative A also requires avoidance of surface-disturbing activities in view within ¼ mile of the Nez Perce (Neeme-poo) NHT and the Bridger Trail and Fort Washakie to Meeteetse to Red Lodge Trail and prohibits the construction of range improvements along 11 WSR eligible segments. Other areas, such as the Brown/Howe Dinosaur Area ACEC, require mitigation or avoidance of impairment following surface disturbance to limit adverse impacts to vegetation.

Livestock Grazing Management

Under Alternative A, the management of the Red Gulch Dinosaur Tracksite ACEC and all WSR eligible waterway segments may restrict livestock grazing use. Alternative A closes the interpretive area of the Red Gulch Dinosaur Tracksite ACEC to livestock grazing and manages all WSRs to prevent an increase in actual grazing use. The closure of the interpretive area would not affect the AUMs for the surrounding allotment, but restrictions on grazing in the WSR eligible segments would prohibit any upward adjustments to grazing in these areas, regardless of on-the-ground rangeland conditions.

Resources

Under Alternative A, the BLM routinely seeds, or requires permittees and operators to seed, disturbed areas with native plant species and requires that vegetation cover of disturbed soils be reestablished within 5 years of initial seeding. These reclamation requirements would benefit livestock forage by promoting short-term forage recovery in areas where surface disturbance has occurred and preventing degradation of rangeland health due to soil loss.

Under Alternative A, beneficial long-term impacts to grassland and shrubland health would occur by managing grassland and shrubland communities on at least 600,000 acres of BLM-administered land toward DPC objectives for watershed protection and livestock grazing. Managing towards DPC objectives improves forage for livestock and wildlife, improves overall DPC health and plant vigor, and reduces potential erosion. However, because these management actions are implemented on only a small fraction of grassland and shrubland communities, Alternative A would have limited beneficial long-term impacts to grassland and shrublands and associated forage for herbivory.

Allowing the surface discharge of produced water if it meets state of Wyoming water quality standards and making this water available for use on a case-by-case basis would benefit livestock by increasing water availability and may improve livestock distribution.

Management under this alternative prohibits surface-disturbing activities within 500 feet of surface water and riparian/wetland areas (70,715 acres) except when such activities are necessary and their impacts can be mitigated, which may affect the use of range improvements. This management may result in adverse impacts to the placement of range improvements in these areas or increased costs from increased mitigation requirements.

Under Alternative A, the BLM manages wildland fires to restore fire-adapted ecosystems and to reduce hazardous fuels, resulting in short-term adverse impacts from forage loss, but long-term beneficial impacts to forage production. The impact of management under this alternative would be progress towards a balance of herbaceous and woody vegetation in treated areas that would provide forage for livestock. Reducing the accumulation of hazardous fuels would have the beneficial impact of reducing the risk of catastrophic wildfires. In areas where fuels exceed historical levels, intense fires would result in the loss of forage over an area, as they may destroy the seeds of perennial grasses and shrubs and alter soils in ways that increase the risk of invasive species establishment. Alternative A would result in the second-greatest area of fuel treatments and prescribed fire with proportional impacts to livestock grazing.

Most of the total projected prescribed fire and fuels treatment acreage (70,000 acres) under Alternative A would be applied to grassland and shrubland communities not meeting DPC objectives. FRCC Classes 2 and 3 have the highest risk of catastrophic fire or of having lost or losing key ecosystem components. There is a risk in these areas that the vegetation management acreage under Alternative A would be inadequate to reduce fuel conditions enough to substantially diminish the risk of catastrophic fire and prevent associated adverse impacts to livestock grazing.

Alternative A prohibits the placement of salt, mineral, or forage supplements within ¼ mile of water, wetlands, riparian areas, reclaimed or reforested areas, or as determined by the authorized officer, which would beneficially impact livestock by distributing herbivory to maintain vegetation health and plant vigor across the landscape but may restrict permittees' flexibility in the placement of range improvements to maximize livestock grazing use.

Wildlife management actions that avoid or prohibit surface-disturbing activities under Alternative A also restrict the location, cost, and timing of range improvement project construction and maintenance. Generally, Alternative A determines wildlife seasonal protections for surface-disturbing and disruptive activities related to the maintenance and operation of projects on a case-by-case basis. Specific restrictions to range improvements include a prohibition on new water developments for livestock in elk crucial winter range (unless adverse impacts can be avoided or mitigated) and direction to retain riparian vegetation when cleaning or removing sediment from wet reservoirs where feasible. Prohibitions on new water developments would have adverse impacts to the placement of range improvements, and may result in the placement of projects in locations that are not optimal for livestock grazing management. Additional design requirements or mitigation would increase the cost of range improvement construction and maintenance.

The management of special status species under Alternative A would result in adverse impacts to livestock grazing. Under Alternative A, the BLM reviews all range improvement projects for potential impacts to special status plant species and requires avoidance, minimization and/or compensation measures on a case-by-case basis. Adverse impacts to the location and cost of range improvements may result, and would be of a similar type to those identified under impacts from wildlife management.

The application of Standard Paleontological Resources Protection Stipulations (see *Glossary*) to authorizations for surface-disturbing activities on PFYC 3, 4 or 5 formations, including a prohibition of surface-disturbing activities within at least 50 feet of the outer edge of the paleontological locality, may have adverse impacts to the placement of range improvement projects.

Under Alternative A, the Planning Area is managed primarily as VRM Class III and IV, with only approximately 15 percent managed as VRM Class I and II. Depending on their visibility, range improvement projects in areas managed as VRM Class I or II may need to be designed to minimize their contrast with the surrounding landscape or placed in locations where they are less likely to attract the attention of viewers. In Class I and II areas, this may result in adverse impacts to grazing management through additional costs to permittees and restrictions on the placement of range improvements.

Proactive Management

Under Alternative A, most of the Planning Area is open to livestock grazing and management of grazing is designed to provide for protection or enhancement of other resource values. Areas closed to livestock grazing include campgrounds, exclosures, and areas specifically closed under the Management Actions Common to All Alternatives.

Limited, but beneficial impacts to livestock grazing would result from the apportionment of any additional sustained yield forage to meet multiple-use objectives, after meeting DPC objectives, and to satisfy the suspended permitted use of permittees/lessees (148,394 AUMs) in the allotment where the forage is available. While this management would help to replace suspended AUMs, the focus would remain on meeting broader multiple-use objectives.

Alternative A requires range improvement projects be designed to meet allotment management objectives, resulting in localized beneficial impacts. The focus of these projects under Alternative A would be to meet multiple-use objectives.

The issuance of permits/leases for livestock grazing on parcels that are not currently included in grazing allotments would increase available AUMs. The increase in actual forage may be limited due to the small size of most unallocated parcels and the expense and challenge of managing these areas.

Reserve common allotments are not considered under this alternative, which would reduce the flexibility of providing alternate forage options to permittees whose allotments are rested following rangeland restoration activities.

Alternative B

Surface Disturbance

Management actions under Alternative B are projected to result in approximately 73,940 acres of surface disturbance on BLM-administered land over the life of the plan; this disturbance would result in the short-term loss of approximately 7,042 AUMs, or roughly 352 AUMs per year. Most of this (63,047 acres) would be reclaimed in the short term, reducing the long-term loss of AUMs (see Table 4-32). The total long-term loss of AUMs under Alternative B due to surface disturbance and the loss of active (use) AUMs due to livestock grazing closures (Map 82) would be 163,609 AUMs (an approximately 54 percent reduction from the baseline active [use] AUMs for the Planning Area). The projected surface disturbance under Alternative B would result in less long-term and short-term adverse impact to AUMs due to loss of forage than Alternative A; however, the total AUM loss from closures under this alternative is larger than under Alternative A.

Resource Uses

The use of silvicultural treatments would result in benefits similar to Alternative A, although to a lesser extent because the BLM would treat less acreage under Alternative B. Prohibiting clear cuts and precommercial thinning for reasons other than fuel reduction and restricting timber harvesting to areas where natural processes are unable to accomplish forest health goals would result in a more closed canopy than Alternative A. Therefore, although areas would still be moved toward DPC, less understory vegetation would be available for grazing compared to Alternative A.

Impacts from livestock flushing would be similar to Alternative A.

Alternative B closes approximately 170,253 acres of BLM-administered land to motorized vehicle use, an increase of approximately 150 percent over Alternative A, which would result in fewer impacts to rangeland health and forage palatability but may have the greatest adverse impact to permittee access to livestock and range improvements compared to the other alternatives.

Special Designations

Adverse impacts to the construction of range improvements would be greater under Alternative B than Alternative A because the alternative designates more ACECs and expansion areas, and more restrictive management in special designations. Under Alternative B, the BLM would manage seven of the ACECs to limit or prohibit surface-disturbing activities, and this alternative would expand the area where surface-disturbing activities are avoided to include areas in view within 5 miles of NHTs, other trails, and National Historic Landmarks. Alternative B would also result in greater adverse impacts to the construction of range improvements along WSR suitable waterways than Alternative A, prohibiting their construction along all segments.

Unlike Alternative A, managing lands with wilderness characteristics to maintain their wilderness characteristics under Alternative B may adversely affect the ability to construct range improvements projects, because these projects are only allowed where their short-term adverse impacts to wilderness

characteristics can be mitigated. Mitigation requirements may increase the cost of range improvements in these areas or may prohibit these developments altogether if mitigation is not possible.

Resources

Under Alternative B, the BLM requires the reestablishment of healthy native plant communities in disturbed areas to 50 percent pre-disturbance levels of desired vegetative cover within three growing seasons and 80 percent within 5 years. Though the use of native plants may slow reclamation time, the vegetative cover requirements under this alternative would result in greater short- and long-term benefits to livestock by requiring more forage restoration in a shorter amount of time than under Alternative A. These reclamation requirements would have a greater beneficial impact to livestock grazing. Long-term beneficial impacts to forage quality and stability would also result from the reestablishment of native plant communities.

Alternative B would result in the least acreage of vegetation treatments (Appendix T). Alternative B would result in a limited beneficial impact towards improving vegetation conditions to achieve or make progress towards achieving the reference state plant community (based on the ESD for the site) in all grasslands and shrublands described by this alternative. This alternative would be less effective at moving these vegetation communities towards DPC objectives, and would result in less beneficial impacts, such as the improvement in forage for livestock, to rangeland health than described under Alternative A.

Prohibiting the surface discharge of produced water and surface-disturbing activities within ¼ mile of riparian/wetland areas (162,887 acres) would reduce or remove beneficial impacts to livestock grazing realized under Alternative A. Eliminating the surface discharge of produced water would remove a potential water source for livestock that would be available under Alternative A. The surface-disturbing activity prohibitions under Alternative B would affect a larger acreage than Alternative A, and would result in a larger adverse impact on the construction of range improvements.

Fewer vegetation treatments to reduce hazardous fuels are projected under Alternative B than Alternative A (Appendix T), resulting in less projected beneficial impact to long-term forage production and an increased risk of forage loss due to catastrophic wildfires.

Impacts from restrictions on the placement of salt, mineral, or forage supplements would be similar to Alternative A, although to a greater extent because under Alternative B, the buffer width increases to ½ mile from water, wetlands, riparian areas, or reclaimed or reforested areas.

Wildlife management actions under Alternative B would result in greater adverse impacts to livestock grazing than under Alternative A (Table 4-32 and Map 82). The BLM does not allow new livestock grazing use in elk and bighorn sheep crucial winter range under Alternative B. The closure of all crucial winter range for elk and bighorn sheep (270,834 acres) and greater sage-grouse Key Habitat Areas (1,232,583 acres) to livestock grazing would result in the loss of approximately 143,183 AUMs, or 47 percent of the total current active (use) AUMs in the Planning Area. Please refer to Section 4.8.2 *Economic Conditions* for additional information on the effects of changes in AUMs on livestock operations.

Impacts to the construction and maintenance of range improvements from wildlife management actions would be greater under Alternative B than Alternative A. In addition to management discussed under Alternative A, Alternative B expands prohibitions on livestock water developments to include greater sage-grouse nesting areas and areas important for special status species, and also applies seasonal restrictions when the actions are determined to be detrimental to wildlife. This alternative also prohibits surface-disturbing activities within ½ mile of big game migration corridors (97,808 acres), closing these areas to new construction.

Livestock Grazing Management

The management of special status species under Alternative B would result in greater adverse impacts to livestock grazing than Alternative A. In addition to the management under Alternative A, Alternative B requires avoidance of reservoir work during amphibian mating and metamorphosis periods (April to July), which would adversely affect livestock permittees' ability to conduct maintenance on reservoirs. Under Alternative B, additional adverse impacts to the construction of range improvements and placement of forage supplements would occur, due to prohibitions within ½ mile of known special status plant species occurrences.

The management of cultural and paleontological resources under Alternative B would result in greater adverse impacts to the construction of range improvements than Alternative A. Under this alternative, the BLM avoids surface-disturbing activities in view within 5 miles of important cultural sites and in view within ¼ mile of significant segments of historic sites. Alternative B also prohibits surface-disturbing activities within at least 100 feet of the outer edge of the paleontological locality, regardless of PFYC.

Alternative B includes a higher percentage of VRM Class I and II areas than Alternative A, with more than 61 percent of the Planning Area in these most restrictive classes; therefore Alternative B would have greater adverse impacts on the cost and placement of range improvement projects.

Proactive Management

Livestock grazing management under Alternative B focuses on meeting multiple-use objectives, rather than maximizing forage or benefits for livestock. Alternative B apportions any additional sustained yield forage primarily to wild horses and wildlife, and does not allow permits/leases on parcels not included in a grazing allotment. Therefore, Alternative B would not result in beneficial impacts to suspended forage replacement and increased AUMs from new permits and leases as would Alternative A. Alternative B also requires range improvements projects, including vegetation treatments, be designed to maximize multiple-use benefits.

Alternative B establishes and manages reserve common allotments on a voluntary basis, resulting in beneficial impacts to livestock grazing. Reserve common allotments would increase management flexibility and the ability to rest allotments following vegetation treatments, allowing more intensive vegetation treatments and the temporary removal of livestock for more effective rangeland recovery. Intensive vegetation treatments would contribute to vegetation class diversity and greater long-term forage production, but would also temporarily decrease forage in treated areas.

Alternative C

Surface Disturbance

Management actions under Alternative C are projected to result in approximately 245,642 acres of surface disturbance on BLM-administered land over the life of the plan; this disturbance would result in the short-term loss of approximately 23,395 AUMs, or roughly 1,170 AUMs per year. Most of this acreage, 204,157 acres, would be reclaimed in the short term, meaning that the long-term loss of AUMs would be reduced. The projected surface disturbance under Alternative C would result in the greatest long-term (Table 4-32) and short-term adverse impact livestock grazing due to the resulting loss of AUMs. The loss of AUMs due to closing areas to livestock grazing would be similar to Alternative A. Overall, the total loss AUMs due to closures and long-term surface disturbance under this alternative would be greater than under Alternative A and less than under Alternative B, representing a loss of less than 1 percent of the baseline 305,264 AUMs (Table 4-32; Map 81).

Resource Uses

The use of silvicultural treatments would result in beneficial impacts similar to Alternative A, although to a greater extent because Alternative C treats more area. Forest and woodland management under Alternative C would result in the greatest beneficial impact to forage for livestock. Alternative C allows the most timber harvesting of any alternative, and earlier precommercial thinning and larger clear cuts than Alternative A. Under Alternative C, the BLM also manages juniper and limber pine stands to enhance livestock grazing. Activities that control juniper encroachment or stimulate herbaceous growth in the forest and woodland understory would benefit grazing because forage production would increase.

The BLM does not require livestock flushing under Alternative C. This would benefit permittees by reducing costs and allowing more flexibility to move herds, but may cause long-term adverse impacts by increasing the potential for establishment and spread of invasive species, which may reduce forage.

Alternative C closes approximately 9,274 acres of BLM-administered land to motorized vehicle use, an approximately 86 percent decrease compared to Alternative A, and would have the least adverse impact on permittee access but the largest potential impact to rangeland health and forage palatability of any alternative.

Special Designations

Alternative C would result in the least adverse impact on the construction of range improvements from the management of special designations. Impacts from the management of the Brown/Howe Dinosaur Area ACEC would be the same as under the other alternatives, but restrictions and mitigation associated with surface-disturbing activities in other areas managed as ACECs and WSRs under alternatives A and B would not occur. Impacts from the management of the NHT and Other Historic Trails would be similar to those described under Alternative A.

Resources

Alternative C would have a beneficial impact on the short-term production of forage in areas of surface disturbance. The use of nonnative and native seed mixes and a focus on increasing commodity production (e.g., livestock grazing) may result in increased short-term forage production compared to the other alternatives. However, a lower standard for the reestablishment of desired vegetative cover than Alternative B, including the use of nonnative seeding to create more short-term forage production, may result in less forage quality and stability in the long term.

Alternative C would result in the most acreage of vegetation treatments to improve vegetation conditions (Appendix T); however, no grasslands and shrublands are managed towards DPC and are instead managed to achieve or to make progress towards achieving the *Wyoming Standards for Healthy Rangelands* (Appendix N). Alternative C would result in the fewest beneficial impacts from proactive management towards achieving historical community structure and composition. However, the projected area of prescribed burns and vegetation treatments under Alternative C would result in beneficial impacts across the greatest area to achieve rangeland health standards, relative to the other alternatives.

The management of produced water and riparian/wetland areas under Alternative C would benefit livestock grazing. The surface disposal of produced water would create a larger beneficial impact for livestock grazing than under Alternative A due to a requirement that discharged water be put to use (e.g., for livestock watering). This alternative also allows surface-disturbing activities or livestock supplements in flood plains or riparian/wetland areas on a case-by-case basis, increasing permittees' flexibility in the placement of range improvements to maximize livestock grazing use but also the

Livestock Grazing Management

potential for concentrated livestock grazing to degrade long-term vegetation health and plant vigor in these areas.

Management under Alternative C emphasizes vegetation treatments as a tool to enhance livestock forage and has the largest projected area of vegetation treatments to reduce hazardous fuels (Appendix T). Depending on the FRCC class in which it occurs (see Section 4.3 *Fire and Fuels Management*), this management would result in the greatest short-term loss of forage. However, there would be more benefits to long-term forage production. Increased fire and fuels treatments would result in the smallest risk of forage loss due to catastrophic wildfires and less stress related to finding pasture for livestock following wildfire events compared to other alternatives.

Wildlife management actions under Alternative C are the least restrictive to livestock grazing management. The BLM allows domestic sheep grazing on pronghorn crucial winter range and does not apply seasonal restrictions on maintenance and operation actions to protect wildlife. Adverse impacts to livestock grazing from the elimination of approximately 143,183 AUMs within elk and bighorn sheep crucial winter range and greater sage-grouse Key Habitat Areas under Alternative B would not occur under this alternative. Alternative C would result in the least adverse impacts from wildlife management, due to surface-disturbance restrictions, on the construction of range improvements. However, management under this alternative does allow the greatest potential for contact between elk and cattle, and may increase the transmission of brucellosis.

The management of special status species under Alternative C would result in impacts to livestock grazing. Impacts to reservoir maintenance from restrictions during amphibian mating and metamorphosis periods would be the same as under Alternative A. Adverse impacts to the construction of range improvements in special status plant species habitat would be greater than under alternatives A and D, but less than under Alternative B.

The management of cultural resources under Alternative C (i.e., restricting surface-disturbing activities in view within ¼ mile of certain important cultural sites) would result in greater adverse impacts to the construction of range improvements than under Alternative A, but less than under alternatives B and D.

Adverse impacts from the management of paleontological resources would be less than the other alternatives because surface-disturbing activities are prohibited within only 50 feet of the outer edge of the paleontological locality and standard Paleontological Resources Protection Stipulations are only attached to authorizations for surface-disturbing activities in PFYC 4 or 5 areas.

Impacts from the management of visual resources on range improvements would be similar to those described under Alternative A.

Proactive Management

Management under Alternative C would be the most beneficial to livestock grazing due to its focus on maximizing livestock forage use instead of the enhancement of other resource values. The BLM apportions additional sustained yield primarily to satisfy suspended permitted use, which would result in greater beneficial impacts to livestock forage availability than under alternatives A and B, and similar impacts to those under Alternative D. Range improvements under Alternative C would also be designed to maximize livestock forage and distribution.

Under Alternative C, the BLM allows the issuance of permits/leases for unallocated parcels and does not establish reserve common allotments; the impacts would be similar to those described for this management action under Alternative A.

Alternative C does not establish reserve common allotments and would not result in the beneficial impacts afforded by these allotments described for alternatives A and C.

Alternative D

Surface Disturbance

Management actions under Alternative D are projected to result in approximately 140,175 acres of surface disturbance on BLM-administered land over the life of the plan; this disturbance would result in the short-term loss of approximately 13,350 AUMs, or roughly 668 AUMs per year. Most of this acreage, 121,869 acres, would be reclaimed in the short term, meaning that the long-term loss of AUMs would be reduced. The total long-term loss of AUMs under Alternative D due to surface disturbance and closing areas to livestock grazing would be slightly greater than under Alternative A, representing a loss of less than 1 percent of the baseline 305,264 AUMs (Table 4-32; Map 81).

Resource Uses

The use of silvicultural treatments would result in impacts similar, but to a greater extent than alternatives A and B, and a lesser extent than under Alternative C. The earlier use of precommercial thinning and clear-cut practices similar to those under Alternative C may reduce canopy cover and increase forage more than Alternative A. Other silvicultural activities and associated impacts from the management of aspen, juniper, and limber pine stands and timber harvesting would be the same as those under Alternative A.

The impacts from livestock flushing practices under Alternative D would be the same as those under Alternative A.

Alternative D closes approximately 61,010 acres of BLM-administered land to motorized vehicle use, or an approximately 10 percent decrease in areas closed compared to Alternative A. Impacts to permittee access and rangeland health and forage palatability would be similar to Alternative A, but to a lesser extent.

Special Designations

Adverse impacts from the management of special designations to the construction of range improvements and the availability of areas for grazing would be less than under Alternative B, but greater than under alternatives A and C. Except for the Carter Mountain ACEC, Alternative D includes all of the Alternative A ACECs, with the same management of surface-disturbing activities. Alternative D allows surface-disturbing activities across the Carter Mountain ACEC if the effects can be avoided or mitigated, which may reduce adverse impacts to the placement of range improvements. Similar to Alternative A, Alternative D would avoid surface-disturbing activities near NHTs and Other Historic Trails, although the area affected may be greater (i.e., the foreground of these trails up to either 3 miles [NHTs] or 2 miles [Other Historic Trails]). Unlike alternatives A and B, under Alternative D, the BLM would not manage any of the WSR eligible waterway segments as suitable for inclusion in the NWSRS, thereby eliminating any adverse impacts to range improvement placement or limitations to increases in grazing along these waterway segments. The interpretive area of the Red Gulch Dinosaur Tracksite is closed to livestock grazing under this alternative, but this management would not affect the AUMs for the surrounding allotment.

Resources

In disturbed areas, Alternative D allows the reestablishment of healthy native or DPCs based on pre-disturbance/desired plant species composition and judges successful reclamation by whether conditions are equal to or better than pre-disturbance site conditions. Reclamation practices under Alternative D would restore forage to disturbed areas more quickly than under alternatives A and C. Compared to Alternative B, this alternative provides additional flexibility that may shorten the reclamation time by allowing the use of beneficial nonnative plants, but may result in reduced long-term beneficial impacts to forage quality and stability from using nonnative species.

Alternative D would result in the same acreage of vegetation treatments as described under Alternative A (Appendix T), and would manage some vegetation communities for a higher plant community state or phase (based on state and transition models in ESDs) where site-specific management objectives determine that a higher plant community state or phase is desirable. The impacts of this alternative on grasslands and shrublands and the associated forage would be similar to those described under Alternative A. Alternative D also would result in approximately the same acreage of burns from wildland fire as Alternative A, although the emphasis under Alternative D to use burns to accomplish other resource management objectives (e.g., livestock grazing forage improvement) may result in greater benefits to livestock forage production than Alternative A.

As under alternatives A and C, Alternative D allows the use of produced water by livestock. This alternative would result in greater beneficial impacts to livestock water availability and distribution than the other alternatives because it removes the case-by-case stipulation for the use of produced water.

Management under this alternative prohibits or restricts surface-disturbing activities near surface water and riparian/wetland areas over a larger area (within 500 feet and ¼ mile), with appropriate mitigation, than under Alternative A. Such management would, therefore, result in greater beneficial impacts to vegetation health (and, therefore, forage productivity) than alternatives A and C, but less than Alternative B. However, it also may increase mitigation costs compared to Alternative C. Prohibiting the placement of salt, mineral, and forage supplements in sensitive areas (i.e., within ¼ mile of water, wetlands, riparian areas, reclaimed or reforested areas) would result in the same impacts as Alternative A.

Wildlife management actions would generally result in fewer adverse impacts to livestock grazing management under Alternative D than under alternatives A or B, and more than under Alternative C. Impacts from wildlife management actions that avoid or prohibit surface-disturbing activities and therefore restrict the location, cost, and timing of range improvement project construction and maintenance would be similar to those described under Alternative A. Mitigation requirements under Alternative D may be less restrictive than under Alternative A, which may result in fewer adverse impacts to the placement of new range improvements or reduced costs for range improvement construction and maintenance due to design requirements.

Adverse impacts to livestock grazing management due to the management of special status species would generally be less than under Alternative B, but more than under alternatives A and C. Alternative D includes a smaller mile avoidance area than Alternative B near BLM special status plant species populations for range improvements that may concentrate herbivory. This alternative also allows water development projects in sage-grouse nesting habitat with 10 inches or less annual precipitation if adverse effects can be avoided or mitigated based on site-specific analysis, a less restrictive requirement for allowing water development than that under Alternative B. Reservoir maintenance practices and avoiding reservoir work during amphibian mating and metamorphosis periods under Alternative D would result in similar impacts to those under Alternative B. Alternative D would also include greater

sage-grouse seasonal habitat objective management that would provide for and maintain sustainable sagebrush and grass cover types. As a result, Alternative D may result in additional beneficial impacts to livestock grazing by increasing available forage in greater sage-grouse breeding and brood-rearing habitats.

Unlike under the other alternatives, Alternative D prioritizes allotments in PHMAs for field checks to help ensure compliance with the terms and conditions of grazing permits. While these checks could result in beneficial impacts where they identify issues with livestock grazing management that are degrading rangeland health conditions, they could also adversely affect livestock grazing where they identify conflict with greater sage-grouse that results in corrective actions that make certain areas unavailable for livestock grazing or change grazing management practices.

The management of cultural and paleontological resources under Alternative D would result in less adverse impacts to the construction of range improvements than under Alternative B, but more than under alternatives A and C. Alternative D requires the avoidance of surface-disturbing activities in view within 3 miles or the visual horizon, whichever is closer (the setting consideration zone) where setting is an important aspect of the integrity for the site and uses BMPs to avoid, minimize and/or compensate adverse impacts. Similar to Alternative B, this alternative attaches standard Paleontological Resources Protection Stipulations to authorizations for surface-disturbing activities regardless of PFYC. Unlike the other alternatives however, this alternative does not prohibit surface-disturbing activities within a certain distance from the outer edge of paleontological localities if the impacts can be mitigated and written authorization to proceed is issued by the authorized officer.

Alternative D includes the third largest area of VRM Class I and II areas, with more than 27 percent of the Planning Area in these most restrictive classes. Therefore, Alternative D likely would result in more adverse impacts to the cost and placement of range improvement projects than Alternative C, but less than alternatives A and B.

Proactive Management

As under Alternative A, most of the Planning Area is open to livestock grazing. Specific closures under Alternative D are the same as under Alternative A (see Table 4-32); however, unlike Alternative A, Alternative D allows livestock grazing in areas closed to livestock grazing as a tool to maintain or improve resource conditions. Under Alternative D, the BLM would manage livestock grazing to support other resource objectives, and would require mitigation for new resource uses to minimize or avoid conflicts with livestock grazing. Requiring avoidance, minimization and/or compensation when a resource use conflicts with livestock grazing would result in a beneficial impact to livestock grazing management that may not occur under the other alternatives.

The design requirements, management focus, and impacts of range improvement projects under Alternative D would be the same as under Alternative A.

The management focus under this alternative – to apportion additional sustained yield to satisfy suspended permitted use of permittees/lessees and to meet multiple-use objectives – would be similar to that under Alternative A and would result in similar beneficial impacts to forage availability as under described under that alternative.

Similar to Alternative B, this alternative establishes and manages reserve common allotments on a voluntary basis, but, unlike Alternative B, this alternative also establishes reserve common allotments on abandoned allotments on a case-by-case basis thereby further increasing beneficial impacts to livestock grazing management flexibility by increasing the acreage where intensive rangeland-improving vegetation treatments could be performed (in accordance with existing policy, WO IM 2013-184).

However, upon voluntarily relinquishment of a grazing permit or lease, the BLM would consider whether these areas should remain available for livestock grazing or be used for other resource management objectives. If lands are made unavailable for grazing, this would be an adverse impact to livestock grazing. Currently, there are no reserve common allotments in the Planning Area (Appendix P). Similar to alternatives A and C, this alternative would result in beneficial impacts to livestock grazing by allowing the case-by-case issuance of permits/leases for livestock grazing for parcels that are not included in a grazing allotment.

Alternative E

Surface Disturbance

Management actions under Alternative E are projected to result in approximately 71,829 acres of surface disturbance on BLM-administered land over the life of the plan; this disturbance would result in the short-term loss of approximately 6,841 AUMs, or roughly 342 AUMs per year. Most of this acreage (62,008 acres) would be reclaimed in the short term, reducing the long-term loss of AUMs. The total long-term loss of AUMs under Alternative E due to surface disturbance and the loss of active (use) AUMs due to livestock grazing closures (Map 83) would be 163,601 AUMs (an approximately 54 percent reduction from the baseline active (use) AUMs for the Planning Area; see Table 4-32). The projected surface disturbance and closure-related effects on AUMs would be similar to Alternative B, and the type and magnitude of impacts would be the same as Alternative B.

Resource Uses

The management of resource uses under Alternative E is the same as Alternative B in all areas available for livestock grazing, and the type and magnitude of impacts under Alternative E would be the same as Alternative B. However, the use of herbicides to control invasive species would be minimized within the Greater Sage-Grouse Key Habitat Areas ACEC under Alternative E. Flash burners, mowing, and selected hand-cutting would be prioritized in these areas. Therefore, Alternative E may restrict grazing permit holders to more labor-intensive methods to control weeds when compared to Alternative B.

Special Designations

Management of special designations under Alternative E, except in the Greater Sage-Grouse Key Habitat Areas ACEC (1,232,583 acres), is the same as Alternative B. Because greater sage-grouse Key Habitat Areas are closed under Alternative B, no additional adverse impacts on livestock grazing management are anticipated from restrictions for this ACEC in Alternative E.

Resources

The management of resources under Alternative E is the same as Alternative B in all areas available for livestock grazing, and the type and magnitude of impacts under Alternative E would be the same as Alternative B.

Proactive Management

Livestock grazing management is the same as Alternative B and places higher consideration on other resources, rather than maximizing forage or benefits for livestock. Therefore, the beneficial and adverse impacts under Alternative E would be the same as Alternative B.

Alternative F

Surface Disturbance

Management actions under Alternative F are projected to result in approximately 137,064 acres of surface disturbance on BLM-administered land over the life of the plan; this disturbance would result in the short-term loss of approximately 13,054 AUMs, or roughly 653 AUMs per year. Most of this acreage, 119,384 acres, would be reclaimed in the short term, meaning that the long-term loss of AUMs would be reduced. The total long-term loss of AUMs under Alternative F due to surface disturbance and closing areas to livestock grazing would be slightly more than under Alternative A, representing a loss of less than 1 percent of the baseline 305,264 AUMs (Table 4-32; Map 81). The projected surface disturbance and closure-related effects on AUMs would be similar to Alternative D, and the type and magnitude of impacts would be the same as Alternative D.

Resource Uses

The silvicultural management actions prescribed under Alternative F are the same as Alternative D, and the associated beneficial impacts would be the same as Alternative D.

Under Alternative F, livestock flushing practices and associated impacts are similar to Alternative A.

The acreage of BLM-administered land closed to motorized vehicle use under Alternative F is the same as Alternative D. Impacts to rangeland health, forage palatability, and permittee access would be similar to Alternative A. As stated under Alternative A, authorized or permitted uses that specify allowable access are not affected by travel management designations.

The use of herbicides to control invasive species would be minimized within the Greater Sage-Grouse PHMAs ACEC under Alternative F. Flash burners, mowing, and selected hand-cutting would be prioritized in these areas. Therefore, Alternative E may restrict grazing permit holders to more labor-intensive methods to control weeds when compared to Alternative D.

Special Designations

Alternative F designates 1,116,698 acres as the Greater Sage-Grouse PHMAs ACEC in addition to the same ACECs designated under Alternative D. Management of and effects from ACECs to the construction of range improvements would be similar to Alternative D, but to a greater extent because of the restrictions on surface-disturbing activities in the Greater Sage-Grouse PHMAs ACEC (similar to Alternative E). Adverse impacts would be greater under Alternative F than alternatives A, C, and D, but less than alternatives E and B.

Resources

Habitat restoration and vegetation management under Alternative F is the same as Alternative D, except within greater sage-grouse PHMAs where restoration and maintenance of greater sage-grouse habitat is the priority consideration for all vegetation management decisions. Reclamation practices under Alternative F require forage restoration in disturbed areas similar to Alternative D but to a greater extent, and more effectively than under alternatives A and C. Under Alternative F, vegetation treatments that reduce sagebrush for the purpose of increasing livestock forage are avoided within greater sage-grouse PHMAs. In PHMAs, any vegetation treatment plan under Alternative F must include pretreatment data on wildlife and habitat condition, establish non-grazing exclosures, and include long-term monitoring for at least three years post-treatment before livestock grazing returns. Monitoring would continue for five years after livestock are returned to the area. Current management for livestock grazing would continue as permitted until the vegetation treatment is implemented. Compared to

alternatives A and D, Alternative F would remove the ability of grazing permittees to perform vegetation treatments to improve forage quality for livestock, and could limit the ability to access new forage following reclamation and treatment.

Alternative F would result in the same acreage of prescribed fire treatment as alternatives A and D, although the emphasis of protecting and enhancing greater sage-grouse habitat for treatments in PHMAs under Alternative F could reduce the benefits to livestock grazing forage availability compared to those alternatives. In particular, Alternative F excludes livestock grazing in burned PHMAs (35 percent of BLM-administered surface lands) until woody and herbaceous plants achieve sage-grouse habitat objectives; such a requirement could adversely affect livestock grazing in a substantial portion of the Planning Area since sagebrush may take multiple years to reestablish (Manier et al. 2013). Similar to Alternative E, the fire and fuels management of Alternative F may also result in an increased risk of forage loss due to catastrophic fire.

Alternative F allows the use of produced water by livestock, and the beneficial impacts associated with produced water disposals would be the same as Alternative D.

The management of surface-disturbing activities and livestock grazing near surface water and riparian/wetland areas under Alternative F is the same as Alternative D, except in the Greater Sage-Grouse PHMAs ACEC. In these areas surface disturbance limitations would result in beneficial impacts to vegetation health and forage productivity compared to alternatives A, C, and D, but would limit the ability of permittees to implement surface-disturbing rangeland improvement projects. Alternative F manages grazing use of riparian/wetland and wet meadow areas consistent with Alternative D, except in the greater sage-grouse PHMAs where closures to hot-season grazing and adjustments to the seasonal distribution of livestock may apply.

Alternative F applies the same wildlife and special status species management action as Alternative D, except in greater sage-grouse PHMAs. Under Alternative F, grazing in lekking, nesting, brood-rearing, and winter habitats would be seasonally avoided. These restrictions on location and season of use would have adverse impacts on forage availability for livestock grazing compared to alternatives A and D, where these restrictions do not apply.

Alternative F applies the same VRM and cultural and paleontological management actions as Alternative D, and impacts to livestock grazing would be the same as described under Alternative D.

Proactive Management

As with alternatives A and D, most of the Planning Area would be open to livestock grazing under Alternative F. Specific closures under Alternative F would be the same as under alternatives A and D (Table 4-32). Similarly, livestock grazing management practices and associated impacts of Alternative F would be the same as Alternative D, with the exception of lands within the Greater Sage-Grouse PHMAs ACEC. In general, the livestock grazing management practices of Alternative F focus on the conservation, enhancement, and restoration of greater sage-grouse habitat within the Greater Sage-Grouse PHMAs ACEC.

Within priority sage-grouse habitat, objectives and management considerations that benefit greater sage-grouse are incorporated into all BLM grazing allotments through AMPs or permit renewals, and additional restrictions would be placed on riparian/wetland and wet meadow areas to promote recovery or maintenance of appropriate vegetation and water quality. Under Alternative F, grazing and trailing would also be avoided within lekking, nesting, brood-rearing, and winter habitats of priority sage-grouse habitat during periods of the year when sage-grouse are utilizing such areas. A focus on greater sage-grouse habitat considerations in the Greater Sage-Grouse PHMAs ACEC, over consideration that would

provide greater benefits to livestock grazing management, would result in adverse impacts from seasonal and other closures and a reduced ability to perform vegetation treatments.

Management considerations under Alternative F would result in similar beneficial impacts to forage availability as alternatives A and D, except within the Greater Sage-Grouse PHMAS ACEC. Additional vegetation management restrictions within priority sage-grouse habitat would reduce the availability of livestock forage over a larger acreage than alternatives A and D. In addition, Alternative F would create seasonal and spatial limitations on grazing activities within the Greater Sage-Grouse PHMAS ACEC.

4.7 Special Designations and Other Management Areas

4.7.1 Areas of Critical Environmental Concern

This section describes impacts related to the 20 existing, existing with proposed expansion, and new proposed ACECs in the Planning Area (see Table 4-33). The BLM manages ACECs to provide special management for important and relevant resources, values, natural systems, and natural hazards (referred to here as values of concern). This section also addresses impacts related to two other Management Areas (the Craig Thomas Little Mountain SMA and the Chapman Bench Management Area) closely related to the existing and proposed ACECs. Section 4.4.6 *Wildlife* describes the impacts of the Absaroka Front Management Area; Section 4.2.5 *Leasable Minerals – Oil and Gas* describes impacts from Oil and Gas Management Areas.

The discussion of ACECs and other Management Areas considers impacts in two ways: (1) the impacts of management in these special designations to other resources and resource uses and (2) the impacts of management to the protection of the values of concern for which the BLM proposes that designation. Most of the values of concern are resources in their own right and are further discussed and analyzed by alternative in the corresponding sections of this chapter. For example, this section describes impacts to paleontological values of concern in the Big Cedar Ridge ACEC, but Section 4.5.2 *Paleontological Resources* describes overall impacts to paleontology from management under the alternatives. The impacts analysis in this section focuses on high-level comparisons of potential adverse and beneficial impacts among the alternatives. While simply designating an ACEC would not produce effects that can be analyzed, the management prescriptions applied to the ACEC would result in effects.

4.7.1.1 Methods and Assumptions

The introduction to Chapter 4 identifies the assumptions used in this impact analysis. Assumptions related to other resources and resource uses discussed in this section apply to the analysis of ACECs and other Management Areas. There are no additional specific assumptions.

To allow for a consistent analysis, the ACEC boundaries designated under Alternative B are used as the area of analysis for all alternatives. Using Alternative B boundaries, the analysis evaluates the impacts of key management actions listed in Chapter 2 (e.g., mineral development, ROWs, and travel management) to ACEC values of concern, other resources, and resource uses. For the purposes of this analysis, “values of concern” refers to relevant and important ACEC values described in the Draft Areas of Critical Environmental Concern Evaluation Report (BLM 2010c). When an alternative proposes an ACEC, the BLM also considered how management actions specific to that ACEC could impact ACEC values of concern, other resources, and resource uses. When an alternative does not propose an ACEC, the BLM based the determination of impacts on a GIS analysis of management for that area under that alternative. For example, the BLM would not manage the Big Cedar Ridge area as an ACEC under Alternative C. However, to ensure the analysis is comparable across alternatives, Alternative C describes management for minerals, ROWs, and travel for this same geographic area. The adverse and beneficial impacts of not designating this area as an ACEC under Alternative C are then compared to the adverse and beneficial impacts of managing this same area as an ACEC under alternatives A and B.

To evaluate impacts to the exploration and development of mineral resources, the BLM overlaid GIS data depicting the occurrence and/or development potential for locatable minerals, leasable minerals, and mineral materials (based on information in the *Solid Mineral Occurrence and Development Potential Report* [BLM 2009d] and *Reasonable Foreseeable Development Potential Report for Oil and Gas* [BLM

2014 a)] with the Alternative B ACEC boundaries. The BLM used the mineral potential and the specific management of minerals in the area as the basis of analysis when comparing impacts to mineral resources from management under the alternatives.

Table 4-33. Existing and Proposed ACECs and other Management Areas by Alternative

Area	Alternative					
	A	B	C	D	E	F

Source: BLM 2013a

¹Although not proposed for expansion under Alternative D, the BLM manages a portion of the proposed expansion area as the Craig Thomas Little Mountain Special Management Area.

²Although not proposed as an ACEC under Alternative D, the BLM manages a portion of this area as the Chapman Bench Management Area.

³Although not proposed under Alternative D, a portion of this area falls within the proposed PETM ACEC.

⁴Although not proposed under Alternative B, the entire area of the PETM ACEC is within the Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch Paleontological Area, and McCullough Peaks South Paleontological Area ACECs.

ACEC Area of Critical Environmental Concern

4.7.1.2 Analysis of Alternatives

Impacts Common to All Alternatives

Although the values of concern vary by area and ACEC, the effects of key management (i.e., ROWs, CTTM, VRM, and mineral development) on these values and other resource uses would have some similarities. The following paragraphs describe the general effects of key management.

Restrictions placed on the exploration for, or development of, mineral resources in an area designated as an ACEC would generally result in adverse impacts to mineral development. Withdrawing or closing an area designated as an ACEC to mineral or oil and gas development removes the potential to develop that resource. NSO, CSU, and TLS restrictions and limitations, or restrictions on surface-disturbing activities in ACECs can limit potential development, increase timeframes and costs, and may decrease the feasibility of economic recovery of mineral resources. Within an area designated as an ACEC, the BLM would require a plan of operations and associated NEPA analysis addressing the values of the ACEC for all locatable mineral exploration (except casual use) and development, including disturbances of 5 acres or less (43 CFR 3809). The BLM would not automatically require a plan of operations absent such a designation (see Section 4.2.1 *Locatable Minerals* for more information). In parts of ACECs with low development potential, the adverse impacts of such restrictions and stipulations generally would be lower because the resource is either not present in commercial quantities or is uneconomical to mine.

Closing an area to, or withdrawing an area from, mineral development or applying other restrictions or mitigation to minerals development generally results in beneficial impacts to scenic quality, vegetation, soils, wildlife habitat, cultural resources, and other values of concern in ACECs by protecting the identified important and relevant resources from disturbance or degradation.

Impacts from ROW management in ACECs and other Management Areas generally affects the ROW program and the values of concern for the ACEC. Managing an area with more ROW restrictions, such as ROW avoidance areas, generally would require additional mitigation, application of BMPs, or other design considerations that would result in adverse impacts to ROWs in the form of additional expense and delay of project development. Restrictions, limitations, or required mitigation for ROW authorizations generally result in beneficial impacts to the values of concern in ACECs by protecting these resources from disturbance or mitigating adverse impacts to an acceptable level.

Unless otherwise noted in the following sections, permitted livestock grazing use would be allowed within ACECs in agreement with the *Wyoming Standards for Healthy Rangelands*. Livestock trampling and wallowing in areas of concentrated livestock use can damage the natural, educational, and scientific values within ACECs. However, proper livestock grazing management can mitigate these impacts by improving the distribution of livestock.

Under all alternatives, management that restricts travel would result in adverse impacts to access and OHV use. Managing an area as limited to designated roads and trails, for example, would limit the roads and trails available for use and may adversely affect the ability to access certain areas. Restrictive travel management designations benefit values of concern for the ACEC by, for example, closing a route that may damage resources or limiting disturbances to wildlife in crucial winter ranges.

Any resource use that results in authorized or unauthorized road or trail development (e.g., oil and gas development or user-pioneered trails) can have a direct impact on paleontological resources, wildlife habitat, and other resource values because the road or trail may physically pass through or over these resources and damage or destroy them. In addition, an indirect impact from road and trail development may occur when the road provides access to a previously remote and/or inaccessible location. People

who gain access may inadvertently damage fragile resources or disrupt wildlife during sensitive life stages.

Managing an area with more restrictive VRM classifications (Classes I and II) would result in adverse impacts to BLM-authorized actions that create surface disturbance or contrast with the visual setting. Adverse impacts to these BLM-authorized actions in areas with restrictive VRM classifications would result from changes to the size, scope, location, required mitigation, or BMPs for the actions. Managing an area with more restrictive VRM classifications would generally result in beneficial impacts to the important and relevant resources in an ACEC. Requiring additional design consideration and mitigation to preserve the visual setting in the area reduces the potential for facilities or development that could adversely affect important and relevant resources. Conversely, managing areas with less restrictive VRM classifications (Classes III and IV) would generally result in adverse impacts to values of concern, especially if the values of concern in an ACEC are associated with scenic quality.

Existing ACECs (No Expansion Proposed)

Big Cedar Ridge

Under alternatives A, B, D, E, and F the BLM manages the Big Cedar Ridge area (264 acres) as an ACEC (Maps 84, 85, and 87-89); the BLM would not manage it as an ACEC under Alternative C. Paleontological resources (in the form of paleobotanical fossils of late Cretaceous age) are the values of concern in the Big Cedar Ridge area. Threats to the values of concern in this area include potential surface disturbance from mineral and ROW development, and theft and vandalism of paleontological resources.

4.7.1.3 Summary of Impacts by Alternative

Management under alternatives A, B, D, E, and F would be the most effective for protecting the paleontological values of concern in the Big Cedar Ridge area, but also would result in the greatest restrictions on ROW authorizations and mineral development in the area. Alternative C would be less effective for protecting the values of concern, but would be more beneficial to ROWs and other surface-disturbing activities than alternatives A, B, D, E, and F.

4.7.1.4 Detailed Analysis of Alternatives

Alternative A

Under Alternative A, Big Cedar Ridge area is an ACEC with management objectives designed to protect and maintain paleontological resources and provide hands-on educational experiences for visitors and groups.

Under Alternative A, restrictions on mineral development could result in adverse impacts to the use of these resources in the ACEC. The low potential for most mineral resources in the ACEC minimizes the potential for adverse impacts from these restrictions on mineral development. Restrictions on mineral development would benefit the paleontological values of concern in the ACEC.

The ACEC is withdrawn from appropriation under the mining laws and the fossil concentration area (264 acres) is closed to mineral materials disposal. Withdrawing the ACEC could result in adverse impacts to locatable mineral development in the ACEC by prohibiting development of these minerals. However, the likelihood of adverse impacts is limited because of the low occurrence in the ACEC for bentonite and

Areas of Critical Environmental Concern

gypsum (the only locatable minerals currently extracted in commercial quantities in the Planning Area) and low development potential for sand and gravel. Withdrawing the Big Cedar Ridge ACEC would reduce the potential for destruction or degradation of paleontological resources.

Alternative A manages the ACEC as open to mineral leasing with an NSO restriction and a prohibition of surface disturbance from geothermal exploration and development. Allowing mineral leasing with an NSO restriction may result in adverse impacts to mineral development in the ACEC by requiring directional drilling or other development techniques that may limit economically feasible recovery of these resources. NSO restrictions would benefit the ACEC values of concern by reducing the potential for destruction or degradation of paleontological resources. However, the low development potential for oil and gas and the historically limited interest in such development in this area may minimize impacts to and from oil and gas development.

Managing the ACEC as a ROW exclusion area, closing it to the use of heavy equipment, and limiting motorized vehicle use to existing roads and trails would result in adverse impacts to these resource uses in the ACEC. Restrictions on these resource uses would benefit paleontological resources in the ACEC by preventing direct disturbance to these resources and by limiting the potential for indirect impacts from theft and vandalism, which increases with accessibility.

Management that allows the collection of fossils and provides educational research opportunities (including working with museums), while also protecting the resource, would result in beneficial impacts by protecting and promoting the paleontological values of the area. Allowing the use of hand tools in the ACEC to collect plant fossils for research and casual use in the fossil concentration areas, and only allowing mechanized collection on a case-by-case basis pending approval, would further increase benefits to paleontological values associated with research and allows the BLM to limit the use of heavy equipment or other excavation methods that could destroy or degrade resources.

Site-specific surveys for cultural and historic resources for casual use collection of plant fossils are not required. Because only casual use collection and use of hand tools are allowed for collection of fossils, these activities would not be likely to result in the destruction of cultural or historic resources if they are discovered.

Providing a focus area for recreational collection would benefit recreation in the Planning Area by allowing opportunities for legal recreational collection of common fossils. Recreational collection may result in long-term adverse impacts to paleontological resources in the ACEC because these resources would be lost to scientific and educational public uses.

Alternative B

The management of and impacts from designating the Big Cedar Ridge ACEC under Alternative B are the same as under Alternative A.

Alternative C

Under Alternative C, the BLM would not manage the Big Cedar Ridge area as an ACEC, but manages it in accordance with multiple use principles consistent with other resource objectives. Standard guidelines related to surface-disturbing activities would apply.

Under Alternative C, the area is available for locatable mineral entry, open to mineral leasing (with moderate constraints on 214 acres and standard stipulations on the remainder), and open to mineral materials disposal. Management of this area under Alternative C would be the least restrictive to

mineral development, and may result in the greatest adverse impact to the paleontological values of concern.

Under Alternative C, the BLM manages the Big Cedar Ridge area primarily as a ROW avoidance area (223 acres), and manages the remaining area as open to ROW authorizations. ROWs are allowed under this alternative, which would result in an increased potential for damage to known paleontological resources compared to the other alternatives.

Motorized vehicle use is limited to existing roads and trails under this alternative, and impacts from travel management would be the same as under Alternative A.

Applicable laws and regulations and the management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative C. These decisions include protective management, such as surveying and monitoring requirements in PFYC 5 formations, but generally would provide less protection for the paleontological values of concern than the other alternatives.

Alternative D

The management of and impacts from designating the Big Cedar Ridge ACEC under Alternative D are the same as under Alternative A.

Alternative E

Management of and impacts to values of concern in the Big Cedar Ridge area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Big Cedar Ridge area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for cave and karst resources under Alternative D is representative of the impacts anticipated under Alternative F.

Red Gulch Dinosaur Tracksite

Under alternatives A, B, D, E, and F, the BLM manages the Red Gulch Dinosaur Tracksite area as an ACEC (1,798 acres) (Maps 84, 85, and 87-89); the BLM would not manage the area as an ACEC under Alternative C. Paleontological resources (in the form of trace fossils of early Jurassic age) are the values of concern in the Red Gulch Dinosaur Tracksite ACEC. Threats to the values of concern in this area include surface disturbance from mineral and ROW development, and theft and vandalism.

4.7.1.5 Summary of Impacts by Alternative

Management of the Red Gulch Dinosaur Tracksite ACEC under alternatives A, B, D, E, and F would be the most effective for protecting the paleontological values of concern, and these alternatives would result in minimal impacts to ROW and minerals development in the area. Alternative C, which does not designate the Red Gulch Dinosaur Tracksite as an ACEC, may result in adverse impacts to the paleontological values of concern. Management under Alternative C would be more beneficial to ROWs and other surface-disturbing activities than alternatives A, B, D, E, and F.

4.7.1.6 Detailed Analysis of Alternatives

Alternative A

Under Alternative A, management objectives in the Red Gulch Dinosaur Tracksite ACEC strive to protect and maintain the paleontological resources, including the largest dinosaur tracksite in Wyoming and other Middle Jurassic fossil deposits.

Surface-disturbing activities are prohibited in the ACEC, except for the construction of roads, trails, interpretive signs, and other facilities to enhance public education and recreation and activities allowed under a paleontological resources use permit.

Prohibiting or restricting surface-disturbing activities in the ACEC would result in adverse impacts to ROWs, renewable energy, and other types of development. Restrictions on surface-disturbing activities would reduce the potential for destruction or degradation of paleontological resources and values. Under Alternative A, restrictions on mineral development would result in adverse impacts to the use of these resources in the ACEC. Under Alternative A, withdrawing the Red Gulch Dinosaur Tracksite ACEC from appropriation under the mining laws and managing it as open to mineral leasing with an NSO restriction in the Sundance Formation would result in minimal adverse impacts to development of mineral resources, as no mineral development has been proposed in this area. Withdrawing the ACEC could result in minimal impacts on locatable mineral development in the ACEC, particularly in areas where gypsum deposits may be present. Valid existing mining claims represent valid existing rights and would not be affected by the withdrawal (see Section 4.2.1 *Locatable Minerals*). The development potential for oil and gas in the ACEC is very low and impacts from the restrictions on mineral leasing would be limited. Due to the low potential for sand and gravel across the entire ACEC, impacts to mineral materials disposal from restricting surface-disturbing activities in the ACEC would be limited. Withdrawals and closures to mineral development in the Red Gulch Dinosaur Tracksite ACEC would reduce the potential for destruction or degradation of paleontological values.

Management actions restricting motorized vehicle use and setting paleontological resources use permitting requirements could result in adverse impacts to these resource uses by limiting travel and access in the ACEC. Restrictions on these resource uses would result in additional protection of and benefits to the paleontological values of concern in the ACEC. Motorized vehicle restrictions may benefit paleontological resources by reducing the potential for vehicle-caused damage to near-surface paleontological resources, such as dinosaur tracks, and limiting unauthorized access to important paleontological sites. All scientific and educational researchers studying the dinosaur tracks or working in that geologic horizon in the Red Gulch Dinosaur Tracksite ACEC are required to obtain a paleontological resources use permit. Permit requirements would protect the integrity of the resources and enable the advancement of scientific knowledge by allowing excavations to continue.

Closing the interpretive area of the Red Gulch Dinosaur Tracksite ACEC to livestock grazing would not affect AUMs, but may provide additional protection for near surface paleontological resources that may be damaged by the passage of livestock.

Prohibiting the use of heavy equipment and chemical and dye retardants may adversely affect the ability to control wildland fires in the area. Reducing surface disturbance and the application of chemicals that may damage exposed dinosaur tracks would be beneficial to the protection of these resources. However, reducing available suppression tactics for wildland fire may increase its area and severity, which may damage paleontological resources close to the surface.

Alternative B

The management of and impacts from the Red Gulch Dinosaur Tracksite ACEC under Alternative B are the same as under Alternative A.

Alternative C

Under Alternative C, the BLM does not manage the Red Gulch Dinosaur Tracksite area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

Under Alternative C, the area is open to locatable mineral entry, mineral leasing, and mineral materials disposal. There would be moderate constraints on oil and gas development in a portion of the area (1,674 acres), and the remainder of the area would be open to mineral leasing subject to standard lease stipulations. Alternative C includes the fewest restrictions on mineral development and would result in the smallest impact on the development of these resources. This management would result in the greatest adverse impacts to the paleontological values of concern compared to the other alternatives.

Management of the area under Alternative C could result in more surface disturbance than alternatives A and B. Under Alternative C, the BLM manages the Red Gulch Dinosaur Tracksite area primarily as a ROW avoidance area (1,674 acres) or open to ROW authorizations. Alternative C would allow for more potential ROW development in the area compared to the other alternatives, which would result in the greatest potential for damage to near-surface paleontological resources, although standard guidelines for surface disturbance would still apply under this alternative.

Alternative C limits motorized vehicle use to designated roads and trails; impacts to and from travel management would be the same as under alternatives A and B.

Applicable laws and regulations and the management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative C. These decisions include protective management, such as surveying and monitoring requirements in PFYC 5 formations, but generally would provide less protection for the paleontological values of concern than the other alternatives.

Alternative D

The management of and impacts from the Red Gulch Dinosaur Tracksite ACEC under Alternative D are the same as under Alternative A.

Alternative E

Management of and impacts to values of concern in the Red Gulch Dinosaur Tracksite area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Red Gulch Dinosaur Tracksite area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Sheep Mountain Anticline

Under alternatives A, B, D, E, and F, the BLM would designate the Sheep Mountain Anticline area an ACEC (11,520 acres) (Maps 84, 85, and 87-89), and would not designate it as an ACEC under Alternative C. The values of concern in the Sheep Mountain Anticline ACEC are geologic features, caves, cultural resources, and scenic qualities. The primary geologic feature of interest in the ACEC is the Sheep Mountain Anticline, a classic and internationally known Laramide structure. Threats to the resource values in this area include surface disturbance from mineral and ROW development.

4.7.1.7 Summary of Impacts by Alternative

Alternatives A, B, D, E, and F would be the most effective for protecting the values of concern in the Sheep Mountain Anticline area because they would restrict locatable mineral development and prohibit surface-disturbing activities above caves and cave passages. Restrictions that limit surface disturbance, particularly under alternatives D and F, would reduce the potential for the disturbance of cultural resources and adverse impacts to the geology and associated scenic qualities of the area. However, these alternatives also would result in the greatest restrictions to mineral development and other surface-disturbing activities, particularly alternatives B, D, E, and F, which, respectively, either manage the ACEC as closed to mineral leasing or impose NSO/CSU stipulations. Alternative C would be least effective for protecting the values of concern, but would be more beneficial for mineral development and other surface-disturbing activities.

4.7.1.8 Detailed Analysis of Alternatives

Alternative A

Under Alternative A, the BLM manages the Sheep Mountain Anticline to protect its geologic features and its recreational and interpretive uses. Management for the area is designed to protect outstanding scenic values while continuing to provide limited developed recreational facilities and motorized access.

The limited development potential for mineral resources in the ACEC would minimize the potential adverse impacts of restrictions on mineral development. Restrictions on minerals development would benefit the values of concern by reducing the potential degradation of resources and the development of facilities and infrastructure that would impact scenic values.

Under Alternative A, the BLM withdraws the Sheep Mountain Anticline ACEC from appropriation under the mining laws and requires a plan of operations for existing mining claims for all locatable mineral exploration (except casual use). Withdrawing the ACEC could result in adverse impacts to locatable mineral development by prohibiting new claims—particularly in areas of potential occurrence for gypsum (1,982 acres) and bentonite (223 acres). Valid existing mining claims represent valid existing rights and would not be affected by the withdrawal (see Section 4.2.1 *Locatable Minerals*).

Under Alternative A, the Sheep Mountain Anticline ACEC is open to oil and gas leasing with primarily major and moderate constraints; however, the low development potential for oil and gas resources in this area would limit potential impacts to oil and gas development as well as limit development that may impact the values of concern in the ACEC.

Under Alternative A, prohibiting surface-disturbing activities such as geophysical exploration (except casual use), mineral materials disposal, and construction activities (except those related to development of recreation facilities or wildlife habitat) above caves and cave passages would result in adverse impacts

to these resource uses by limiting these activities in the ACEC. Surface-disturbing activities elsewhere in the ACEC would be allowed, subject to restrictions on such activities addressed under other resources. The low potential for sand and gravel in most of the ACEC would limit adverse impacts to mineral materials disposal. The low potential for sand and gravel would also limit mineral material extraction and associated adverse impacts to cave and geologic values.

Limiting motorized travel in the ACEC to designated roads and trails and managing the area for the existing semi-primitive motorized and primitive recreational settings would result in adverse impacts to motorized vehicle use. Limiting motorized travel to designated roads and trails would reduce the available routes. These restrictions would maintain or enhance the recreational settings by eliminating unnecessary or undesirable vehicle routes, increasing opportunities for nonmotorized use, and allowing the closure of routes that result in adverse impacts to the values of concern.

Alternative B

With the exception of oil and gas leasing, management and impacts under Alternative B are the same as those under Alternative A.

Under Alternative B, managing the ACEC as closed to oil and gas leasing would result in greater adverse impacts to the development of these resources than under Alternative A. The low to very low development potential for oil and gas in the ACEC would minimize these adverse impacts. Managing the ACEC as closed to oil and gas leasing would provide more protection to the values of concern than Alternative A.

Alternative C

Alternative C does not designate the Sheep Mountain Anticline as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area is open to locatable mineral entry (except 172 acres), mineral leasing, and mineral materials disposal under Alternative C. There are moderate (358 acres) or major (3,369 acres) constraints on oil and gas development in most of the area, with these activities subject to standard restrictions in the remainder. Minerals management under Alternative C may result in greater development of these resources and therefore greater adverse impacts to the values of concern, compared to the other alternatives.

Alternative C limits motorized vehicle use to designated roads and trails; impacts from travel would be the same as alternatives A and B.

Alternative D

Except for oil and gas leasing, restrictions on surface-disturbing activities, and VRM, management and impacts under Alternative D would be the same as under Alternative A.

Under Alternative D, the BLM applies an NSO restriction on most of the ACEC and a CSU on the remainder. This management could result in greater adverse impacts to the development of leasable minerals than Alternative A, but these adverse impacts would be minimized because of the low to very low development potential for oil and gas in the area. The restrictions on leasable minerals would provide greater protection to the values of concern than alternatives A and C, but less than Alternative B.

Areas of Critical Environmental Concern

Under Alternative D, the BLM manages the Sheep Mountain Anticline ACEC as VRM Class II. Although none of the other alternatives includes specific VRM for this ACEC, the area is VRM Class II under alternatives B and C and VRM Classes III and IV (5,120 acres) under Alternative A, due to other resource considerations. Management as VRM Class II would require changes to the design and mitigation of BLM-authorized actions that could result in adverse impacts in the form of additional costs and delay for discretionary projects in the ACEC. Conversely, this VRM could benefit the values of concern, particularly the scenic qualities, by reducing or mitigating the visual contrast of BLM-authorized actions.

Alternative D imposes more restrictions on surface-disturbing activities than alternatives A and B. In addition to surface disturbance restrictions over caves and cave passages, this alternative only approves surface-disturbing activities elsewhere in the ACEC if the effects can be mitigated. Such a requirement would benefit geologic and related scenic values of concern for the area by limiting alterations to the visual environment, but may result in additional delay or expense for range improvements, ROW authorizations, and other surface-disturbing activities.

Alternative E

Management of and impacts to values of concern in the Sheep Mountain Anticline area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Sheep Mountain Anticline area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Spanish Point Karst

This area is designated an ACEC under all the alternatives (6,298 acres) (Maps 84-89). The values of concern managed for in the Spanish Point Karst ACEC are caves, recreational opportunities, sinking stream segments, an important aquifer recharge area, and important water quality functions. Threats to this ACEC include surface disturbance from mineral and ROW development and aerial spraying of pesticides onto aquifer recharge areas. Management and impacts to the area are the same under all alternatives.

4.7.1.9 Summary of Impacts by Alternative

The Spanish Point Karst area is designated as an ACEC with the same management under all alternatives, and impacts to the ACEC would be the same under all alternatives. Restrictions on resource uses in the ACEC would provide protection for the cave and karst system, important aquifer recharge zone, sinking stream segments, and the groundwater quantity and quality values of concern, but could result in adverse impacts to the restricted resource uses.

4.7.1.10 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

The management objective for the Spanish Point Karst area is the protection of the cave and karst system, important aquifer recharge zone, sinking stream segments, and the groundwater quantity and quality the area provides. Impacts from the management of the Spanish Point Karst area do not vary by alternative. Pursuing agreements for the cooperative management of surface activities in watersheds on USFS-administered and private lands in and adjacent to the Spanish Point Karst ACEC could result in beneficial impacts to the values of concern in the area by coordinating management for the protection of water resources. To the extent possible, the BLM also maintains compatible management prescriptions between these lands and those administered by the BLM.

Restrictions on minerals development would reduce potential adverse impacts from activities that could degrade values of concern. Restrictions on minerals development include withdrawing the ACEC from appropriation under the mining laws, closing it to mineral leasing, and geophysical exploration. The potential for all mineral resources in the ACEC is low to very low, which minimizes adverse impacts to minerals development.

Managing the Spanish Point Karst ACEC as a ROW avoidance area and closing it to motorized vehicle use would have direct adverse impacts on these activities. Restrictions on these resource uses could enhance protection for caves, opportunities for primitive recreation, and water quality by minimizing surface disturbance and the potential for erosion and vegetation loss that would adversely affect these values.

Under all alternatives, managing basal vegetative cover to maximize (or maintain) ground cover in good or better ecological condition would benefit water quality by reducing erosion and the movement of sediment into water resources.

Existing ACECs (and Proposed Expansions)

Brown/Howe Dinosaur Area

This area is designated an ACEC under all the alternatives (Maps 84-89). The BLM manages it within the existing boundaries under alternatives A, C, D, and F (5,501 acres) and expand it by 15,233 acres under alternatives B and E. Management of this ACEC would vary by alternative. The values of concern managed for in both the existing and expansion area of the Brown/Howe Dinosaur Area are paleontological resources, most notably dinosaur fossils from the suborder Theropoda and Sauropoda. Threats to the area proposed under alternatives A, C, D, and F include surface disturbance from mineral and ROW development, and theft and vandalism; threats to the area proposed for expansion under alternatives B and E do not include theft and vandalism.

4.7.1.11 Summary of Impacts by Alternative

Management under alternatives B and E would be the most effective for protecting the paleontological values of concern in the existing Brown/Howe Dinosaur Area ACEC and the proposed expansion area, but also place the most restrictions on ROW authorizations and mineral development. Impacts under alternatives A, C, D, and F would be similar and would be less restrictive toward mineral resource development in the existing and expansion areas than under alternatives B and E. Management under

Areas of Critical Environmental Concern

alternatives A, C, D, and F would provide less protection for paleontological values compared to the expanded Brown/Howe Dinosaur Area ACEC under alternatives B and E.

4.7.1.12 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Under all alternatives, mitigating surface-disturbing activities in the Brown/Howe Dinosaur Area ACEC would benefit the protection the paleontological values of concern.

Prohibiting the sale or exchange of lands in the ACEC, unless such disposals are consistent with management objectives, could improve the effectiveness and efficiency of resource management and protection in the area. Allowing exchanges consistent with resource objectives (paleontological values) would allow management flexibility to acquire high-value paleontological resources in the area while preventing land disposal that would transfer these resources out of BLM management.

Under all alternatives, limiting motorized vehicle use to designated roads and trails would reduce the routes available for recreational and other uses. Restrictions on motorized travel would decrease the potential for impacts to surface paleontological resources by allowing the closure of routes that result in adverse impacts to paleontological values.

All alternatives require fencing and signing of quarry sites in the Brown/Howe Dinosaur Area ACEC, which would benefit visitor safety and may reduce degradation of paleontological values from human disturbance.

All alternatives only allow fossil collection, excavation, or removal in the Brown/Howe Dinosaur Area ACEC under a permit issued by the Wyoming BLM State Director and only by institutions and individuals engaged in BLM-approved research, museum, or educational projects. These requirements would result in beneficial impacts by protecting the integrity of paleontological resources and enabling the advancement of scientific knowledge and research on these values in the area.

Alternative A

Allowing surface-disturbing activities in the ACEC, only if they are preceded by a paleontological sensitivity survey and monitored during construction, when necessary, could result in adverse impacts to ROW and minerals development and other surface-disturbing activities. The survey may delay activities or require mitigation or placement to limit impacts to paleontological values, but would continue to allow some activities while protecting the integrity of fossil-bearing material in the area. Restrictions on surface disturbance would benefit paleontological values of concern in the ACEC.

Managing the Brown/Howe Dinosaur Area ACEC as available for locatable mineral entry, open to mineral leasing, and open to mineral materials disposal would benefit these resource uses. Allowing mineral development could have an adverse impact on the paleontological values of concern in the ACEC. However, the low potential for development of these resources (BLM 1994c) would minimize the adverse and beneficial impacts of allowing locatable mineral entry. Requiring oil and gas operations and mineral materials disposal to conform to the applicable provisions of the regulations (43 CFR 3100) and other terms and conditions determined necessary by the authorized officer to avoid damage to these resources would minimize adverse impacts to paleontological resources. Restrictions from the management of the ACEC and other resources result in major (411 acres) and moderate (4,933 acres) constraints on oil and gas development in this area.

Under Alternative A, the Brown/Howe Dinosaur Area ACEC is open to ROW authorizations, subject to the requirements for surface-disturbing activities described above, which would result in adverse impacts to paleontological resources in the ACEC. Requiring paleontological sensitivity surveys before approving minor ROW authorizations in the Brown/Howe Dinosaur Area ACEC may cause long-term adverse impacts to ROWs by increasing authorization processing times and potentially requiring mitigation, relocation, or modification of facilities if paleontological resources are found. Due to the small size of this area compared to the size of the Planning Area, these impacts may be minimal.

Alternative B

Under Alternative B, the BLM would expand the Brown/Howe Dinosaur Area ACEC by 15,233 acres. The management and impacts described under *Impacts Common to All Alternatives* and, unless otherwise noted, under Alternative A, would apply to the expanded ACEC area. Expanding the ACEC would increase restrictions on resource uses in the area and increase the protection of the paleontological values of concern in the area.

Under Alternative B, restrictions on mineral development in the expanded ACEC could result in greater adverse impacts to the use of these resources than under Alternative A. Restrictions on minerals development would result in greater beneficial impacts to paleontological values of concern compared to Alternative A.

The expanded ACEC is withdrawn from appropriation under the mining laws, closed to mineral leasing, and closed to mineral materials disposal under Alternative B. Withdrawal from locatable mineral entry could result in adverse impacts to the use of mineral resources because no new claims could be staked; these impacts would be most likely to occur in the approximately 1,462 acres of known or potential occurrence for bentonite and 3,079 acres of known or potential occurrence for gypsum in the expanded ACEC.

The development potential for oil and gas in the ACEC is very low; therefore, adverse impacts to this resource use from the restrictions under Alternative B are unlikely to occur. Adverse impacts from closing the area to mineral materials disposal would be greatest on the approximately 1,659 acres of high-potential for sand and gravel. Mineral restrictions, including the withdrawal, under Alternative B would result in greater beneficial impacts to paleontological resources in the area compared to Alternative A by decreasing mineral activity and associated disturbance that could degrade paleontological values. Decreased mineral activity also may reduce new roads and may decrease access opportunities for recreational collectors or access that could degrade resource values.

Under Alternative B, managing the ACEC as a ROW avoidance area would result in greater adverse impacts to this resource use by limiting new ROW authorizations in the ACEC. Under Alternative A, the area proposed for expansion under Alternative B is open to ROW authorizations, subject to the standard requirements for surface-disturbing activities and paleontological resources. The more restrictive ROW management under Alternative B would reduce or mitigate surface disturbance and would provide more protection for paleontological resources than under Alternative A.

Alternative C

The management of and impacts from the Brown/Howe Dinosaur Area ACEC under Alternative C are the same as those under Alternative A.

Under Alternative C, the BLM manages the area proposed for expansion under Alternative B primarily as a ROW avoidance area (11,047 acres), with only a small portion (4,186 acres) open to ROW

Areas of Critical Environmental Concern

authorization. Therefore, ROW management is more restrictive than under Alternative A and impacts to the values of concern in this area would be similar to those under Alternative B.

Alternative D

The management of and impacts from the Brown/Howe Dinosaur Area ACEC under Alternative D are the same as those under Alternative A, except for surface-disturbing activities and VRM.

Similar to Alternative A, Alternative D allows surface-disturbing activities if preceded by an on-the-ground survey and monitoring in all PFYC 4 and 5 formations; therefore, impacts would be same as under Alternative A. Compared to the other alternatives, Alternative D may result in fewer adverse impacts to ROW placement and other surface-disturbing activities.

Under Alternative D, adverse impacts to locatable and leasable mineral uses and beneficial impacts to paleontological values of concern would be less than under Alternative B. Under Alternative D, the BLM manages the existing ACEC and the expansion area proposed under Alternative B as open to mineral materials disposal. Impacts would be the same as under alternatives A and C.

Under Alternative D, the BLM manages the Brown/Howe Dinosaur Area ACEC and the area proposed for expansion under Alternative B as ROW avoidance areas. Impacts would be the same as under Alternative B.

Under Alternative D, the BLM manages the Brown/Howe Dinosaur Area ACEC and the area proposed for expansion under Alternative B as VRM Class III. Although none of the other alternatives includes specific VRM for this ACEC, managing it as VRM Class III would be more restrictive than VRM Class IV under Alternative C (10,201 acres) and less restrictive than VRM Class II under alternatives A and B (7,357 acres and 15,222 acres, respectively). Management as VRM Class III would allow BLM-authorized actions that result in surface-disturbing activities with reduced mitigation and siting restrictions, and related benefits to some resource uses and adverse impacts to paleontological resources, compared to VRM Class I and II areas.

Alternative E

Management of and impacts to values of concern in the Brown/Howe Dinosaur Area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Brown/Howe Dinosaur Area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for cave and karst resources under Alternative D is representative of the impacts anticipated under Alternative F.

Carter Mountain

The BLM designates the Carter Mountain area as an ACEC under alternatives A, D, and F (10,867 acres) (Maps 84, 87, and 89), and designates and expands this ACEC area by 5,706 acres under alternatives B and E (Maps 85 and 88). The BLM does not designate the Carter Mountain area as an ACEC under Alternative C. Management of this area varies by alternative. The values of concern in the Carter Mountain area are vegetation and wildlife resources, including alpine tundra and crucial winter range.

Threats to this area include surface disturbance from mineral, ROW, and renewable energy development, and theft and vandalism of cultural resources. In addition, the proposed expansion area under alternatives B and E contains cultural features, recreational opportunities, special status species habitat, and fragile soils, and supports watershed functions. Threats to the expansion area are the same as those to the ACEC under Alternative A, except that they do not include theft and vandalism.

4.7.1.13 Summary of Impacts by Alternative

Management under alternatives B and E would be the most effective for protecting the values of concern in the ACEC and expanded ACEC area. Alternatives B and E place the greatest restrictions on ROW authorizations, mineral development, and motorized vehicle use of any of the alternatives. Alternatives A and C would result in similar adverse and beneficial impacts. Alternative A includes more prohibitions for surface disturbance on slopes, and more restrictions on fire and fuels and recreation site development than Alternative C. However, the restrictions on motorized vehicle use and VRM classifications are more extensive under Alternative C. Both alternatives A and C would result in similar impacts to the development of mineral resources in the area.

4.7.1.14 Detailed Analysis of Alternatives

Alternative A

Prohibiting surface-disturbing activities on slopes of more than seven percent would result in adverse impacts on the ability to construct range improvements, explore and develop certain minerals, authorize ROWs, and perform other activities. These restrictions could reduce surface-disturbing activities, which would benefit fragile soils, alpine tundra, crucial winter range, and the control of invasive species that could degrade the vegetation and wildlife values of concern in the ACEC. Areas with steep slopes are particularly prone to erosion and can be difficult to reclaim following surface disturbance.

Managing the Carter Mountain ACEC as available for mineral entry, open to minerals leasing, and open to mineral materials disposal would result in adverse impacts to the values of concern by increasing the potential for surface-disturbing activities that could degrade soils and disturb vegetation and wildlife resources. Managing the ACEC as primarily open to these types of mineral development could benefit the use of these resources; however, the low potential for mineral development in the ACEC would also reduce the potential for adverse impacts to the values of concern. There would be major constraints on oil and gas development across most of the ACEC (9,954 acres), with smaller areas of closure and moderate constraints across the remainder.

Acquiring 840 acres in the Carter Mountain ACEC under Alternative A could result in long-term beneficial impacts in the ACEC by improving the effectiveness and consistency of management for the area's watershed and habitat values through consolidation of land ownership.

Under Alternative A, managing the Carter Mountain ACEC as a ROW avoidance area applies restrictions to ROW authorizations and would result in adverse impacts to ROW authorizations by limiting these authorizations or requiring specific lease stipulations. These restrictions could benefit the values of concern by reducing development and increasing impact mitigation measures. Requiring intensive mitigation for new ROWs would further benefit the values of concern by reducing the impacts of any new ROWs on vegetation, crucial winter range, and wildlife using the area.

Under Alternative A, limiting motorized vehicle use to designated roads and trails in the Carter Mountain ACEC, with a seasonal closure from November 15 to June 15 or later if weather or road

Areas of Critical Environmental Concern

conditions are unfavorable, would result in adverse impacts to motorized vehicle use. Adverse impacts to travel may be minimized because the BLM commits to maintaining existing public access and pursuing additional access opportunities under this alternative. Seasonal restrictions and limiting travel to designated roads and trails would benefit the values of concern by protecting fragile soils and alpine tundra and eliminating disturbances to big game habitat during sensitive periods. Requiring approval before snow is removed from BLM-administered roads in big game crucial winter range would further help minimize disturbance to wildlife.

Prohibiting the construction of new recreational sites and restricting the use of heavy equipment in the Carter Mountain ACEC could result in adverse impacts to recreation and fire and fuels management. Under this alternative, restrictions on recreational facility development may affect the BLM's ability to provide desired recreation experiences in the area for those seeking more middle-country RSCC. Heavy equipment restrictions may result in difficulties controlling or suppressing wildland fires in the ACEC, although the use of prescribed fire to control fuels is allowed. Restrictions on recreation and fire and fuels management would benefit the values of concern. These restrictions would prevent surface-disturbing activities that could affect wildlife and vegetation to protect fragile soils and alpine tundra.

Managing the Carter Mountain ACEC as VRM Class II could result in adverse impacts to resource uses by limiting certain activities in the ACEC. Activities such as range improvement projects and oil and gas facility development could be adversely affected because no activity would be allowed to attract the attention of the casual observer; therefore additional mitigation or design consideration may be required. Management as VRM Class II could also benefit vegetation and wildlife habitat values of concern by limiting the size and types of development and surface disturbance that would be allowed, and potentially increasing mitigation for activities that did occur.

Alternative B

Under Alternative B, the BLM would expand the Carter Mountain ACEC by 5,706 acres. Management and impacts described for Alternative A, except for mineral and recreational facilities, apply to the expanded area unless otherwise noted. The larger size of the expanded ACEC and the expansion of common management to include this area means that the impacts from such management would be comparatively larger under Alternative B than under Alternative A.

Under Alternative B, restrictions on mineral development would result in adverse impacts to the use of these resources. The ACEC is withdrawn from appropriation under the mining laws, closed to mineral leasing, and closed to mineral materials disposal. The known or potential occurrence for gypsum and bentonite in the ACEC is low; therefore, adverse impacts to the use of these resources would be minimal. Managing the ACEC as closed to oil and gas development could result in the greatest adverse impacts of any alternative because 1,780 acres with moderate development potential for oil and gas would be closed to leasing; the remainder of the ACEC has very low development potential. Likewise, closure to mineral materials disposal could result in the greatest adverse impacts of any alternative on the 1,872 acres with high-potential for sand and gravel in the ACEC. Minerals management under Alternative B is more restrictive than under Alternative A and could result in greater adverse impacts to mineral resources by further limiting development. Restrictions on minerals development could benefit the values of concern. Under Alternative A, the area proposed for expansion under Alternative B is available for locatable mineral entry and open to mineral leasing. Under Alternative B, more restrictive management limiting surface disturbance from minerals development would result in greater beneficial impacts, compared to Alternative A, in the existing and expansion areas on the vegetation, soils, big game crucial winter range, and cultural and recreational values of concern for these areas.

Managing the Carter Mountain ACEC expansion area as a ROW avoidance area, limiting motorized vehicle use to designated roads and trails, and managing the area as VRM Class II would result in more restrictive management than under Alternative A. Under Alternative A, the area proposed for expansion under Alternative B is managed as a ROW avoidance area. Under Alternative B, increasing resource use restrictions could result in greater adverse impacts to ROW authorizations, travel, and development activities compared to Alternative A. Managing the expansion area as VRM Class II places additional stipulations on the types and locations of activities that would be allowed in the ACEC compared to Alternative A. Under Alternative A, the BLM manages the area proposed for expansion under Alternative B as VRM Class IV (4,348 acres) or Class II (1,358 acres). Managing the existing and expansion areas as VRM Class II under Alternative B would maintain the visual environment more than Alternative A and provide the greatest benefits to recreational and other uses compared to the other alternatives.

Restricting travel to designated roads and trails in this area provides more protection than Alternative A for fragile soils, vegetation communities, wildlife habitat, watershed functions, and cultural resources. Under Alternative A, the BLM limits motorized vehicle use in the area proposed for expansion under Alternative B to existing roads and trails (5,135 acres), and limits the remainder to designated roads and trails (571 acres).

Alternative B allows the construction of recreational facilities to address visitor health and safety, use and user conflicts, and resource protection, which could result in greater beneficial impacts to recreational values than under Alternative A. This management may also increase surface disturbance and visitation to sensitive areas compared to Alternative A, which may result in adverse impacts to the non-recreational values of concern.

Alternative C

Under Alternative C, the BLM does not designate the Carter Mountain as an ACEC, and manages it in accordance with multiple use principles consistent with other resource objectives.

Management under Alternative C has the lowest potential to adversely impact the development of oil and gas resources and ROW authorizations. Similar to Alternative A, the area would be available for locatable mineral entry, open to mineral leasing, and open to mineral materials disposal. Constraints on oil and gas development would be lowest under this alternative, with moderate constraints on oil and gas development throughout most of the area (15,563 acres), with major constraints on the remainder. Under Alternative C, the BLM manages the Carter Mountain area as open to ROW authorizations. Standard guidelines related to surface disturbance would apply. These resource uses would result in additional surface disturbance in the area compared to alternatives A and B, leading to potential damage to the identified values of concern.

Applying only the standard guidelines for surface-disturbing activities under Alternative C would reduce the beneficial impacts on the protection of fragile soils, scenic quality, vegetation communities, wildlife habitat, watershed functions, and cultural resources compared to the other alternatives.

Managing motorized vehicle use as limited to designated roads and trails (5,135 acres) or with seasonal restrictions (11,438 acres) would result in impacts similar to those under Alternative A for the existing ACEC. Travel management in the proposed expansion area under alternatives B and D is more restrictive than under Alternative C and, therefore, Alternative C may result in fewer adverse impacts to travel. Compared to Alternative A, management of motorized vehicle use under Alternative C may result in fewer adverse impacts to the values of concern.

Areas of Critical Environmental Concern

Under Alternative C, the BLM manages the Carter Mountain area as VRM Class II, and impacts would be the similar to those under Alternative B.

Alternative D

Management of and impacts from the Carter Mountain ACEC under Alternative D are the same as under Alternative A, with the exceptions described below.

Management of and impacts to travel in the ACEC and the area proposed for expansion under Alternative D is the same as under Alternative B. Unlike alternatives A and B, this alternative does not pursue additional public access to the area, which may reduce the beneficial impacts to public access described for Alternative A.

Alternative D would consider the acquisition of other parcels from willing sellers in the Carter Mountain area. Such acquisitions may result in additional long-term beneficial impacts to management for the area's watershed and habitat values compared to Alternative A.

Under Alternative D, the BLM manages ROW authorizations in the Carter Mountain ACEC and the expansion area proposed under Alternative B the same as under Alternative B. However, unlike alternatives A and B, intensive mitigation is not required for additional ROW authorizations, and associated adverse impacts to ROW authorizations and beneficial impacts to habitat and sensitive wildlife from this mitigation would not occur. Alternative D allows some surface-disturbing activities other than mineral leasing or ROW throughout the ACEC if the effects on alpine tundra could be avoided or mitigated based on site-specific analysis. Compared to alternatives A and B, allowing the construction of range improvements and other surface-disturbing activities throughout the ACEC would reduce adverse restrictions to these resource uses and would reduce the benefits of prohibiting these activities in habitat and alpine tundra on steep slopes.

Impacts from the construction of recreational facilities would the same as under Alternative B.

Under Alternative D, the management of mineral resources is generally more restrictive than alternatives A and C, but less than Alternative B. Alternative D withdraws a smaller portion of the ACEC from locatable mineral entry (4,998 acres) than Alternative B, but, similar to Alternative B, the BLM manages the entire area as closed to oil and gas leasing. Like Alternative B, adverse impacts could occur to oil and gas development on 1,780 acres with moderate development potential that would be closed to leasing. Similar to alternatives A and C, the entire area is available for mineral materials disposal. Overall, the management of locatable mineral entry and mineral materials disposal would have similar beneficial and adverse impacts as Alternative A, while the management of oil and gas leasing would have similar beneficial and adverse impacts as Alternative B.

VRM classifications and associated impacts in the Carter Mountain ACEC and the expansion area proposed under Alternative D are the same as under Alternative B.

Alternative E

Management of and impacts to values of concern in the Carter Mountain area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Carter Mountain area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for cave and karst resources under Alternative D is representative of the impacts anticipated under Alternative F.

Five Springs Falls

The BLM designates the Five Springs Falls area as an ACEC under alternatives A, D, and F (163 acres) (Maps 84, 87, and 89) and designates and expands this ACEC area by 1,646 acres under alternatives B and E (Maps 85 and 88). The BLM would not designate the Five Springs Falls ACEC or its expansion area as an ACEC under Alternative C. Management of this area would vary by alternative. The values of concern in the Five Springs Falls ACEC include special status species plants and scenic and recreational features. In addition, the proposed expansion area contains geologic features and is managed to improve public awareness of natural geologic hazards in the area. Threats in the area of the ACEC proposed under alternatives A and D include damage to rare and endemic plants caused by recreation. Threats to the expansion area proposed under Alternative B include surface disturbance from mineral and ROW development.

4.7.1.15 Summary of Impacts by Alternative

Management under alternatives B and E would be the most effective for protecting the special status plant species, scenic, recreational, and geologic values of concern within the ACEC boundary designated under alternatives A, D, and F, and the expanded ACEC designated under alternatives B and E. Alternatives B and E also would result in the greatest restrictions on surface-disturbing activities and mineral development because the extent of the area to which this management is applied would be greater than under alternatives A, D, and F. Alternative C would be less effective for protecting the values of concern in the ACEC and in the ACEC expansion area. Alternative C would be more beneficial than the other alternatives to ROW authorizations and other uses that require surface disturbance.

4.7.1.16 Detailed Analysis of Alternatives

Alternative A

Alternative A prohibits surface-disturbing activities such as geophysical exploration (except casual use) and construction activities (except those related to development of recreation or interpretive areas dealing with rare plants). Prohibiting surface-disturbing activities would result in adverse impacts by limiting these activities. This restriction would benefit special status plant species and scenic and recreational values of concern in the ACEC.

Withdrawing the ACEC from appropriations under the mining laws would result in minimal adverse impacts to locatable minerals because there are few areas of known and potential occurrence for gypsum and bentonite in the ACEC. The Five Springs Falls ACEC is open to exploration and development of salable minerals and leasable minerals are open with an NSO restriction. However, there is no identified development potential for oil and gas and there is low potential for sand and gravel within this ACEC. Therefore, impacts would be minimal for these minerals.

Under Alternative A, managing the Five Springs Falls ACEC as a ROW avoidance area could result in adverse impacts to this resource use by limiting new ROW authorizations in the ACEC. ROW

Areas of Critical Environmental Concern

management that reduces or mitigates surface disturbance may help protect scenic and recreational values of concern. Requiring intensive mitigation for new ROWs would further benefit these values by reducing the impacts of new ROWs.

Limiting motorized travel in the ACEC to designated roads and trails would result in adverse impacts to motorized vehicle use. This travel restriction would reduce the available routes and would allow the closure of routes that result in adverse impacts to the values of concern.

Under Alternative A, restricting the use of heavy equipment in the Five Springs Falls ACEC may result in adverse impacts to fire and fuels management by limiting the ability to effectively and efficiently control wildland fires in the ACEC. Restricting these surface-disturbing activities would result in beneficial impacts by limiting potential degradation or destruction of the values of concern. However, limiting available options to control the spread or severity of wildfire may result in more catastrophic wildfires.

Alternative B

Alternative B expands the Five Springs Falls ACEC by 1,646 acres. Management and impacts described for Alternative A, with the exception of minerals, would apply to the expanded area unless otherwise noted. The larger size of the expanded ACEC, and the expansion of common management to include this area, would result in similar types of impacts to Alternative A, but to a greater extent.

Withdrawing the expansion area from appropriation under the mining laws could result in greater adverse impacts than Alternative A; however, no locatable mineral development is anticipated in this ACEC due to the absence of areas of known or potential occurrence. Valid existing mining claims represent valid existing rights and would not be affected by the withdrawal, although no new claims could be staked. This withdrawal could benefit the values of concern by reducing the impacts of surface disturbance. The degree of impacts from this withdrawal would be greater than under Alternative A, under which not withdrawing the area and allowing the staking of mining claims may result in adverse impacts to special status plant species habitat and scenic quality due to disturbance associated with mineral development. Managing the ACEC as closed to mineral leasing and closing it to mineral materials disposal would result in minimal adverse impacts because the development potential for oil and gas ranges from low to none and the potential for sand and gravel is low. Both the adverse and beneficial impacts of these actions would be greater than for the existing area and the expansion area than under Alternative A, under which the BLM manages the area as open to mineral leasing and mineral materials disposal.

Managing the existing and expansion area of the Five Springs Falls ACEC as a ROW avoidance area would result in greater adverse and beneficial impacts than under Alternative A, under which the expansion area is primarily open to ROW authorizations.

As under Alternative A, Alternative B limits motorized vehicle use in the existing and expansion area of the Five Springs Falls ACEC to designated roads and trails.

Alternative C

Under Alternative C, the BLM does not designate the area as an ACEC, and manages it in accordance with multiple use principles consistent with other resource objectives.

Alternative C includes the least restrictions on mineral development because the area is available for locatable mineral entry, open to mineral leasing, and open for mineral materials disposal. Impacts to

values of concern in the Five Springs Falls area from the development of minerals would be similar to those under Alternative A.

Management under this alternative is likely to result in the least adverse impacts to ROW authorizations because the area is primarily open to ROW authorizations and other surface-disturbing activities. Standard guidelines related to surface-disturbing activities would apply, but there would be more surface disturbance in the area compared to alternatives A and B, increasing the potential for damage to values of concern.

Under Alternative C, the BLM limits motorized vehicle use to designated roads and trails (1,646 acres) and closes some areas to motorized travel (163 acres). Impacts from travel management would be similar to Alternative A.

Alternative D

Under Alternative D, management of and impacts from the Five Springs Falls ACEC would be the same as under Alternative A, with the exceptions identified below.

As under Alternative B, the BLM closes the existing Five Springs Falls ACEC to mineral materials disposal and mineral leasing under Alternative D. Therefore, impacts under Alternative D would be the same as under Alternative B in this area. Similar to Alternative C, the area proposed for expansion under Alternative B would be available for locatable mineral entry, primarily open to oil and gas leasing with moderate constraints (1,526 acres), and open to mineral materials disposal. Under Alternative D, impacts from the management of mineral exploration and development in the Alternative B expansion area would be similar to Alternative C.

As under Alternative B, under Alternative D the BLM manages the existing Five Springs Falls ACEC and the expansion area proposed under Alternative B as a ROW avoidance area. However, unlike Alternative B, intensive mitigation is not required for additional ROW authorizations. The additional potential for adverse impacts to ROWs and benefits to special status plants species and scenic and recreational features from this additional mitigation would not occur under this alternative.

As under Alternative A, the existing area of the Five Springs Falls ACEC and the expansion area proposed under Alternative B are limited to designated roads and trails under Alternative D; impacts from this management would be the same as described under Alternative A.

Alternative E

Management of and impacts to values of concern in the Five Springs Falls area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Five Springs Falls area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Little Mountain

Under Alternative A, the BLM designates the Little Mountain area as an ACEC (21,476 acres) (Map 84) and designates and expands the area by 50,575 acres under alternatives B and E (Maps 85 and 88). The BLM does not designate these areas as ACECs under Alternative C. Under alternatives D and F (Maps 87 and 89), the BLM designates the ACEC with the Alternative A boundaries, and manages the area proposed for expansion under alternatives B and E as the Craig Thomas Little Mountain SMA (Maps 85 and 88). Although the Craig Thomas Little Mountain SMA would maintain its existing designation under all the alternatives, the BLM only proposes special management for this area under alternatives D and F. Management of this area would vary by alternative. Values of concern for this area includes caves, cultural and paleontological resources, and scenic qualities. In addition, the proposed expansion area contains wildlife and vegetation resources, including big game and special status species habitat and important plant populations. Threats to the ACEC and SMA include surface disturbance from mineral (including gravel pits, uranium, and limestone) and ROW development, timber extraction, recreational and OHV use, and invasive species, which affect habitat for special status species and have the potential to disturb wintering wildlife.

4.7.1.17 Summary of Impacts by Alternative

Management under alternatives B and E would be the most effective for protecting the caves, cultural and paleontological resources, scenic, wildlife, and vegetation values of concern. ACEC alternatives A, D, and F, and ACEC expansion or SMA alternatives B, D, E, and F would be the most effective for protecting the values of concern because they allow the least development. Alternatives B and E implement the greatest restrictions on surface-disturbing activities, mineral development, ROW authorizations, and motorized travel on the largest area, resulting in the greatest adverse impacts to these resource uses. Alternatives D and F would result in impacts similar to alternatives B and E, although the adverse impacts to mineral leasing and locatable mineral entry and the beneficial impacts to the values of concern from restricting these mineral uses would both be less under alternatives D and F. Alternative C would be the least effective for protecting the values of concern in the ACEC area designated under alternatives A, D, and F, and the ACEC expansion or SMA areas proposed under alternatives B, D, E, and F, respectively. Alternative C would be more beneficial to mineral development, ROW authorizations, and motorized travel than the other alternatives.

4.7.1.18 Detailed Analysis of Alternatives

Alternative A

Under Alternative A, the Little Mountain ACEC is available for locatable mineral entry, which could result in long-term adverse surface-disturbance impacts to the cultural, paleontological, and scenic values of concern for this area. As with all ACECs, the BLM has the ability to institute case-by-case withdrawals that may result in beneficial impacts to the values of concern by allowing for the protection of important sites. All cave and karst areas in the Planning Area also are withdrawn from appropriation under the mining laws, which would protect the Horsethief, Natural Trap, and other caves in the ACEC. Allowing locatable mineral entry would benefit this resource use, particularly areas of known potential for gypsum occurrence (3,154 acres).

Alternative A manages the ACEC as open to oil and gas leasing with an NSO restriction on the areas above these caves. Allowing mineral leasing with an NSO restriction could have adverse impacts on

mineral leasing in the ACEC by requiring directional drilling or other development techniques that may limit economically feasible recovery of these resources. NSO restrictions would benefit the values of concern in the ACEC by reducing their potential for destruction or degradation.

Under Alternative A, the Little Mountain ACEC is managed as a ROW avoidance area, which could result in adverse impacts to ROW authorizations. Managing the ACEC as a ROW avoidance area and requiring intensive mitigation for new ROWs could also benefit the values of concerns by reducing the impact of new ROWs on caves, cultural and paleontological resources, and scenic quality values of concern.

Under Alternative A, limiting motorized vehicle use to designated roads and trails would limit access and opportunities for travel. Travel management under Alternative A may result in beneficial impacts to the values of concern by eliminating routes that damage resources and limiting access to sensitive cultural, paleontological, and cave areas. Placing warnings signs around safety hazards in the Little Mountain ACEC to warn the public of health and safety hazards posed by radioactivity at uncovered mine entrances and adits would benefit visitor health and safety in the area.

Alternative B

Alternative B would expand the Little Mountain ACEC by 50,575 acres. Management and impacts described for Alternative A would apply to the expanded area unless otherwise noted. The larger size of the expanded ACEC, and the expansion of common management to include this area, would result in similar types of impacts, but to a greater extent than Alternative A.

Under Alternative B, restrictions on mineral development would result in adverse impacts to the use of these resources. The ACEC is withdrawn from appropriation under the mining laws and closed to mineral leasing within the entire Little Mountain ACEC. Withdrawing the entire ACEC under Alternative B could have the greatest adverse impacts on locatable mineral development due to the withdrawal of 13,264 acres with known gypsum occurrence. Withdrawal would eliminate the potential to develop locatable minerals because no new claims could be staked; valid existing mining claims represent valid existing rights and would not be affected by the withdrawal (see Section 4.2.1 *Locatable Minerals*). Adverse impacts to mineral development would be greater under Alternative B than under Alternative A, under which the BLM manages the expansion area as available for locatable mineral entry on 50,575 acres and would protect more area.

Management of mineral leasing in the expansion area under Alternative B is more restrictive than under Alternative A. However, the development potential for oil and gas in the existing ACEC and expansion area ranges from very low to none, which may minimize the impact of this more restrictive management. Beneficial impacts to the values of concern as a result of restrictions on mineral development under Alternative B are greater than under Alternative A.

Managing the proposed ACEC expansion area as a ROW avoidance area could result in greater adverse impacts to the authorization of ROWs than Alternative A, which manages a portion of the expansion areas as open to ROW authorizations. Managing the entire expansion area as a ROW avoidance area may benefit the values of concern in the ACEC by limiting ROW development in the area or requiring mitigation to reduce adverse impacts.

Limiting motorized vehicle use in the ACEC to designated roads and trails would result in greater adverse impacts to motorized vehicle access and greater beneficial impacts to the values of concern than Alternative A in the Alternative B expansion area. Under Alternative A, the expansion area is limited to existing roads and trails.

Alternative C

Alternative C does not designate the Little Mountain area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

Similar to Alternative D, only a small portion of the area under Alternative C (488 acres) is withdrawn from appropriation under the mining laws. This management may result in greater adverse impacts to the values of concern in the Little Mountain area than alternatives A and B by increasing mineral activity and associated surface disturbance.

Management of ROWs and motorized vehicle use under Alternative C would be similar to that under Alternative A. Applying standard guidelines related to surface disturbance for ROWs would result in a lower standard for the mitigation of surface disturbance compared to alternatives A and B, leading to greater potential for adverse impacts to the values of concern under Alternative C than the other alternatives.

Alternative D

Under Alternative D, the management of and impacts from the Little Mountain ACEC and the Craig Thomas Little Mountain SMA are the same as under Alternative B, except for authorizations for renewable energy development, locatable mineral entry, and mineral leasing in the SMA.

Under Alternative D, the Craig Thomas Little Mountain SMA is a renewable energy exclusion area. Excluding renewable energy could result in adverse impacts to the development of wind energy in the Little Mountain area, but would also reduce the possibility of damage to the values of concern from surface disturbance and prevent adverse impacts from the introduction of new contrasting elements, such as wind turbines, on scenic qualities. Management of renewable energy is more restrictive than the other alternatives, which primarily manage the area as an open or avoidance area for renewable energy.

The Little Mountain ACEC and the Craig Thomas Little Mountain SMA are available for locatable mineral entry. As noted for Alternative A, the BLM has the ability to institute withdrawals for ACECs on a case-by-case basis and withdraws cave and karst resources from appropriation under the mining laws. Allowing locatable mineral entry would benefit the development of these resources, particularly in the 13,264 acres with known gypsum occurrence, and the 2,195 acres with known bentonite occurrence. Allowing locatable mineral entry would result in long-term adverse surface-disturbance impacts to the values of concern for this area, particularly cultural and paleontological resources, scenic qualities, and wildlife and special status species habitat.

Under Alternative D, the restrictions on mineral leasing in the Craig Thomas Little Mountain SMA could result in adverse impacts to the use of these resources, particularly on the 53,221 acres managed as closed. Management of mineral leasing in the Craig Thomas Little Mountain SMA under Alternative D is more restrictive than under alternatives A and C, but less restrictive than under Alternative B. As noted for Alternative B, the very low to no development potential for oil and gas in this area may minimize the impact of restrictive management to mineral development. Conversely, beneficial impacts to the values of concern as a result of restrictions on mineral development may be greater than under alternatives A and C, but less than under Alternative B.

Alternative E

Management of and impacts to values of concern in the Little Mountain area and the Craig Thomas Little Mountain SMA under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Little Mountain area and the Craig Thomas Little Mountain SMA under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for cave and karst resources under Alternative D is representative of the impacts anticipated under Alternative F.

Upper Owl Creek Area

Alternative A designates the Upper Owl Creek area as an ACEC (13,758 acres) (Map 84); alternatives B and E designate and expand the Upper Owl Creek ACEC by 18,975 acres (Maps 85 and 88). Alternative C does not designate the Upper Owl Creek area as an ACEC. Management of this area varies by alternative. Values of concern in the Upper Owl Creek area include cultural sites, fisheries habitat, recreational opportunities, scenic qualities, shallow soils, special status species and wildlife habitat, and important vegetation communities. Threats to the values of concern in the ACEC proposed under Alternative A include surface disturbance from mineral and ROW development. In the expansion area proposed under alternatives B and E, threats to the values of concern also would include timber extraction and land disposals.

4.7.1.19 Summary of Impacts by Alternative

Alternatives B and E would provide the greatest protection for the cultural sites, fisheries habitat, recreational opportunities, scenic qualities, shallow soils, special status species and wildlife habitat, and important vegetation communities that are the values of concern for the Upper Owl Creek area. Adverse impacts to the values of concern from travel management and surface disturbance would be greatest under Alternative C, but adverse impacts from ROW authorizations would be greater under alternatives A, D, and F. Alternative C generally would be the least restrictive to resource uses in the area, while alternatives B and E would include the most restrictions.

4.7.1.20 Detailed Analysis of Alternatives

Alternative A

Under Alternative A, limiting or prohibiting surface-disturbing activities in the Upper Owl Creek ACEC would restrict the ability to perform activities such as geophysical exploration and road construction. Restricting surface-disturbing activities would protect fragile soils, alpine tundra, important wildlife habitat, and scenic values of concern. Additional protection for these values would be provided by requiring a detailed activity plan before approval of any proposal for a major surface-disturbing activity.

Under Alternative A, restrictions on mineral development would result in minimal adverse impacts to these resources in the ACEC. Alternative A includes a withdrawal from appropriation under the mining laws for the Upper Owl Creek ACEC; however, gypsum and bentonite are unlikely to be developed in this

Areas of Critical Environmental Concern

ACEC. Therefore, development and potential impacts would be low. The Upper Owl Creek ACEC is open to oil and gas leasing with an NSO restriction; however, the development potential for oil and gas in the ACEC is very low and adverse impacts from this management are likely to be minimal. Restrictions on minerals development may benefit the values of concern by reducing surface disturbance that could decrease the recreational setting, fragment or disturb special status species and wildlife habitat and vegetation communities, and reduce the potential for erosion and disturbance to shallow soils.

Managing the Upper Owl Creek ACEC as open for future ROW authorizations would result in adverse impacts to the values of concern by allowing development and disturbance associated with ROWs. There may be some impacts to fragile soils, vegetation, and wildlife habitat from ROW surface disturbance, although prohibiting and limiting surface-disturbing activities in this ACEC would minimize adverse impacts. Allowing ROW authorizations in this ACEC would benefit ROWs.

Restricting motorized travel to designated roads and trails would limit the roads and trails available for travel, potentially resulting in adverse impacts to travel and motorized recreational use. This designation may benefit the values of concern in the area by reducing the number roads and trails and closing routes that damage soils and vegetation; impact scenic quality; alter the desired primitive RSCC, experiences, and benefits; and impact wildlife habitat values of concern.

Encouraging coordination between the BLM and local stakeholders in landscape management may provide opportunities to improve wildlife habitat, decrease the fragmentation of vegetation communities, maintain or enhance the visual qualities, and provide for exceptional primitive type recreational opportunities, experiences, and benefits across jurisdictional boundaries within the mixed land ownership pattern of the ACEC.

Alternative B

Alternative B would expand the Upper Owl Creek ACEC by 18,975 acres. Management and impacts described for Alternative A would apply unless otherwise noted. The larger size of the expanded ACEC, and the expansion of common management to include this area, would result in similar, but comparatively greater impacts, to those under Alternative A.

The area withdrawn from appropriation under the mining laws is larger under Alternative B (13,016 acres) than Alternative A. The proposed expansion area includes few areas with known or potential bentonite and gypsum occurrence. Therefore, the withdrawal is expected to result in minimal adverse impacts to locatable mineral development in the area. In addition, managing the ACEC as closed to oil and gas leasing would be more restrictive than under Alternative A, which manages the area as open, although the low to very low development potential for oil and gas in the area may minimize adverse impacts to mineral leasing. Although Alternative B expands restrictions on mineral development in comparison to Alternative A, minimal adverse impacts to the use of these resources are anticipated due to the low potential for occurrence or development. Management that restricts mineral development may benefit the values of concern by reducing the potential for surface disturbance associated with mineral development.

Expanding the ROW avoidance area to include the expansion area could result in greater adverse impacts to the authorization of ROWs under Alternative B compared to Alternative A, which manages the expansion area as open to ROW authorizations. This management also would increase protection for the values of concern compared to the other alternatives.

Impacts to and from travel management would be similar to Alternative A, because most of the area under both alternatives is limited to designated roads and trails. Alternative A limits motorized vehicle

use in the expansion area primarily to designated roads and trails (18,080 acres) with a smaller area limited to existing roads and trails (1,640 acres).

Alternative C

Alternative C does not designate the Upper Owl Creek area as an ACEC; the BLM manages it in accordance with multiple use principles consistent with other resource objectives.

The area is available for locatable mineral entry under Alternative C, but adverse and beneficial impacts would be minimal because gypsum and bentonite are not present in production-scale quantities. Due to the low to no development potential for oil and gas in the area, impacts would be minimal and similar to Alternative A.

Alternative C manages the Upper Owl Creek area as open to ROW authorizations (29,699 acres) and as a ROW avoidance area (3,034 acres). ROW management under Alternative C is more restrictive than under Alternative A, and the adverse impacts to ROW authorizations are likely to be greater under Alternative C than under alternatives B and D. Beneficial impacts to the values of concern from ROW authorizations may be greater than under Alternative A due to increased area excluded and avoided to ROW authorizations. Only standard guidelines related to surface disturbance would apply, so the impacts from the additional restrictions on surface disturbance realized under alternatives A and B would not occur.

Under Alternative C, managing motorized vehicle use as limited to existing (19,720 acres) and limited to designated (13,057 acres) roads and trails would result in the greatest adverse impacts from motorized travel to the values of concern by increasing access and opportunities for travel that could degrade or damage resources. This alternative places the fewest restrictions on motorized travel of any alternative.

Alternative D

Under Alternative D, management of and impacts from the Upper Owl Creek ACEC (Map 87) are the same as under Alternative A, except for ROW authorizations, locatable mineral entry, and mineral leasing. However, under Alternative D, management of the area proposed for expansion under Alternative B differs from management under Alternative A.

Under Alternative D, management to limit or prohibit surface-disturbing activities in the existing ACEC would result in impacts as described for Alternative A. In the proposed Alternative B expansion area, only standard guidelines related to surface disturbance would apply. Therefore, the impacts from the additional restrictions on surface disturbance realized under Alternative B would not occur under Alternative D.

Unlike Alternative A, Alternative D manages the Upper Owl Creek ACEC as available for locatable mineral entry, closed to oil and gas leasing, and as a ROW avoidance area, which could result in adverse impacts to mineral leasing and ROW authorizations. Alternative D manages the area of the existing ACEC as closed to oil and gas leasing and the area proposed for expansion under Alternative B as open with primarily moderate constraints (4,228 acres). This management may result in greater adverse impacts to mineral leasing and greater beneficial impacts to the values of concern than alternatives A and C, but less than Alternative B. Unlike alternatives A and C, this alternative does not withdraw the existing ACEC or the Alternative B expansion area, and impacts to and from locatable mineral entry would therefore be similar to Alternative C. However, as with all ACECs, the BLM has the ability to institute case-by-case withdrawals that may result in beneficial impacts to the values of concern in the existing ACEC by allowing for the protection of important sites.

Areas of Critical Environmental Concern

Managing the existing ACEC as a ROW avoidance area and open to ROW authorizations in the expansion area proposed under Alternative B would result in impacts to the authorization of ROWs and the values of concern similar to those for Alternative A, and fewer adverse impacts to ROW authorization and beneficial impacts to the values of concern than under Alternative B.

As under alternatives A and B, the existing area of the Upper Owl Creek ACEC and the expansion area proposed under Alternative B are limited to designated roads and trails under Alternative D. Impacts from this management would be the same as for the other alternatives.

Alternative E

Management of and impacts to values of concern in the Upper Owl Creek area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Upper Owl Creek area under Alternative F (Map 89) would be the same as those described under Alternative D; therefore, the impacts analysis for the Upper Owl Creek area under Alternative D is representative of the impacts anticipated under Alternative F.

Proposed ACECs

Chapman Bench

Alternatives B and E designate the Chapman Bench area as an ACEC (23,326 acres) (Maps 85 and 88), but alternatives A and C do not. Although not proposed as an ACEC under alternatives D and F, the BLM manages a portion of this area as the Chapman Bench Management Area (Maps 87 and 89). Values of concern in the proposed Chapman Bench ACEC are special status bird species, vegetation, and wildlife habitat. Threats to this area include potential mining interests when this reserved land is opened to all public land laws, which would affect special status bird species (e.g., long billed curlew, mountain plover, and greater sage-grouse) in the area.

4.7.1.21 Summary of Impacts by Alternative

Alternatives B and E are the only alternatives that designate the Chapman Bench area as an ACEC and would be the most effective for protecting the special status bird species, vegetation, and wildlife habitat values of concern in the Chapman Bench area. Alternatives B and E would also result in the greatest restrictions on the ROW authorizations, mineral leasing, and other surface-disturbing activities. Alternatives D and F designate a portion of this area as the Chapman Bench Management Area and apply management to protect the values of concern; this management is less restrictive to resource uses and would provide fewer protections to special status species and wildlife habitat than alternatives B and E. Alternatives A and C allow mineral development and are less restrictive of ROW authorizations than alternatives B and E. Alternatives D and F restrict locatable mineral entry, mineral materials disposal, and ROWs similar to alternatives B and E in the Chapman Bench ACEC, but manages these activities similar to Alternative C across the remainder. Alternatives B, C, and E would be the most

restrictive of travel in the area, and would therefore provide the greatest protection to values of concern from fragmentation and disruption related to motorized vehicle use.

4.7.1.22 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the Chapman Bench area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The Chapman Bench area has been closed to mineral entry because the BOR previously administered the land; Alternative A would open the area to mineral entry. Trace quantities of placer gold have been reported in stream sediment and gravel of Big Sand Coulee in the general area of Chapman Bench. Gold in the Big Sand Coulee area occurs as fine flakes and pin-point sized fragments (Thomas 1965). Managing the area as available for locatable mineral entry could result in adverse impacts to wildlife habitat if speculative placer gold claims were located in the area. The area has a low potential for gypsum and bentonite occurrence, which may minimize the potential for development and associated impacts to the values of concern. Under Alternative A, the area is open to mineral leasing with primarily moderate constraints, which could result in adverse impacts to the special status bird species, vegetation, and wildlife habitat values of concern due to surface disturbance and disruption. However, the development potential for oil and gas (9,206 acres of low potential and 14,121 acres very low potential) in the area may minimize the potential for development and associated impacts.

The area is open to mineral materials disposal, and adverse impacts to the values of concern would likely occur on the 5,852 acres where the potential for sand and gravel is high. Beneficial impacts to mineral development from this management would likely occur on this 5,852 acres by allowing disposal of mineral materials in this area, subject to BLM review.

The Chapman Bench area is managed primarily as open to ROW authorizations (18,668 acres), with a smaller area managed as a ROW avoidance area (4,694 acres). Standard guidelines related to surface disturbance would apply. Allowing ROW authorizations could result in surface disturbance and disruption and related adverse impacts to the values of concern, such as the spread of invasive species or the loss of vegetation. Managing the area as primarily open to ROW authorizations would benefit this resource use.

Alternative A manages motorized vehicle use in the Chapman Bench areas as limited to existing roads and trails, which would benefit motorized travel in the area. Travel management would benefit special status bird species, vegetation, and wildlife habitat by restricting off-road driving and damage to habitat or disruption of wildlife.

Alternative B

Under Alternative B, the BLM manages the Chapman Bench area as an ACEC for the retention, enhancement, and success of the greater sage-grouse, mountain plover, and long-billed curlew. Prohibiting surface-disturbing activities in the Chapman Bench ACEC would restrict and result in adverse impacts to activities such as geophysical exploration and road construction. This restriction may benefit special status bird species and wildlife in the area by limiting the potential for disruptions, habitat fragmentation, or invasive species infestations that would degrade their habitat.

Areas of Critical Environmental Concern

Under Alternative B, restrictions on mineral development are likely to result in greater adverse impacts to these resource uses than under Alternative A. The ACEC is withdrawn from appropriation under the mining laws and closed to mineral leasing; however, the potential for gypsum and bentonite occurrence is low, and the development potential for oil and gas in the area consists of 9,206 acres of low potential and 14,121 acres of very low potential. Due to the low oil and gas development potential, development and resulting impacts would be minimal. The ACEC is closed to mineral materials disposal, and adverse impacts to mineral development would be greatest on the 5,852 acres with high-potential for sand and gravel. Restrictions and closures of the area to mineral activity could benefit the values of concern in the ACEC by preventing mining-related surface disturbance, habitat fragmentation, and general degradation of the habitat and disturbance of special status species. Several of the sensitive bird species proposed for management in this ACEC prefer habitat composed of shortgrass or similar vegetation cover and bare ground. This preferred vegetation cover can be compromised by increases in cover, for example, cheatgrass which will increase overall cover and make habitat less suitable. Disturbance in preferred habitat types may encourage invasive weeds (e.g., cheatgrass and halogeton) to dominate instead of native shortgrass species. Locally, the BLM has not observed preferential selection of habitat removed through blading or similar action by invasive weed species. Local nesting locations are in a condition not modified through mechanical means and are composed of native shortgrass short statured plant species providing appropriate nesting cover. Management under Alternative B would also not allow mineral development near known nest sites, which are susceptible to disruption by such activities and are used year after year by individuals.

Under Alternative B, most of the Chapman Bench ACEC is a renewable energy and ROW avoidance area (17,897 acres) and a ROW exclusion area on the remainder (5,430 acres). Of all the alternatives, this management is the most restrictive to future ROW authorizations and the most restrictive of ROW-related surface disturbance and disruption. This management is likely to result in the greatest beneficial impacts to the wildlife and vegetation values of concern.

Alternative B limits motorized vehicle travel in the ACEC to existing roads and trails, and impacts under Alternative B would be the same as those under Alternative A.

Seasonally stipulating, where feasible, vegetative treatments, invasive, nonnative pest species control, fuels management, and maintenance of existing facilities in the Chapman Bench ACEC would protect wildlife and special status species during sensitive times of the year, while still allowing maintenance and treatments to occur.

Alternative C

Alternative C does not designate the Chapman Bench as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The management of and impacts associated with mineral resources under Alternative C would be similar to those under Alternative A.

Alternative C manages the Chapman Bench area as an avoidance area for ROW authorizations (19,664 acres), and manages a smaller area as open to ROW authorizations (3,662 acres). Management under this alternative may result in greater adverse impacts to ROW authorizations than under Alternative A because a larger portion is a ROW avoidance area subject to development constraints or additional mitigation and monitoring that could affect construction costs. Such constraints could benefit special status bird species and wildlife that would be adversely affected by such developments. Standard guidelines related to surface disturbance would apply on portions managed as open to ROW authorizations.

Alternative C limits motorized vehicle use primarily to designated roads and trails (23,268 acres). This alternative is the most restrictive to motorized travel and would result in the greatest potential for adverse impacts to travel and transportation management in the area. This alternative represents the smallest potential for travel-related impacts to the values of concern of any of the alternatives.

Alternative D

Under Alternative D, the BLM manages the Chapman Bench area as a Management Area for the retention and success of the greater sage-grouse, mountain plover, and long-billed curlew. The 3,425 acres of BLM-administered surface ownership managed for these values are all within the Alternative B ACEC (23,326 acres) boundaries. The BLM allows surface-disturbing activities across the entire Chapman Bench area, consistent with other resource objectives and standard guidelines for surface-disturbing activities. The adverse and beneficial impacts of prohibiting such activities, as described for Alternative B, would not occur under this alternative.

The Chapman Bench Management Area is withdrawn from appropriation under the mining laws, open to mineral leasing with an NSO restriction, and closed to mineral materials disposal. The larger area proposed as an ACEC under Alternative B is open to locatable mineral entry, open to mineral leasing with moderate constraints, and open to mineral materials disposal. The management of mineral uses in the Chapman Bench Management Area could result in adverse impacts to mineral exploration and development and benefits to the values of concern similar to Alternative B. In the larger area designated as an ACEC under Alternative B, impacts to and from mineral development under this alternative would be less beneficial to the values of concern and more beneficial to mineral development.

ROW management and associated impacts across the Chapman Bench area would be similar to those under Alternative C. Under Alternative D, the Chapman Bench Management Area is a renewable energy and ROW avoidance area. The larger area designated as an ACEC under Alternative B is mostly managed as a ROW avoidance area, with a smaller area managed as open to ROW authorizations (3,691 acres).

Under Alternative D, management of and impacts from motorized vehicle use across the entire Chapman Bench area would be the same as under Alternative A.

Similar to Alternative B, under Alternative D the BLM can stipulate, where feasible, treatment and maintenance activities in the Chapman Bench Management Area to protect wildlife, while still allowing maintenance and treatments to occur. In the larger area proposed as an ACEC under Alternative B, the standard guidelines related to surface disturbance and the management of other resource objectives would apply to these activities; therefore, under Alternative D, impacts in this area would be similar to those under alternatives A and C.

Alternative E

Management of and impacts to values of concern in the Chapman Bench area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Chapman Bench area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Clarks Fork Basin/Polecat Bench West Paleontological Area

Alternatives B and E designates the Clarks Fork Basin/Polecat Bench West Paleontological Area as an ACEC (23,895 acres) (Maps 85 and 88); alternatives A, C, D, and F would not. Although not proposed under alternatives D and F, a portion of this area falls within the proposed PETM ACEC (Maps 87 and 89). The values of concern in the proposed Clarks Fork Basin/Polecat Bench West Paleontological Area ACEC are paleontological resources in the form of mammalian and paleobotanical fossils and geochemical data used in the study of a major Carbon Isotope Excursion recorded during an ancient period of global warming known as the PETM. Scenic and geologic features also are valuable features in this ACEC. Threats to the area include additional surface disturbance from mineral development (e.g., oil and gas, mineral materials, and possible locatable mineral mining), and ROW development, timber extraction, recreational and OHV use, and invasive and nonnative species infestations. These activities threaten habitat for special status species and create disturbances in crucial winter range during sensitive periods. Heavy public recreational use and existing SRPs also threaten the values of concern in the area. Water quality and quantity issues, as a result of surface and groundwater withdrawals and untreated irrigation outflows, also threaten the area.

4.7.1.23 Summary of Impacts by Alternative

Alternatives B and E are the only alternatives that designate the Clarks Fork Basin/Polecat Bench West Paleontological area as an ACEC, and would be the most effective for protecting the paleontological values of concern. Alternatives B and E also place the greatest restrictions on surface-disturbing activities, mineral development, ROWs, and motorized travel. Alternatives B and E include specific requirements related to paleontological sensitivity surveys and monitoring that would benefit the protection of the values of concern to a greater extent than the other alternatives. The management of mineral development are similar under alternatives A and C, but ROW and motorized travel management under Alternative C is more restrictive than under Alternative A. A portion of the Clarks Fork Basin/Polecat Bench West Paleontological area is included in the PETM ACEC under alternatives D and F; the *Paleocene-Eocene Thermal Maximum* section describes management of and impacts to this area under alternatives D and F.

4.7.1.24 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area is open to locatable mineral entry, open to mineral leasing (with primarily moderate constraints on 10,249 acres), and open to mineral materials disposal on 23,113 acres under Alternative A. A plan of operations would not be required for notice-level locatable minerals activities. The known and potential gypsum and bentonite occurrence, the low (23,320 acres) to very low (575 acres)

development potential for oil and gas, and the low potential for sand and gravel in the area would result in fewer adverse impacts to minerals development activities.

Alternative A manages the Clarks Fork Basin/Polecat Bench West Paleontological Area as open to ROW authorizations (20,068 acres), and manages a smaller area as a ROW avoidance area (3,271 acres). Standard guidelines related to surface disturbance would apply. ROW management would benefit this resource use in open areas, but may limit such development in avoidance areas or require specific mitigation that may increase project costs and timeframes. Restrictions on ROW developments would generally benefit paleontological resources by reducing surface-disturbing activities and potential destruction of paleontological values.

Alternative A limits motorized vehicle use to existing roads and trails, which may result in adverse impacts to values of concern by allowing access to travel that may disturb and degrade paleontological values of concern in the area.

The Clarks Fork Basin/Polecat Bench West Paleontological Area is open to livestock grazing under Alternative A. Livestock trampling and wallowing in areas of concentrated livestock use can damage exposed paleontological resources. While in most instances, concentrated livestock use would result in adverse impacts to paleontological values, proper livestock grazing management can mitigate these impacts by improving the distribution of livestock.

Restricting surface disturbance solely through application of the standard guidelines for surface disturbance may lead to damage to the identified values of concern, soil erosion, spread of invasive species, and impacts to water quality. Management under this alternative is the least restrictive of ROW authorizations and other surface-disturbing activities, and would result in the largest adverse impact to the identified values of concern.

Alternative B

Management of surface-disturbing activities in the ACEC emphasizes avoiding impairment of the management objectives and existing values, while protecting the integrity of fossil-bearing material. Under Alternative B, avoiding or prohibiting surface-disturbing activities and the use, occupation, construction, or maintenance of facilities in the Clarks Fork Basin/Polecat Bench West Paleontological ACEC that are inconsistent with the management direction and objectives for the area would restrict development and maintenance activities, but would benefit the protection of paleontological resources. Requiring that minor ROW authorizations and other minor surface-disturbing activities be preceded by paleontological sensitivity surveys and potential monitoring during construction, may have long-term impacts by increasing processing times of authorizations and potentially requiring mitigation, relocation, or modification of facilities if paleontological resources are found. These ROW and surface-disturbance stipulations would further protect paleontological resources in the area.

Under Alternative B, withdrawing the Clarks Fork Basin/Polecat Bench West Paleontological ACEC from appropriation under the mining laws and closing the area to geophysical exploration would likely result in greater adverse impacts to mineral development than Alternative A. Restricting mineral development would benefit the ACEC by reducing the potential for destruction or degradation of paleontological values and the other adverse impacts associated with surface disturbance (e.g., the potential spread of invasive species).

Under Alternative B, the Clarks Fork Basin/Polecat Bench West Paleontological ACEC is a renewable energy exclusion area and motorized vehicle use is limited to designated roads and trails. Excluding renewable energy would result in adverse impacts to the ability to develop renewable energy. Limiting

Areas of Critical Environmental Concern

motorized vehicle use to designated roads and trails would restrict access in the area by limiting the roads available for recreational and other motorized travel. Restrictions on renewable energy and motorized travel would reduce the possibility of damage to paleontological resources from surface disturbance and would allow the closure of routes that may result in damage to paleontological resources. Management of travel and renewable energy is more restrictive under Alternative B than under Alternative A and resulting beneficial impacts for the values of concern would be greater under Alternative B.

Management under Alternative B continues livestock grazing provided it does not disturb the natural, educational, and scientific research values of the ACEC. The flexibility to restrict livestock grazing if use becomes concentrated or adversely affects other resource values may result in beneficial impacts to the values of concern by reducing potential degradation by livestock. Conversely, any restrictions could adversely affect livestock grazing by reducing the number of AUMs available in the ACEC from its current level of 1,344.

Fossil collection, excavation, or removal in the Clarks Fork Basin/Polecat Bench West Paleontological ACEC would be allowed under a permit issued by the Wyoming BLM State Director and only to institutions and individuals engaged in BLM-approved research, museum, or educational projects. This management would protect the integrity of the resources and enable the advancement of scientific knowledge in the area, but also would restrict recreational collection of fossils.

Alternative C

Alternative C does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area would be open to locatable mineral entry and open to mineral leasing (with primarily moderate constraints on 10,153 acres), and primarily open to mineral materials disposal (21,058 acres). Impacts would be similar to those under Alternative A.

Alternative C manages the Clarks Fork Basin/Polecat Bench West Paleontological area as an avoidance area for ROW authorizations (11,099 acres), and manages a smaller area managed as open to ROWs (12,796 acres). Standard guidelines related to surface disturbance would apply, but the additional restrictions under Alternative B would not. As under Alternative B, Alternative C limits motorized vehicle use to designated roads and trails. Management under Alternative C is more restrictive to ROW development and motorized travel than under Alternative A.

The standard guidelines related to surface disturbance would apply and may result in additional surface disturbance in the area compared to alternatives A or B, leading to potential soil erosion, spread of invasive species, impacts to water quality and damage to the identified values of concern. Management under Alternative C would be the least restrictive of ROW authorizations and other surface-disturbing activities and would result in the largest adverse impact on the identified values of concern.

Alternative D

Alternative D does not designate this area as an ACEC. Part of the Clarks Fork Basin/Polecat Bench West Paleontological area (4,972 acres) is within the proposed PETM ACEC. See the *Paleocene-Eocene Thermal Maximum* section for an analysis of the effects of management in this area.

Alternative E

Management of and impacts to values of concern in the Clarks Fork Basin/Polecat Bench West Paleontological Area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Clarks Fork Basin/Polecat Bench West Paleontological Area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Clarks Fork Canyon

The Clarks Fork Canyon area is designated as an ACEC under alternatives B and E (12,249 acres) (Maps 85 and 88) and alternatives D and F (4,746 acres) (Maps 87 and 89); it is not designated as an ACEC under alternatives A or C. The values of concern in the proposed Clarks Fork Canyon ACEC are geologic features, including the Canyon Mouth Anticline, and glacial features, open space, recreational opportunities, special status species plants and wildlife, and wildlife habitat. Threats to this proposed ACEC include surface disturbance from mineral and ROW development.

4.7.1.25 Summary of Impacts by Alternative

Alternatives B, D, E, and F are the only alternatives that designate the Clarks Fork Canyon area as an ACEC. Due to the larger size and more restrictive management, alternatives B and E would be the most effective for protecting the glacial features, open space, recreational opportunities, special status species plants and wildlife, and wildlife habitat values of concern in the ACEC. Alternatives B and E would be most effective for managing threats from motorized vehicle use and surface disturbance resulting from ROW development and locatable mineral entry by including the greatest restrictions on these activities. Management of mineral materials disposal and oil and gas leasing under alternatives B, D, E, and F would be similar within their respective ACEC boundaries, although the larger area managed under alternatives B and E would be less restrictive under alternatives D and F. Alternative A generally would provide the least restrictive management and would be the least effective for protecting the values of concern. Alternative A management would be the most beneficial to motorized travel and would include management for locatable and mineral materials similar to Alternative C. Alternative C management would be the most beneficial to ROW authorizations.

4.7.1.26 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area is mostly open for locatable mineral entry with a withdrawal on 1,714 acres, open to mineral leasing (with primarily major constraints on 5,876 acres), and primarily open to mineral materials disposal (8,950 acres). Allowing mineral development could result in surface disturbance that would

Areas of Critical Environmental Concern

degrade wildlife and special status species habitat and may damage the glacial features and recreational setting values of the area.

The Clarks Fork Canyon area is managed as open to ROW authorizations on 5,758 acres and as a ROW avoidance area on 5,389 acres. Managing a portion of the area as open to ROW authorizations could result in adverse impacts to the values of concern, including degradation of wildlife and special status species habitat and damage to glacial features and the recreational setting.

Alternative A limits motorized vehicle use to existing roads and trails (5,294 acres), and manages seasonal closure within the Bald Ridge Area (5,739 acres).

Alternative B

Prohibiting surface-disturbing activities in the Clarks Fork Canyon ACEC would restrict and have an adverse impact on such activities as geophysical exploration and road construction. Restrictions on surface disturbance would benefit special status species plants and wildlife in the area by limiting the potential for disruptions, habitat fragmentation, or invasive species infestations that may degrade their habitat.

Restrictions on mineral development under Alternative B would result in greater adverse impacts to the use of these resources compared to Alternative A. The ACEC is withdrawn from appropriation under the mining laws and closed to mineral leasing. Adverse impacts from mineral withdrawal generally are likely to be greatest in the approximately 483 acres with known or potential gypsum occurrence and 892 acres with known or potential bentonite occurrence, but because of the lack of commercial-grade resources, impacts to mineral development would be minimal. Adverse impacts to mineral materials disposal would be greatest on 4,720 acres with higher potential for sand and gravel. The very low development potential for oil and gas would minimize the potential for adverse impacts to leasable minerals development as a result of managing the area as closed to leasing.

Alternative B manages the Clarks Fork Canyon ACEC as a ROW avoidance area, a renewable energy exclusion area, and closed to motorized and mechanized vehicle use or limited to designated roads and trails, including seasonal closure within the Bald Ridge Area. Adverse impacts to these resource uses would be greater under Alternative B than Alternative A because there would be more restrictions on use. More restrictive ROW management would reduce or mitigate surface disturbance and could result in greater protection for values of concern than under Alternative A. In addition, more restrictive motorized travel management would reduce disturbance to wildlife compared to Alternative A.

Allowing and seasonally stipulating vegetative treatments, invasive/nonnative pest species control, fuels management, and maintenance of existing facilities would protect wildlife and special status species during sensitive periods, while still allowing maintenance and treatments to occur.

Alternative C

Alternative C does not designate the Clarks Fork Canyon area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

Management of locatable minerals is similar to Alternative A (withdrawn on 1,766 acres), and the area is open to mineral leasing (with moderate constraints on 8,640 acres and major constraints on the 924 acres) and primarily open to mineral materials disposal (9,097 acres). Alternative C would be less restrictive to mineral development than Alternative A, and adverse impacts to the values of concern in the area may be greater under Alternative C.

Alternative C manages the Clarks Fork Canyon area as primarily open to ROW authorizations (10,890 acres), manages a smaller area for ROW avoidance (1,369 acres), and applies standard guidelines related to surface-disturbing activities. Alternative C manages motorized vehicle use as limited to designated roads and trails on 12,233 acres and under seasonal restrictions in 5,724 acres in the area. Alternative C is more restrictive to ROW and motorized travel management than Alternative A, but less restrictive than Alternative B. Under Alternative C, there would be more benefits to the values of concern from ROW and travel management than under Alternative A, but less than under Alternative B.

Alternative D

Allowing surface-disturbing activities in the Clarks Fork Canyon ACEC consistent with the goals of the ACEC could eliminate many of the beneficial impacts to special status species plants and wildlife, and the adverse impacts to surface-disturbing activities, predicted to result from the surface disturbance prohibition under Alternative B. However, because surface-disturbing activities would need to be consistent with the goals of the ACEC, this alternative may increase adverse impacts to resource uses and beneficial impacts to the values of concern compared to alternatives A and C, under which only standard restrictions on surface disturbance are applied.

Under Alternative D, restrictions on mineral development could result in greater adverse impacts to the use of these resources than under alternatives A or C, but less than under Alternative B. Management of and impacts from the management of locatable minerals would be the same as under alternatives A and C. As with Alternative B, the ACEC is closed to mineral leasing and mineral materials disposal; however, similar to Alternative C, under Alternative D the additional area proposed under Alternative B is primarily managed as open to mineral leasing with moderate constraints (9,094 acres) and is open to mineral materials disposal. The very low development potential for oil and gas and low-potential for sand and gravel would minimize the potential for adverse impacts to mineral development in the closed portions of the Clarks Fork Canyon area.

Adverse impacts to renewable energy and ROWs and beneficial impacts to the values of concern would be similar to those under Alternative B across the Clarks Fork Canyon area.

Under Alternative D, management of and impacts from motorized travel in the area designated as an ACEC and the larger area proposed under Alternative B would be the same as under Alternative C. Alternative D would manage 6,025 acres within the Bald Ridge area under a seasonal closure and the impacts would be similar to those under Alternative A.

Alternative D allows and seasonally stipulates vegetative treatments, invasive, nonnative pest species control, fuels management, and maintenance of existing facilities, resulting in the same impacts as Alternative B. However, these beneficial impacts would occur over a smaller area because these activities would be governed by other resource considerations in the additional area proposed under Alternative B.

Alternative E

Management of and impacts to values of concern in the Clarks Fork Canyon area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Clarks Fork Canyon area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for cave and karst resources under Alternative D is representative of the impacts anticipated under Alternative F.

Foster Gulch Paleontological Area

Alternatives B and E designate the Foster Gulch Paleontological Area as an ACEC (27,302 acres) (Maps 85 and 88); the other alternatives do not. The values of concern in the proposed Foster Gulch Paleontological Area ACEC are typically paleontological resources in the form of mammalian and paleobotanical fossils and geochemical data used in the study of a major Carbon Isotope Excursion recorded during an ancient period of global warming known as the PETM. Scenic and geologic features also are valuable in this ACEC. Threats to this proposed ACEC include surface disturbance from mineral (primarily oil and gas) and ROW development.

4.7.1.27 Summary of Impacts by Alternative

Alternatives B and E would be the most effective for protecting the paleontological and geological values of concern in the Foster Gulch Paleontological Area. These alternatives also place the greatest restrictions on mineral development, ROW authorizations, and other surface-disturbing activities; motorized travel; livestock grazing management; and the excavation of paleontological resources. Impacts under alternatives A and C would be similar and would allow mineral development, would open more routes to motorized travel, and would be less restrictive to the authorization of ROWs and surface disturbance in areas with paleontological resources. A portion of the Foster Gulch Paleontological Area is included in the PETM ACEC under alternatives D and F; the *Paleocene-Eocene Thermal Maximum* section describes management of and impacts to this area under alternatives D and F.

4.7.1.28 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area is open to locatable mineral entry, open to mineral leasing (with primarily moderate constraints on 10,854 acres and standard stipulations on the remaining 16,448 acres), and open to mineral materials disposal. Mineral development is one of the threats to the paleontological and geological values of the area, and allowing this type of development with minimal restrictions would result in surface disturbance that could cause adverse impacts to values of concern. Except for a small area of high-potential for sand and gravel, low occurrence of bentonite and gypsum and low to very low development potential for oil and gas may minimize adverse impacts to minerals development.

The Foster Gulch Paleontological Area is primarily open to ROW authorizations (24,541 acres), with the remainder managed as a ROW avoidance area (2,761 acres). Managing this area as primarily open to ROW authorizations could result in adverse impacts to the values of concern associated with surface disturbance and ROW development. Managing most of the area as open to ROW authorizations would result in beneficial impacts to ROWs, if ROWs are authorized in the area.

Alternative A limits motorized vehicle use to existing roads and trails in the area. Limiting motorized travel to existing roads and trails may benefit the values of concern in the ACEC by preventing open access that could degrade paleontological resources.

The Foster Gulch Paleontological Area is open to livestock grazing under Alternative A. Managing this area as open to livestock grazing could result in adverse impacts to paleontological resources that may be damaged by livestock trampling and wallowing in areas of concentrated livestock use. Proper management of livestock grazing can mitigate the impacts of grazing by improving the distribution of livestock.

Applicable laws and regulations and the management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative A. These decisions include protective management, such as surveying and monitoring surface-disturbing activities for all PFYC 4 and 5 formations that would provide some protection to the paleontological values.

Alternative B

Management for the ACEC under Alternative B is designed to reduce adverse impacts to paleontological and geological values of concern from surface disturbance. Management under this alternative requires avoiding or prohibiting surface-disturbing activities in the Foster Gulch Paleontological Area ACEC, and prohibiting the use, occupation, construction, or maintenance of facilities in the Foster Gulch Paleontological Area ACEC that are inconsistent with the management direction and objectives for the area. Allowing minor surface-disturbing activities in the Foster Gulch Paleontological Area ACEC if they are preceded by a paleontological sensitivity survey and, if necessary, are monitored during construction, would help protect paleontological resources in the area. Restricting surface-disturbing activities could increase delay or expense, but would continue to allow some activities while also protecting the integrity of fossil-bearing material in the area.

Under Alternative B, withdrawing the Foster Gulch Paleontological Area ACEC from appropriation under the mining laws, managing the area as **closed** to mineral leasing, and closing it to mineral materials disposal and geophysical exploration could result in greater adverse impacts to mineral development than under Alternative A. Restricting mineral development would result in greater beneficial impacts to the paleontological and geologic values in the area than Alternative A. The low potential for mineral resources in the area may minimize these impacts.

Alternative B is more restrictive than Alternative A in managing ROWs, motorized vehicle use, and livestock grazing; adverse impacts to these resource uses would be greater than under Alternative A. Alternative B manages the Foster Gulch Paleontological Area ACEC as a ROW and renewable energy avoidance area, limits motorized vehicle use to designated roads and trails, and allows livestock grazing under existing regulations, provided it does not disturb the natural, educational, and scientific research values of the Foster Gulch Paleontological Area ACEC. This management would reduce the potential for surface disturbance and would provide increased flexibility to further restrict activities (such as livestock grazing and resource-degrading travel routes) determined to be adverse to the values of concern. Any restrictions on grazing could reduce the currently available 1,206 AUMs in the ACEC and adversely impact livestock grazing.

Alternative B allows fossil collection, excavation, or removal in the Foster Gulch Paleontological Area ACEC only under a permit issued by the Wyoming BLM State Director and only by institutions and individuals engaged in BLM-approved research, or museum and educational projects that provide for detailed recordation, reporting, care of specimens, and availability of specimens to other scientists and

Areas of Critical Environmental Concern

museums. Such requirements may result in beneficial impacts by protecting the integrity of the resources and enable the advancement of scientific knowledge.

Alternative C

Alternative C does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The management of and impacts associated with mineral development under Alternative C would be the same as under Alternative A.

Similar to Alternative A, Alternative C manages the Foster Gulch Paleontological Area as primarily open to ROW authorizations (25,621 acres), and manages a smaller area as a ROW avoidance area (1,681 acres). ROW management could result in impacts to the values of concern similar to Alternative A.

Alternative C is more restrictive to motorized vehicle use than Alternative A (travel is limited to designated roads and trails on 17,591 acres and existing roads and trails on 9,711 acres), but less restrictive than Alternative B. Therefore, Alternative C would result in greater beneficial impacts to the values of concern more than Alternative A, but less than Alternative B.

Applicable laws and regulations and the management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative C. This management is less restrictive to surface disturbance that could adversely impact values of concern than under Alternative A, because it does not require on-the-ground surveys for PFYC 4 formations.

Alternative D

Alternative D does not designate this area an ACEC. Part of the Foster Gulch Paleontological area (4,974 acres) is within the proposed PETM ACEC. See the *Paleocene-Eocene Thermal Maximum* section for an analysis of the effects of management of this area.

Alternative E

Management of and impacts to values of concern in the Foster Gulch Paleontological Area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Foster Gulch Paleontological Area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Greater Sage-Grouse Key Habitat Areas and Greater Sage-Grouse Priority Habitat Management Areas

The greater sage-grouse is a USFWS federal candidate species for listing and protection under the ESA. The proposed Greater Sage-Grouse Key Habitat Areas and Greater Sage-Grouse PHMAs ACECs were developed in response to the greater sage-grouse habitat management policy guidance set forth in WY BLM IM No. WY-2012-019 (BLM 2012f), and in accordance with the BLM Washington Office IM No.

2012-44, *BLM National Greater Sage-Grouse Land Use Planning Strategy*. Proposal and consideration of these ACECs represent proactive conservation measures that reduce or eliminate threats to greater sage-grouse to minimize the likelihood of and need for listing of this species under the ESA.

Alternative E designates the greater sage-grouse Key Habitat Areas as an ACEC (1,232,583 acres) (Map 88); the other alternatives do not. Alternative F designates the Greater Sage-Grouse PHMAs as an ACEC (1,116,698 acres) (Map 89); the other alternatives do not. The values of concern for both proposed ACECs are sagebrush steppe vegetation communities that provide habitat for special status wildlife species, including areas designated as greater sage-grouse Key and PHMAs. The boundaries of the greater sage-grouse Key Habitat Areas under Alternative E (also analyzed in the Draft RMP and Draft EIS) are based on Version 2 of the State of Wyoming EO *Greater Sage-grouse Core Area of Protection* (WY EO 2008-2) (Wyoming Office of the Governor 2008), however, the boundaries were modified by the Wyoming BLM to remove large portions of private lands and developed oil fields. In addition, the boundaries of the Key Habitat Areas are generally consistent with greater sage-grouse PHMAs, with the inclusion of additional productive habitats identified by the BLM as important to greater sage-grouse in the Planning Area. The boundaries of the Greater Sage-Grouse PHMAs ACEC are based on Version 3 of WY EO *Greater Sage-grouse Core Area of Protection* (WY EO 2010-4) (Wyoming Office of the Governor 2010), which was delineated by the Wyoming Governor's Implementation Team and Local Working Groups through a collaborative mapping process and includes breeding, later brood-rearing, and winter concentration areas that have been identified as highly important to the health and viability of greater sage-grouse populations. The Wyoming Greater Sage-Grouse Core Area Protection strategy was subsequently updated and supplemented through the issuance of Executive Orders 2011-5 and 2013-3 (Wyoming Office of the Governor 2011 and 2013).

Portions of Key and PHMAs (referred to generally as priority habitat areas) are also designated as important bird areas by the Audubon Society, and many other BLM sensitive animal species are also dependent upon this ecosystem for grazing, pollination, winter range, and nesting areas (i.e., mountain plover, burrowing owl, white-tailed prairie dog, black-tailed prairie dog, long-billed curlew, and Baird's sparrow).

The proposed ACECs are located within portions of the WAFWA Sage-Grouse Management Zone I (Northern Great Plains) and Management Zone II (Wyoming Basin). Major threats to sage-grouse habitats and populations in Management Zone I include oil and gas developments and conversion of native rangeland to crops (Manier et al. 2013). Within Management Zone II, the primary threats include energy development and supporting infrastructure, prolonged drought, and bush eradication programs (Manier et al. 2013; USFWS 2013a). In southern portions of Management Zone II, loss of habitat from subdivision and housing development and associated infrastructure is the primary threat to sage-grouse populations (Manier et al. 2013). Additional threats to the proposed ACECs and greater-sage grouse populations in the Planning Area include livestock grazing, mining and associated activities, fire risk, invasive species, urban development, powerlines, vertical structures, and railroads. Management planning for the protection of greater sage-grouse within the Planning Area would be most effective where the impacts of energy and mineral development, primarily oil and gas, bentonite mining, and sand and gravel extraction, have been accounted for and large, intact sage-grouse priority habitats are delineated prior to the onset of widespread development (Taylor et al. 2012).

4.7.1.29 Summary of Impacts by Alternative

Alternative E would most effectively protect the values of concern for the greater sage-grouse ACECs. Alternative F would provide similar beneficial impacts for the values of concern, but to a lesser degree since it allows more resource use activity in greater sage-grouse priority habitat than Alternative E. Alternatives B and E would result in the greatest restrictions on mineral development, ROW authorizations, and other surface-disturbing activities; motorized travel; and livestock grazing management. Alternatives D and F both allow livestock grazing, mineral development, and ROWs in greater sage-grouse priority habitats, but also manage resources with avoidance objectives that would have beneficial impacts on ACEC values of concern. Impacts under alternatives A and C would be similar and would provide the most opportunities for mineral development and open the most routes to motorized travel; these alternatives apply the fewest restrictions to ROW authorization and surface disturbance, and would provide the least protection for greater sage-grouse priority habitats.

4.7.1.30 Detailed Analysis of Alternatives

Alternatives A-D

The greater sage-grouse Key Habitat Areas and PHMAs are not proposed as ACECs under alternatives A, B, C, or D. Table 4-34 details the management of those Key Habitat Areas and PHMAs under these alternatives absent ACEC designation.

Table 4-34. Summary of Management by Alternative in the Greater Sage-Grouse Key and Priority Habitat Management Areas ACECs

Sources: BLM 2009a; BLM 2013a

Alternative E

Under Alternative E, the BLM designates greater sage-grouse Key Habitat Areas as an ACEC. Management of the Greater Sage-Grouse Key Habitat Areas ACEC under Alternative E would reduce adverse impacts to the values of concern in the area by reducing the potential for surface-disturbing and disrupting activities to a greater extent than any other alternative. Specifically, anthropogenic disturbances (e.g., roads, oil and gas wells, pipelines, etc.) in Key Habitat Areas are managed to not exceed one disturbance per 640 acres and cover less than 3 percent of the total sage-grouse habitat. Under Alternative E, vegetative and silviculture treatments, invasive and nonnative pest species control, fuels management, and maintenance of existing facilities in the Greater Sage-Grouse Key Habitat Areas ACEC are subject to additional constraints and seasonal stipulations to protect greater sage-grouse during sensitive times of the year.

Withdrawing the majority of the Greater Sage-Grouse Key Habitat Areas ACEC from appropriation under the mining laws (1,227,152 acres), managing the entire area (1,232,583 acres) as closed to mineral leasing, and closing the entire area to mineral materials disposal and geophysical exploration could result in the greatest adverse impacts to minerals development when compared to the other alternatives. Designating greater sage-grouse Key Habitat Areas as an ACEC would require any new notice level activity related to locatable minerals exploration be submitted as a Plan of Operations and subject to analysis under National Environmental Policy Act (NEPA). Conversely, restricting minerals development could result in greater beneficial impacts to the ACEC values of concern than any other alternative.

Alternative E would limit potential adverse effects from resource uses to greater sage-grouse and other sensitive wildlife species and habitats during important mating and nesting time periods to the greatest extent of any alternative. Restrictions on ROWs, renewable energy, livestock grazing, and motorized vehicle use under Alternative E are greater than Alternative A and similar to Alternative B. The entire Greater Sage-Grouse Key Habitat Areas ACEC is managed as a ROW and renewable energy exclusion area, which would reduce the potential for adverse impacts to greater sage-grouse priority habitats more than any other alternative. Livestock grazing management and CTTM in the ACEC would be the same as Alternative B, which closes greater sage-grouse Key Habitat Areas to livestock grazing and limits motorized vehicle use to designated roads and trails with seasonal closures from March 15 to June 30. Closure of the ACEC to livestock grazing would eliminate potential adverse effects from concentrated livestock grazing on sagebrush steppe habitats, reducing the potential for overgrazing or trampling effects by domestic animals. Conversely, these restrictions on resource uses under Alternative E would result in greater adverse impacts to availability of public lands for resource uses than any other alternative. In particular, adverse impacts to locatable minerals development under Alternative E may be greater than any other alternative, due to the withdrawal of 96,981 acres with known or potential bentonite occurrence and 30,929 acres with known or potential gypsum occurrence from mineral entry within the ACEC.

Overall, the relative size and additional restrictions on surface-disturbing activities and resource uses in the proposed Greater Sage-Grouse Key Habitat Areas ACEC under Alternative E would provide the greatest protections to greater sage-grouse and other special status species habitat by reducing fragmentation, the potential for invasive species infestation, and the disturbance of sensitive status species or their habitat during sensitive times of the year.

Alternative F

Under Alternative F, the BLM designates greater sage-grouse PHMAs as an ACEC. In this ACEC, the BLM manages the density of disturbance (e.g., roads, oil and gas wells, pipelines, etc.) to not exceed one disturbance per 640 acres and cover less than 3 percent of existing sagebrush habitat. As a whole, management of surface-disturbing activities within this ACEC would provide greater protection for values of concern than alternatives A, C, and D, but fewer than alternatives B and E.

Adverse impacts to this proposed ACEC from mineral resource activities would be slightly greater than under Alternative A and similar to Alternative D, with the exception of additional constraints on oil and gas development. Under Alternative F, the Greater Sage-Grouse PHMAs ACEC is managed as open to locatable mineral entry (1,056,007 acres), open to mineral leasing (with major constraints on 685,181 acres, moderate constraints on 366,619 acres, and no area with standard constraints), and open to mineral materials disposal subject to density of disturbance limitations. Designating PHMAs as an ACEC would require any new Notice level activity related to locatable minerals exploration be submitted as a Plan of Operations and subject to analysis under NEPA. Mineral development is one of the primary threats to the values in this area, and allowing this type of development may result in adverse impacts from surface disturbance and disruption, as well as increased fragmentation and invasive species infestation. Conversely, this ACEC could adversely affect mineral development through additional restrictions on the number and size of potential leasable or salable minerals developments that make it more difficult to develop these resources. Unlike Alternative E (and to a lesser extent Alternative B), the Greater Sage-Grouse PHMAs ACEC would not preclude mineral development.

Alternative F management of ROW and renewable energy would reduce potential adverse impacts to the values of concern under Alternative A, though to a lesser extent than Alternative E. Similar to minerals development, surface disturbance from ROW and renewable energy development would result in adverse impacts from increased habitat fragmentation and other factors; in addition, these types of developments may provide perches for raptors and create permanent disruptions that also adversely affect greater sage-grouse and other sagebrush obligates. The development of wind energy would result in adverse impacts to the values of concern in this ACEC due to large wind turbines, construction activities, and required infrastructure (e.g., roads, transmission lines, and facilities). Conversely, restrictions and required mitigation for ROW development in the ACEC may result in adverse impacts to project proponents through increases in project costs and development timeframes.

Alternative F limits motorized vehicle use to designated roads and trails (1,113,611 acres) in the ACEC over a greater area than alternatives A, C, and D, which would reduce the potential for habitat fragmentation in greater sage-grouse and other sensitive species habitats in comparison to these alternatives.

McCullough Peaks South Paleontological Area

Alternatives B and E designate the McCullough Peaks South Paleontological Area as an ACEC (6,994 acres) (Maps 85 and 88); the other alternatives do not. The values of concern in the proposed McCullough Peaks South Paleontological Area ACEC are paleontological resources in the form of mammalian and paleobotanical fossils and geochemical data used in the study of a major Carbon Isotope Excursion recorded during an ancient period of global warming known as the PETM. Scenic and geologic features also are valuable in this ACEC. Threats to this proposed ACEC include surface disturbance from mineral (primarily oil and gas) and ROW development.

4.7.1.31 Summary of Impacts by Alternative

Alternatives B and E would be the most effective for protecting the paleontological and geological values of concern in the McCullough Peaks South Paleontological Area. Alternatives B and E also place the greatest restrictions on mineral development, ROW authorizations and other surface-disturbing activities; motorized travel; livestock grazing; and the excavation of paleontological resources. Alternatives A and C allow mineral development, open more routes to motorized travel, and are less restrictive to the authorization of ROWs and surface disturbance in the area. Alternative A is the least restrictive for oil and gas development and ROW authorizations, and may therefore result in the greatest potential for adverse impacts to the values of concern from surface disturbance due to these threats. A portion of the McCullough Peaks South Paleontological Area is included in the PETM ACEC under alternatives D and F; the *Paleocene-Eocene Thermal Maximum* section describes management of and impacts to this area.

4.7.1.32 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The McCullough Peaks South Paleontological area is open to locatable mineral entry on 6,994 acres, open to mineral leasing (with primarily moderate constraints on 4,626 acres and major constraints on the remaining 8 acres), and primarily open to mineral materials disposal (6,567 acres). Mineral development is one of the threats to the paleontological and geological values of the area, and allowing this type of development with minimal restrictions could result in surface disturbance that would cause adverse impacts to the values of concern. Except for a small area of high-potential for sand and gravel, the low potential for bentonite and gypsum occurrence and very low development potential for oil and gas may minimize these adverse impacts.

The McCullough Peaks South Paleontological Area is primarily managed as open to ROW authorizations (5,709 acres), with the remainder managed as a ROW avoidance area (1,250 acres). Allowing ROW authorizations in the area would result in beneficial impacts to these authorizations. Managing this area as primarily open to ROW authorizations could result in adverse impacts to the values of concern by increasing the potential for surface disturbance and associated with ROW development.

Motorized vehicle use is limited to designated roads and trails in the area; thereby limiting access and use of certain roads in the area and limiting disturbance or degradation to the values of concern.

The McCullough Peaks South Paleontological Area is open to livestock grazing under Alternative A, which may result in adverse impacts to the paleontological values of concern in the area. However, impacts from concentrated livestock use, which can damage exposed paleontological resources, can be mitigated through proper livestock management that improves livestock distribution.

Applicable laws and regulations and the management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative A. These decisions include protective management, such as surveying and monitoring surface-disturbing activities for all PFYC 4 and 5 formations that would provide some protection to the paleontological values.

Alternative B

Management for the McCullough Peaks South Paleontological Area ACEC under Alternative B reduces adverse impacts from surface disturbance and development to the paleontological and geological values of concern in the area. Alternative B requires avoiding or prohibiting surface-disturbing activities in the McCullough Peaks South Paleontological Area ACEC, and prohibiting the use, occupation, construction, or maintenance of facilities that are inconsistent with the management direction and objectives for the area. Allowing minor surface-disturbing activities in the ACEC if they are preceded by a paleontological sensitivity survey and, if necessary, monitored during construction, would help to protect paleontological resources in the area. Restricting surface-disturbing activities may increase project costs and timeframes, but would continue to allow some activities while also protecting the integrity of fossil-bearing material in the area.

Withdrawing the McCullough Peaks South Paleontological Area ACEC from appropriation under the mining laws, managing the area as **closed** to mineral leasing, and closing it to mineral materials disposal and geophysical exploration could result in greater adverse impacts to mineral development than Alternative A. Restricting mineral development may result in greater beneficial impacts to the paleontological and geologic values in the area than Alternative A. As described for Alternative A, the low potential for mineral resources in the area may minimize these impacts.

Alternative B is more restrictive than Alternative A regarding ROW management, motorized vehicle use, and livestock grazing; therefore, adverse impacts to these resource uses are **likely to** be greater than under Alternative A. Alternative B manages the McCullough Peaks South Paleontological Area ACEC as a renewable energy and ROW avoidance area, limits motorized vehicle use to designated roads and trails, and allows livestock grazing under existing regulations provided it does not disturb the natural, educational, and scientific research values of the ACEC. This management would reduce the potential for surface disturbance and would provide increased flexibility to further restrict activities (such as livestock grazing and resource-degrading travel routes) determined to be adverse to the values of concern. Conversely, any restrictions on grazing could reduce the currently available 722 AUMs in the ACEC and adversely affect livestock grazing. Requiring paleontological sensitivity surveys prior to approval of minor ROW authorizations may have long-term impacts by increasing processing times of authorizations and potentially requiring mitigation, relocation, or modification of facilities if paleontological resources are found.

Alternative B allows fossil collection, excavation, or removal in the McCullough Peaks South Paleontological Area ACEC only under a permit issued by the Wyoming BLM State Director and only by institutions and individuals engaged in BLM-approved research and museum or educational projects that provide for detailed recordation, reporting, care of specimens, and availability of specimens to other scientists and museums. Such requirements could, however, result in beneficial impacts by protecting the integrity of the resources and enabling the advancement of scientific knowledge in the area.

Alternative C

Alternative C does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

Management of and impacts associated with mineral development under Alternative C would be similar to those under Alternative A. The area is open to mineral leasing (with primarily moderate constraints on **3,951** acres, standard restrictions on 2,161 acres, and major constraints on the remainder), and open to mineral materials disposal on 6,772 acres.

ROW management in the McCullough Peaks South Paleontological Area under Alternative C is more restrictive than under Alternative A, but less than under Alternative B. The area is primarily an avoidance area for ROW authorizations (3,776 acres) and open for ROW authorizations (3,218 acres) on the remainder. Management of ROWs under Alternative C would result in greater beneficial impacts to the values of concern in the ACEC than Alternative A, but less than Alternative B.

Management of and impacts associated with motorized vehicle use under Alternative C would be the same as under Alternative A.

Applicable laws and regulations and management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative C. This management would be less restrictive to surface disturbance than Alternative A, because it does not require on-the-ground surveys for PFYC 4 formations.

Alternative D

Alternative D does not designate this area an ACEC. Part of the McCullough Peaks South Paleontological Area (4,958 acres) is within the proposed PETM ACEC. See the *Paleocene-Eocene Thermal Maximum* section for an analysis of the effects of management of this area.

Alternative E

Management of and impacts to values of concern in the McCullough Peaks South Paleontological Area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the McCullough Peaks South Paleontological Area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Rainbow Canyon

Alternatives B and E designate the Rainbow Canyon area as an ACEC (1,443 acres) (Maps 85 and 88); the other alternatives do not. The values of concern in the proposed Rainbow Canyon ACEC are paleontological resources in the form of dinosaurian and paleobotanical fossils, and weathered and eroded geologic and scenic features. Threats to this proposed ACEC include surface disturbance from mineral and ROW development.

4.7.1.33 Summary of Impacts by Alternative

Alternatives B and E would be the most effective for protecting visual resources, and the paleontological and geologic values of concern in the Rainbow Canyon area. These alternatives also would result in the greatest restrictions on mineral development, ROW authorizations, and other surface-disturbing activities; livestock grazing; and the excavation of paleontological resources. Alternatives A and C allow mineral development and are less restrictive to the authorization of ROWs and surface disturbance in areas with paleontological and visual resources than Alternative B. Alternative C would be the least restrictive for oil and gas development and ROW authorizations, and may therefore result in the

Areas of Critical Environmental Concern

greatest potential for adverse impacts to the values of concern from surface disturbance due to these threats. Alternatives D and F manage mineral development similar to alternatives A and C and ROW authorizations similar to alternatives B and E.

4.7.1.34 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area is open to locatable mineral entry, open to mineral leasing (with moderate constraints), and open to mineral materials disposal. Mineral development is one of the threats to the area and allowing this type of development, with minimal restrictions, could result in surface disturbance that would cause adverse impacts to the values of concern. The 1,238 acres with potential bentonite occurrence would be the most likely location of minerals development; the development potential for oil and gas and sand and gravel are very low, and there are no areas of known or potential gypsum occurrence. The very low potential for most minerals may minimize the potential for adverse impacts to the values of concern.

The Rainbow Canyon area is primarily open to ROW authorizations (1,222 acres), with the remainder managed as a ROW avoidance area (221 acres). Managing most of this area as open to ROW authorizations could result in adverse impacts to the values of concern by increasing the potential for surface disturbance and ROW development.

Motorized vehicle use is limited to designated roads and trails, which may result in fewer roads available to motorized travel in the area, compared to areas limited to existing roads and trails.

The Rainbow Canyon area is open to livestock grazing under Alternative A. Livestock trampling and wallowing in areas of concentrated livestock use can damage exposed paleontological resources. While, in most instances, concentrated livestock use would result in adverse impacts to paleontological values, proper management of livestock grazing can mitigate these impacts by improving livestock distribution.

Applicable laws and regulations and management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative A. These decisions include protective management, such as surveying and monitoring surface-disturbing activities for PFYC 4 and 5 formations that may protect paleontological values of concern. The area under Alternative A is managed under VRM Class III objectives, which would allow for a more moderate change in the scenic quality rating units that encompass Rainbow Canyon than VRM Class II objectives. VRM Class III would allow for more contrasting elements to be present from surface-disturbing activities that are generated from ROW actions and mineral developments.

Alternative B

Management for the Rainbow Canyon ACEC under Alternative B reduces adverse impacts to the paleontological and geological values of concern from surface disturbance and development. Management under this alternative requires avoiding or prohibiting surface-disturbing activities in the Rainbow Canyon ACEC, and prohibiting the use, occupation, construction, or maintenance of facilities in the Rainbow Canyon ACEC that are inconsistent with the management direction and objectives for the area. Allowing minor surface-disturbing activities in the Rainbow Canyon ACEC if they are preceded by a paleontological sensitivity survey and, if necessary, monitored during construction, would help protect

paleontological resources. Restricting surface-disturbing activities could increase project costs and timeframes, but would continue to allow some activities while also protecting the integrity of fossil-bearing material in the area.

Withdrawing the Rainbow Canyon ACEC from appropriation under the mining laws, managing the area as closed to mineral leasing, and closing the area to mineral materials disposal and geophysical exploration may result in greater adverse impacts to mineral development than Alternative A. Restricting mineral development could result in greater beneficial impacts to the paleontological and geologic values in the area than Alternative A. As noted for Alternative A, impacts from the withdrawal are likely to be greatest on the 1,238 acres with known or potential gypsum occurrence; the low potential for other mineral resources in the area may minimize impacts from other types of mineral exploration and development.

Management under Alternative B is more restrictive than under Alternative A for ROWs and livestock grazing. Therefore, adverse impacts to these resource uses would be greater than under Alternative A. Alternative B manages the Rainbow Canyon ACEC as a renewable energy and ROW avoidance area and allows livestock grazing under existing regulations, provided it does not disturb the natural, educational, and scientific research values of the Rainbow Canyon ACEC. This management would reduce the potential for surface disturbance and would provide increased flexibility to further restrict activities (such as livestock grazing) determined to be adverse to the values of concern. Any restrictions on grazing could reduce the currently available 23 AUMs in the area and adversely impact livestock grazing.

Management of and impacts associated with motorized vehicle use under Alternative B are the same as under Alternative A.

Alternative B allows fossil collection, excavation, or removal in the Rainbow Canyon ACEC only under a permit issued by the Wyoming BLM State Director and only by institutions and individuals engaged in BLM-approved research, museum, or educational projects that provide for detailed recordation, reporting, care of specimens, and availability of specimens to other scientists and museums. Such requirements would, however, result in beneficial impacts by protecting the integrity of the resources and enable the advancement of scientific knowledge.

The area would be managed under VRM Class II objectives, which require contrasting elements created by surface-disturbing activities to be subordinate to the surrounding natural elements. VRM Class II objectives would assist in maintaining the values of concern more than alternatives A, C, D, and F.

Alternative C

Alternative C does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

Management of and impacts associated with locatable and salable mineral development under Alternative C would be similar to those under Alternative A. However, the management of leasable minerals would be the least restrictive of any alternative because the area is managed as open to mineral leasing with primarily standard constraints (1,433 acres).

ROW management in the Rainbow Canyon area under Alternative C is less restrictive than alternatives A and B. The Rainbow Canyon area is managed as open to ROW authorizations (1,443 acres). Fewer restrictions on ROWs could result in more adverse impacts to the values of concern compared to the other alternatives.

Areas of Critical Environmental Concern

Management of and impacts associated with motorized vehicle use under Alternative C would be the same as under Alternative A.

Applicable laws and regulations and management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative C. This management is less restrictive to surface disturbance that could adversely impact values of concern than under Alternative A, because it does not require on-the-ground surveys for PFYC 4 formations on a case-by-case basis.

Alternative C would manage the area under VRM Class III and IV objectives, which do not require minimizing the contrasting elements created by surface-disturbing activities as a priority. Alternative C would allow for observable visual intrusions within the scenic quality rating units, to the degree which may alter the current visual resource rating to a lower quality rating.

Alternative D

Alternative D does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

Management of and impacts associated with mineral development under Alternative D would be the same as under Alternative A.

Under Alternative D, the Rainbow Canyon area is managed as a ROW avoidance area and impacts would be the same as those under Alternative B.

Management of and impacts associated with motorized vehicle use under Alternative D would be the same as under Alternative A.

Applicable laws and regulations and management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative D. These decisions include protective management, such as surveying and monitoring surface-disturbing activities for PFYC 4 and 5 formations and attaching standard Paleontological Resources Protection Stipulations for PFYC 1-5 formations that would provide some protection to the paleontological values, but less than under Alternative B.

Alternative D visual resource management of impacts associated with surface-disturbing activities would be the same as under Alternative C.

Alternative E

Management of and impacts to values of concern in the Rainbow Canyon area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Rainbow Canyon area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Paleocene-Eocene Thermal Maximum (PETM)

Alternatives D and F would designate the PETM, in the Clarks Fork Basin/Polecat Bench, Foster Gulch, and McCullough Peaks South areas, as an ACEC (14,906 acres) (Maps 87 and 89); alternatives A and C

would not. Under alternatives B and E, the area of the PETM ACEC is entirely within the proposed Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs (58,191 acres total) (Maps 85 and 88). The values of concern in the PETM ACEC are the same as those in the Clarks Fork Basin/Polecat Bench, Foster Gulch, and McCullough Peaks South ACECs (i.e., fossil resources and geochemical data from an ancient period of global warming). The PETM ACEC includes a portion of the deposits of these resources protected under the Alternative B ACECs (referred to here as the greater-PETM area). Threats to the area of the PETM ACEC include surface disturbance from mineral (oil and gas, mineral materials, and possible locatable mineral mining), recreational and OHV use, invasive and nonnative species infestations, and ROW development.

Management of and impacts from ACECs in the greater-PETM area under alternatives B and E, and management in this area without ACEC designations under alternatives A and C, are addressed in the *Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACEC* sections.

4.7.1.35 Summary of Impacts by Alternative

Only alternatives D and F designate the PETM ACEC. However, alternatives B and E manage ACECs that completely overlap this area, making them the most effective alternatives for protecting the paleontological and geological values of concern. In both the PETM ACEC area and the greater-PETM area covered by the Clarks Fork Basin/ Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs, alternatives B and E would be the most restrictive of oil and gas development, withdrawals, renewable energy development, ROW authorizations and other surface-disturbing activities, and motorized vehicle use. Under alternatives A and C, none of the area in the PETM ACEC or the greater-PETM area is designated as an ACEC for the protection of paleontological values of concern. Management under these alternatives generally would be the least restrictive of mineral use and would provide the least protection from surface disturbance for the paleontological resources in the area. Alternative A would be the least restrictive of ROW and motorized vehicle use, followed by alternatives C, D, and F.

4.7.1.36 Detailed Analysis of Alternatives

Alternatives A and C

Alternatives A and C do not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives. The proposed PETM ACEC is entirely within the Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs proposed under Alternative B. See the *Detailed Analysis of Alternatives* discussions for those ACECs for management of and impacts to this area under alternatives A and C.

Alternative B

Alternative B does not designate a PETM ACEC, but does manage a larger area as the Clarks Fork Basin/ Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs to protect the same values of concern. See the *Detailed Analysis of Alternatives* for the Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs for management of and impacts to this area under Alternative B.

Alternative D

Under Alternative D, the BLM designates a portion of the area managed as the Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs under Alternative B as the PETM ACEC to protect paleontological resources and geochemical data.

Allowing surface-disturbing activities and the use, occupation, construction, or maintenance of facilities that are consistent with the goals of the ACEC, would result in fewer adverse impacts, similar to those described for alternatives A and C in the Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs. In the greater-PETM area boundary proposed under Alternative B, impacts to paleontological resources would be the same as under alternatives A and C, because only standard restrictions on surface disturbance would apply. Alternative D restrictions throughout this area would be less effective for protecting paleontological resources than Alternative B, but also would cause fewer adverse impacts to project costs and timeframes associated with surface-disturbing activities, such as range improvements.

Under Alternative D, management of mineral development in the PETM ACEC and the greater-PETM area is less restrictive than under Alternative B and similar or slightly more restrictive than management under alternatives A and C. As with alternatives A and C, Alternative D manages most of the area as open for mineral leasing with moderate constraints; however, this alternative also applies a more restrictive NSO stipulation on the PETM ACEC itself and contains less area open with standard constraints on the greater-PETM area. Alternative D manages the PETM ACEC and the greater-PETM area as available for locatable mineral entry. However, unlike similar management under alternatives A and C, the area in the PETM ACEC would require a plan of operations for most locatable mineral exploration and development. The PETM ACEC is closed to mineral materials disposal, as is this area under Alternative B, and the greater-PETM area is managed as open to mineral materials disposal, similar to alternatives A and C. Although these restrictions would result in adverse impacts to mineral uses, these impacts may be minimized in the ACEC and the greater-PETM area because these areas consist of 9,933 acres of very low and 4,973 acres of low development potential for oil and gas, the low occurrence potential for bentonite, gypsum, and low development potential for sand and gravel across most of the area. Restricting mineral development could result in beneficial impacts to the values of concern for the ACEC by reducing the potential for destruction or degradation of paleontological values and the other adverse impacts often associated with surface disturbance (e.g., the potential spread of invasive species).

Similar to Alternative C, under Alternative D approximately half of the PETM ACEC and the greater-PETM area are open to ROW authorizations and half is managed as ROW avoidance areas. This management is more restrictive than Alternative A, but less restrictive than Alternative B. Alternative D would implement more restrictions on motorized travel within the PETM ACEC and the greater-PETM area than Alternative A, but fewer restrictions than alternatives B and C. Management of ROWs and motorized vehicle use under Alternative D would reduce the potential for impacts to these activities compared to Alternative B, but also would result in increased surface disturbance and other adverse impacts to the values of concern compared to that alternative. However, allowing ROW authorizations in the PETM only where consistent with the protection of paleontological resources would reduce these adverse impacts by allowing the further restriction of these activities where they would not be compatible with protecting the paleontological values of concern.

Management of and impacts from the collection, excavation, or removal of fossils in the PETM ACEC would be similar to in the Clarks Fork Basin/Polecat Bench West Paleontological Area, Foster Gulch, and McCullough Peaks South ACECs. In the greater-PETM area, the applicable laws, regulations, and

management described in Section 4.5.2 *Paleontological Resources* control the collection of fossils under Alternative D. These decisions include protective management, such as surveying and monitoring surface-disturbing activities for PFYC 4 and 5 formations and attaching standard Paleontological Resources Protection Stipulations for PFYC 1-5 formations, that would provide some protection to the paleontological values, but less than under Alternative B.

Alternative E

Management of and impacts to values of concern in the PETM under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the PETM under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Rattlesnake Mountain

Alternatives B and E designate the Rattlesnake Mountain area as an ACEC (19,137 acres) (Maps 85 and 88); the other alternatives do not. The values of concern to be managed for in the proposed Rattlesnake Mountain ACEC are special status species wildlife, varied vegetation communities and sensitive plants, and wildlife winter and transition habitat. Threats to this proposed ACEC include surface disturbance from mineral (including gravel pits) and ROW development, renewable energy developments (wind energy), timber extraction, heavy recreational and OHV use, and invasive, nonnative species infestations. These activities threaten rare plants and habitat for special status species, and have the potential to create disturbances for wintering wildlife.

4.7.1.37 Summary of Impacts by Alternative

Alternatives B and E would be the most effective for protecting the special status species, vegetation, and wildlife winter and transition habitat values of concern in the Rattlesnake Mountain area. This alternative would result in the least habitat fragmentation due to surface disturbance and the smallest potential for invasive species infestation. Alternative B also would result in the greatest restrictions on mineral development, ROW authorizations, renewable energy development, and surface-disturbing activities. Alternatives A, C, D, and F would allow mineral development and would be less restrictive to travel and surface disturbance. Alternatives D and F would be more restrictive of ROWs than alternatives A and C. Alternative C would be the least restrictive for oil and gas development and ROW authorizations (including renewable energy development), and may therefore result in the greatest potential for adverse impacts to the values of concern. Alternatives A, D, and F would result in the greatest potential for adverse impacts to wildlife due to travel-related disturbance during sensitive times of the year.

4.7.1.38 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area would be open to locatable mineral entry, open to mineral leasing (with primarily major constraints on 696 acres and moderate constraints on 10,181 acres), and open to mineral materials disposal. Mineral development would be most likely on the small areas with known or potential gypsum occurrence (184 acres) and sand and gravel (910 acres); there is low bentonite occurrence and the development potential for oil and gas is very low. Surface disturbance from mineral development is one of the threats and allowing this type of development, with minimal restrictions, would result in surface disturbance and increased potential for invasive species infestations. This type of development also would result in adverse impacts to special status species and wildlife winter and transition habitat due to increased fragmentation and increased potential for disturbance of wildlife during sensitive times of the year when these habitats are in use.

The Rattlesnake Mountain area is managed as open to ROW authorizations (9,188 acres) and as a ROW avoidance area (9,949 acres). Areas open to ROW authorizations would be more likely to experience surface disturbance, an identified threat to the values of concern, and adverse impacts similar to those from mineral development. Areas with fewer restrictions would benefit ROW authorizations by increasing the potential for development in these areas. Interest in ROW authorizations in the form of wind-energy development are of concern in this area. Development of wind energy would result in adverse impacts to the values of concern due to large wind turbines, construction activities, and required infrastructure (e.g., roads, transmission lines, facilities).

Alternative A limits motorized vehicle use primarily to designated roads and trails (18,662 acres), with a much smaller area limited to existing roads and trails (457 acres). Managing the area as primarily limited to designated roads and trails would reduce fragmentation of habitat and reduce stress on wildlife during sensitive times of the year.

Standard guidelines related to surface disturbance would apply in the area. Although these standard guidelines may reduce the severity of impacts to the values of concern from surface disturbance, adverse impacts still would be likely if surface-disturbing activities are authorized.

Alternative B

Management for the Rattlesnake Mountain ACEC under Alternative B reduces adverse impacts to the values of concern in the area by prohibiting surface-disturbing activities. Surface disturbance prohibitions would result in beneficial impacts to special status species and wildlife winter and transition habitat because it would reduce fragmentation, the potential for invasive species infestation, and the disturbance of wildlife during sensitive times of the year when these habitats are in use. This management is more restrictive to surface-disturbing activities in the Rattlesnake Mountain area compared to the other alternatives.

Withdrawing the Rattlesnake Mountain ACEC from appropriation under the mining laws, managing the area as closed to mineral leasing, and closing the area to mineral materials disposal and geophysical exploration would result in more adverse impacts to mineral development than Alternative A. Conversely, restricting mineral development would result in greater beneficial impacts to the values of

concern than Alternative A. However, the low potential for most mineral resources in the area may minimize these impacts.

Alternative B is more restrictive than Alternative A regarding ROWs and motorized vehicle use. The Rattlesnake Mountain ACEC is a ROW exclusion area, a renewable energy exclusion area, and seasonally closed to motorized and mechanized vehicle use on part and limited to designated roads and trails on the remainder. Under Alternative B, more restrictive ROW and travel management would result in greater adverse impacts to ROW and wind-energy development in this area, and would adversely affect the ability of the public to access the area compared to Alternative A by limiting the times of year and routes available for travel. Conversely, limiting travel seasonally would allow additional protection for wildlife during sensitive times of the year, and beneficial impacts to these values of concern would be greater under Alternative B than Alternative A.

Allowing and seasonally stipulating vegetative/silviculture treatments, invasive/nonnative pest species control, fuels management, and maintenance of existing facilities in the Rattlesnake Mountain ACEC would protect wildlife and special status species during sensitive times of the year, while still allowing maintenance and treatments to occur.

Alternative C

Alternative C does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives. Standard guidelines related to surface disturbance would apply, with impacts similar to those under Alternative A.

Management of and impacts associated with mineral development under Alternative C would be similar to Alternative A. The area is open to mineral leasing (with primarily moderate constraints on 159 acres).

The Rattlesnake Mountain area is managed as open to ROW authorizations (18,843 acres), with a smaller portion managed as a ROW avoidance area (294 acres). The area open to ROW authorizations would be greater than under Alternative A, and the extent of adverse impacts to the values of concern described under Alternative A would be greater than under Alternative C. This alternative would be the most beneficial to ROW and wind developments of any alternative by managing the area with the least restrictions on ROW and renewable energy development.

Motorized vehicle use is managed primarily as limited with seasonal stipulations (13,709 acres), with a smaller area limited to designated roads and trails (19,118 acres). Impacts to and from travel would be similar to those described under Alternative B.

Alternative D

Alternative D does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives. Standard guidelines related to surface disturbance would still apply, with similar impacts as Alternative A.

Management of and impacts associated with mineral development under Alternative D would be similar to Alternative C. The area is available for locatable mineral entry, open to mineral leasing (with moderate constraints), and open to mineral materials disposal.

The Rattlesnake Mountain area is managed as a ROW avoidance area. Management of ROW authorizations would be less restrictive (and more beneficial to the values of concern) than under Alternative B, and more restrictive (and less beneficial to the values of concern) than under alternatives A and C.

Areas of Critical Environmental Concern

Alternative D limits motorized vehicle use to designated roads and trails, and impacts would be the same as under Alternative A.

Alternative E

Management of and impacts to values of concern in the Rattlesnake Mountain area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Rattlesnake Mountain area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis under Alternative D is representative of the impacts anticipated under Alternative F.

Sheep Mountain

Alternatives B and E (25,151 acres) (Maps 85 and 88) and alternatives D and F (14,200 acres) (Maps 87 and 89) would designate the Sheep Mountain area as an ACEC; alternatives A and C would not. The values of concern in the proposed Sheep Mountain ACEC are varied vegetation communities, sensitive plants, and big game wildlife habitat.

4.7.1.39 Summary of Impacts by Alternative

Alternatives B, D, E, and F are the only alternatives that designate the Sheep Mountain area as an ACEC. Due to the larger size and more restrictive management, alternatives B and E would be the most effective for protecting the vegetation communities, sensitive plants, and big game wildlife habitat in the Sheep Mountain area due to resource use restrictions and travel designations. Management under alternatives B and E includes the greatest restrictions on ROWs, minerals development, and other surface-disturbing activities in the area, resulting in the greatest adverse impacts to these resource uses compared to the other alternatives. Alternatives B and E would be the most restrictive of travel in the area, and would therefore provide the greatest protection of the values of concern from fragmentation and disruption related to motorized vehicle use.

4.7.1.40 Detailed Analysis of Alternatives

Alternative A

Alternative A does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area would be open to locatable mineral entry, open to mineral leasing (with primarily major constraints on 7,934 acres and moderate constraints on the remaining 14,116 acres), and open to mineral materials disposal on 24,574 acres and closed on 579 acres. Allowing mineral development in areas open to minerals would result in beneficial impacts to these resource uses. Mineral development would result in surface disturbance and habitat fragmentation that would result in adverse impacts to vegetation and big game wildlife habitat values in the area.

The Sheep Mountain area is managed as open to ROW authorizations (19,475 acres) or as a ROW avoidance area (5,607 acres). Standard guidelines related to surface disturbance would apply. Alternative A limits motorized vehicle use primarily to designated roads and trails (23,316 acres), and limits motorized vehicle use in a smaller area to existing roads and trails (1,827 acres).

Standard guidelines related to surface disturbance would apply and may reduce the severity of impacts to the values of concern from surface disturbance. There would still be adverse impacts if surface-disturbing activities are authorized.

Alternative B

Under Alternative B, prohibiting surface-disturbing activities in the Sheep Mountain ACEC would restrict such activities as geophysical exploration and road construction, but would benefit vegetation communities, sensitive plants, and big game habitat by limiting the potential for fragmentation or invasive species infestations that would degrade vegetation and habitat.

Under Alternative B, restrictions on mineral development would result in adverse impacts to the use of these resources or beneficial impacts to the values of concern by reducing surface-disturbing activities and disruptions. The ACEC is withdrawn from appropriation under the mining laws and closed to mineral materials disposal. Adverse impacts to mineral resources would be greatest in areas with known or potential bentonite occurrence (1,178 acres) or sand and gravel (2,294 acres). The ACEC is closed to mineral leasing, but the development potential for oil and gas is very low to low and adverse impacts would be minimal.

Under Alternative B, the Sheep Mountain ACEC is a ROW and renewable energy avoidance area. Compared to Alternative A, this management is more restrictive to future ROW authorizations and ROW-related surface disturbance and disruption that would adversely affect the wildlife and vegetation values of concern. Therefore, management of ROWs and renewable energy would result in greater beneficial impacts to the values of concern in the ACEC compared to Alternative A.

A portion (13,242 acres) of the Sheep Mountain ACEC is seasonally restricted and the remainder (25,143 acres) is limited to designated roads and trails for motorized and mechanized vehicle use. Limiting or closing the ACEC to motorized vehicle use would result in adverse impacts to travel and access and beneficial impacts on the values of concern. Closing this area would eliminate disruption from motorized vehicles to wildlife and may reduce disturbance of vegetation and sensitive plants. Management under this alternative would be more restrictive to motorized vehicle travel, but would result in the greater beneficial impacts to the values of concern in the area compared to Alternative A.

Seasonally stipulating, where feasible, vegetative/silviculture treatments, invasive/nonnative pest species control, fuels management, and maintenance of existing facilities in the Sheep Mountain ACEC would protect wildlife during sensitive times of the year, while still allowing maintenance and treatments to occur.

Alternative C

Alternative C does not designate the area as an ACEC; the BLM manages the area in accordance with multiple use principles consistent with other resource objectives.

The area would be open to locatable mineral entry except on 165 acres, open to mineral leasing (with primarily moderate constraints on 5,026 acres, major constraints on 387 acres, and standard stipulations on 19,737 acres), and entirely open to mineral materials disposal. Management of minerals would allow

Areas of Critical Environmental Concern

for the greatest level of mineral development in the area and would result in the greatest adverse impacts to the values of concern compared to the other alternatives.

ROW management in the Sheep Mountain area is open to ROW authorizations (19,865 acres), with a smaller portion managed as avoidance for ROW (5,288 acres). Standard guidelines related to surface disturbance would apply; however, the additional restrictions under Alternative B would not. Alternative C is less restrictive to ROW authorizations than Alternative A. Management of ROWs under Alternative C would result in the greatest adverse impacts to the values of concern in the area compared to the other alternatives.

Alternative C limits motorized vehicle use primarily to designated roads and trails (24,868 acres), and limits a smaller area to existing roads and trails (275 acres). Impacts to motorized travel are generally expected to be similar to Alternative A.

Standard guidelines related to surface disturbance would apply and could result in additional surface disturbance in the area compared to alternatives A and B, leading to potential increased degradation of the values of concern in the area.

Alternative D

Surface-disturbing activities are allowed in the Sheep Mountain ACEC and the larger area managed as an ACEC under Alternative B, reducing the potential for adverse impacts to activities such as ROWs and range improvement projects compared to Alternative B. Allowing these activities would result in adverse impacts to the values of concern similar to Alternative A, although these impacts would be reduced in the ACEC under Alternative D. Surface-disturbing activities in the ACEC are limited to slopes of 15 percent or less, except where needed to improve watershed function, wildlife habitat, or land health.

Alternative D does not pursue a withdrawal for the Sheep Mountain ACEC, except on a case-by-case basis to meet other resource objectives. Management of and impacts from locatable mineral entry under this alternative would be similar to Alternative A, and the adverse impacts to mineral uses and beneficial impacts to habitat identified under Alternative B would not occur except in areas withdrawn.

As under Alternative B, the Sheep Mountain ACEC is closed to mineral materials disposal and closed to mineral leasing; however, the larger area designated as an ACEC under Alternative B is available for locatable mineral entry, open to mineral materials disposal, and only managed as closed to oil and gas leasing on a portion (20,280 acres) under this alternative. Impacts in the Alternative D ACEC would be the same as under Alternative B; impacts in the larger area managed as an ACEC under Alternative B would be less adverse to the use of mineral resources. The less restrictive management of mineral uses under this alternative would reduce the beneficial impacts to the values of concern compared to Alternative B. As noted for Alternative B, the very low to low development potential for oil and gas would minimize both adverse impacts to leasing and the benefit of leasing restrictions on the values of concern under Alternative D. However, adverse impacts to mineral materials disposal would still exist in areas of high-potential for sand and gravel. Under Alternative D, management of and impacts from ROWs and renewable energy in the Sheep Mountain ACEC and the larger area designated as an ACEC under Alternative B would be the same as under Alternative B.

Under Alternative D, motorized vehicle use in the Sheep Mountain ACEC and most of the larger area managed under Alternative B is limited to designated roads and trails (25,143 acres). Impacts to motorized travel would be similar to Alternative A.

Similar to Alternative B, under Alternative D, the BLM can stipulate, where feasible, treatment and maintenance activities in the Sheep Mountain ACEC to protect wildlife, while still allowing maintenance and treatments to occur. In the larger area proposed as an ACEC under Alternative B, the standard guidelines related to surface disturbance and the management of other resource objectives would apply to these activities; therefore, under Alternative D, impacts in this area would be similar to Alternative A.

Alternative E

Management of and impacts to values of concern in the Sheep Mountain area under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Management of and impacts to values of concern in the Sheep Mountain area under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for cave and karst resources under Alternative D is representative of the impacts anticipated under Alternative F.

4.7.2 National Back Country Byways

This section describes the impacts of each alternative to National Back Country Byways, which are an important recreational resource on BLM-administered lands. These travel routes are frequently used and are susceptible to impacts over the long term. Adverse impacts to National Back Country Byways result from management actions that substantially limit or prevent public use. Beneficial impacts result from actions that enhance the use of National Back Country Byways. Direct impacts include any action that substantially alters the use of the byways. Indirect impacts include actions that alter the setting of the byways and influence user experiences.

The Red Gulch/Alkali Road National Back Country Byway is the only currently designated back country byway in the Planning Area (Map 90). Under Alternative B, two additional back country byways, the Hyattville Logging Road and the Hazelton (33-Mile) Road, are proposed for designation (Map 90).

4.7.2.1 Methods and Assumptions

Methods and assumptions used in this impact analysis include the following:

- Under Alternative B, no additional land use constraints are associated with designation of the Hyattville Logging Road and the Hazelton (33-Mile) Road Back Country Byways.
- Impacts to other resources from management of the cultural values along the proposed and existing back country byways are discussed in Section 4.5.1 Cultural Resources.
- Establishment of the Hyattville Logging Road and the Hazelton (33-Mile) Road Back Country Byways will increase use of the roads and increase human presence in these areas.

4.7.2.2 Summary of Impacts by Alternative

National Back Country Byways are designated to protect important recreational travel routes; the primary impacts to these routes include management that limits or prevents public use. Designation of the Red Gulch/Alkali Road National Back Country Byway would continue under all alternatives. Alternatives B and E designate two additional back country byways, Hyattville Logging Road and the

Hazelton (33-Mile) Road. Alternatives D and F do not designate additional byways, but would consider additional designations on a case-by-case basis. Alternatives A and C do not designate additional byways. Designation of additional back country byways would provide beneficial impacts by increasing opportunities for interpretation and education. Management for the development of interpretive facilities and educational materials under alternatives B and E is more extensive than under alternatives A, C, D, and F, and may result in beneficial impacts to user experiences and increases in appropriate use that does not degrade the byways. Regardless of whether they are designated, adverse and beneficial impacts from the Red Gulch/Alkali Road National Back Country Byway, Hyattville Logging Road, and the Hazelton (33-Mile) Road on other resource values would be negligible under all alternatives.

4.7.2.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Management of the Red Gulch/Alkali Road National Back Country Byway does not change substantially across alternatives; therefore, all impacts are common to all alternatives.

Under all alternatives, the Red Gulch/Alkali Road National Back Country Byway continues its existing designation. Management of cultural and environmental interpretation and education along the byway would continue according to the Red Gulch/Alkali Road National Back Country Byway Interpretive Master Plan (BLM 1994a). Existing adverse and beneficial impacts from the Red Gulch/Alkali Road National Back Country Byway, Hyattville Logging Road, and the Hazelton (33-Mile) Road will continue under all alternatives regardless of designation and are considered negligible. Long-term adverse impacts from the current Type III and IV character of the roads (see *Glossary*) are the same as impacts from similar primitive roads in the Planning Area and include habitat fragmentation, fugitive dust, increased erosion, and potential spread of invasive, nonnative plant seeds and/or parts.

Alternative A

Developing educational materials for the Red Gulch/Alkali Road National Back Country Byway may result in beneficial impacts by increasing knowledge and appropriate use of the area. Beneficial impacts from the Red Gulch/Alkali Road National Back Country Byway include maintaining a viable transportation route, back country access, and recreation, wildlife, and scenic viewing opportunities. These benefits allow a positive change for residents and visitors, providing the opportunity to experience aesthetic appreciation, identify with a special place, improve perception of the quality of life, and improve the image of the area and its recreational opportunities. Environmental benefits include creating a sense of “ownership” and stewardship of the area, while protecting natural habitats and open space by reducing the temptation for users to engage in unethical outdoor behavior, such as off-road motorized use. Economic benefits include retaining recreational spending in local areas, increased contributions to local economies, and increased attractiveness of the area.

Potential adverse impacts from maintaining the back country byway include increased use of Red Gulch/Alkali Road and potential increases in soil erosion, road maintenance, and fugitive dust from traffic. In addition, increased human presence and activity in the area may adversely affect biological and cultural resources due to litter, unauthorized plant collection, the spread of invasive species, vandalism, and wildlife disturbance.

Alternative A does not designate other back country byways.

Alternative B

Alternative B would designate two additional back country byways, the Hyattville Logging Road and the Hazelton (33-Mile) Road.

Developing interpretive facilities (including interpretive pull-outs, parking areas, trailheads, etc.) on all back country byways (including the Red/Gulch Alkali Road National Back Country Byway), and publishing educational brochures displaying the multiple uses, resource values, and unique character of each byway would result in beneficial impacts by enhancing users' experiences and encouraging appropriate use that does not degrade the byways. Beneficial and adverse impacts from designating the additional two back country byways would be similar to those under Alternative A. However, the extent of impacts under Alternative B would be greater as the designations affect more areas, possibly including areas outside the Planning Area's jurisdiction, such as the Casper and Buffalo Field Offices, due to the influence and connectivity of the Hazelton (33-Mile) Road.

Alternative C

Developing educational materials for the Red Gulch/Alkali Road National Back Country Byway would result in the same beneficial impacts as Alternative A.

Alternative C does not designate other back country byways.

Alternative D

Alternative D retains the Red Gulch/Alkali Road National Back Country Byway and would consider the designation of new back country byways on a case-by-case basis. Beneficial and adverse impacts from maintaining the Red Gulch/Alkali Road National Back Country Byway and consideration of new byways would be the same as anticipated under Alternative A.

Impacts to National Back Country Byways under Alternative D would be the same as those described under Alternative A.

Alternative E

Impacts to National Back Country Byways under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis for National Back Country Byways under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Impacts to National Back Country Byways under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for National Back Country Byways under Alternative D is representative of the impacts anticipated under Alternative F.

4.7.3 National Historic Landmarks

The Heart Mountain Relocation Center National Historic Landmark is on BLM-administered mineral estate with BLM-administered surface in view of the site. National Historic Landmarks are very high profile by definition, so adverse impacts to these areas are more controversial than impacts to NRHP sites. Adverse impacts to the Heart Mountain Relocation Center National Historic Landmark would be

similar to those described in Section 4.5.1 *Cultural Resources*, with a greater emphasis on impacts to the viewshed of the National Historic Landmark. BLM actions that alter the scenic characteristics of the landscape around the Heart Mountain Relocation Center National Historic Landmark or adversely affect the viewshed would adversely impact the integrity of the National Historic Landmark and, therefore, could affect the historical significance of this resource. Beneficial impacts are those that preserve the setting around the National Historic Landmark to maintain its historical character and significance.

4.7.3.1 Methods and Assumptions

Certain projects, due to size or topography, may require consideration of visual intrusions into the setting beyond the foreground or middle-ground zones to comply with NHPA Section 106.

See Section 4.5.1 *Cultural Resources* for assumptions applicable to the impacts analysis for National Historic Landmarks.

4.7.3.2 Summary of Impacts by Alternative

The Heart Mountain Relocation Center National Historic Landmark is on BLM-administered mineral estate with BLM-administered surface in view of the site. Impacts to the National Historic Landmark principally result from activities that affect the site's historical setting (i.e., viewshed). Under all the alternatives, the 72-acre National Historic Landmark would be withdrawn from appropriations under the mining laws and protected from direct impacts from surface-disturbing activity associated with mineral development. The greatest adverse impacts to the National Historic Landmark would occur under Alternative A, which applies the fewest restrictions on mineral development within the viewshed of the National Historic Landmark (Map 93). Alternatives B and E restrict surface-disturbing mineral development in the viewshed of the National Historic Landmark to the greatest degree, resulting in the greatest beneficial impacts, followed by alternatives F, D, C, and A respectively.

4.7.3.3 Detailed Analysis of Alternatives

Impacts from surface-disturbing activities, resource uses, and proactive management actions may result in adverse and beneficial impacts to the Heart Mountain Relocation Center National Historic Landmark.

Impacts Common to All Alternatives

The BLM complies with NHPA Section 106 for all undertakings with the potential to affect historic properties (i.e., cultural resources eligible for, or listed on, the NRHP, including those designated as National Historic Landmarks). If historic properties are present, the BLM consults with the SHPO, Indian tribes, and other interested parties in evaluating the potential effects of the undertaking and seeking to resolve adverse effects to historic properties. These measures would avoid, minimize or mitigate such effects to the Heart Mountain Relocation Center National Historic Landmark under all of the alternatives.

Under all of the alternatives, the BLM pursues a withdrawal from appropriation under the mining laws for the 72 acres of BLM-administered mineral estate underlying private and other federal agency-administered surface lands in the Heart Mountain Relocation Center National Historic Landmark. Preventing mining activities on areas in the National Historic Landmark would result in beneficial impacts by maintaining the historic setting of the area to its historical significance.

Surface-disturbing activities and ROW development would have similar impacts on the Heart Mountain Relocation Center National Historic Landmark under all alternatives, but their intensity is likely to vary. Therefore, these impacts are analyzed under each alternative. Proactive management would result in varying beneficial impacts to the National Historic Landmark under each alternative.

Alternative A

Surface Disturbance

Oil and gas development, mining, and other surface-disturbing activities would threaten the historical landscape and viewshed around the Heart Mountain Relocation Center National Historic Landmark. Projected surface disturbance under Alternative A (Table 4-1) would result in the potential for alterations of the scenic characteristics in the surrounding landscape that may adversely affect the historical significance of the National Historic Landmark.

Resource Uses

ROW authorizations, especially for wind-energy development, also may cause visual impacts that may affect the setting and viewshed of the National Historic Landmark. Under Alternative A, the BLM considers renewable energy development on a case-by-case basis throughout the Planning Area and manages 940,943 acres as ROW avoidance areas and 61,147 acres as ROW exclusion areas. Less restrictive ROW management actions would allow for dispersed ROW development and the potential for visual impacts. Therefore, Alternative A would result in potential adverse impacts to the National Historic Landmark from ROW development.

Proactive Management

Other than the withdrawal specified under *Impacts Common to All Alternatives*, no alternative-specific proactive management actions are prescribed for the Heart Mountain Relocation Center National Historic Landmark under Alternative A.

Alternative B

Surface Disturbance

Impacts to the National Historic Landmark from surface disturbance would be similar to, but less than, under Alternative A. Projected surface disturbance under Alternative B (Table 4-1) would result in less potential for alterations of the scenic characteristics in the surrounding landscape that may result in adverse impacts to the setting and viewshed of the National Historic Landmark relative to Alternative A.

Resource Uses

Impacts to the National Historic Landmark from ROW development under Alternative B are similar to, but less than, under Alternative A. Under Alternative B, the Planning Area is open to renewable energy development unless managed as a renewable energy or ROW exclusion or avoidance area. The BLM manages 2,710,695 acres as ROW avoidance areas and 225,447 acres as ROW exclusion areas, with 251,203 acres open to renewable energy. This alternative consolidates new ROW development more than Alternative A, which may reduce the potential for impacts to the setting and viewshed of the Heart Mountain Relocation Center National Historic Landmark compared to the other alternatives.

Proactive Management

Under Alternative B, the BLM avoids surface-disturbing activities in view within 5 miles (7,367 acres) of the Heart Mountain Relocation Center National Historic Landmark, except within existing utility corridors; manages areas within 3 miles as closed to mineral leasing and applies a CSU stipulation in view within 5 miles or the visual horizon; and closes the area within 3 miles and in view within 5 miles to mineral materials disposal. These proactive management actions would provide a greater benefit to the National Historic Landmark, compared to Alternative A, by protecting the setting around the National Historic Landmark and contributing to the preservation of its historical integrity.

Alternative C

Surface Disturbance

Impacts to the Heart Mountain Relocation Center National Historic Landmark from surface disturbance would be similar to, but greater than, those under Alternative A. Projected surface disturbance under Alternative C (Table 4-1) would result in the greatest potential for alterations to the viewshed, resulting in adverse impacts to the setting of the National Historic Landmark.

Resource Uses

Impacts from ROW development near Heart Mountain Relocation Center National Historic Landmark under Alternative C would be similar to those described for Alternative A, but less than under Alternative A and more than under alternatives B and D. Under Alternative C, the Planning Area is open to renewable energy development unless managed as a ROW exclusion or avoidance area. The BLM manages 1,173,162 acres as ROW avoidance areas and 7,586 acres as ROW exclusion areas, with 1,428,360 acres open to renewable energy.

Proactive Management

Proactive management under Alternative C would result in fewer beneficial impacts to the Heart Mountain Relocation Center National Historic Landmark than under Alternative B. The BLM does not apply a buffer to prohibit surface-disturbing activities around the National Historic Landmark, but does manage areas within the footprint of the original Heart Mountain Urban Area (912 acres) as closed to mineral leasing and closes areas within ¼ mile (387 acres) and in view within 1 mile to mineral materials disposal.

Alternative D

Surface Disturbance

Impacts to the Heart Mountain Relocation Center National Historic Landmark from surface disturbance under Alternative D would be similar to those under Alternative A. Alternative D results in 3 percent more short-term and 17 percent more long-term surface disturbance than Alternative A, with a proportional degree of potential adverse impacts to the National Historic Landmark. Overall, surface disturbance under Alternative D would result in the second highest potential for adverse impacts to the National Historic Landmark.

Resource Uses

Impacts to the Heart Mountain Relocation Center National Historic Landmark from ROW development near the National Historic Landmark under Alternative D would be similar to impacts under Alternative

C, and more than impacts under Alternative B. Under Alternative D, the Planning Area is open to renewable energy development unless managed as a ROW exclusion or avoidance area. The BLM manages 2,408,662 acres as ROW avoidance areas and 40,802 acres as ROW exclusion areas, with 1,315,309 acres open to renewable energy.

Proactive Management

Proactive management under Alternative D would result in fewer beneficial impacts than under Alternative B, but more than under alternatives A and C. Measures to preserve the viewshed around the Heart Mountain Relocation Center National historic Landmark under Alternative D, including not authorizing undertakings of moderate or strong contrast, except ROWs within the utility corridors (Map 66); requiring all undertakings in the viewshed to have a visual contrast rating and visual simulation, as appropriate; and avoiding, minimizing and/or compensation for adverse impacts from all undertakings within the viewshed would protect the National Historic Landmark's historical setting and contribute to the preservation of its historical integrity. Alternative D also restricts mineral leasing in the vicinity of the National Historic Landmark similarly to, but more than Alternative C, and prohibits mineral materials disposal within the 72 acres of the National Historic Landmark Urban Center. Overall, proactive management actions under Alternative D would protect the historical setting of the National Historic Landmark more than alternatives A and C, but less than Alternative B.

Alternative E

Impacts to the Heart Mountain Relocation Center National Historic Landmark under Alternative E would be the same as those described under Alternative B; therefore, the impacts analysis for National Historic Landmarks under Alternative B is representative of the impacts anticipated under Alternative E.

Alternative F

Impacts to the Heart Mountain Relocation Center National Historic Landmark under Alternative F would be the same as those described under Alternative D; therefore, the impacts analysis for National Historic Landmarks under Alternative D is representative of the impacts anticipated under Alternative F.

4.7.4 National Historic Trails and Other Historic Trails

The Nez Perce (Nee-me-poo or Nimi'ipuu) NHT is the only NHT in the Planning Area. A number of Other Historic Trails also pass through the Planning Area, including trails of importance to Native Americans, routes from the early historic period, such as the Bridger Trail, and roads and highways from the late 19th and early 20th centuries. Maps 91 and 92 illustrate the Nez Perce NHT and Other Historic Trails.

The Nez Perce NHT is managed to protect its historical values while providing recreation opportunities in a natural appearing landscape consistent with *The 1990 Nez Perce National Historic Trail Comprehensive Plan* and any revisions (USFS 1990). On the trail sections of the Nez Perce NHT, the only allowed use is hiking and horseback riding (USFS 1990) however, the Planning Area does not contain a designated trailhead at this time.

Congressional designation of a trail as part of the National Trails System signifies that the resource is of exceptional scenic, recreational, and/or historic value. NHTs and Other Historic Trails are fragile, nonrenewable resources that provide a direct and tangible link to human history in the Planning Area. As resources on public land under the jurisdiction of a federal agency, the BLM is responsible for their

protection and interpretation, and must consider their resource, qualities, values, and associated settings and the primary use or uses when making land use decisions.

Adverse impacts to trail resources are primarily the result of direct impacts from actions that disturb the soil or alter characteristics of the surrounding environment that contribute to the trail's significance. This includes the introduction of visual elements out of character with the existing scenery, or other actions that alter the setting or result in neglect of the resource to the extent that it deteriorates or is destroyed. For example, surface-disturbing activities that impact trail ruts are considered adverse impacts because the trail segments are nonrenewable. In contrast, actions that result in data collection and preservation of NHTs and Other Historic Trails can be considered beneficial impacts. Beneficial impacts also include proactive trail management, such as hardening NHT-related sites to protect the NHT resource while allowing for public use.

Indirect impacts to NHTs and Other Historic Trails primarily result from project-related increases or decreases in activity in the Planning Area. For example, the construction of a recreational facility may increase visitor use, which would result in an indirect impact to previously undisturbed trail segments. Recreation in particular is a complex issue, because actions taken to preserve historic values can result in both beneficial and adverse impacts for the resource, and for heritage tourism and trail enthusiasts. Beneficial impacts from recreation management is an extended knowledge and appreciation of the historical values, which enhances the beneficial outcomes desired by enthusiasts, which in turn fosters ethical use and support to sustain the unique resource values. Construction in an area some distance from a trail also can result in erosion or deposition at a trail location.

Because of the nonrenewable nature of NHTs, there is little distinction between short-term and long-term impacts. An exception to this would be visual impacts related to temporary construction or fire-related impacts. For example, a change in vegetation resulting from fire or clearing would be a temporary impact, as long as it did not lead to erosion of the trail. Similarly, if construction activity temporarily intruded into the trail's viewshed, this would be a temporary impact, as long as the construction itself did not directly affect the trail or result in a condition that may lead to indirect impacts.

4.7.4.1 Methods and Assumptions

This impact analysis employs BLM Manual 6280 (BLM 2012d) and trail management guidelines (BLM 1986b) to determine the impacts to NHTs and Other Historic Trails from the management of other resources, as described in this RMP. Other Historic Trails are trails eligible for listing on the NRHP, whether or not they have been listed. Completion of the evaluation step of Section 106 compliance may be necessary before moving forward with an undertaking that impacts a trail. Trails will be evaluated for eligibility based on the guidelines provided in the 1986 trails management guide, as interpreted in light of contemporary understanding of eligibility criteria.

Methods and assumptions used in this impact analysis include the following:

- Protection of NHTs and Other Historic Trails and related sites occurs in accordance with federal laws and BLM regulations, policy, and agreements, including the BLM National Programmatic Agreement (BLM, ACHP, and National Conference of SHPO 2012) and the Wyoming State Protocol (BLM and Wyoming SHPO 2014), regardless of whether the trails are specifically identified in the RMP.
- Direct and indirect impacts, including substantial interference with the nature and purposes of the NHT can result from a variety of natural and human-caused events, such as those that

physically alter, damage, or destroy all or part of the trail, and impact the resources, qualities, values, and associated settings, and the primary uses of the NHT; improve access, bringing increased use to an area, altering characteristics of the surrounding environment that contribute to the trail's importance; the introduction of visual or audible elements out of character with the trail or that alter its setting; and neglect of the trail to the extent that it deteriorates or is destroyed.

- The intensity of surface disturbance by alternative as identified in Appendix T equates to levels of development and, in turn, increased access to public lands.
- Current livestock management practices and wildlife use do not pose a threat to the Nez Perce NHT or Other Historic Trails, but improper management of livestock or concentrated herbivory could lead to accelerated deterioration of National Historic Trails or Other Historic Trails.
- The BLM looks favorably at opportunities to cooperate with private landowners to minimize or eliminate disturbance to NHTs and Other Historic Trails.
- Recognizing that historic trails often comprise numerous routes rather than a single trace, all protective zones begin at the outer edges of trails rather than at a centerline, which is difficult to define.
- Certain projects, due to size or topography, may require consideration of visual intrusions into the setting beyond the foreground or middle-ground zones to become consistent with the modern understanding of impacts, and to comply with Section 106 of the NHPA.

4.7.4.2 Summary of Impacts by Alternative

Principal impacts to the Nez Perce NHT, the only NHT in the Planning Area, and Other Historic Trails arise directly from development activities and intrusions into the viewshed that alter the environment that contributes to the trail's significance. These development activities and intrusions may impact other resources, qualities, values, and associated settings, and the primary use or uses of the NHT, including loss of trail-related recreation opportunities, and a decline in the visual, recreation, and natural trail settings. Alternatives B and E provide the greatest protection for these trails through the application of a larger management corridor for surface-disturbing activity (both NSO and CSU) and restrictions on motorized vehicle use. The larger acreage of special designations and greater limitations on resource use under Alternative E reduce the potential for direct and indirect adverse impacts to a greater extent than the other alternatives. Alternative C allows the greatest resource use and provides the least protection through special designations, but it does provide more effective proactive management, including NSO and CSU restrictions, than Alternative A. Alternative A, the existing management, includes the least effective proactive management, in part because of the change in understanding of the adverse impact of viewshed intrusions that has evolved since this management was developed. However, management under Alternative A would result in less resource use than Alternative C, and adverse impacts would likewise be less under this alternative. Alternatives D and F provide for similar protection to these trails, which is more than alternatives A and C, but less than alternatives B and E.

4.7.4.3 Detailed Analysis of Alternatives

Impacts Common to All Alternatives

Standard procedures have been developed over the years to help address potential adverse impacts to NHT resources. Because they are Congressionally Designated Trails, priority is given to avoiding,

minimizing and/or compensating impacts from development and use. Standard management and protection procedures, guided by the National Trails System Act and the NHPA, include avoidance, screening projects from the trails behind natural features, innovative redesign or camouflaging of projects, and using existing disturbances along trails for placement of projects. These standard procedures have protected NHT resources from adverse impacts and damage in many cases. However, if total avoidance has not been feasible, mitigation measures designed to minimize impacts to the NHTs and their historic settings have been continually improved and implemented over the years. All of the alternatives are guided by these standard procedures.

The BLM manages the Nez Perce NHT in accordance with the Nez Perce Comprehensive Management Plan (USFS 1990) guidance and direction, including any future revisions. For all federal undertakings that may impact NHTs and Other Historic Trails, the BLM complies with NHPA Section 106 before implementing the undertaking. Although resource avoidance is the preferred mitigation, other solutions may be reached. Section 106 compliance typically includes inventory, evaluation, and consultation with the SHPO.

Application of the standards specified in BLM trail management guidance, and in the 1986 historic trails plan (BLM 1986b), also will limit adverse impacts to trail resources. These standards include:

- Avoid impacts to all physical remains with good integrity.
- Avoid impacts to locales with good environmental integrity.
- Cross the setting where the integrity of setting has already been compromised.
- Avoid running a linear project parallel to a trail.
- Cross at 90 degrees using a dog-leg or S-curve.
- Relocate the proposed disturbance where it will be less visible from the trail (i.e., behind a rise).
- Restrict the width of a working ROW within a visual buffer on either side of a trail.
- Avoid any blading on a ROW within the National Trail Management Corridor if a track can do the job.
- Consider special rehabilitation measures (such as revegetation) which will help reestablish the integrity of the trail.
- Consider special interpretive measures (such as signing) which will help mitigate the impact of the project.

BLM Manual 6280, Appendix 1 (BLM 2012d) provides additional design features and BMPs that may be applied to avoid adverse impacts to the Nez Perce NHT site-specific permitting and plan implementation.

Allowable uses and management actions that may impact NHTs and Other Historic Trails include changes in ownership, access, and proactive NHT and Other Historic Trails management actions. Any surface-disturbing activity, regardless of type, on or adjacent to NHTs or Other Historic Trails may cause adverse impacts to contributing segments of the trails, or may cause substantial interference. Recreation and educational uses of the trails under any alternative may have both a beneficial and an adverse impact. Information about the trails may promote preservation, but also may encourage visitation and use, which may degrade trails. Under all alternatives, motorized vehicle use is anticipated to increase in the Planning Area, bringing greater access and the potential for greater adverse impacts. Travel on Nez Perce NHT trail segments in the Planning Area is limited to foot or horseback, which would limit the potential for these adverse impacts; however, unauthorized motorized vehicle use on the NHTs

or Other Historic Trails with similar restrictions may still adversely impact contributing segments of trails and desired recreational settings.

Visual impacts from development, such as wind turbines, or incompatible use, such as motorized vehicles on intact trails, are possible even with the applications of protective actions listed above. The existing plans considered the maintenance of a ¼-mile National Trail Management Corridor adequate protection in most trail situations, with the occasional application of a 5-mile National Trail Management Corridor a generous allowance that would provide protection to the viewshed of the Nez Perce NHT. However, with the introduction of new technology, particularly wind turbines that are often grouped into wind farms and visible from long distances, a ¼-mile National Trail Management Corridor may not adequately protect the Nez Perce NHT's viewshed. As setting has gained importance in determining the NRHP eligibility of significant trails, trail management must approach the application of viewshed criteria with flexibility, considering the distance from the resource and the type of intrusion when determining the impact. On a case-by-case basis, and as appropriate for some projects, project decisions will consider the importance of viewshed integrity in a resource's eligibility, and the distance necessary to protect its NRHP significance.

Alternative A

Surface Disturbance

The BLM avoids surface-disturbing activities in the vicinity of the Nez Perce NHT and Other Historic Trails under Alternative A. Standard compliance with NHPA Section 106 before approving an action would provide additional protection from direct impacts. If direct impacts are unavoidable, the BLM and the SHPO would consult to develop and implement a treatment plan to mitigate adverse impacts to contributing segments, which may result in project relocation. Detailed recording and mapping or interpretation are some of the techniques that may be used for mitigation, depending on the specific trail segment and the nature of the potential adverse impacts.

Restrictions on surface-disturbing activities for the protection of other resources (e.g., soil, water, biological resources, and special designations) under Alternative A provide additional protection for trail resources.

Resource Uses

Lands and realty actions on BLM-administered surface land can result in both beneficial and adverse impacts to the Nez Perce NHT and Other Historic Trails. The survey that would be required for NHPA Section compliance in the case of either disposal or acquisition would result in a beneficial impact to cultural resources because of data that furthers understanding of trail resources in the Planning Area. If contributing segments were identified during an inventory for disposal of lands, there would be an adverse impact due to a change in the protective measures for cultural resources. If the BLM acquired the land, the impact would be beneficial. Although land-tenure adjustment is classified as an adverse impact (in terms of Section 106), development of a treatment plan for contributing trail segments would mitigate that impact. The plan would be developed through consultation between the BLM and SHPO in compliance with Section 106 and BLM trail guidance.

Actions regarding renewable energy projects and linear resources, including ROWs, corridors, and recreational trails management may all impact the Nez Perce NHT and Other Historic Trails, not only adversely through direct disturbance of the trail, but indirectly because the routes traveled by trails may also be the best route for these other resource uses. Under Alternative A, the Nez Perce NHT and Other Historic Trails are provided with a maximum buffer from surface disturbance and visual impacts of

¼ mile. Renewable energy is one of the more problematic resource uses, because the infrastructure to exploit solar and wind energy may be highly visible, depending on the terrain, but the buffer to protect the trail viewshed is limited to ¼ mile. Some beneficial impacts may result from inventory and the identification of previously unrecorded segments. In all cases, adverse impacts must be mitigated in compliance with NHPA Section 106.

Travel management and recreation also may result in both direct and indirect, and adverse and beneficial impacts. Where recreational uses occur along the Nez Perce NHT and Other Historic Trails, use may degrade the surface of the trail or impact the viewshed from the trail. Improved access and construction of trailheads, educational signs, and/or kiosks may increase use of the trails and expose them to vandalism. Limiting vehicle travel to existing roads and trails on BLM-administered lands in most areas along the Nez Perce NHT and limiting travel to foot or horseback along the trail would reduce the potential for these adverse impacts.

Special Designations

Special designations would tend to have beneficial impacts to the Nez Perce NHT and Other Historic Trails. The main exception would be back country byways, which would indirectly and adversely impact historic trails resources through increased access. However, vehicle travel and heritage tourism on the segment of the Nez Perce NHT Auto Route, which runs concurrently with the Chief Joseph National Scenic Byway, may have beneficial impacts by imparting travelers with an extended knowledge and appreciation of the NHT's historical values.

Resources

The impact of fire and fuels management would be primarily adverse. Because of the unique nature of trails, there is little to distinguish between long- and short-term impacts, because once trail ruts or original markers are disrupted or destroyed, they cannot be restored. Use of a trail corridor to access a fire location for suppression, stabilization and rehabilitation, and creation of fire breaks, can all result in direct, adverse impacts. Approximately 70,000 acres of short-term disturbance from fire and fuels management are anticipated under Alternative A (Appendix T).

Cultural resources and VRM would both have direct and indirect beneficial impacts to the Nez Perce NHT and Other Historic Trails. Because management of both these resources overlaps with management of historic trails, the trails would benefit from protections and proactive activities for these other resources. The Nez Perce NHT and surrounding public lands are generally managed as VRM Class II, which would help to retain the integrity of the associated settings and scenic values for which the NHT was designated.

Proactive Management

Proactive management actions under Alternative A generally result in beneficial impacts to the Nez Perce NHT and Other Historic Trails but may provide inadequate protection in areas where development is permitted within trail viewsheds. Under existing management, an NSO stipulation is applied within ¼ mile of the Nez Perce NHT and Other Historic Trails. Because trails often comprise multiple traces, the ¼-mile National Trail Management Corridor extends from the outer edges of the overall trace (1,638 acres of BLM-administered surface land). Current management also avoids surface-disturbing activities in view within ¼ mile of both the Nez Perce NHT and significant segments of Other Historic Trails, including the Bridger Trail and Fort Washakie to Meeteetse to Red Lodge Trail.

Alternative B

Surface Disturbance
